Taphozous mauritianus is found throughout much of subsaharan Africa and is also on several islands (including the Tanzanian island of Unguja [=Zanzibar] [see O'Brien, 2011: 287]), Bioko and Pagalu (Equatorial Guinea), and Sao Tomé and Príncipe). The most northerly records are from the border area between Senegal and Mauritania and at the head of the Nile River in Sudan. It is present throughout southern and eastern Madagascar, but it usually only occurs at lower altitudes and there are no records from the central plateau or above 900 m. It is known from Aldabra (von Brandis (2004: 135), Mauritius, the Comoros and Réunion. Records from the Western Cape region in southern Africa are unverified, with known records extending as far south as Mossel Bay. It is also recorded in an isolated location in the Northern Cape, near Hartwater (Taylor, 2000; Skinner and Chimimba, 2005). In the RSA, the species' distribution is linked with land use/land cover (Babiker Salata, 2012: 50).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,454,841 km^2.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 532; Taylor *et al.*, 2018b: 62); Benin (Capo-Chichi *et al.*, 2004: 162); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 535); Burkina Faso (Thiombiano *et al.*, 2021: 26); Cameroon; Central African Republic; Chad; Comoros (Louette, 2004; Goodman *et al.*, 2010c: 125; Hume and Middleton, 2011: 33); Congo (Bates *et al.*, 2013: 335); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Monadjem *et al.*, 2010d: 535); Côte d'Ivoire; Equatorial Guinea (Annobón, Bioko); Eswatini (Monadjem *et al.*, 2010d: 535, Monadjem *et al.*, 2021: 5); Ethiopia; Gabon; Gambia (Emms and Barnett, 2005: 50); Ghana; Kenya; Madagascar; Malawi (Happold *et al.*, 1988; Ansell and Dowsett, 1988: 29; Monadjem *et al.*, 2010d: 535); Mauritius; Mayotte (Ramasindrazana *et al.*, 2015a: 109); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 535); Namibia (Monadjem *et al.*, 2010d: 535); Nigeria; Réunion; São Tomé and Príncipe (Juste and Ibáñez, 1993c: 906; Rainho *et al.*, 2010a: 35); Senegal; Seychelles [Aldabra]; Sierra Leone; Somalia; South Africa (Monadjem *et al.*, 2010d: 535); Sudan; Tanzania; Togo; Uganda; Zambia (Ansell, 1967; Ansell, 1969; Ansell, 1978;Ansell, 1986; Cotterill, 2004a: 260; Monadjem *et al.*, 2010d: 535); Zimbabwe (Monadjem *et al.*, 2010d: 535).

Presence uncertain: Burundi; Guinea; Guinea-Bissau; Liberia; Mali; Mauritania; Rwanda.

GEOGRAPHIC VARIATION:
Krutzsch (2000: 114) [referring to Rosevear (1965), Smithers and Lobão Tello (1976) and Happold (1987)] indicates that geographic variation is evident in the gular sac in this species. In Nigeria and Mozambique, it is only present in males, while in West Africa the males have a functioning sac and females have a vestigial pouch.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Fenton (1992: 49) indicates that the grizzled dorsal pelage contributes to the bat's camouflage while resting on natural surfaces. In the resting position, the striking white venter is completely concealed.

From western Uganda, Monadjem *et al.* (2011: 30) reported the following data for 2 specimens: Fa: 60.25 mm, mass: 27.0 g, wing loading: 13.3 N/m^2, aspect ratio: 5.8.

ECHOLOCATION:
See Taylor (1999b), and Taylor (2000: 63).

Rainho *et al.* (2010a: 21) and Rainho *et al.* (2022: 605) reported the calls of 5 individuals from São Tomé: F_{min}: 24.2 ± 0.7 (23.4 - 25.2) kHz, F_{max}: 31.9 ± 0.6 (31.4 - 32.5) kHz, F_{maxE}: 28.3 ± 0.2 (28.1 - 28.4) kHz, duration: 14.8 ± 1.7 (12.8 - 16.8) ms and interpulse interval: 77.4 ± 6.4 (70.7 - 86.4) ms.

For 10 calls of specimens from Soutpansberg and Waterberg, South Africa, Taylor *et al.* (2013b: 18)

recorded the following parameters: F_{max}: 29.0 ± 1.17 (27.8 - 31.1) kHz, F_{min}: 25.3 ± 1.49 (22.1 - 27.9) kHz, F_{knee}: 28.3 ± 1.29 (27.0 - 30.2) kHz, F_{char}: 26.2 ± 0.94 (24.9 - 27.9) kHz, duration: 2.9 ± 0.64 (2.0 - 3.6) ms.

Weier *et al.* (2020: Suppl.) reported on seven calls from the Okavango River Basin with the following characteristics: F_{max}: 28.71 ± 2.38 kHz, F_{min}: 23.88 ± 2.10 kHz, F_{knee}: 26.96 ± 1.67 kHz, F_{char}: 24.96 ± 1.72 kHz, slope: 79.41 ± 58.64 OPS, duration: 3.06 ± 0.94 ms.

From western Uganda, Monadjem *et al.* (2011: 32) report the following values: F_{min}: 13.13 kHz, F_{max}: 13.48 kHz, F_{char}: 13.43 kHz, F_{knee}: 13.18 kHz, duration: 9.1 ms. They also indicate (p. 33) that the F_{peak} of 25.6 [actually 25.9] kHz reported by Schoeman and Jacobs (2008: Table S1) is probably for an harmonic.

Barataud and Giosa (2013: 150) reported on 57 sequences from Réunion with F_{start}: 26 ± 5.8 kHz, F_{end}: 21.8 ± 6.7 kHz, bandwidth: 4.2 ± 3.7 kHz, $F_{fund\ max}$: 14 ± 1 khz, $M_{1har\ max}$: 27.1 ± 1.6 kHz and duration: 13 ± 3.7 ms.

For Swaziland, Monadjem *et al.* (2017c: 179) recorded the following parameters: F_{min}: 25.1 ± 0.72 (24.3 - 25.9) kHz, F_{knee}: 28.6 ± 0.60 (28.1 - 29.5) kHz, F_{char}: 25.9 ± 1.20 (24.3 - 27.2) kHz, and duration: 2.7 ± 0.27 (2.4 - 3.0) kHz.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 14 bats: F_{max}: 28.35 ± 2.05 kHz, F_{min}: 22.97 ± 6.79 kHz, F_{knee}: 27.43 ± 1.74 kHz, F_{char}: 26.05 ± 1.61 kHz, slope: -215.69 ± 1248.24 OPS, duration: 5.71 ± 3.76 ms. 15 calls recorded at the Venatia mine by Cory-Toussaint and Taylor (2022: Tabls S1) had a duration of 6.13 ± 1.57 ms, F_{min}: 25.07 ± 0.68 kHz, F_{max}: 25.92 ± 0.93 kHz, F_{knee}: 25.76 ± 0.89 kHz and F_{char}: 25.19 ± 0.71 kHz.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 25.9 kHz and duration: 7.4 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 24 *Taphozous mauritianus* calls from the Kruger Park (RSA): F_{min}: 25.7 ± 2.2 (23.7 34.7) kHz, Duration: 3.0 ± 0.5 (2.1 3.8) ms, F_{max}: 33.2 ± 8.0 (26.9 40.2) kHz, F_{knee}: 30.1 ± 3.7 (24.6 42.5) kHz, F_{char}: 27.9 ± 2.5 (24.3 35.9) kHz, 69 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 22 - 29 kHz, F_{max}: 29 - 31 kHz, F_{char}: 25 - 28 kHz, F_{knee}: 27 - 30 kHz and duration 3 ms.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 27.90 ± 2.50 kHz, F_{max}: 33.20 ± 8.00 kHz, F_{min}: 25.70 ± 2.20 kHz.

Parker (2022: 20) reported the following data from 232 passes at Mountain Zebra National Park (RSA): F_{min}: 24.90 ± 3.84 kHz, F_{char}: 26.48 ± 3.62 kHz and F_{max}: 29.78 ± 5.25 kHz.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 27.90 ± 2.50 kHz, F_{max}: 33.20 ± 8.00 kHz and F_{min}: 25.70 ± 2.20 kHz.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

Molecular Biology:

Karyotype

Rautenbach *et al.* (1993) reported for specimens from South Africa, 2*n* = 42, FN = 64, BA = 24, a metacentric X chromosome, and a submetacentric Y chromosome.

Protein / allozyme - Unknown.

Habitat:

Open savanna and forest edges in the wetter northern and eastern parts of the subcontinent (Taylor, 2000: 62).

On São Tomé, Castro-Fernandes *et al.* (2024: 2) reported this species to be an open-space forager.

Habits:

Fenton and Griffin (1997: 248) recorded one call above 24 kHz, which they attributed to *T. mauritianus* at an altitude of 500 - 550 m above a *Brachystegia* woodland in Zimbabwe.

Roost:

In the Durban area, Taylor *et al.* (1999: 67) found most of the roosts (72 %) being associated with the outer walls of houses at a height between 2 and 12 metres. The colony size varied from 1 to 5.

In a rural area on Madagascar; Rakotondramanana *et al.* (2017: 133) found a colony roosting on the trunk of a palm tree (*Cocos nucifera*), under dried fronds. They left the roost about 30 minutes after sunset. Ravelomanantsoa *et al.* (2019: 110) report it also roosting in *Tamarindus indica*.

In Malawi, O'Malley *et al.* (2020: 1) found that roosts in building were selected both on building and landscape level: the occupied buildings were

situated closer to woodlands than random buildings (709 versis 1847 m); these buildings generally had exposed roof beams, and the roosts were situated on larger areas and taller (brick) walls. O'Malley *et al.* (2020: 3) also indicated that day roosts are commonly found in the open, but away from direct sunlight, either on outer walls of buildings, cliff faces or large tree trunks.

DIET:
They feed primarily on moths (Allen *et al.*, 1917); termite alates such as *Macrotermes falciger* (Happold and Happold, 1988), and other insects (Smithers, 1971). See also (Taylor, 2000: 62; 2005: 275).

In Senegal, Sow *et al.* (2020: 4) used molecular analyses to identify the presence of *Heliocheilus albipunctella* de Joannis) (Lepidoptera, Noctuidae) in the faeces of *T. mauritianus*.

For Madagascar, Goodman *et al.* (2022: 1903) [referring to Razafimalala (2017)] mentioned the following volume percentages: Hymenoptera (45 %), Lepidoptera (30 %), and, to a much lesser extent, Coleoptera, Homoptera, Diptera, Orthoptera, and Odonata. Immature animals were found to eat more Lepidoptera than adults.

PREDATORS:
Demeler (1981: 133) found remains of *T. mauritianus* in pellets of *Bubo africanus* in the Yankari Game Reserve (Nigeria).

Mikula *et al.* (2016: Supplemental data) mention Wahlberg's eagle (*Hieraaetus wahlbergi* (Sundevall, 1851)) as a diurnal avian predator.

Goodman *et al.* (2015c: 78) found the remains of one individual in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar. Malan *et al.* (2022: 167) reported six individuals in pellets from this hawk in the RSA.

Goodman *et al.* (2022: 1903) mentioned predation by *Tyto alba* (Scopoli, 1769) in southwestern Madagascar.

POPULATION:
Structure and Density
Taphozous mauritianus is not rare and is easy to find. It usually roosts under covering vegetation on the outer bark of trees (Hutson *et al.*, 2008f; IUCN, 2009; Monadjem *et al.*, 2017bb).

Trend
2016: Unknown (Monadjem *et al.*, 2017bb). 2008: Unknown (Hutson *et al.*, 2008f; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Kaudern (1914: 12) reported that he received a female with a very small foetus from villagers in Fenerive (Madagascar) on 6 January 1912.

Krutzsch (2000: 113) mentioned that *T. mauritianus* is monoestrous in parts of its range and polyoestrous in others.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births from October to December and from February to March.

In Malawi, births were reported in November-December and March-April (Happold and Happold, 1990b: 564).

PARASITES:
HEMIPTERA
Polyctenidae
Eoctenes intermedius (Speiser, 1904) from the DRC (Haeselbarth *et al.*, 1966: 16; Szentiványi *et al.*, 2022: 5).

DIPTERA
Nycteribiidae
Tripselia blainvillii (Leach, 1817) distributed over the Madagascan region and tropical Africa from west to east between lat. 10° north and south (Haeselbarth *et al.*, 1966: 113). Hutson (2004a: 129) mentions that *Basilia (Tripselia) blainvilli* (Nycteribiidae) is a widespread parasite of *Taphozous mauritianus*. (synonyms: *Nycteribia (Acrocholidia) fryeri*, *Tripselia fryeri*).

SIPHONAPTERA
Ischnopsyllidae
Chiropteropsylla brockmani Rothschild, 1915 widespread (Haeselbarth *et al.*, 1966: 192).

VIRUSES:
In their country-wide survey of Kenyan bats, Waruhiu *et al.* (2017) found the following viruses in *Taphozous mauritianus*: Astroviruses, Paramyxoviruses and Rotaviruses.

Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested between 1986 and 1999, for antibody to SARS-CoV in sera in one individual from Limpopo Province, South Africa, none were tested positive (0/1).

In their overview table, Maganga *et al.* (2014a: 8) reported that no viruses were ever found in this bat species.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burundi, Cameroon, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Eswatini, Ethiopia, Gabon, Ghana, Guinea-Bissau, Kenya, Madagascar, Malawi, Mauritius, Mozambique, Namibia, Nigeria, Réunion, Rwanda, Senegal, Sierra Leone, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

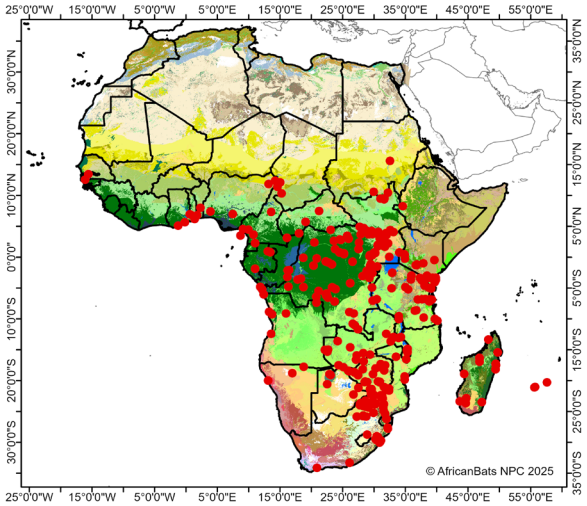

Figure 148. Distribution of *Taphozous mauritianus*.

Taphozous nudiventris Cretzschmar, 1830

*1830-1831. *Taphozous nudiventris* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 70, pl 27b. Publication date: 1830-1831. Type locality: Egypt: Giza province: Giza [30 01 N 31 13 E]. [Goto Description]. Lectotype: SMF 4310: ad ♂, skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1824. Old catalog II.J.1.a; see Mertens (1925: 20), Qumsiyeh (1985: 26). Paralectotype: RMNH MAM.35962: mounted skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell. Paralectotype: RMNH MAM.35964: ad, mounted skin (skull not removed). Collected by: Wilhem Peter Edward Simon Rüppell. - Comments: Kock (1969a: 83) mentioned the type locality as "Egypt, Nubia" and indicates that Giza is the type locality of the lectotype. Corbet and Hill (1992: 87) only mention "Egypt". Allen (1939a: 67) mentioned 1826 as year of description, whereas Kock (1969a: 83) mentioned 1830. Grubb *et al.* (1998: 73) mentions "1830, vel 1831". - Etymology: From the masculine Latin adjective *nùdus*, meaning "naked" and the masculine Latin substantive *vènter*, meaning"belly", as the fur stops short of the end of the body both dorsally and ventrally (see Lanza *et al.*, 2015: 221). (Current Combination).

1841. *Taphozous nudiventer:* Temminck, Monographies de mammalogie ou description de quelques genres de mammifères, dont les espèces ont été observées dans les différens musées de l'Europe. Tome Seconde, 2 (14): 280, pl 60, figs 10 - 12. Publication date: 1841. - Comments: Lapsus (Allen, 1939a: 67).
. (Lapsus).

1877. *Nycticejus serratus* Heuglin, Reise in Nordost Afrika, 2: 35. Publication date: 1877. Type locality: Sudan: ?Abyssinia: on the Araschkol and nearby mountains: "Sherq el Aqabah" [14 15 N 32 10 E]. [Goto Description]. - Comments: According to Simmons (2005) this is an enigmatic taxon, which is variously referred to either *Taphozous nudiventris* (e.g. Allen, 1939a: 67; Koopman, 1993a) or *Scotophilus nigrita leucogaster* (Allen, 1939a) [implying that it might either be *S. dinganii* or *S. leucogaster*], but which may not represent either of those species. Kock (1969a: 83) includes it with a question mark in the synonymy of *Taphozous nudiventris*, and Happold (2013bm: 434) mentions it as a possible synonym of that species.

1885. *Taphozous perforatus var. assabensis* Monticelli, Ann. Accad. O. Costa de Aspir. Nat. Napoli, ser 1, 1: 78, pl 7. Type locality: Eritrea: Assab [13 01 N 42 43 E]. - Comments: Allen (1939a: 67) indicates that Monticelli considered it a synonym of *perforatus*, but Senna (1905), who examined the type, says it is *T. nudiventris*. The type specimen was collected by prof. G.B. Licata.

1964. *T(aphozous) mudiuemtris:* Walker, Mammals of the World, I: 241. (Lapsus).

2013. *Taphozous nudiuentris:* Liu, Wang, Zhang, Li, He, Huang, Jiang, Murphy and Shi, Proc. R. Soc. Lond., B 281 (1776): 20132950 3 (for 2014). Publication date: 18 December 2013. (Lapsus).

? *Liponycteris nudiventris:* (Name Combination).

? *Taphozous (Liponycteris) nudiventris:* (Name Combination).

? *Taphozous nudiventris nudiventris:* (Name Combination).

TAXONOMY:
Simmons (2005) assigns four subspecies to *Taphozous nudiventris*: *T. n. kachhensis* Dobson, 1872; *T. n. magnus* Wettstein 1913; *T. n. nudaster* Thomas, 1915; and *T. n. zayidi* Harrison, 1955.

Uvizl *et al.* (2019: 31) consider *zayidi* to be a junior synonym of *T. n. nudiventris*, and also indicate that there is need for further investigation to ascertain the position of the other subspecies.

The enigmatic taxon *T. n. serratus* Heuglin, 1877 has been variously referred to either *Taphozous nudiventris* (e.g., Allen, 1939a, Koopman, 1993a) or *Scotophilus leucogaster* (e.g., Allen, 1939a; Koopman, 1993a), although it might not represent either of these species. See Felten (1962), Hayman and Hill (1971), Harrison and Bates

(1991), Bates and Harrison (1997) and Barkley (1984) for further information on this taxon.

COMMON NAMES:
Albanian: Pipistreli i varrezave barkzhveshur. Arabian: Khafash Abu Bouz, Khaffash. Armenian: Մերկփոր պարկաթև. Azerbaijani: Ilpaqqarın məzar yarasası. Basque: Hilobi-saguzar gibelsoil. Swedish: Nakengumpsfladdermus. Tamil: திறந்த ரம்ப்டு கல்லறை வௌவால், Iṟanta Rampṭu Kallaṟai Veḷ

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, tolerance of a degree of habitat modification, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Bates *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bq).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bq). 2008: LC ver 3.1 (2001) (Bates *et al.*, 2008; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004bp; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is tolerant of a certain level of human disturbance. Loss of some roosts (e.g., in buildings) and use of pesticides probably impact some populations negatively, but overall it is not significantly threatened (Bates *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bq).

CONSERVATION ACTIONS:
Bates *et al.* (2008) [in IUCN (2009)] and Monadjem *et al.* (2017bq) report that there are international legal obligations for protection through the Bonn Convention (Eurobats) in areas to which this applies. However, through most of its range, no specific conservation measures are place for this species. It occurs in many protected areas across its wide range. A study on the impacts of pesticides is required, especially ways in which the impact might be minimised.

GENERAL DISTRIBUTION:
Taphozous nudiventris has a much larger range than previously believed. It has been recorded throughout the southern desert and sub-desert belt of western and central Palaearctic, from Morocco, through the Saharan region across northern Africa to Egypt and north through the Middle East to southern Turkey, and the more arid areas of the Indian subcontinent. The most southerly record is from northern Tanzania. There are two isolated records from Myanmar (the southernmost locality being in the general vicinity of Bago (Pegu) Yoma (Bates *et al.*, 2000)).

In South Asia this species is presently known from Afghanistan (Kabul, Kandahar and Nangarhar provinces), Bangladesh, India (Andhra Pradesh, Bihar, Delhi, Gujarat, Karnataka, Madhya Pradesh, Maharashtra, Rajasthan, Sikkim, Tamil Nadu, Uttar Pradesh and West Bengal) and Pakistan (Punjab and Sind) (Molur *et al.*, 2002).

Native: Afghanistan; Algeria (Horáček *et al.*, 2000: 104); Burkina Faso (Kangoyé *et al.*, 2015a: 614); Cape Verdian Islands (Tranier and de Naurois, 1985: 304; Borloti *et al.*, 2020: 2); Chad; Congo (The Democratic Republic of the); Djibouti (Pearch *et al.*, 2001: 396); Egypt; Eritrea (Lavrenchenko *et al.*, 2004b: 138); Ghana; Guinea-Bissau (Castella *et al.*, 2000; Rainho and Ranco, 2001: 38); India; Iran, Islamic Republic of; Iraq; Israel; Jordan; Kenya; Macronesian Islands (Cape Verd islands (Tranier and de Naurois, 1985; de Naurois, 1994; Hazevoet, 1995; Masseti, 2010); Mauritania; Morocco (Dbiba *et al.*, 2025: 6); Myanmar; Niger; Nigeria; Pakistan; Palestinian Territory, Occupied; Saudi Arabia; Senegal; Somalia; Sudan; Syrian Arab Republic; Tanzania; Togo; Tunisia (Dalhoumi *et al.*, 2023: 1); Turkey; United Arab Emirates (Anonymus, 2008: 38); Yemen.

Presence uncertain: Ethiopia; Kuwait; Libyan Arab Jamahiriya; Oman; Qatar; Uganda; Western Sahara. The records from Lebanon were revoked by Benda and Engelberger (2016: 17).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 22.4 Pa, aspect ratio 9.5 and tip shape index of 1.14 for a wingspan of 46 cm and a wing area of 219 cm^2 and a body mass of 50 g.

ECHOLOCATION:
In Jordan, Benda *et al.* (2010b: 204) registered the following parameter for 17 calls: F_{start}: 26.1 ± 1.0 (24.4 - 27.6) kHz, F_{end}: 22.2 ± 0.6 (20.3 - 22.9) kHz, F_{peak}: 24.5 ± 0.5 (23.6 - 25.3) kHz, Pulse duration: 15.4 ± 2.6 (11.0 - 19.5) ms, and Inter-pulse interval: 363.9 ± 115.1 (188.0 - 571.0) ms.

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats): F_{peak}: 23.38 kHz, F_{start}: 24.39 kHz, F_{end}: 22.8 kHz, Band width: 1.59 kHz, and duration: 12.99 ms.

From Israel, Hackett *et al.* (2016: 223) reported the following parameters for 74 calls: Pulse duration: 12.99 ± 3.50 ms, F_{start}: 24.39 ± 1.55 (22.3 - 25.3) kHz, F_{end}: 22.80 ± 1.29 (20.4 - 26.3) kHz, F_{peak}: 23.38 ± 1.31 (21.3 - 26.3) kHz.

MOLECULAR BIOLOGY:
Karyotype
Đulić (1984), Yaseen *et al.* (1994), Hood and Baker (1986), Asan and Albayrak (2007) reported $2n$ = 42, FN = 64, BA = 24. However, Robbins (1983b: 35) reported $2n$ = 42 and FN = 68 and Sreepada *et al.* (1995) $2n$ = 42, FN = 66, BA = 26 for specimens from India. In Turkey, Karataş and Sözen (2003: 359) and Arslan and Zima (2014: 7) reported $2n$ = 42, FNa = 64, FN = 68, a meta-/submetacentric X and an acrocentric Y chromosome. The autosomal chromosomes consist of 12 metacentric and submetacentric pairs and 8 acrocentric pairs.

Genetics
See Hoofer and Van Den Bussche (2003).

Capanna *et al.* (1968: 240) already pointed out that there was a cytotaxonomic difference between the Vespertilioninae and the Miniopterinae, especially in the average length of the aploid female set.

Platt *et al.* (2016: 9) analysed the genome data for *M. natalensis* and compared it with that of several other vesper bats and they concluded that *Helitrons* and hATs were introduced into the genome of the Vespertilionidae after their divergence from *Miniopterus*.

HABITAT:
Although *T. nudiventris* has a medium to high wing loading and flexible roost requirements, which could be advantageous for urban life, Marsden *et al.* (2023: 7) found no evidence that it is an urban resident.

Becker *et al.* (2025: 2) indicate that *Taphozous nudiventris* occupies eight distinct habitat types as defined by the IUCN.

HABITS:
Lučan and Šálek (2012: 235) report on the mobbing behaviour of *T. nudiventris* on a barn owl (*Tyto alba*) in the Dakhla Oasis in Egypt. The bats were able to detect the owl when it was on route to their roost, but it could not be determined how the bats were able to do this. There were no alarm or distress calls from other bats, so possibly visual cues or acoustic signals (e.g., sounds made by the feathers of the flying owl) might be involved.

ROOST:
Davis (2007: 10) found that in the United Arab Emirates, they may roost in groups of 200 to 1,000+ individuals. During late pregnancy and lactation, the females form separate groups.

Węgiel *et al.* (2024: 3) reported this species (400 bats) from undamaged domed tombs at the Old Dongola archaeological site (Sudan), and also indicated that none of the damaged tombs housed bats. An additional colony of about 40 bats was found in an old mosque.

DIET:
Benda *et al.* (2012a: 282) report that the most important food categories in Syria, Sudan, Oman and Turkey are Coleoptera (Scarabaeidae) and Orthoptera. Desai *et al.* (2012) [in Benda *et al.*, 2012a: 282] found seasonal changes in the food composition of these bats in Gujarat (India): Coleoptera and Orthoptera prevailed in winter, while Isoptera, Lepidoptera, Orthoptera, Neuroptera and Hymenoptera (Vespoidea) were most consumed in summer.

PREDATORS:
In Algeria, Djilali *et al.* (2016: 161) found remains of 2 *T. nudiventris* specimens in 516 preys captured by the Short-eared Owl (*Asio flammeus* (Pontoppidan, 1763)).

In Sudan, Tryjanowski *et al.* (2024: 2) found remains of this bat in scats of the striped polecat (*Ictonyx striatus* (Perry, 1810)).

POPULATION:
Structure and Density
It is common in some places, and less so in others. It is an uncommon species in the western part of its range: colonies in Africa and the Mediterranean region are generally restricted to a few individuals, although large colonies (dozens to hundreds) have been found in eastern Africa (Bates *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bq). The species is common in its range in South Asia, however, a declining trend in its population has been observed in recent years (Bates and Harrison, 1997).

Trend
2016: Stable (Monadjem *et al.*, 2017bq). 2008: Stable (Bates *et al.*, 2008; IUCN, 2009). *T. nudiventris* populations within the Asia Minor and Levant region are predicted to have a stable population trend, under climate change scenarios (Bilgin *et al.*, 2012: 433).

REPRODUCTION AND ONTOGENY:
Kurta and Kunz (1987: 82) report that, at birth, the young has a forearm length of about 34.4 % of that of the mother (27.5 against 80.0 mm).

In the United Arab Emirates, Davis (2007: 10) indicates that they arrive in their summer roosts in March, and a single young is born in mid-April. Young are carried by their mothers until 8 weeks of age.

In Gujarat (India), Desai *et al.* (2012: 33) found that pregnancy lasted for 87 days and parturition occurred in August/September. The young reached their full adult size in nine months, when females become sexually mature. The males only become mature at the age of 20 months.

MATING:
In Gujarat (India), Desai *et al.* (2012: 33) report that copulation and fertilization takes place during the last week of March and the first week of April.

PARASITES:
Duszynski (2002: 20) indicates that *T. nudiventris* might be a host for *Eimeria dukei* Lavier, 1927, but as Černá and Ryšavý (1976) did not provide any proof about the parasite, the identification might be wrong, given the fact that eimerians are reasonably host specific.

HEMIPTERA
Cimicidae
Leptocimex vespertilionis Ferris and Usinger, 1957 known only from the Sudan (Zeidab, Khartoum, Wad Medani) (Haeselbarth *et al.*, 1966: 13).

ACARI
Argasidae
Sándor *et al.* (2021a: 4) mentioned *Chiropterargas boueti* (Roubaud and Colas-Belcour, 1933), *Chiropterargas confusus* (Hoogstraal, 1955), and *Carios vespertilionis* Latreille, 1802.

Dermanyssidae
Zumpt and Till (1954: 49) mentions that Hirst (1926) described *Steatonyssus sudanensis* from a "*Liponycteris nudiventris*" from near Khartoum, Sudan, but that this mite hasn't been found since.

Rosensteiniidae
Fain (1979: 125) mentioned a *Nycteriglyphus camerounensis* Fain, 1972 and *Nycterilichus longitarsis* Fain, 1972.

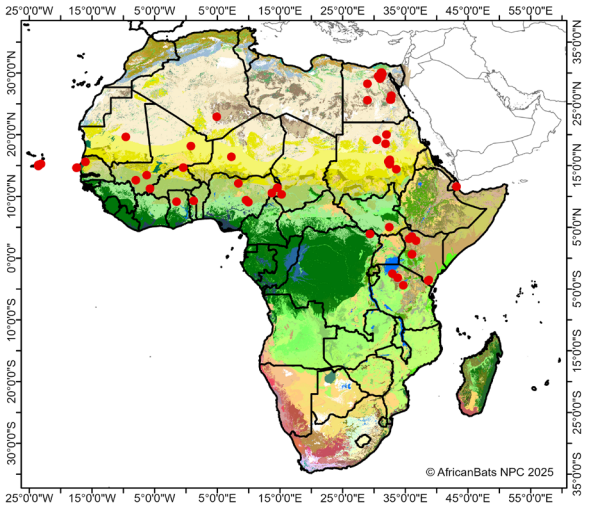

Figure 149. Distribution of *Taphozous nudiventris*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: "Africa", Algeria, Burkina Faso, Cameroon, Cape Verde, Congo (Democratic Republic of the), Djibouti, Egypt, Ethiopia, Ghana, Kenya, Mali, Mauritania, Niger, Nigeria, Senegal, Somalia, South Sudan, Sudan, Tanzania, The Gambia, Togo.

Taphozous perforatus E. Geoffroy St.-Hilaire, 1818

*1818. *Taphozous perforatus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 126. Publication date: 1818. Type locality: Egypt: Kom Ombo [24 26 N 32 57 E]. Holotype: MNHN ZM-MO-1986-1100: ad, alcoholic (skull not removed). Numbers "198" and "A.372" in Rode (1941: 243), who indicates the type might be a male. Previously mentioned as A.372. Paratype: MNHN ZM-AC-1880-236: complete skeleton. Collected by: Etienne Geoffroy-Saint-Hilaire. Paratype: MNHN ZM-AC-A6801: skull only. Collected by: Etienne Geoffroy-Saint-Hilaire. Paratype: MNHN ZM-MO-1985-272: alcoholic (skull not removed). Collected by: Etienne Geoffroy-Saint-Hilaire. - Comments: Allen (1939a: 66) mentioned "Egypt" only as type locality. Restricted to Ombos (=Kom Ombo), between Edfu and Aswan by Kock (1969a: 74): see Meester *et al.* (1986: 32). Mahoney and Walton (1988a: 116) in Grubb *et al.* (1998: 72) considered the date of Geoffroy's publication to be 1813. Gardner and Hayssen (2004: 12) mention that the correct date should be 1818, not 1813 as mentioned on the publication itself. - Etymology: From the masculine scientific Latin adjective *perforàtus*, meaning "perforated", since the tail, as in all Emballonuridae, seems to perforate the uroparagium (see Lanza *et al.*, 2015: 227). (Current Combination).

1877. *Taphozous maritimus* Heuglin, Reise in Nordost Afrika, 2: 25. Publication date: 1877. Type locality: Sudan: Suakin [19 06 N 37 22 E].

1915. *Taphozous perforatus hædinus* Thomas, J. Bomb. nat. Hist. Soc., 24: 62. Publication date: 30 September 1915. Type locality: Kenya: Northern Guaso Nyiro: Chanler Falls [=Chandler's Falls] [00 47 N 38 04 E, 2 000 ft]. Holotype: NHMUK 1912.7.1.46: ad ♂, skin only. Collection date: 3 September 1911; original number: 756.

2014. *Taphozous perforates:* Kohl and Kurth, Viruses, 6 (8): 3115. Publication date: 13 August 2014. (Lapsus).

2023. *Taphozous perforattus:* Al Obaid, Shuraim, Al Boug, Al Jbour, Neyaz, Aloufi and Amr, Diversity, 15 (6): 5. Publication date: 24 May 2023. (Lapsus).

2024. *Taphazois perforatus:* Gippoliti, J. Vertebr. Biol., 73 (23110): 2. Publication date: 5 April 2024. (Lapsus).

? *Taphozous (Taphozous) perforatus:* (Name Combination).

? *Taphozous perforatus haedinus:* (Name Combination).

TAXONOMY:

Harrison (1958b, 1962) regards *sudani* as a separate species, but is not followed in this by subsequent authors (Rosevear, 1965; Kock, 1969a; Hayman and Hill, 1971; Koopman, 1975). Hayman and Hill (1971) make no attempt to recognize subspecies within *perforatus*, but Kock (1969a) recognizes three, *perforatus*, *sudani* and *haedinus*. Koopman (1975) does not agree entirely with the geographic limits suggested by Kock but appears to accept the validity of the names proposed. Simmons (2005) recognized three subspecies: *haedinus* Thomas, 1916; *sudani* Thomas, 1915; and *senegalensis* Desmarest, 1820.

Uvizl *et al.* (2019: 30) could not find any genetic structuring to distinguish *haedinus* from *perforatus* and reject the recognition of subspecies in the Middle East and north-eastern Africa. However, they did not examine material from the type locality, nor from any other East African locality, and therefore do not draw any conclusions about the subspecific status of *haedinus*. A genetic sequence obtained by Benda *et al.* (2025: 31) from a Kenyan bat did not differ from the sequences from other African regions. Therefore, they reject the subspecific status of *haedinus* and consider it a junior synonym of *perforatus*..

Uvizl *et al.* (2019: 30) also indicate that *T. perforatus* is probably of Asian origin, and its occurrence in the Middle East and Africa is the result of a rapid westward expansion, which is illustrated by the lack of genetic structure across its populations.

Benda *et al.* (2025: 73-76) mention that the intraspecific taxonomy of this species is rather controversial and that the subspecific status of *senegalensis* and *sudani* still needs to be confirmed by genetic molecular analyses.

COMMON NAMES:

Afrikaans: Egiptiese witlyfvlermuis. Arabian: Khafash abu bouz saghir, Khaffash. Chinese: 埃及墓蝠. Czech: hrobkovec egyptský, wečerník senegalský, wečerník prowrtaný, netopýr slujový. Dutch: Egyptische grafvleermuis. English: Geoffroy's Tomb Bat, Egyptian Tomb Bat, Tomb Bat, Perforated Taphozous bat, African Taphozous. French: Taphien perforé, Taphien des tombeaux, Chauve-souris des tombes egyptiennes. German: Ägyptische Grabfledermaus. Hebrew: Ashman Katan. Italian: Tafozòo perforàto. Portuguese: Morcego das sepulturas do egipto.

ETYMOLOGY OF COMMON NAME:

The specimen from which this species was described was taken by Geoffroy Saint-Hilaire from a royal tomb in Egypt (see Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Kock *et al.*, 2008d; IUCN, 2009; Monadjem *et al.*, 2017bo; Monadjem *et al.*, 2020c).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bo; Monadjem *et al.*, 2020c). 2008: LC ver 3.1 (2001) (Kock *et al.*, 2008d; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004aa; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: NT D2 ver 3.1 (2001) (Richards *et al.*, 2016b). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
Kock *et al.* (2008d) [in IUCN (2009)], Monadjem *et al.* (2017bo) and Monadjem *et al.* (2020c) report that human disturbance has been highlighted as a threat to *T. perforatus*, but overall it is unlikely that this species is significantly threatened across its very wide range. In South Asia it is threatened by clearing of thorn forests for agricultural purposes, from mining and stone quarrying. Roost disturbance due to human interference and development of old buildings for tourism purposes is also considered serious threats (C. Srinivasulu *pers. comm.*, Molur *et al.*, 2002).

In Egypt, Mansour *et al.* (2017: 109) found that liver and kidney tissues of these bats contained 0.39 µg/g wet weights of DDTs (its usage was prohibited in Egypt in 1980) and 0.11 µg/g wet weights of PCBs (banned worldwide in 1990s). These values showed variations between sexes and seasons.

CONSERVATION ACTIONS:
Kock *et al.* (2008d) [in IUCN (2009)], Monadjem *et al.* (2017bo) and Monadjem *et al.* (2020c) report that this species is present in many protected areas, and no direct conservation measures are currently needed for the species as a whole. The species has not been recorded from any protected areas in Pakistan or India. Being a poorly understood species in the region, more studies on distribution, abundance, reproduction and ecology are recommended (Molur *et al.*, 2002).

GENERAL DISTRIBUTION:
Taphozous perforatus occurs widely throughout northern and sub-Saharan Africa, the Arabian Peninsula, and Asia, east to the Indian Subcontinent. In sub-Saharan Africa, records extend along the Nile and east to Ethiopia and northern Somalia, and west to Mauritania, Senegal, Gambia, Guinea-Bissau, Ghana, Burkina Faso, Benin, Niger, and northern Nigeria, and south to Kenya (including Lamu island), Tanzania, Democratic Republic of Congo, Zimbabwe, and Botswana. In southwest Asia, it has been recorded from Israel, Saudi Arabia, Yemen and Oman. In South Asia, this species is presently known to be widely distributed from southern Pakistan (Roberts, 1977) and western India (Gujarat, Madhya Pradesh and Rajasthan) (Bates and Harrison, 1997, Molur *et al.*, 2002) and recently reported from central Eastern Ghats in Andhra Pradesh (Chakraborty *et al.*, 2004). It has been recorded up to 200 m.

Native: Benin; Botswana (Monadjem *et al.*, 2010d: 535); Burkina Faso (Kangoyé *et al.*, 2015a: 614); Cameroon (Bakwo Fils *et al.*, 2022: 21117); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 535) ; Djibouti (Pearch *et al.*, 2001: 394); Egypt (Benda *et al.*, 2008f: 1); Ethiopia (Lavrenchenko *et al.*, 2004b: 147); Gambia; Ghana; Guinea-Bissau (Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 37); India; Iran, Islamic Republic of; Israel; Kenya; Mali; Mauritania; Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 535); Niger; Nigeria; Oman; Pakistan; Saudi Arabia; Senegal; Somalia; Sudan; Tanzania; Togo; Uganda; Yemen (Benda *et al.*, 2011b: 30); Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 535); Zimbabwe (Monadjem *et al.*, 2010d: 535).

Presence uncertain: Angola; Côte d'Ivoire; Eritrea; Guinea; Namibia (Cotterill, 2004a: 260); Palestinian Territory, Occupied; United Arab Emirates; Zambia.

DETAILED MORPHOLOGY:
Tongue
El-Mansi *et al.* (2019: 24) identified two type of papillae: mechanical, subdivided into two types of conicals (small and large), and filiform (pronged and crown-shaped) papillae; and gustatory, subdivided into vallate (containing about 10 ovoid taste buds) and fungiform types.

ECHOLOCATION:
In Jordan, Benda *et al.* (2010b: 204) registered the following parameters: F_{start}: 31.4 ± 1.5 (29.6 - 34.4) kHz, F_{end}: 27.6 ± 0.6 (26.6 - 28.8) kHz, F_{peak}:

29.2 ± 0.6 (28.5 - 30.0) kHz, duration: 12.4 ± 4.2 (5.8 - 19.7) ms, and interpulse interval: 225.1 ± 110.4 (58.0 - 426.0) ms.

Two sets of data from Iran were presented by Benda *et al.* (2012a: 182): **1**: F_{start}: 31.4 ± 1.6 (30.0 - 34.2) kHz, F_{end}: 29.1 ± 1.7 (28.1 - 31.8) kHz, and F_{peak}: 30.4 ± 2.1 (28.9 - 33.4) kHz; **2** (hand released): F_{start}: 35.9 ± 0.5 (35.3 - 36.6) kHz, F_{end}: 29.9 ± 0.5 (29.4 - 30.8) kHz, F_{peak}: 32.5 ± 0.3 (32.1 - 33.0) kHz, duration: 4.8 ± 0.3 (4.5 - 5.2) ms, and interpulse interval: 47.3 ± 26.8 (12.5 - 81.3) ms.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 32.5 kHz, F_{start}: 35.9 kHz, F_{end}: 29.9 kHz, Band width: 6 kHz, and duration: 4.8 ms.

Götze *et al.* (2016: 2) mentioned that *T. perforatus* doesn't shift the frequency of their echolocation signals (jamming avoidance response - JAR) in the presence of conspecifics.

Molecular Biology:

Karyotype

Đulić (1984) and Yaseen *et al.* (1994) reported 2*n* = 42, FN = 64, BA = 24, a metacentric X chromosome and an acrocentric Y chromosome. Volleth *et al.* (2020b: 258, 260) reported 2*n* = 42 and FNa = 66, containing 12 bi-armed, one subtelocentric and seven acrocentric autosomal pairs, a medium-sized metacentric X and a Y chromosome with the same size as the smallest autosomal, which was too small to determine the shape.

Other

Mansour *et al.* (2016: 66) investigated the presence of heavy metals in bats from two caves in the Saqqara region of Egypt and found that cobalt was not detected in winter and spring, and at very low concentration in the other seasons (ca. 0.01 µg/g tissue). High concentrations were found for Fe, Ca, Mg, and to some extent also Al and Zn, whereas Ba, Cu and Mn were found at relatively lower concentrations, and Cr, Cd, Mo, Ni and Pb were detected at very low concentrations. Ba, Cd, Co, Cr, Mo, Ni and Pb were not detected in kidney tissue. Kidneys of males showed higher concentrations of Mg than those of females.

Roost:

Węgiel *et al.* (2024: 3) reported this species (60 bats) from undamaged domed tombs at the Old Dongola archaeological site (Sudan), and also indicated that none of the damaged tombs housed bats.

Diet:

Rydell and Yalden (1997: 72) report that *T. perforatus* mainly feeds on Lepidoptera (moths - 56 % by volume), but also that Isoptera (14 %), Coleoptera (10 %) and Orthoptera (8 %) are major food categories. Furthermore, Hemiptera, Neuroptera, Hymenoptera and Diptera are eaten.

Predators:

Mikula *et al.* (2016: Supplemental data) mention the Fox kestrel (*Falco alopex* (Heuglin, 1861)) and the Lanner falcon (*Falco biarmicus* Temminck, 1825) as avian predators.

Population:

Structure and Density

It is common in parts of its African range but is less common elsewhere. It is found in small colonies (between six to eight individuals) in the southern African subregion (Skinner and Chimimba, 2005). In South Asia the abundance, population size and trends for this species are not known, and the species has only been recorded from a few localities (Bates and Harrison, 1997).

Trend

2016: Stable (Monadjem *et al.*, 2017bo; Monadjem *et al.*, 2020c). 2008: Stable (Kock *et al.*, 2008d; IUCN, 2009).

Reproduction and Ontogeny:

Krutzsch (2000: 113) indicates that *T. perforatus* is a polyoestrous species, although he also mentions (lower on the same page) that it is monoestrous in parts of its range and polyoestrous in others.

Parasites:

HAEMOSPORIDA

Nycteria medusiformis Garnham and Heisch, 1953 was reported from various countries by Perkins and Schaer (2016: Suppl.).

ARACHNIDA

Argasidae

Sándor *et al.* (2021a: 4) mentioned the presence of *Chiropterargas boueti* (Roubaud and Colas-Belcour, 1933), *Chiropterargas confusus* (Hoogstraal, 1955), and *Reticulinasus salahi* (Hoogstraal, 1953).

DIPTERA

From Iran, Benda *et al.* (2012a: 275) report on the presence of *Raymondia huberi* Frauenfeld, 1855 (Streblidae). They also indicate that this bat fly occurs in a broad area from East Africa to the Middle East. Other parasites reported by Benda *et al.* (2012a: 276) from the north African part of the bat's range are: *Argas boueti* Roubaud et Colas-Belcour, 1933, *Chiropteropsylla aegyptia*

(Rothschild, 1903), and *C. brockmani* Rothschild, 1915.

Dick *et al.* (2023: 74) mentioned that the nycteribiid fly *Basilia (Tripselia) blainvillii blainvillii* (Leach, 1817) has been found on *Taphozous perforatus* from Egypt.

HEMIPTERA
Polyctenidae
Eoctenes intermedius (Speiser, 1912) was reported from the DRC and Egypt by Szentiványi *et al.* (2022: 5).

VIRUSES:
In bats from Saudi Arabia, Mishra *et al.* (2019: 5) found evidence for the presence of the following viruses: Bat astrovirus, Bat Coronavirus, Bat mastadenovirus, Bat papillomavirus, Chuvirus, Rotavirus.

Astroviridae
El Taweel *et al.* (2020: 8) found viruses belonging to the genus Mamastrovirus in bats from Egypt.

Bunyaviridae
Willoughby *et al.* (2017: Suppl.) report the presence of Kaeng Khoi orthobunyavirus.

Coronaviridae - Coronaviruses
Gortazar and Segalés (2013: 954) indicate that recently a virus was identified from a Saudi-Arabian *T. perforatus* specimen that showed 100 % nucleotide identity with MERS-CoV (Middle East Respiratory Syndrome) in a conserved portion of its CoV genome, suggesting that this species might be the host for the MERS-CoV virus [=*Betacoronavirus cameli*].

Flaviviridae
Flavivirus
Dakar bat virus was isolated from the pooled bat organs and salivary glands of this species in 1974 (Williams *et al.*, 1964; Kemp *et al.*, 1974). Reported in this species by de Jong *et al.* (2011: 10), Luis *et al.* (2013: Suppl.), Blitvich and Firth (2017: 3), Willoughby *et al.* (2017: Suppl.).

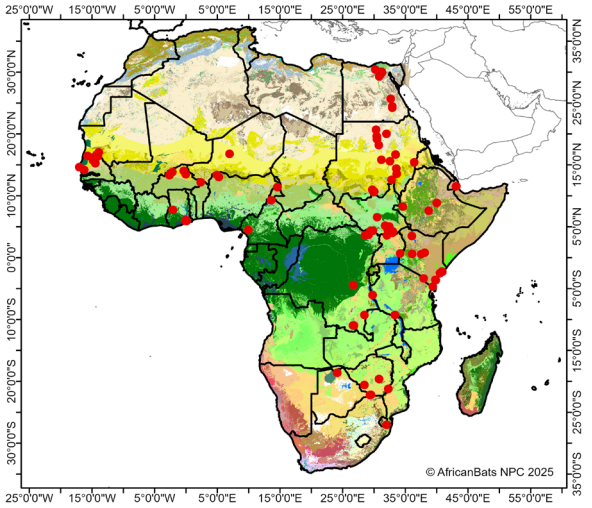

Figure 150. Distribution of *Taphozous perforatus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Botswana, Burkina Faso, Cameroon, Congo (Democratic Republic of the), Djibouti, Egypt, Ethiopia, Ghana, Kenya, Mauritania, Niger, Nigeria, Senegal, South Africa, South Sudan, Sudan, Tanzania, Togo, Uganda, Zambia, Zimbabwe.

Taphozous perforatus perforatus E. Geoffroy St.-Hilaire, 1818

*1818. *Taphozous perforatus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 126. Publication date: 1818. Type locality: Egypt: Kom Ombo [24 26 N 32 57 E]. Holotype: MNHN ZM-MO-1986-1100: ad, alcoholic (skull not removed). Numbers "198" and "A.372" in Rode (1941: 243), who indicates the type might be a male. Previously mentioned as A.372. Paratype: MNHN ZM-MO-1985-272: alcoholic (skull not removed). Collected by: Etienne Geoffroy-Saint-Hilaire. - Comments: Allen (1939a: 66) mentioned "Egypt" only as type locality. Restricted to Ombos (=Kom Ombo), between Edfu and Aswan by Kock (1969a: 74): see Meester *et al.* (1986: 32). Mahoney and Walton (1988a: 116) in Grubb *et al.* (1998: 72) considered the date of Geoffroy's publication to be 1813. Gardner and Hayssen (2004: 12) mention that the correct date should be 1818, not 1813 as mentioned on the publication itself. - Etymology: From the masculine scientific Latin adjective *perforàtus*, meaning "perforated", since the tail, as in all Emballonuridae, seems to perforate the uroparagium (see Lanza *et al.*, 2015: 227). (Current Combination).

1820. *Taphozous senegalensis* Desmarest, Encyclopédie Méthodique, (Zoologie, Mammalogie), 1: 130. Publication date: 1820. Type locality: Senegal: "Senegal". - Comments: Based on "le lérot-volant" of Daubenton, Mém. Acad. Paris, p. 366, 1759 (see Allen, 1939a: 66).

1958. *Taphozous perforatus swirae* Harrison, Durban Mus. Novit., 5 (11): 144. Publication date: 15 December 1958. Type locality: Nigeria: N Nigeria: Sokoto [13 02 N 05 16 E]. Holotype: NHMUK 1967.1226: ad, skin and skull. Collected by: Mrs. Pamela Swire; collection date: 26 August 1958. Skin made up by D.L. Harrison, formerly in HZM collection 12.2690. - Comments: Grubb *et al.* (1998: 72) mention the locality as Sokoyo. Considered a valid subspecies by Grubb *et al.* (1998: 73), but see Kock (1969a: 80 - 81).

? *Taphozous perforatus perforatus:* (Name Combination, Current Combination).

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Burkina Faso, Egypt, Ethiopia, Ghana, Kenya, Mauritania, Niger, Nigeria, Senegal, South Sudan, Sudan, Tanzania, Uganda.

Taphozous perforatus sudani Thomas, 1915

*1915. *Taphozous Sudani* Thomas, Ann. Mag. nat. Hist., 8, 15 (90): 561. Publication date: 1 June 1915. Type locality: Sudan: Equatoria Province: Upper Nile, N of Lado: Mongalla [05 10 N 31 50 E, 500 m]. [Goto Description]. Holotype: NHMUK 1902.7.4.2: ad ♂. Collected by: W.L.S. Loat Esq. Presented/Donated by: W.L.S. Loat Esq. - Etymology: Referring to the country where the type specimen was collected.

1962. *Taphozous sudani australis* Harrison, Occ. Pap. Nat. Mus. S. Rhod., 26B: 763. Type locality: Zimbabwe: Junction between Limpopo and Shashi rivers [22 12 S 29 23 E]. [Goto Description]. Holotype: [Unknown] |TS18|: ad ♂. Collected by: M.P. Stuart Irwin *et al.*; collection date: 5 May 1960; original number: 9932. Rhodesian School Exploration Society Sentinel Ranch Expedition. - Comments: Homonym of *T. australis* Gould, 1854, from Australia (Harrison, 1964a; Kock, 1969a: 74; Meester *et al.*, 1986: 32; Simmons, 2005).

1964. *Taphozous sudani rhodesiae* Harrison, Arnoldia Rhod., 1 (3): 2. - Comments: Renaming of *australis* Harrison, 1962, preoccupied.

? *Taphozous perforatus sudani:* (Current Combination, Current Spelling).

PARASITES:
ACARI
Myobiidae
Fain (1973: 297, 299; 2003: 42) reported *Ugandobia barnley* (Radford, 1951), *Ugandobia garambensis* Fain, 1973 and *Ugandobia vachoni* Fain, 1973 on bats from the DRC and Congo.

HEMIPTERA
Polyctenidae
Eoctenes intermedius (Speiser 1904) from the Congo (Haeselbarth *et al.*, 1966: 16).

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Congo (Democratic Republic of the), South Sudan, Tanzania, Uganda.

†Genus ***Vespertiliavus*** Schlosser, 1887

*1887. *Vespertiliavus* Schlosser, Beitr. Pal. Geol. Österr.-Ung, 6: 70; pl I, figs 37, 40, 44, 45, 47, 48, 50-60,.

†***Vespertiliavus aenigma*** (Ravel, 2016)

*2016. *?Vespertiliavus aenigma* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 356, 384, figs 14, 15. Publication date: 30 September 2016. Type locality: Tunisia: Kassérine governorate: Djebel Chambi National Park: Chambi [35 14 03 N 08 45 29 E, 630 m]. - Etymology: From the Latin *aenigma*, meaning enigma, puzzle or riddle, referring to the original morphology of the specimens, which makes it difficult to assign them systematically (see Ravel *et al.*, 2016: 384).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS: Timeframe: Late lower Eocene (Ypresian - Brown *et al.*, 2019: Suppl.) to early middle Eocene.

†***Vespertiliavus kasserinensis*** (Ravel, 2016)

*2016. *Vespertliavus kasserinensis* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 356, 377, figs 11 - 13. Publication date: 30 September 2016. Type locality: Tunisia: Chambi [35 14 03 N 08 45 29 E, 630 m]. - Etymology: The name refers to the city of Kasserine, at the foot of Djebel Chambi (see Ravel *et al.*, 2016: 377).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS: Timeframe: Late lower Eocene (Ypresian - Centeno-Cuadros *et al.*, 2019: Suppl.) to early middle Eocene.

Family NYCTERIDAE Van der Hoeven, 1855

*1855. *Nycteridae* Van der Hoeven, Handboek Dierkunde, 2nd ed, 2: 1028. - Comments: Type genus: *Nycteris* Cuvier and Geoffroy, 1795. - Etymology: The family gets its name from the Greek name for a bat, *Nycteris* (see Taylor, 2005). (Current Combination).

1866. *Nyctericina* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 91. Publication date: 1 February 1866.

1910. *Petaliidæ* Miller, Proc. Biol. Soc. Wash., 22: 90 [Goto Description]. - Comments: Type genus: *Nycteris* Cuvier and Geoffroy, 1795. Replacement name for Nycteridae Dobson, 1875, due to the fact that Miller (1910) considered the name for the type genus (*Nycteris* Geoffroy 1803) to be antedated by *Nycteris* Borkhausen, 1797).
1984. *Nycteridídae:* Butler, Palaeovert., 14 (3): 117, 185. Publication date: 15 November 1984. (Emendation).
2015. *Nycteriidae:* Anti, Owusu, Agbenyega, Annan, Badu, Nkrumah, Tschapka, Oppong, Adu-Sarkodie and Drosten, Emerg. Inf. Dis., 21 (8): 1419. Publication date: August 2015. (Lapsus).
2018. *Nicteridae:* Malekani, Musaba, Gembu, Bugentho, Toengaho, Badjedjea, Ngabu, Mutombo, Laudisoit, Ewango, Van Cakenberghe, Verheyen, Asimonyo, Masudi, Bongo and Ngbolua, Nat. Conserv. Res., 3 (1): 68. Publication date: January 2018. (Lapsus).

Taxonomy:

Koopman (1993a) mentions Van der Hoeven (1855) as author whereas Corbet and Hill (1992: 88) mention Dobson (1875e: 348).

Flower (1900: 344), Sclater (1901: 120), Medway (1978: 19), Sigé and Legendre (1982), Kock *et al.* (2002b: 82), Hand and Archer (2005: 376), and Lanza *et al.* (2015: 232) use the name Nycteridídae, but we follow Gunnell and Simmons (2005: 212), who state (when referring to the Tanzanycteridae): "This family is a new taxon named by Gunnell *et al.* (2003) for *Tanzanycteris*. They spelled the family name Tanzanycteridídae, but we follow Simmons and Geisler (1998: 133, footnote 13), who argued that all bat family group names based on generic epithets ending with the Greek root -nycteris should be spelled the same way, i.e., -nycteridae rather than -nycteridídae."

Simmons and Geisler (1998: 133) state: "Despite Russell and Sigé (1970)'s argument about the nature of the greek root of -nycteris, we think that it is counterproductive to spell some family-group names in one fashion and others differently. Because Nycteridae is widely accepted as the spelling of the family-group name based on *Nycteris*, we argue that all family-group names based on genera ending in -nycteris should be spelled in the same fashion."

Currently (Simmons and Cirranello, 2024a) recognized genus in the family Nycteridae: ***Nycteris*** G. Cuvier and E. Geoffroy, 1795.
Additionally, there is a fossil genus: *Khoufechia* Ravel, 2016.

Common Names:

Afrikaans: Langoor-vlermuise. Czech: rýhonosovití, nykteridovití. Dutch: Spleetneusvleermuizen. English: Slit-faced bats, Hollow-faced bats, Hispid bats, Long-eared bats. Finnish: Valkopäälepakot. French: Nyctéridés, Chauve-souris à face creuse, Nyctères. German: Schlitznasenfledermäuse, Schlitznasen-Fledermäuse, Schlitznasen. Norwegian: Hullneser, striflaggermus.

Palaeontological or archaeological records:

Shi and Rabosky (2015: 1537) calculated the family-level stem age and crown age to be respectively 52.8 and 17.9 MYA.

The split off from the Emballonuridae occurred according to Amador *et al.* (2016: 22) some 51 MYA, and the diversification within the family started about 33 MYA.

Ravel *et al.* (2016: 415, 418) indicate that *Koufechia gunnelli* represents the basal taxon of the Nycteridae. They also suggest that the family originated in Africa in the Lower Eocene and migrated to Europe in the Oligocene, and even more recently to Asia.

Detailed morphology:

Vomeronasal complex
Smith *et al.* (2024: 13) confirmed a previous observation by Bhatnagar (1980) that VNCs are absent in these bats, but that there are cartilaginous projections, which lead to a nearly separate bar on the animal's right side, and disappear into a mass of bone on the left side.

Molecular Biology:

Karyotype
The karyotype of the various species in this family has a 2*n* value between 34 and 42 (Sotero-Caio *et al.*, 2017: 5).

Parasites:

BACTERIA
Esteves *et al.* (2022: 1) indicate that the Nycteridae - together with the Rhinonycteridae - are the bat families that are most heavily infected by (*Leptospira* bacteria.

Viruses:

Gutiérrez-Guerrero *et al.* (2020: Suppl. Fig 3A) report that worldwide 14 % of the species belonging to this family are confirmed viral carriers.

Filoviridae
Although no Ebolaviruses have been reported from representatives of this family, Shapiro *et al.* (2020b: 1) indicated that the outbreaks or spillover events of Ebola occurred in areas with

high species richness of nycterid bats (and low levels of both anthropogenic disturbance and human population density). They also suggested that more research is required to investigate the role of the Nycteridae in Ebola spillover to humans as up until now the presence of *Ebolavirus* was only examined in one single species: *Nycteris hispida*, which turned out to be negative for this virus.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: "Africa".

†Genus ***Khoufechia*** Ravel, 2016

*2016. *Khoufechia* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 391. Publication date: 30 September 2016. - Etymology: From the Arabian "*Khouféche*", a term to designate abat (see Ravel *et al.*, 2016: 391).

TAXONOMY:
Ravel *et al.* (2016: 358) indicate that this genus has a basal position within the Nycteridae.

†***Khoufechia gunnelli*** Ravel, 2016

*2016. *Khoufechia gunnelli* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 356, 391, figs 18 - 20. Publication date: 30 September 2016. Type locality: Tunisia: Kassérine governorate: Djebel Chambi National Park: Chambi [35 14 03 N 08 45 29 E, 630 m]. - Etymology: In honour of Gregg Gunnell for his numerous contributions to the study of African paleogene bats (see Ravel et al., 2016: 394). (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe: Late lower Eocene (Ypresian - Brown *et al.*, 2019: Suppl.) to early middle Eocene.

Genus ***Nycteris*** E. Geoffroy and G. Cuvier, 1795

*1795. *Nycteris* E. Geoffroy and G. Cuvier, Mag. Encyclop. , 1 année 2: 186. - Comments: Type: *Vespertilio hispidus* Schreber, 1774. Notice that the order of the authors is "Geoffroy and Cuvier" and not "Cuvier and Geoffroy" as most offten mentioned. - Etymology: From the Greek "*νυκτορισ*", meaning "nocturnal", or from the feminine Greek substantive "*νυκτερίς*" (nykterís), "bats" (see Lanza *et al.*, 2015: 234). (Current Combination).
1803. *Nicteris:* Desmarest, Nouveau Dictionnaire d'Histoire Naturelle, 15: 501. (Lapsus).
1813. *Nycterus:* G. Fischer, Zoognosia, ed. iii, I: 18. (Lapsus).
1838. *Petalia* J. E. Gray, Mag. Zool. Bot., Edinburgh, 2 (12): 494. Publication date: 1 February 1838. - Comments: Type species: *Nycteris Javanicus* E. Geoffroy Saint-Hilaire, 1813.
1845. *Nyctoris:* ?, London Encyclopedia, 22: 738. (Lapsus).
1866. *Nycterops* J. E. Gray, Proc. zool. Soc. Lond., 1866, I (vi): 83. Publication date: May 1866 [Goto Description]. - Comments: Type species: *Nycterops pilosa* Gray, 1866 (=*Vespertilio hispidus* Schreber, 1774). - Etymology: Derived from Nycteris and the Greek "*οψ*", meaning aspect (see Palmer, 1904: 465).
1866. *Pelatia:* J. E. Gray, Proc. zool. Soc. Lond., 1866, I (vi): 83. Publication date: May 1866. (Lapsus).
1977. *Petelia:* Lekagul and McNeeley, Mammals of Thailand, 107. (Lapsus).
1998. *Nyteris:* Van Cakenberghe and De Vree, Bonn. zool. Beitr., 48 (2): 123. (Lapsus).
? *Nycteris sp. DMR-2017*
? *Nycteris sp.:*

TAXONOMY:
Meester *et al.* (1986) state that Andersen (1912b) divided *Nycteris* into four groups, three of which, viz. *hispida*, *aethiopica* (= *macrotis* - Koopman, 1965, 1975) and *thebaica*, occur in Southern Africa. The fourth group (*arge*) is limited to the African forest block.

Ellerman and Morrison-Scott (1951 1: 106), Corbet and Hill (1992: 88) mention *Nycteris* to be a *nomen nudum*, which was validated by Opinion 111 (Anonymus, 1929) [See also Stiles (1914: 66)]. Revised by Van Cakenberghe and De Vree (1985, 1993a, 1993b, 1999a). A key is provided by Gray *et al.* (1999: 1, Mammalian Species, 612).

Using mitochondrial and nuclear DNA, Demos *et al.* (2019b) distinguished at least 16 lineages in African *Nycteris*, 10 of which were wholly or partly occurring in East Africa, which made them suspect that more lineages will be found in Central and West Africa. Their analyses confirmed the four species groups recognized within the genus. They distinguish the following putative species: *arge* 1, *arge* 2, *grandis, hispida/aurita*, cf. *hispida/aurita, macrotis* 1, *macrotis* 2, *macrotis* 3, *nana* 1, *nana* 2, *thebaica* 1, *thebaica* 2, *thebaica* 3, *thebaica* 4, *thebaica 5*,

thebaica 6, cf. *thebaica* 1, cf. *thebaica* 2, cf. *thebaica* 3.

Based on morphometric and cyt-*b* analyses, Demos *et al.* (2021: 30) concluded that *N. madagacariensis* G. Grandidier, 1937 is a junior synonym of *Nycteris macrotis* Dobson, 1876. Furthermore, their review of the Grandidier's notes and itinerary suggests that the type specimens were not collected on Madagascar, but rather on coastal East Africa (northern Tanzania or Kenya).

Simmons and Cirranello (2023b: 26;2024a:26) assigned *aurita, grandis, hispida, macrotis, parisii* and *woodi* (as well as the extralimital *javanica* and *tragata*) to the subgenus *Nycteris*. Furthermore, they assigned *gambiensis, intermedia, major, nana* and *thebaica* to an "unnamed" subgenus, and did not assign a subgenus to *arge* ("unassigned")..

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Nycteris*: ***arge*** Thomas, 1903; ***aurita*** (K.Andersen, 1912); ***gambiensis*** (K. Andersen, 1912); ***grandis*** Peters, 1865; ***hispida*** (Schreber, 1774); ***intermedia*** Aellen, 1959; *javanica* E. Geoffroy Saint-Hilaire, 1813 – Java, Nusa Penida (near Bali) and Kangean Isl (Indonesia) (Simmons, 2005: 392); ***macrotis*** Dobson, 1876; ***major*** (K. Andersen, 1912); ***nana*** (K. Andersen, 1912); ***parisii*** (De Beaux, 1924); ***thebaica*** E. Geoffroy Saint-Hilaire, 1818; *tragata* (K. Andersen, 1912) – Burma, Thailand, western Malaysia, Sumatra, Borneo (Simmons, 2005: 394); ***woodi*** K. Andersen, 1914.

COMMON NAMES:
Czech: rýhonosi, šerowecové, dutonosecové, nykteridy. English: Hollow-faced bats, Slit-faced bats. French: Nyctères. German: Schlitznasen-Fledermäuse, Schlitznasen. Italian: Nitterìdi, Nicterìdi. Kiluba (DRC): Kasusu. Kiande (DRC): Kakorokombe.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Avery (2007: 619) reported on the presence of *Nycteris* sp. in Pleistocene deposits at Wonderwerk Cave, South Africa. The approximate fossil date for the genus was reported by Shi and Rabosky (2015: 1532) to be about 5.332 million years ago.

DENTAL FORMULA:
All of the recent *Nycteris* species examined by Czaplewski and Baker (2022: 269) possessed deep carnassiform notches (CN) on the cristid obliqua, but never on the postcristid. They suggest these notches increase the functional efficiency at sectioning chitin.

ECHOLOCATION:
One call from a non-identified *Nycteris* from Zambia was reported by Taylor-Boyd *et al.* (2025: 116): Interpulse interval: 68.5 ms; F_{max}: 71.3 kHz; Start slope: -17.7 kHz/ms; End slope: 16.5 kHz/ms; Ledge duration: 0.5 ms.

Fernandes *et al.* (2025: 6) remark that *Nycteris* species are sometimes not detected acoustically, most probably as a result of their short FM pulses that are often excluded as noise by the sound analysis software.

MOLECULAR BIOLOGY:
Genetics
In their study of the *FoxP2* gene, Li *et al.* (2007: 6) found that *Nycteris* shows the highest rate of non-synonymous change at exon 17, which they link with the evolution of nasal emission, multi-harmonic call structure and prey location by passive listening.

HABITS:
Rainho *et al.* (2023: 7) assigned the *Nycteris* bats in Meru county (Kenya) to a low-flying guild as they are flying at altitudes less than 3.5 m.

ROOST:
In the Ruaha National Park in Tanzania, Dorward *et al.* (2021: 1) reported bats belonging to this genus roosting in latrine cesspits.

In Kenya (Taita-Taveta county), Jackson *et al.* (2023: 5) mentioned four roosts in buildings of which one was shared with another species.

DIET:
Nsengimana *et al.* (2023: 8) analyzed fecal pellets of four sp. individuals from eastern Rwande and found none of these to contain Lepidoptera, but one species of *Conocephalus* Thunberg, 1815 (Orthoptera).

PARASITES:
HAEMOSPORIDA
Perkins and Schaer (2016: Suppl.) reported *Nycteria medusiformis* Garnham and Heisch, 1953 from various countries in Africa.

ACARI
Demodecidae
Fain (1960: 84) described *Stomatodex cornett* from a *Nycteris* sp. from Astrida (= Butare), Rwanda.

Myobiidae
Fain (1994: 1280) indicates that one species of *Ewingana* has been reported from a *Nycteris*, but this is possibly due to a museum contamination. Various species of the genus *Nycteris* do harbour one species of the monotypic genus *Nycterimyobia* (also see Fain, 1994: 1280).

DIPTERA
Nycteribiidae
Penicillida pachymela Speiser, 1901, from Somalia, Sudan, Kenya, Tanzania, the Congo, Guinea and the Cameroon Mts (Haeselbarth *et al.*, 1966: 114; Dick *et al.*, 2023: 78).

HEMIPTEA
Polyctenidae
Eoctenes nycteridis (Horváth, 1910) was reported by Szentiványi *et al.* (2022: 4).

VIRUSES:
Coronaviridae
None of the 18 Kenyan bats tested positive for CoV (Tao *et al.*, 2017: Suppl.). In Guinea, 1 out of 3 *Nycteris* specimens tested by Lacroix *et al.* (2020: 7) was positive for CoV. Widagdo *et al.* (2017: 1) indicate that MERS-CoV-like viruses were detected in 24.9 % of the Ghanaian *Nycteris* bats.

Paramyxoviridae
Mortlock *et al.* (2015: 1841) reported that one of two examined *Nycteris* specimens from Kenya tested positive for *Paramyxovirus* sequences.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Horton *et al.* (2014: Table S1) tested 1 Tanzanian and 1 Kenyan *Nycteris* sp. specimen, but failed to find neutralising antibodies to IKOV (Ikoma lyssavirus).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Cameroon, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Egypt, Ethiopia, Gabon, Ghana, Guinea, Kenya, Mozambique, Namibia, Nigeria, Senegal, Somalia, South Africa, South Sudan, Sudan, Tanzania, Togo, Uganda, Zambia, Zimbabwe.

Nycteris arge Thomas, 1903

*1903. *Nycteris arge* Thomas, Ann. Mag. nat. Hist., ser 7, 12 (72): 633. Publication date: 1 December 1903. Type locality: Cameroon: SW Cameroon: Efulen [02 46 N 10 42 E]. [Goto Description]. Holotype: NHMUK 1904.2.8.2: ad ♂, skull and alcoholic. Collected by: George Latimer Bates Esq. - Etymology: From the Greek "*argos*" meaning shiny, bright, nimble, swift, rapid. (Current Combination).
1910. *Petalia arge:* Thomas and Wroughton, Trans. Linn. Soc. Lond., 19 (5) (63): 488. (Name Combination).
2002. *Nycteris argae:* Fenton and Bogdanowicz, Can. J. Zool., 80: 1008. (Lapsus).
2014. *Nycteris arge 2:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1023. Publication date: 20 August 2019.
2019. *Nycteris arge 1:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 ((4): 1023. Publication date: 20 August 2019.
? *Nycteris arge complex sp. 1 TD-2019*
? *Nycteris arge complex sp. 2 TD-2019*

TAXONOMY:
Formerly included *intermedia* (Hayman and Hill, 1971: 19), but see Van Cakenberghe and De Vree (1985).

arge species group (Van Cakenberghe and De Vree, 1985; Simmons, 2005: 391).

COMMON NAMES:
Castilian (Spain): Murciélago de Cara Hueca. Chinese: 淡色凹脸蝠. Czech: rýhonos guinejský. English: Bates's Slit-faced Bat, Nimble Slit-faced Bat. French: Nyctère de Bates. German: Bates' Schlitznasen-Fledermaus. Kiluba (DRC): Katutu. Tshokwe (Angola): Kafukufuku.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bf; IUCN, 2009; Monadjem *et al.*, 2017ar).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017ar). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bf; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004by; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It parts of its range it is presumably threatened by conversion of forest to agricultural land, and the logging of roost trees (Mickleburgh *et al.*, 2008bf; IUCN, 2009; Monadjem *et al.*, 2017ar).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bf) [in IUCN (2009)] and Monadjem *et al.* (2017ar) reported that in view of the species wide range, it is presumably present in some protected areas. Further studies are needed into the distribution and threats to this species.

GENERAL DISTRIBUTION:
Nycteris arge is widely distributed over much of West and Central Africa. It ranges from Sierra Leone in the west, through West Africa and the Congo Basin to western Uganda, southern Sudan, western Kenya, northern Tanzania and Burundi. It is distributed as far south as southern parts of the Democratic Republic of the Congo and northern Angola.

Amori *et al.* (2016: 217) [referring to Grubb *et al.* (1998: 74)] pointed out that the record from Togo (reported until ACR, 2015) is actually from Ghana.

Native: Angola (Hayman, 1963; Simmons, 2005: 391; Monadjem *et al.*, 2010d: 547); Burundi; Cameroon (Simmons, 2005: 391); Central African Republic (Lunde *et al.*, 2001: 537); Congo (Bates *et al.*, 2013: 335); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Simmons, 2005: 391; Monadjem *et al.*, 2010d: 547); Côte d'Ivoire; Equatorial Guinea [= Bioko] (Simmons, 2005: 391); Gabon; Ghana (Decher and Fahr, 2007: 12 - 13); Guinea (Fahr *et al.*, 2006a: 72); Kenya (Webala *et al.*, 2004: 171; Simmons, 2005: 391); Liberia (Monadjem and Fahr, 2007: 50); Nigeria; Rwanda; Sierra Leone (Simmons, 2005: 391); Sudan (Simmons, 2005: 391); Tanzania; Uganda (Kityo and Kerbis, 1996: 60).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
From western Uganda, Monadjem *et al.* (2011: 30) reported the following data for 11 specimens: Fa: 45.23 ± 0.880 mm, mass: 10.9 ± 0.94 g, wing loading: 5.9 ± 0.50 N/m^2, aspect ratio: 4.8 ± 0.49.

Ferreira *et al.* (2020a: 88) reported on a piebald *Nycteris arge* that was captured in Equatorial Guinea and had distinct white patches on its body and normally pigmented eyes. 90

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
Eisenberg and Wilson (1978: 743) indicate that *N. arge* has a relatively larger cranial volume than its congeners, which they link to differences in feeding strategy and habitat selection.

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 3.15 - 4.28 mm in length; the shaft is long, slender, parallel-sided and essentially straight; the base is expanded and round; in lateral profile it is sometimes angled ventrally while the tip is simple, with only a small expansion (Thomas *et al.*, 1994: 19).

Brain
Tambusso and Fariña (2015: Suppl.) mention a brain mass of 0.36 g for an average body mass of 10.6 g.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Monadjem *et al.* (2011)] mention a wing loading value of 5.9 Pa, aspect ratio 4.8 for a wingspan of 30 cm and a wing area of 181 cm^2 and a body mass of 11 g.

ECHOLOCATION:
From western Uganda, Monadjem *et al.* (2011: 32) reported two different sets of data for two calls each: F_{min}: 21.55 kHz, F_{max}: 22.11 kHz, F_{char}: 21.88 kHz, F_{knee}: 21.77 kHz, duration: 4.1 ms; F_{min}: 46.43 kHz, F_{max}: 47.83 kHz, F_{char}: 47.23 kHz, F_{knee}: 47.23 kHz, duration: 5.9 ms. The authors indicate that these different data might represent harmonics.

Tanshi *et al.* (2022a: 332) mention that the echolocation calls are multi-harmonic steep FM sweeps, which span a range between 13 and 107.7 kHz.

A sound file is available at the Chirovox website (https://www.chirovox.org/), e.g.: https://chirovox.elte.hu/sounds/A003656_DPFCVGLACA.WAV

MOLECULAR BIOLOGY:
Karyotype
Ngene *et al.* (2025: 6) reported 2n = 40 and FN = 78 for Nigerian bats.

Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
R.B. Woosnam [in Thomas and Wroughton, 1910: 488] reported it to be flying low over the water of the Aruwimi River.

Monadjem *et al.* (2016y: 367) recorded this species widely from forested habitats between 400 and 1,000 m in the Mount Nimba area.

POPULATION:
Structure and Density
This is a common species (Mickleburgh *et al.*, 2008bf; IUCN, 2009; Monadjem *et al.*, 2017ar).

Trend
2016: Stable (Monadjem *et al.*, 2017ar). 2008: Stable (Mickleburgh *et al.*, 2008bf; IUCN, 2009).

PARASITES:
HAEMOSPORIDA
Schaer *et al.* (2015a: 381) found *Nycteria* cf. *eradi* parasites in *N. arge* from Sierra Leone. Landau *et al.* (2012: 142) and Perkins and Schaer (2016: Suppl.) mention this parasite as *Nycteria eradi* Rosin, Landau *et al.*, 1978.

HEMIPTERA
Polyctenidae
Eoctenes nycteridis (Horváth 1910) from Liberia, Congo, Ruanda-Urundi, Tanzania, Uganda and Eritrea (Haeselbarth *et al.*, 1966: 17; Szentiványi *et al.*, 2022: 6).

VIRUSES:
Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested [as *N. argae*] between 1986 and 1999, for antibody to SARS-CoV in sera in one individual from Oriental Province, DRC, none tested positive (0/1).

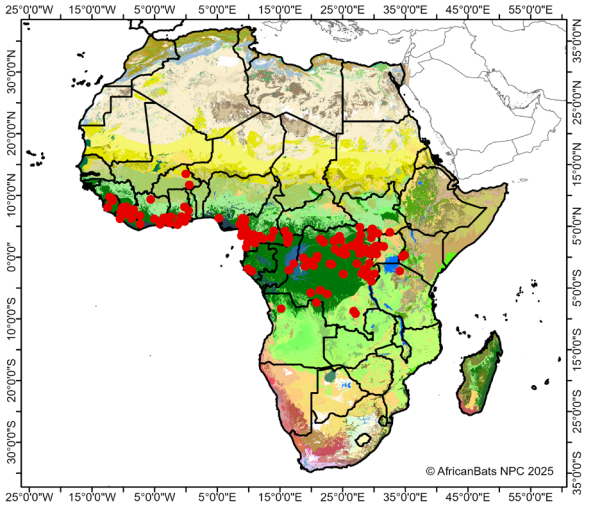

Figure 151. Distribution of *Nycteris arge*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Burkina Faso, Burundi, Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Gabon, Ghana, Guinea, Kenya, Liberia, Nigeria, Sierra Leone, South Sudan, Tanzania, Uganda.

Nycteris aurita (K. Andersen, 1912)

*1912. *Petalia aurita* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): 547. Publication date: 1 November 1912. Type locality: Kenya: Kilifi [03 38 N 39 51 E]. [Goto Description]. Holotype: NHMUK 1889.1.11.1: ad ♀, skull and alcoholic. Collected by: G.D. Trevor-Roper. Presented/Donated by: G.D. Trevor-Roper. - Etymology: From the feminine Latin adjective *aurìta*, meaning "long-eared" (see Lanza *et al.*, 2015: 236).
1924. *Nycteris aurita:* de Beaux, Atti Sic. Lig. Sci. Lett., ns, 3 (1): ???. (Name Combination, Current Combination).
1957. *Nycteris hispida aurita:* Ansell, Ann. Mag. nat. Hist., ser 12, 10: ???. (Name Combination).
2019. *Nycteris cf. hispida/aurita:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1021. Publication date: 20 August 2019.
2019. *Nycteris hispida/aurita:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Syst. Evol. Res., 57 (4): 1021. Publication date: 20 August 2019.
? *Nycteris hispida/aurita complex sp. TD-2019*
? *Nycteris hispida:* (Name Combination).

GENERAL COMMENTS:
Lanza *et al.* (2015: 236) pointed out that we erroneously mentioned Kitui as type locality for this taxon, whereas this should be Kilifi.

TAXONOMY:
Nycteris aurita is often considered as a synonym or subspecies of *N. hispida* (Blyth, 1863: 391), but see Van Cakenberghe and De Vree, 1993b).

hispida species group Van Cakenberghe and De Vree, 1993b; Simmons, 2005: 391).

COMMON NAMES:
Chinese: 安氏凹脸蝠. Czech: rýhonos východoafrický. English: Andersen's Slit-faced Bat. French: Nyctère d'Andersen, Nyctère à longues oreilles. German: Andersens Schlitznasen-Fledermaus. Italian: Nitterìde orecchiùta, Nicterìde orecchiùta.

CONSERVATION STATUS:
Global Justification
Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population (it is common where it has been recorded), and because its savanna habitat is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008r; IUCN, 2009; Monadjem *et al.*, 2017f).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017f). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008r; IUCN, 2009). 2004: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2004n; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known, however, it is likely that there are no major threats to the species, as it has been recorded from an extensive habitat that is not severely declining (Mickleburgh *et al.*, 2008r; IUCN, 2009; Monadjem *et al.*, 2017f).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008r) [in IUCN (2009)] and Monadjem *et al.* (2017f) report that it is not known if there are any direct conservation measures in place, or if the species is present within any protected areas. Further studies are needed into the distribution, natural history and possible threats to this little-known species.

GENERAL DISTRIBUTION:
Nycteris aurita is known from scattered records in East Africa. It has been recorded from northern Somalia in the north of its range, through southern Ethiopia and Sudan, into Kenya and Tanzania in the south.

Native: Ethiopia (Lavrenchenko *et al.*, 2004b: 147; Simmons, 2005: 391); Kenya (Simmons, 2005: 391); Somalia (Simmons, 2005: 391); Sudan; Tanzania (Simmons, 2005: 391), United Republic of; Uganda; Zambia.

POPULATION:
Structure and Density
There is little information available on the abundance of this species, but it seems to be common where it has been recorded (Mickleburgh *et al.*, 2008r; IUCN, 2009; Monadjem *et al.*, 2017f).

Trend
2016: Unknown (Monadjem *et al.*, 2017f). 2008: Unknown (Mickleburgh *et al.*, 2008r; IUCN, 2009).

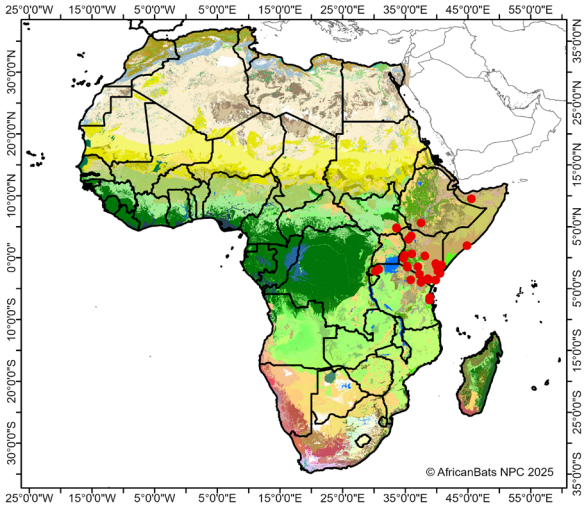

Figure 152. Distribution of *Nycteris aurita*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia, Kenya, Rwanda, Somalia, South Sudan, Tanzania.

Nycteris cf. parisii De Beaux, 1924

2016. *Nycteris cf. parisii* Kruskop, Benda, Vasenkov and Lavrenchenko, Lynx, 47: 60.

TAXONOMY:
Due to the lack of molecular genetic analyses, Kruskop *et al.* (2016: 60) indicate that taxonomic composition and species delimitations in the *N. woodi* complex are rather uncertain. Van Cakenberghe and De Vree (1985) suggested that *parisii* and *benuensis* are synonyms of *N. woodi*, but based on bacular morphology, Thomas *et al.* (1994) suggested that *parisii* is specifically different from *woodi*. Kruskop *et al.* (2016: 60) state that the shape of the baculum of the specimens they report on, is more like that of *woodi*, and not like that of *parisii* which would be the species involved if the complex contains more than one species.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia.

2021.	*Nycteris gambianus:* Coertse, Geldenhuys, le Roux and Markotter, Viruses, 13 (4): 4. Publication date: 29 March 2021. (Lapsus).

TAXONOMY:
Reviewed by Van Cakenberghe and De Vree (1999a).

thebaica species group (Van Cakenberghe and De Vree, 1999a; Simmons, 2005: 392).

COMMON NAMES:
Czech: rýhonos západoafrický. English: Gambian Slit-faced Bat. French: Nyctère de Gambie. German: Gambia Schlitznasen-Fledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Bergmans and Fahr, 2008; IUCN, 2009; Monadjem *et al.*, 2017ah).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017ah). 2008: LC ver 3.1 (2001) (Bergmans and Fahr, 2008; IUCN, 2009). 2004: LC ver 3.1 (2001) (Bergmans and Fahr, 2004; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this species overall. It is threatened in parts of its range by habitat loss, often resulting from conversion of savanna to agricultural use (Bergmans and Fahr, 2008; IUCN, 2009; Monadjem *et al.*, 2017ah).

CONSERVATION ACTIONS:
Bergmans and Fahr (2008) [in IUCN (2009)] and Monadjem *et al.* (2017ah) report that there appear to be no direct conservation measures in place for this species, and it is not known if it occurs in any protected areas. There is a need to protect roosts of this species, and to better determine the eastern limits of the species range.

GENERAL DISTRIBUTION:
Nycteris gambiensis is a West African species which ranges from Senegal and the Gambia, through most of West Africa, as far east as central Nigeria. There is a single uncertain record from Cameroon which requires verification.

A record from Sierra Leone is in error (J Fahr *pers. comm.* in Simmons, 2005: 392)

Native: Benin (Simmons, 2005: 392); Burkina Faso (Simmons, 2005: 392; Kangoyé *et al.*, 2015a: 615); Côte d'Ivoire (Simmons, 2005: 392); Gambia (Simmons, 2005: 392); Ghana (Simmons, 2005: 392); Guinea (Simmons, 2005: 392; Decher *et al.*, 2016: 264); Guinea-Bissau (Monard, 1939; Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 43; Simmons, 2005: 392); Mali; Mauritania; Niger; Nigeria (Simmons, 2005: 392); Senegal (Simmons, 2005: 392); Togo (Simmons, 2005: 392).
Uncertain: Cameroon; Sierra Leone (Simmons, 2005: 392).

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 2.88-3.42 mm in length; the shaft is slender and parallel-sided; the base is expanded and in lateral view is angled ventrally, while the tip is simple with a slight expansion (Thomas *et al.*, 1994:22).

POPULATION:
Structure and Density
It can be a locally common species (Bergmans and Fahr, 2008; IUCN, 2009; Monadjem *et al.*, 2017ah).

Trend
2016: Unknown (Monadjem *et al.*, 2017ah).
2008: Unknown (Bergmans and Fahr, 2008; IUCN, 2009).

PARASITES:
CESTODA
Hymenolepididae
Jenzen and Howell (1983: 135) referred to Edungbola (1981) , who mentioned *Vampirolepsis kerivoulae* (Hübscher, 1937) from a bat from Nigeria

VIRUSES:
Willoughby *et al.* (2017: Suppl.) report the following viruses: Chobar Gorge virus, Lagos bat lyssavirus, Saboya virus.

Coronaviridae - Coronaviruses
Betacoronavirus
Annan *et al.* (2013: 457) reported that 46 out of 185 (24.9 %) *N.* cf. *gambiensis* specimens tested in Ghana were found to be positive for 2c *Betacoronavirus*. They also found that juvenile bats and lactating females were more likely to be infected than adult males and non-lactating females.

Flaviviridae
Flavivirus
de Jong *et al.* (2011: 10) and Luis *et al.* (2013: suppl.) reported Saboya virus occurring on this species. Calderon *et al.* (2016: 8) also mention Sokuluk virus.

Reoviridae
Orbivirus
Fomede virus
Reported in the CDC's Arbovirus Catalogue, to have been isolated in 1978 from the Republic of Guinea, from the brain and internal organs of *N.* cf. *gambiensis*. Reported by de Jong *et al.* (2011: 11) and Luis *et al.* (2013: suppl.).

Rhabdoviridae
Lyssavirus - Rabies related viruses
Lagos bat virus
Isolated in Guinea (Institute Pasteur, 1985). Coertse *et al.* (2021: 4) mention this was the only time LBV was found in an insectivorous bat.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Benin, Burkina Faso, Cameroon, Côte d'Ivoire, Ghana, Guinea, Guinea-Bissau, Nigeria, Senegal, The Gambia, Togo.

Nycteris grandis Peters, 1865

*1865. *Nycteris grandis* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 351, 358. Type locality: Ghana: vicinity of Elmina [05 05 N 01 21 W]. [Goto Description]. Holotype: RMNH MAM.27348: ad, skin only. Collected by: Colonel C.J.M. Nagtglas; collection date: 1863. Previously (before 2025), we had this specimen mentioned as "paralectotype". However, the online catalog mentions this specimen as "holotype", which agrees with Peters (1865a: 359), who mentions a single specimen in the RMNH collection. - Comments: Grubb *et al.* (1998: 76) mention the type locality as 'Usually given as "Guinea" but the type, in the Leiden Museum, was collected in 1863 by Nagtglas, and ascribed to Côte d'Or (Jentink, 1888b: 170). The type locality may be further restricted to the vicinity of Elimina [Ghana] which is the only definite locality Jentink cited for any of the Nagtglas material'. The publicatiion covers a meeting held on 13 July 1865. - Etymology: From the Greek "*grandis*" meaning magnificent (Brown, 1991; Jaeger, 1972, both in Hickey and Dunlop, 2000: 3). (Current Combination).

1866. *Nycteris Baikii* J. E. Gray, in: Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 672 (for 1866). Type locality: "Africa": West Africa: Baikie. - Comments: Meester *et al.* (1986: 34) mention "Gray in Peters" as author. Nomen nudum.

1912. *Petalia grandis:* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): ???. (Name Combination).

1923. *Nycteris marica* Kershaw, Ann. Mag. nat. Hist., ser 9, 12 (70): 534. Publication date: 1 October 1923. Type locality: Tanzania: Kilosa: Tindiga [06 55 S 37 20 E]. [Goto Description]. Holotype: NHMUK 1923.8.2.1: ad, skin and skull. Collected by: Professor Arthur Loveridge; collection date: 24 January 1922.

1925. *Nycteris proxima* Lönnberg and Gyldenstolpe, Ark. Zool. Stockholm, 17B (9): 1. Publication date: 14 May 1925. Type locality: Congo (Democratic Republic of the): Semliki valley: Kartoushi [00 44 N 29 34 E]. [Goto Description]. Holotype: NRM 100755: ad ♂. Collection date: 11 May 1921; original number: 813. See Lönnberg and Gyldenstolpe (1925: 2).

1938. *[Nycteris] narica:* Frechkop, Exploration du Parc National Albert, 50. (Lapsus).

1938. *[Nycteris] praxima:* Frechkop, Exploration du Parc National Albert, 50. (Lapsus).

1981. *N[ycteris] g[randis] marica:* Kock, Senckenb. biol., 61 (5/6): 325. (Name Combination).

1991. *Nycteris graudis:* Baker, Honeycutt and Van den Bussche, Bull. Am. Mus. Nat. Hist., 206: 46. (Lapsus).

2016. *Nycteris grande:* Bhatnagar, Smith, Rai and Frahm, Anat. Rec., 299: 495. Publication date: 21 January 2016. (Lapsus).

TAXONOMY:

Figure 155. *Nycteris grandis*, Zanzibar Island.

Reviewed by Van Cakenberghe and De Vree (1993b). *N. marica* is sometimes recognized as a distinct savanna subspecies, but this does not seem justified based on morphology (Van Cakenberghe and De Vree, 1993b; Hickey and Dunlop, 2000; Simmons, 2005: 392).

hispida species group (Van Cakenberghe and De Vree, 1993b; Simmons, 2005: 392).

COMMON NAMES:

Afrikaans: Groot spleetneusvlermuis. Chinese: 魁凹脸蝠. Czech: rýhonos velký, nycteris velká. English: Large Slit-faced Bat. French: Grande nyctère. German: Große Schlitznase, Große Schlitznasen-Fledermaus. Portuguese: Morcego grande orelhudo.

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bg; IUCN, 2009; Monadjem *et al.*, 2017g).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017g). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bg; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004cd; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

None known.

MAJOR THREATS:

In general, there appear to be no major threats to this species as a whole. It is threatened in parts of its range by habitat loss, particularly the logging of large trees used for roosting. Some populations may be threatened by overharvesting for subsistence food (Mickleburgh *et al.*, 2008bg; IUCN, 2009; Monadjem *et al.*, 2017g).

CONSERVATION ACTIONS:

Mickleburgh *et al.* (2008bg) [in IUCN (2009)] and Monadjem *et al.* (2017g) report that in view of the

species wide range, it is presumably present in a number of protected areas. No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Nycteris grandis is broadly distributed in sub-Saharan Africa. It ranges from Senegal, through West and Central Africa, to southern Sudan, southeastern Kenya and eastern Tanzania, with scattered records as far south as Zambia, Zimbabwe and Mozambique. Also found on the islands of Zanzibar and Pemba (Simmons, 2005: 392). It is a lowland species.

Native: Benin; Burkina Faso (Kangoyé *et al.* (2012: 6025; 2015a: 615); Cameroon; Central African Republic (Lunde *et al.*, 2001: 537); Congo (Bates *et al.*, 2013: 335); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547); Côte d'Ivoire; Equatorial Guinea (Fahr and Ebigbo, 2003: 128); Gabon; Ghana; Guinea; Kenya (Simmons, 2005: 392); Liberia (Fahr, 2007a: 103); Malawi (Happold *et al.*, 1988; Happold and Happold, 1997b: 815; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547); Mozambique (Smithers and Lobão Tello, 1976; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547; Monadjem *et al.*, 2010c: 381); Nigeria; Senegal (Simmons, 2005: 392); Sierra Leone; Sudan; Tanzania (Stanley and Goodman, 2011: 43) (including the islands of Pemba and Unguja [O'Brien, 2011: 289]); Togo (Capo-Chichi *et al.*, 2004: 162); Uganda (Kityo *et al.*, 2009b: 137); Zambia (Ansell, 1969; Ansell, 1986; Monadjem *et al.*, 2010d: 547); Zimbabwe (Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Hickey and Dunlop (2000).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Hickey and Dunlop (2000).

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 3.45-3.54 mm in length and is small in relation to body size; the shaft is stout and deep, unlike that of any other *Nycteris* examined, the base is narrow and in lateral profile is usually angled ventrally, while the tip is squared, with a pronounced ventral projection (Thomas *et al.*, 1994: 21).

Other
For a description of the skull, ears and tragus, and wingshape and aspect ratio see Hickey and Dunlop (2000).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 11.4 Pa, aspect ratio 5.2 for a wingspan of 38 cm and a wing area of 277 cm^2 and a body mass of 32 g.

SEXUAL DIMORPHISM:
N. grandis is not sexually dimorphic in size (Hickey and Dunlop, 2000: 1).

ECHOLOCATION:
See Taylor (1999b) and Hickey and Dunlop (2000).

Keeley *et al.* (2018: 14) indicate that echolocation calls range between 17 and 114 kHz. Tanshi *et al.* (2022a: 332) mention multi-harmonic calls with a range between 32 and 83 kHz.

MOLECULAR BIOLOGY:
Karyotype
Porter *et al.* (2010) reported for a single male Gabonese specimen as $2n = 42$, with 34 biarmed and 6 acrocentric autosomes, with an X as a large subtelocentric and the Y is a small acrocentric.

Ngene *et al.* (2025: 6) reported $2n = 40$ (p. 6) and 42 (p. 11), and FN = 80 (p. 6) and 82 (p. 11) for Nigerian bats.

HABITAT:
This species has been recorded from a variety of lowland habitats, ranging from lowland tropical moist forest (often found near to swampy sites) to drier savanna areas and Miombo woodland (Rosevear, 1965; Fenton *et al.*, 1990; Hickey and Dunlop, 2000; Skinner and Chimimba, 2005). Kangoyé *et al.* (2015a: 615) report it from a gallery forest in Lera, Burkina Faso.

In the Mount Nimba area, Monadjem *et al.* (2016y: 367) recorded this species from forested and forest edge habitats between 400 and 700 m.

HABITS:
See Hickey and Dunlop (2000).

ROOST:
Nycteris grandis generally roosts in hollow trees, but is also found in manmade structures such as houses (Fenton *et al.*, 1990; 1993), disused water towers (Fenton *et al.*, 1990; 1993) and culverts (Rosevear, 1965). They may also roost in hollow

fallen logs, and holes or small caverns in rocks (Rosevear, 1965; Hickey and Dunlop, 2000).

Happold and Happold (2023: 107) mention they can roost singly, in twos or in small groups, and some of these groups can consist of one male and several pregnant or lactating females, possibly making up harems.

DIET:
Fenton *et al.* (1981: 463; 1990: 2, 4) found that in the Mana Pools National Park, in Zimbabwe, *N. grandis* primarily fed on frogs (e.g., *Ptychadena anchietae, P. mossambica, P.* spp., *Xenopus laevis*), bats (e.g., *Nycteris thebaica, Rhinolophus* cf *darlingi*, "*Pipistrellus* cf. *nanus*", *Hipposideros* cf. *caffer*), arthropods, but sometimes also captured birds (*Cisticola fulvicapilla, Apalis flavida*) and fish (*Tilapia rendalli*, *Barbus* sp., *Alestes* sp.).

Based on various publications by Brock Fenton, Gual-Suárez and Medellín (2021: Suppl.) mention the following prey items: Arachnida: Pholcidae and Solifugae. Insects: Coleoptera: *Cybister senegalensis, Heteronitis castelnaui, Onitis* sp., Tenebrionidae; Dictyoptera; Hemiptera; Homoptera: *Platypleura brevis, Platypleura marshalli, Platypleura quadraticollis*; Hymenoptera; Lepidoptera: *Achaea trapezoids, Acherontia atrops, Hypopyra capensis, Pandesma robusta, Polydesma* sp., *Sarangesa motozi, Pachypasa truncate, Agrius convolvuli, Euchloron megaera, Nephele comma, Omomantis zebrata*; Mantodea: *Polyspilota aeruginosa*; Neuroptera; Odonata; Orthoptera: *Aiolopus* sp., *Arantia* sp., *Gryllacris* sp., *Brachytrupes membranaceus*, *Gryllotalpa* sp., *Lobosceliana brevicornis*, *Sia pinguis*, *Conocephalus* sp., *Horatosphaga* sp., *Zabalius* sp.; Trichoptera. They also mention as variety of vertebrates: Fish: *Tilapia rendalli, Barbus* sp., *Alestes* sp.; Frogs: *Hyperolius marmoratus, Chiromantis xerampelina, Xenopus laevis, Ptychadena anchietae, Ptychadena mossambica*; Birds: *Apalis flavida, Cisticola fulvicapilla* and Nectariniidae; and even other bats: *Rhinolophus darlingi, Rhinolophus landeri, Hipposideros caffer, Hipposideros ruber, Neoromicia capensis* and *Neoromicia nanus*.

Tomita (2025: Suppl.) [referring to Bayefsky-Anand, 2005: 95] reported an unidentified cicada as prey item for *Nycteris grandis*, but Bayefsky-Anand (2005: 95) identified two species: *Oxypleura quadraticollis* (Butler, 1874) and *Brevisana brevis* (Walter, 1850) [=Shrill thorntree cicada]. She also identified two species of antlion: *Palpares tristis* Hagen, 1853 and *Syngenes debilis* (Gerstaecker, 1885).

Gual-Suárez and Medellín (2021: 1) considered *Nycteris grandis* to be the only carnivorous bat in Africa and based on its ecology and the seasonality of its habits it was assigned to the group of seasonal predominantly gleaning carnivores (which further included *Megaderma lyra* and *Macroderma gigas*).

Happold and Happold (2023: 106) mention that small vertebrates make up to 80 % of the diet by weight, where frogs were the main prey (in numbers) in March-May, bats in June-July and arthropods in December-February, but this composition can change from year to year.

Vleut *et al.* (2019: 11) [referring to Fenton *et al.* (1990: 4)] mention that these bats can commute up to 2.2 km to their hunting grounds.

POPULATION:
Structure and Density
It appears to be a rare, or rarely recorded, species. The species occurs in small colonies, but is usually found only as single animals or in pairs (Mickleburgh *et al.*, 2008bg; IUCN, 2009; Monadjem *et al.*, 2017g).

Trend
2016: Decreasing (Monadjem *et al.*, 2017g).
2008: Decreasing (Mickleburgh *et al.*, 2008bg; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
See Hickey and Dunlop (2000).

REPRODUCTION AND ONTOGENY:
Krutzsch (2000: 115), referring to Verschuren (1957), indicates that *N. grandis* is polyoestrous with two or more (continuous) cycles per year, a postpartum oestrus and often no anoestrus.

Stanley and Goodman (2011: 43), referring to Verschuren (1957), report on a pregnant female collected on 31 July 1993 in the East Usambara Mountains (Tanzania).
Pakenham (1984: 28) reported a pregnant female on Zanzibar in December.

PARASITES:
Little information is available regarding parasites of *N. grandis* (Hickey and Dunlop, 2000).

HAEMOSPORIDA
Schaer *et al.* (2015a: 381) found two different forms of *Nycteria* sp. parasites in *N. grandis* from Sierra Leone. Karadjian *et al.* (2016: 9834) mentioned *Nycteria medusiformis* and *Nycteria* sp. from the DRC. *Nycteria* sp. parasites were

also found in the single bat from Cameroon examined by Tsague *et al.* (2021: 3).

Keymer (1971) reported "broad trypanosomes" from four of six specimens collected from Zambia.

HEMIPTERA
Polyctenidae
Eoctenes nycteridis (Horváth, 1910) from Liberia, Congo, Ruanda-Urundi, Tanzania, Uganda and Eritrea (Haeselbarth *et al.*, 1966: 17; Szentiványi *et al.*, 2022: 6).

SIPHONAPTERA
Pulicidae
Echidnophaga aethiops Jordon and Rothschild, 1906 locality not mentioned (Haeselbarth *et al.*, 1966: 135).

VIRUSES:
Circoviridae
Vidovszky *et al.* (2023: Suppl.) reported Bat associated cyclovirus 12 from a bat in the DRC.

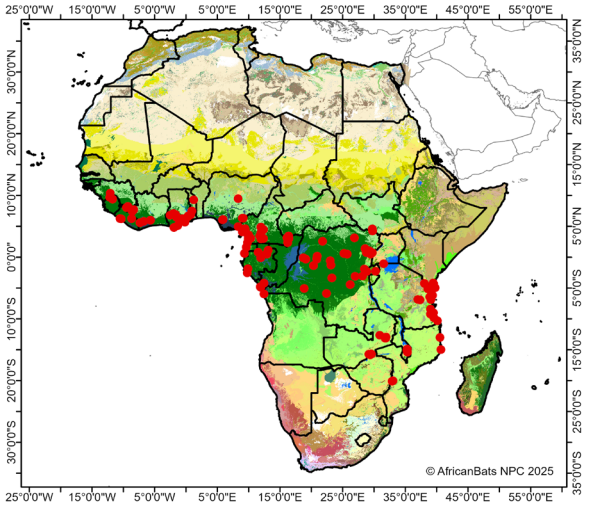

Figure 156. Distribution of *Nycteris grandis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Central African Republic, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Gabon, Ghana, Guinea, Kenya, Liberia, Malawi, Mozambique, Nigeria, Rwanda, Sierra Leone, Tanzania, Togo, Zambia, Zimbabwe.

Nycteris hispida (Schreber, 1774)

*1774. *Vespertilio hispidus* Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, 1 (8): pl 56 + 1 (9): 169, 188. Publication date: 1774. Type locality: Senegal: "Senegal". [Goto Description]. - Etymology: From the masculine Latin adjective *hispidus*, meaning "shaggy", referring to the bristly hair around the facial slit (see Lanza *et al.*, 2015: 242).

1813. *Nycteris Daubentonii* E. Geoffroy Saint-Hilaire, Ann. Mus. Hist. nat. Paris, 20: 19. Publication date: August 1813. Type locality: Senegal: "Senegal". [Goto Description].

1840. *Nycteris hispida:* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 3: ???. (Name Combination, Current Combination).

1843. *Nycteris poensis* J. E. Gray, Catalogue of the species of mammals of the British Museum, 24. Publication date: 13 May 1843. Type locality: Equatorial Guinea: Bioko [formerly Fernando Po] [ca. 03 21 N 08 40 E]. [Goto Description]. Holotype: NHMUK 1855.12.26.252: ad ♀, skin and skull. Presented/Donated by: Captain E. Downes R.N. Intended specimen = *Rhinolophus martini* Fraser: see Meester *et al.* (1986: 33). - Comments: Considered a nomen nudum by Dobson (1878: 162) and Allen (1939a: 69).

1843. *Rhinolophus Martini* Fraser, Proc. zool. Soc. Lond., 1843, V (cxxi): 25. Publication date: July 1843. Type locality: Equatorial Guinea: Bioko [formerly Fernando Po] [ca. 03 21 N 08 40 E]. [Goto Description].

1852. *Nycteris villosa* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 48, pl 11. Publication date: 1852. Type locality: Mozambique: Inhambane [24 00 S 35 28 E]. [Goto Description]. Holotype: ZMB 394/85665: ♂, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008) [skull: ZMB 394 + skeleton: ZMB 85665]. - Comments: Considered a valid subspecies by Taylor (1998: 33).

1866. *Nycterops pilosa* J. E. Gray, Proc. zool. Soc. Lond., 1866, I (vi): 83. Publication date: May 1866. Type locality: "Africa": "Africa".

1878. *Nycteris hispida villosa:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 163. Publication date: 15 June 1878. (Name Combination).

1883. *Nycteris hispidus:* Rochebrune, Act. Soc. Linn. Bordeaux, 37: 93. (Name Combination).

1910. *Petalia hispida:* Thomas and Wroughton, Trans. Linn. Soc. Lond., 19 (5) (63): 488. (Name Combination).

1917. *Nycteris pallida* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 425. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Faradje [03 44 N 29 43 E]. [Goto Description]. Holotype: AMNH 49144: ad ♂. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 1 March 1912; original number: 1858. Paratype: RMCA 12390: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 22 Novermber 1911; original number: formerly AMNH 49119. Topotype: MCZ 17226: ♂, alcoholic (skull not removed). Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 9 March 1912.

1935. *[Nycteris hispida] martini:* Braestrup, Vidensk. Meddr dansk naturh. Foren., 99: 88. (Name Combination).

1935. *N[ycteris] h[ispida] pallida:* Braestrup, Vidensk. Meddr dansk naturh. Foren., 99: 88. (Name Combination).

1935. *Nycteris hispida hispida:* Braestrup, Vidensk. Meddr dansk naturh. Foren., 99: 88. (Name Combination).

2019. *Nycteris cf. hispida/aurita:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1021. Publication date: 20 August 2019.

2019. *Nycteris hispida/aurita:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Syst. Evol. Res., 57 (4): 1021. Publication date: 20 August 2019.
2019. *Nycteris hispidar:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).
? *Nycteris cf. hispida/aurita TD-2019*

TAXONOMY:

Figure 157. *Nycteris hispida*, Zanzibar Island.

Koopman (1975: 377, 378) includes *aurita* and *pallida*. Van Cakenberghe and De Vree (1993b) consider *aurita* as a separate species.

hispida species group (Van Cakenberghe and De Vree, 1993b; Simmons, 2005: 392).

COMMON NAMES:
Afrikaans: Harige spleetneusvlermuis, Harige Langoorvlermuis. Chinese: 粗毛凹脸蝠. Czech: rýhonos štětinatý, šerowec senegalský. English: Hairy Slit-faced Bat, Hairy Long-eared Bat. French: Nyctère hérissée, Nyctère hirsute. German: Rauhaarschlitznase, Gemeine Schlitznasen-Fledermaus, Haarige Schlitznasenfledermaus. Italian: Nitterìde irsùta, Nicterìde irsùta, Nitterìde ìspida, Nicterìde ìspida. Kiluba (DRC): Katutu. Malawian: Liputiputi, Ndemiya, Namzeze. Portuguese: Morcego orelhudo piloso. Tshokwe (Angola): Kafukufuku.

ETYMOLOGY OF COMMON NAME:
Although this species is not hairier than any of the other slit-faced bats, the name is applied to it as a translation of the specific name *hispida*, which is from the Latin *hispidus*, meaning hairy or bristly, referring to the bristly hair around the facial slit (see Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008s; IUCN, 2009; Monadjem *et al.*, 2017h).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017h). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008s; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004m; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016c). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this species. It is locally threatened in parts of its range by habitat loss, largely through the conversion of forest to agricultural use (Mickleburgh *et al.*, 2008s; IUCN, 2009; Monadjem *et al.*, 2017h).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008s) [in IUCN (2009)] and Monadjem *et al.* (2017h) report that in view of the species wide range it is presumably present in a number of protected areas (including the Udzungwa Mountains National Park of Tanzania (Stanley *et al.*, 2005b)). No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
This species has a wide range, encompassing much of sub-Saharan Africa, with the exception of the Horn of Africa and parts of southern Africa. There is an apparently disjunct population in western Mauritania close to the border with Senegal, and an isolated record from central Mali. Also recorded from the island of Unguja [=Zanzibar] (Simmons, 2005: 392; O'Brien, 2011: 289).

The records from Cape of Good Hope are probably invalid (Cotterill, 1996a).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 710,458 km^2.

Native: Angola (Crawford-Cabral, 1989; Hayman, 1963; Simmons, 2005: 392; Monadjem *et al.*,

2010d: 547); Benin (Capo-Chichi *et al.*, 2004: 162); Botswana (Archer, 1977; Cotterill, 2004a: 261; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547); Burkina Faso (Kangoyé *et al.*, 2015a: 615); Burundi; Cameroon; Central African Republic (Lunde *et al.*, 2001: 537); Chad; Congo (Bates *et al.*, 2013: 336); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 547); Côte d'Ivoire; Equatorial Guinea [= Bioko] (Simmons, 2005: 392); Ethiopia (Lavrenchenko *et al.*, 2004b: 132); Gabon; Gambia (Simmons, 2005: 392; Emms and Barnett, 2005: 50); Ghana; Guinea (Fahr *et al.*, 2006a: 72); Guinea-Bissau (Bocage, 1892a; Monard, 1939; Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 41); Kenya; Liberia (Fahr, 2007a: 103); Malawi (Happold *et al.*, 1988; Happold and Happold, 1997b: 815; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547); Mali; Mauritania (Simmons, 2005: 392); Mozambique (Smithers and Lobão Tello, 1976; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547; Monadjem *et al.*, 2010c: 381); Namibia (Monadjem *et al.*, 2010d: 547); Niger; Nigeria; Rwanda; Senegal (Adam and Hubert, 1976; Simmons, 2005: 392); Sierra Leone; Somalia (Simmons, 2005: 392); South Africa (Monadjem *et al.*, 2010d: 547); Sudan; Tanzania (Stanley *et al.*, 2005b); Togo; Uganda (Kityo and Kerbis, 1996: 60); Zambia (Ansell, 1973; Ansell, 1974; Ansell, 1986; Monadjem *et al.*, 2010d: 547); Zimbabwe (Monadjem *et al.*, 2010d: 547).

Detailed morphology:

Baculum

The baculum ranges from 3.33 - 4.16 mm in length, the shaft is long, slender and variably ventrally curved, the base is expanded and in lateral profile is angled ventrally, while the tip is sometimes angled ventrally, it has a projection on the ventral aspect varying between individuals from a slight swelling to a pronounced hook (Thomas *et al.*, 1994: 20).

Functional morphology:

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 5.4 Pa, aspect ratio 4.8 and tip shape index of 2.02 for a wingspan of 27 cm and a wing area of 146 cm^2 and a body mass of 8 g.

Echolocation:

In Benin, the bat's call was categorized as a FMd (Frequency modulation downward) sonotype by Roemer *et al.* (2021: Suppl.).

Tanshi *et al.* (2022a: 332) reported mulit-harmonic calls with a frequency range of 81 - 132 kHz and F^{max} > 100 kHz.

See also Taylor *et al.* (2005).

Molecular Biology:

Karyotype

Lee *et al.* (1989) reported 2*n* = 42, FN = 78, BA = 38, and a metacentric X and Y.

Habitat:

Nycteris hispida has been recorded from a wide variety of habitats, ranging from lowland tropical moist forest, into moist savanna, dry savanna, papyrus swamps and marsh.

R.B. Woosnam [in Thomas and Wroughton, 1910: 488] reported it to be most numerous among the acacia trees on the plains around the south end of the Ruwenzori range.

Monadjem *et al.* (2016y: 367) recorded *N. hispida* sparsely in open savanna on the Liberian side of Mount Nimba.

Roost:

Colonies roost in hollow trees, dense bushes, caves, holes in termite colonies and similar habitats.

Predators:

Mikula *et al.* (2016: Supplemental data) mention *N. hispida* to be taken by the Western marsh harrier (*Circus aeruginosus* (Linnaeus, 1758)).

Population:

Structure and Density

Colonies range in size from individual and pairs of animals to up to 20 bats. This is a very common bat (Mickleburgh *et al.*, 2008s; IUCN, 2009; Monadjem *et al.*, 2017h).

Trend

2016: Stable (Monadjem *et al.*, 2017h). 2008: Stable (Mickleburgh *et al.*, 2008s; IUCN, 2009).

Reproduction and ontogeny:

Krutzsch (2000: 94) reports that the testes are probably permanently scrotal in *N. hispida*, according to Matthews (1941). The specieis's reproductive cycle is polyoestrous with two or more (continuous) cycles per year, a postpartum oestrus and often no anoestrus. Matthews (1941) also noticed that copulation followed shortly after parturition.

In Burkina Faso, Kangoyé *et al.* (2015a: 615) captured females carrying young during the month of September.

From Sierra Leone, Weber *et al.* (2019: 25) reported a lactating female with a young attached on 25 May.

Pakenham (1984: 28) caught a sucking young on 18 November on Zanzibar.

PARASITES:

BACTERIA

Obodoechi *et al.* (2021: 3) investigated the antimicrobial resistance of *E. coli* bacteria recovered from Nigerian bats. 70 % of these showed resistance to one of the antimicrobial agents they tested.

PROTOZOA

Kassahun *et al.* (2015: 168) examined one *N. hispida* specimen from Awash-Methara (Ethiopia) and found it infected by *Leishmania major* Friedlin (see also Azami-Conesa *et al.*, 2021: Suppl.; de Souza *et al.*, 2023: 4).

Based on the original description, Austen and Barbosa (2021: 7) and Sato and Mafie (2022: 2) mention the presence of *Trypanosoma (Megatrypanum) heybergi* from the DRC.

Thiombiano *et al.* (2023: 4) reported one *Nycteris hispida* (only one was examined) from Burkina Faso infected by *Trypanosoma* cf. *livingstonei*.

ACARI

Trombiulidae

Vercammen-Grandjean and Fain (1958: 30) described *Trombigastia (Trombigastia) nycteris* from *N. hispida hispida* from the Astrida region (= Butare), Rwanda (Stekolnikov, 2018a: 120).

HEMIPTERA

Polyctenidae

Eoctenes nycteridis (Horváth, 1910) from Liberia, Congo, Ruanda-Urundi, Tanzania, Uganda and Eritrea (Haeselbarth *et al.*, 1966: 17; Szentiványi *et al.*, 2022: 6).

SIPHONAPTERA

Ischnopsyllidae

Lagaropsylla idea Smit, 1957, primary host being molossids but recorded from this taxon (Haeselbarth *et al.*, 1966: 190).

VIRUSES:

Circoviridae

Porcine circovirus 3 was reported by Vidovszky *et al.* (2023: Suppl.) from a *Nycteris* cf. *hispida* from the DRC.

Coronaviridae - Coronaviruses

SARS-CoV

One fecal sample was tested by Pfefferle *et al.* (2009) in Ghana in February 2008, and this was found to be negative for coronavirus (CoV) RNA.

Hantaviridae (formerly included in Bunyaviridae)

Hantavirus

Weiss *et al.* (2012b: 160) report the presence of a new hantavirus, named Magboi virus [MGBV], in one *N. hispda* specimen collected at the Magboi River, Gola National Park, Sierra Leone. Arai *et al.* (2019b: 2) and Arai and Yanagihara (2020: 7) tentatively included this virus in the genus *Loanvirus*.

Paramyxoviridae

Drexler *et al.* (2012a: Suppl. Table S1) indicated that the single specimen they examined from Ghana did not test positive for *Repirovirus, Henipavirus, Morbillivirus, Rubulavirus* or *Pneumovirus*.

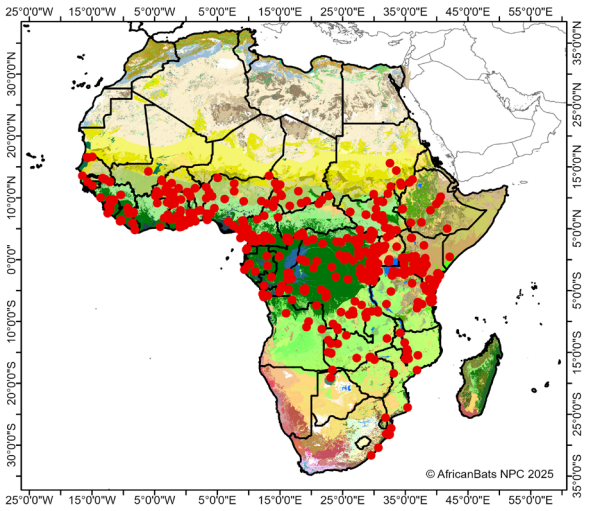

Figure 158. Distribution of *Nycteris hispida*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

"Africa", Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Ethiopia, Gabon, Ghana, Guinea, Guinea-Bissau, Kenya, Lesotho, Liberia, Malawi, Mali, Mauritania, Mozambique, Namibia, Nigeria, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

Nycteris intermedia Aellen, 1959

*1959. *Nycteris intermedia* Aellen, Archs Sci. Genève, 12 (2): 218. Type locality: Côte d'Ivoire: NW of Abidjan: Adiopodoumé [05 19 N 04 08 W, 0 - 30 m]. [Goto Description]. Holotype: MHNG 923.094: ad ♀, skull and alcoholic. Collected by: Dr. Villy Aellen; collection date: 20 July 1953; original number: A1437. Paratype: MHNG 923.095: ad ♀, skull and alcoholic. Collected by: Dr. Villy Aellen; collection date: 24 July 1953; original number: A1438. Paratype: MHNG 923.096: ad ♀, skull and alcoholic. Collected by: Dr. Villy Aellen; collection date: 19 August 1953; original number: A1439. Paratype: ad ♀; alcoholic and skull; Collector: Villy Aellen; Original number: Collection date:. Paratype: MHNG 923.097: ad ♀, skull and alcoholic. Collected by: Dr. Villy Aellen; collection date: 24 July 1953; original number: A1440. - Etymology: Referring to its intermediary size between *Nycteris arge* and *Nycteris nana*. (Current Combination).

TAXONOMY:

Formerly included in *N. arge*, but Van Cakenberghe and De Vree (1985) regard this as a distinct species (Simmons, 2005: 392).

COMMON NAMES:

Czech: rýhonos prostřední. English: Intermediate Slit-faced Bat. French: Nyctère d'Aellen, Nyctère moyen. German: Intermediäre Schlitznasenfledermaus, Intermediäre Schlitznasen-Fledermaus.

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, it occurs in some protected areas, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bh; IUCN, 2009; Monadjem *et al.*, 2017au).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017au). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bh; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004bm; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional

None known.

MAJOR THREATS:

The species is threatened in parts of its range by deforestation including loss of roosting trees (Mickleburgh *et al.*, 2008bh; IUCN, 2009; Monadjem *et al.*, 2017au).

CONSERVATION ACTIONS:

Mickleburgh *et al.* (2008bh) [in IUCN (2009)] and Monadjem *et al.* (2017au) report that there do not appear to be any direct conservation measures in place, however, the species has been recorded from some protected areas (e.g., Comoe National Park and Tai National Park both in Côte d'Ivoire). Further research is needed into the distribution, natural history and threats to this species.

GENERAL DISTRIBUTION:

Nycteris intermedia is broadly distributed in sub-Saharan Africa, ranging from Liberia in the west, to western Tanzania in the east, with records as far south as northeastern Angola. The species appears to be known from around 27 localities. It is typically a lowland species.

Native: Angola (Van Cakenberghe *et al.*, 1999; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 547); Cameroon; Central African Republic (Lunde *et al.*, 2001: 537); Congo (The Democratic Republic of the); Côte d'Ivoire (Simmons, 2005: 392); Equatorial Guinea; Gabon; Ghana; Guinea (Denys *et al.*, 2013: 282); Liberia (Simmons, 2005: 392); Tanzania (Simmons, 2005: 392).

MOLECULAR BIOLOGY:

Karyotype

Denys *et al.* (2013: 282) report the karyotype for one female from the Guinean Mount Nimba area as: $2n = 34$, NFa = 62, including 15 pairs of large to small metacentric and submetacentric chromosomes and one middle-sized acrocentric pair. The X chromosome is submetacentric.

POPULATION:

Structure and Density

This species appears to be relatively rare. It is usually found as small groups of animals (Mickleburgh *et al.*, 2008bh; IUCN, 2009; Monadjem *et al.*, 2017au).

Trend

2016: Decreasing (Monadjem *et al.*, 2017au). 2008: Decreasing (Mickleburgh *et al.*, 2008bh; IUCN, 2009).

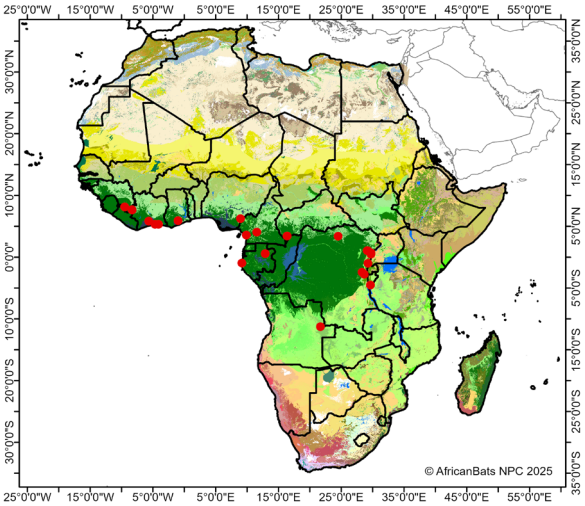

Figure 159. Distribution of *Nycteris intermedia*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Angola, Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Gabon, Ghana, Guinea, Liberia, Nigeria, Tanzania.

Nycteris macrotis Dobson, 1876

*1876. *Nycteris macrotis* Dobson, Monograph of the Asiatic Chiroptera and catalogue of the species of bats in the collection of the Indian Museum Calcutta, 80. Type locality: Sierra Leone: "Sierra Leone". [Goto Description]. Holotype: NHMUK 1866.2.2.2: sad ♂, skull and alcoholic. - Etymology: From the Greeek adjective "*μακρός*" (macròs), meaning "long, large" and the neuter Greek substantive "*οὖς*" (genitive *ώu0964\ός*"; "*ûs*", "*ōtós*"), meaning "ear", although the ear of the species is not of especially outstanding size (see Lanza *et al.*, 2015: 244). (Current Combination).

1878. *Nycteris æthiopica* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, xxxviii, 162, 165, pl 11, fig 3. Publication date: 15 June 1878. Type locality: Sudan: Kordofan province: Sennaar [15 35 N 33 38 E, 425 m]. [Goto Description]. Holotype: NHMUK 1847.5.27.32: ad, skin and skull. Collected by: Theodor Kotschy.

1901. *Nycteris aethiopica aethiopica:* Thomas, Ann. Mag. nat. Hist., ser 7, 8 (43): 30.

1901. *Nycteris aethiopica luteola* Thomas, Ann. Mag. nat. Hist., ser 7, 8 (43): 30. Publication date: 1 July 1901. Type locality: Kenya: Kitui [01 22 S 38 01 E, 3 500 ft]. [Goto Description]. Holotype: NHMUK 1901.5.6.4: ad ♀, skin and skull. Collected by: Dr. Sidney Langford Hinde; collection date: 14 February 1901.

1912. *P[etalia] macrotis:* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): 548. (Name Combination).

1912. *P[etalia]. ?thiopica luteola:* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): 549. (Name Combination).

1912. *P[etalia]. ?thiopica ?thiopica:* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): 549. (Name Combination).

1917. *Nycteris major* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 427. - Comments: Not of Andersen (1912b).

1922. *Nycteris oriana* Kershaw, Ann. Mag. nat. Hist., ser 9, 10 (56): 179. Publication date: 1 August 1922. Type locality: Malawi: Shiré valley: Chiromo [16 32 S 35 09 E, 60 m]. [Goto Description]. Holotype: NHMUK 1922.4.25.3: ad ♀, skin and skull. Collected by: Rodney Carrington Wood Esq. Collection date: 7 June 1918; original number: 312.

1923. *Nycteris luteola:* Loveridge, Proc. zool. Soc. Lond., 1923, II: 396.

1937. *Nycteris madagascariensis* G. Grandidier, Bull. Mus. natn. Hist. nat., Paris, sér 2, 9: 353. Publication date: November 1937. Type locality: Madagascar: N of Diego-Suarez [=Antsiranana]: Rodo valley, N of Pirkana: Ankarana, near the [12 05 S 49 05 E]. [Goto Description]. Holotype: MCZ 45433: skull and alcoholic. Collection date: June 1910. Formerly Grandidier collection; see Helgen and McFadden (2001: 142). Demos *et al.* (2021: 21) indicated that this is an unsexed specimen. Paratype: MCZ 45434: ad ♀, skull and alcoholic. Formerly Grandidier collection; see Helgen and McFadden (2001: 142). - Comments: Based on a review of Grandidier's notes and itinary, Demos *et al.* (2021: 30) conclude that the type specimens were not collected on Madagascar, but on the east coast of the African mainland (possibly either northern Tanzania or Kenya). Mitochondrial material from the type specimen also place this specimen within the continental populations. - Etymology: Referring to the island of Madagascar, where the species occurs.

1939. *Nycteris æthiopica guineensis* Monard, Arq. Mus. Bocage, 10: 66, fig 4. Publication date: March 1939. Type locality: Guinea-Bissau: Mansoa [12 04 N 15 19 W]. [Goto Description]. Syntype: [Unknown] |TS501|: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 1937; original number: 284. Syntype: [Unknown] |TS502|: ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 1937; original number: 282. Syntype: MHNG 1326.005: ad ♂, skull and alcoholic. Collected by: Dr. Albert Monard; collection date: 14 December 1937; original number: 283. Syntype: MHNG 861.052: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 14 December 1937; original number: 283. Syntype: NMBA 5271: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 17 Decembre 1937; original number: 319. Syntype: RMCA 15310: ad ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 1937; original number: 285. - Comments: Monard (1939: 66) mentions a larger series: 282 (♀), 283 (♂), 284 (♂), 285 (♀), 319 (♂).

1939. *Nycteris æthiopica guineensis f. aurantiaca* Monard, Arq. Mus. Bocage, 10: 68. Publication date: March 1939. Type locality: Guinea-Bissau: Pitche [12 20 N 13 57 W]. [Goto Description].

1942. *Nycteris aethiopica oriana:* G.M. Allen and Loveridge, Bull. Mus. comp. Zool., 89 (4): 150, 161.

1953. *Nycteris macrotis macrotis:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 54. (Name Combination).

1953. *Nycteris macrotis oriana:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 54. (Name Combination).
1960. *Nycteris macrotis luteola:* Harrison, J. East Afr. Nat. Hist. Soc., 23 (7) (104): 288. Publication date: December 1960. (Name Combination).
1965. *Nycteris vinsoni* Dalquest, J. Mamm., 46 (2): 254, 256. Publication date: May 1965. Type locality: Mozambique: 212 km SSW Beira, S bank Save river: Zinave [21 26 S 33 52 E]. [Goto Description]. Holotype: KU 105221: ad ♀, skin and skull. Collected by: Prof. Dr. Walter Woelber Dalquest; collection date: 8 October 1963; original number: MWUC 18739. See Jones and Genoways (1969: 130). - Etymology: In honour of J. Vinson, who sponsored an expedition to Mozambique during which the first specimens were collected (see Dalquest, 1965; Taylor, 2005).
1969. *Nycteris macrotis aethiopica:* Kock, Abh. Senckenberg. naturforsch. Ges., 521: 97. (Name Combination).
2011. *Nycteris macrotus:* Altringham, Bats, Plate 12. (Lapsus).
2018. *Nycteris macrotis lutreola:* Gunnell and Manthi, J. Hum. Evol., Suppl. Publication date: 6 April 2018. (Lapsus).
2019. *Nycteris macrotis 1:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1023. Publication date: 20 August 2019.
2019. *Nycteris macrotis 2:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1023. Publication date: 20 August 2019.
2019. *Nycteris macrotis 3:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1023. Publication date: 20 August 2019.
? *Nycteris aethiopica:* (Alternate Spelling).
? *Nycteris macrotis complex sp. 1 TD-2019*
? *Nycteris macrotis complex sp. 2 TD-2019*
? *Nycteris macrotis complex sp. 3 TD-2019*
? *Nycteris marcrotis oriana:* (Name Combination).

Taxonomy:

Meester *et al.* (1986) indicate that both Koopman (1965, 1975, 1982) and Kock (1969a) included the extralimital [to southern Africa] *aethiopica* Dobson, 1878, and *luteola* Thomas, 1901, as subspecies in this species. While Hayman and Hill (1971) treat *macrotis* and *aethiopica* as separate species, they confirm that the distinction is by no means certain.

N. macrotis macrotis Dobson, 1876 may include also *Plecotus aethiopicus* Fitzinger, 1866, from the White Nile, a *nomen nudum* (Kock, 1969a).

Kock (1969a) regards *oriana* as a synonym of the extralimital *luteola*, but Ansell (1978) and Smithers (1983) treat it as a separate subspecies.

Includes *madagascariensis* Grandidier, 1937 (see Demos *et al.*, 2021: 30) and *vinsoni* Dalquest, 1965 (see next paragraph).

Nycteris vinsoni

Bronner *et al.* (2003) state that is was originally described from Mozambique (Dalquest, 1965). Kock (1969a) considered *Nycteris vinsoni* a synonym of *N. macrotis luteola*, based on the size and position of the second lower premolar. Hayman and Hill (1971) suggest that *N. vinsoni* is a variant of *N. aethiopica*, itself considered a member of the *N. macrotis* group (Koopman, 1965; Kock, 1969a). Koopman (1975) argued that the size and position of the second lower premolar is extremely variable, and instead recognised *vinsoni* as a distinct species closely related to *N. thebaica*, based on the presence of a pyriform tragus (and see Koopman, 1982). He later concluded that the tragus of the holotype is actually semilunate and therefore synonymised *vinsoni* under *N. macrotis oriana* (Koopman, 1992, 1993a). Swanepoel *et al.* (1980), Meester *et al.* (1986), Corbet and Hill (1992) and Simmons (2005: 394) retained *vinsoni* as a distinct species, a treatment endorsed by limited morphometric comparisons (Van Cakenberghe and De Vree, 1999a). However, Van Cakenberghe and De Vree (1999a: 132) and Simmons (2005: 394) consider it a member of the *thebaica* species group.

Simmons (2005: 393) recognises three subspecies - *aethiopica* Dobson, 1878; *luteola* Thomas, 1901; and *oriana* Kershaw, 1922.

Figure 160. *Nycteris macrotis*, Zanzibar Island.

Common Names:

Afrikaans: Groter spleetneusvlermuis. Chinese: 大耳凹脸蝠. Czech: rýhonos velkouchý, nykteris velkouchá. English: Large-eared Slit-faced Bat, Greater Slit-faced Bat, Big-eared slit-faced bat. French: Nyctère de Dobson, Nyctère à grandes

oreilles. German: Großohrige Schlitznasen-Fledermaus. Italian: Nitterìde di Dòbson, Nicterìde di Dobsòn. Malawian: Liputiputi, Ndemiya, Namzeze. Tshokwe (Angola): Kafukufuku.

ETYMOLOGY OF COMMON NAME:
Although the specific name *macrotis* is derived from the Greek "*makros*" and "*otis*" meaning large eared, the species' ears are in fact smaller than in species such as the Egyptian slit-faced bat (*N. thebaica*) (see Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008aa; IUCN, 2009; Monadjem *et al.*, 2017k).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017k). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008aa; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004at; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
In general, there are no major threats to this species. In parts of its range it is threatened by general habitat loss, presumably mostly through the conversion of land to agricultural use (Mickleburgh *et al.*, 2008aa; IUCN, 2009; Monadjem *et al.*, 2017k).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008aa) [in IUCN (2009)] and Monadjem *et al.* (2017k) report that in view of the species wide range it is presumably present in some protected areas (it has been found in at least one, i.e. Parc National du 'W' (Poché, 1975)). No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Nycteris macrotis is a widespread African species which ranges from Senegal in the west, to Somalia in the east, being recorded as far south as northern Botswana. Found on the island of Zanzibar (Simmons, 2005: 392). It has been recorded between sea level and 2,200 m asl.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,466,326 km^2.

Native: Angola (Hayman, 1963; Van Cakenberghe and De Vree, 1985; Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 547); Benin (Capo-Chichi *et al.*, 2004: 162); Botswana (Monadjem *et al.*, 2010d: 547); Burkina Faso (Kangoyé *et al.*, 2015a: 616); Burundi; Cameroon; Central African Republic; Chad; Congo (Bates *et al.*, 2013: 336); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Gallagher and Harrison, 1977; Van Cakenberghe and De Vree, 1985; Dowsett *et al.*, 1991: 259; Monadjem *et al.*, 2010d: 547); Côte d'Ivoire; Equatorial Guinea; Ethiopia (Simmons, 2005: 392); Gabon; Gambia (Emms and Barnett, 2005: 50; Simmons, 2005: 392); Ghana; Guinea; Guinea-Bissau (Seabra, 1900a; Monard, 1939; Rainho and Ranco, 2001: 44); Kenya; Liberia (Fahr, 2007a: 103); Malawi (Happold *et al.*, 1988; Van Cakenberghe and De Vree, 1985; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 548); Mali (Meinig, 2000: 105); Mauritania (1st record: Benda *et al.*, 2011a: 267); Mozambique (Lopes and Crawford-Cabral, 1992; Simmons, 2005: 392; Monadjem *et al.*, 2010d: 548; Monadjem *et al.*, 2010c: 381); Niger; Nigeria; Rwanda; Senegal (Simmons, 2005: 392); Sierra Leone; Somalia; Sudan; Tanzania (including the island of Unguja [O'Brien, 2011: 289]); Togo; Uganda (Kityo and Kerbis, 1996: 60); Zambia (Ansell, 1967; Ansell, 1973; Ansell, 1978; Cotterill, 2002b: 6; Monadjem *et al.*, 2010d: 548); Zimbabwe (Simmons, 2005: 392; Monadjem *et al.*, 2010d: 548).

Presence uncertain: Namibia (Cotterill, 2004a: 261).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Fain (1953b: 102) reported on the exceptional yellowish-orange colour of some specimens from a cave near the Nyumba Mission (Rwanda). Other specimens from the save cave were uniformly orange or somewhat darker, or yellowish-brown with a few grey hairs, brownish-grey with orange-yellowish hairs, and brownish-grey with a pale belly without any yellowish or orange hairs. These colour differences were not found to be linked with either the sex or the age of the specimens

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 3.84 to 5.12 mm in length, the shaft is long, parallel-sided and usually straight, thickening towards the base, the base has two basal lobes of varying development, in lateral view it is sometimes

angled ventrally, while the tip is expanded and trifid with three variably developed processes (Thomas *et al.*, 1994: 21).

Brain
Based on specimens from Bénin, Amrein *et al.* (2007) reported that proliferating cells, detected with Ki-67 and MCM2, in the subgranular layer of the dentate gyrus was found to be absent. Amrein *et al.* (2007) also reported moderate to ample proliferating cells (Ki-67 positive cells) and migrating young neurons (DCX positive cells) in the rostral migratory stream. Furthermore, Amrein *et al.* (2007) detected few DCX positive cells in the rostral migratory stream and the olfactory bulb. No NeuroD was detected in the hippocampal granule cells (Amrein *et al.*, 2007).

Femur
Louzada *et al.* (2019: 136) provided a detailed description of the femur, which has a well-developed medial ridge that begins on the shaft of the femur, a short and well-developed lateral ridge, and well-developed trochanters. The latter nearly reach the same level proximally. The femur is greatly sinusoidal, and the torsion of the proximal epiphysis is the most conspicuous of all the bat families they examined.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 7.1 Pa, aspect ratio 5.2 and tip shape index of 1.84 for a wingspan of 29 cm and a wing area of 159 cm^2 and a body mass of 12 g.

ECHOLOCATION:
Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 76.7 kHz and duration: 1.2 ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd (Frequency modulation downward) sonotype.

MOLECULAR BIOLOGY:
Karyotype
In the absence of data on a male of this species (only one female from Somalia), Lee *et al.* (1989) described the karyotype as having a diploid number of 2*n* = 40, FNa = 74, BA = 36, X = M, and suggested that the Y chromosome might be a small metacentric as in the other *Nycteris* species. Volleth *et al.* (2020a: 272) reported that a male from Benin had the following karyotype: 2*n* = 40, FNa = 76, with all of the chromosomes bi-armed, consisting of two large submetacentric pairs, 17 medium to small meta- to submetacentric, a medium-sized metacentric X and a very small metacentric Y. Based on the different FNa number, Volleth *et al.* (2020a: 276) suggest that the two specimens might belong to closely related but different species. They also suggest that the Somalian specimen might possibly belong to *Nycteris parisii*, "*aethiopica*", or "*Nycteris* cf. *parisii*" (sensu Kruskop *et al.*, 2016: 60).

HABITAT:
Monadjem *et al.* (2016y: 367) reported one specimen from the Mount Nimba area, which was recorded from a disturbed habitat close to a settlement at 500 m.

HABITS:
Mazur *et al.* (2019: 172) radio-tracked a number of *N. macrotis* specimens in Ghana, and found these to display regular activity patterns of approximately three foraging flights per night. After each foraging bout, they returned to their day roost without using any additional night roosts.

ROOST:
In the Parc National du 'W' in Niger Republic, 300 km west of Sokoto, they have been found roosting in thatched huts and others were found in abandoned mine shafts (Poché, 1975). Stanley *et al.* (2007c: 60) refer to Koopman (1975), who mentions that *N. macrotis* is known to roost in burrows in the ground made by aardvarks (*Orycteropus afer*) or porcupines (*Hystrix cristata*). Weber and Fahr (2006: 4) indicate that *N. macrotis* largely or exclusively depends on the availability of caves as day roosts in Guinea.

Webala *et al.* (2022: 2) report on a group of about 15 bats using a pit latrine as a day roost in Kenya.

Happold and Happold (2023: 109) indicate that *N. macrotis* usually roosts singly or in small groups, which generally include one adult male and one or more adult females, and sometimes also subadult females, which suggest a harem structure.

POPULATION:
Structure and Density
In the Parc National du 'W' in Niger Republic, 300 km west of Sokoto, they have been found roosting in groups of 10-20 individuals (Poché, 1975). Happold (1987) notes that they are solitary or live in small groups.

Trend
2016: Unknown (Monadjem *et al.*, 2017k). 2008: Unknown (Mickleburgh *et al.*, 2008aa; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Krutzsch (2000: 115) indicates that most nycterid species (including *N. aethiopica* = *N. macrotis*) are polyoestrous with two or more (continuous) cycles per year, a postpartum oestrus and often no anoestrus. In the DRC and Rwanda, Anciaux de Faveaux (1978c) reported copulations in August and October.

Happold and Happold (1990b: 566) reported that, in Malawi, young were born in the wet season and early dry season, suggesting an aseasonal or extended seasonal reproduction, and that females are not in reproductive synchrony.

Matthews (1937) [in Krutzsch (2000: 115)] noted that male *N. luteola* [= *N. macrotis*] collected at the time of post partum oestrus were reproductively functional. For the same "species", Martin and Bernard (2000: 32) reported that the corpus luteum is only present for the first half of pregnancy. Krutzsch (2000: 94) furthermore reports that the testes are probably permanently scrotal.

Pakenham (1984: 28) collected a very young animal and a juvenile on 4 November on Zanzibar.

PARASITES:
BACTERIA
15 out of 17 Nigerian *Nycteris macrotis* specimens that were examined by Kamani *et al.* (2021: 4) tested positive for *Leptospira borgpetersenii*.

PROTOZOA
Schaer *et al.* (2015a: 381) found *Nycteria* sp. parasites in *N. macrotis* from South Sudan. Based on older references, Austen and Barbosa (2021: 7) mentioned *Trypanosoma (Megatrypanum) mpapuense* from "*Nycteris aethiopica*" from Tanganyika and *Trypanosoma (Megatrypanuml) thomlasi* from the DRC. In northern Nigeria; Kamani *et al.* (2022a: Suppl.) found 11 out of 16 *Nycteris* cf. *macrotis* specimens to be infected by *Trypanosoma* cf. *livingstonei*. A single *N. macrotis* from Uganda was also reported with *T. livingstonei* by Babyesiza *et al.* (2025: 4).

HEMIPTERA
Polyctenidae
Eoctenes nycteridis (Horváth, 1910) from Liberia, Congo, Ruanda-Urundi, Tanzania, Uganda and Eritrea (Haeselbarth *et al.*, 1966: 17; Szentiványi *et al.*, 2022: 6).

ACARI
Macronyssidae
Orlova *et al.* (2020c: 951) mention the presence of *Steatonyssus after* Radovsky and Yunker, 1963 on bats frm Angola.

Psorergatidae
Cierocka *et al.* (2022: 10) mention the presence of *Psorergatoides nycteris* Fain, 1959 on the ears of bats from the DRC.

Trombiculidae
Stekolnikov (2018b: 280) examined one larva of *Trombigastia nycteris* Vercammen-Grandjean and Fain, 1958, which was collected from an unknown locality in Rwanda (the slide label refers to "Ada", which might refer to "Astrida" [=Butare]). Stekolnikov (2018a: 162; 2018b: 284) also reported on three larvae of *Microtrombicula nycteris* (Jadin, Vercammen-Grandjean and Fain, 1955), collected in Butare.

DIPTERA
Streblidae
Raymondi alulata Speiser, 1908 from Angola, the Congo, Malawi and Somalia (Haeselbarth *et al.*, 1966: 102). *Raymondia scopigera* Jobling, 1954 in Cameroon (Haeselbarth *et al.*, 1966: 103, host referred to *N. aethiopica*), Senegal and Sierra Leone (Shapiro *et al.*, 2016: 255).

VIRUSES:
Hermida Lorenzo *et al.* (2021: 6) reported unidentified viruses belonging to the Riboviria realm from Guinean bats.

Adenoviridae
Hermida Lorenzo *et al.* (2021: 6) mentioned the presence of unclassified Adenoviridae, Bat Mastadenovirus C and Canine Bat Mastadenovirus A in bats from Guinea.

Coronaviriddae
Joffrin *et al.* (2020: 6) reported Beta-C coronaviruses from Mozambican bats they identified as "*Nycteris thebaica*" (but were actually *N. macrotis* according to Demos *et al.*, 2019b).

Meyer *et al.* (2024: 4) found Ghanaian bats to be infected by CoV 2b and CoV 2c viruses.

Flaviviridae
In Uganda, Kading *et al.* (2018: 3) found neutralizing antibodies against non-specific Flaviviruses.

Herpesviridae
Hermida Lorenzo *et al.* (2021: 6) reported Rhinolophus gammaherpesvirus from Guinean bats.

Retroviridae
Bat gammaretrovirus was reported by Hermida Lorenzo *et al.* (2021; 7) from bats from Guinea.

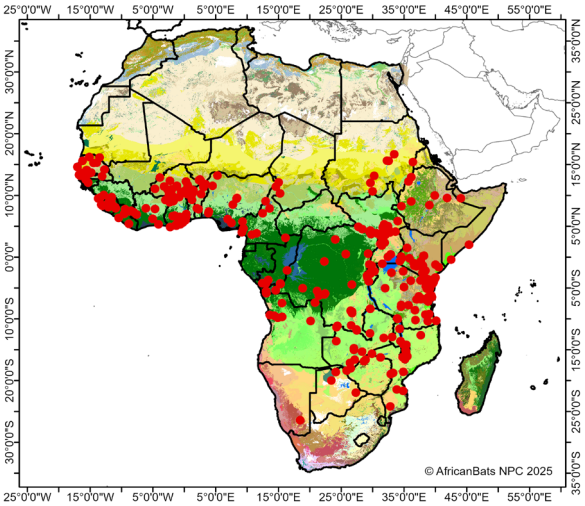

Figure 161. Distribution of *Nycteris macrotis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Ethiopia, Ghana, Guinea, Guinea-Bissau, Kenya, Liberia, Malawi, Mali, Mauritania, Mozambique, Namibia, Niger, Nigeria, Rwanda, Senegal, Sierra Leone, Somalia, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

Nycteris major (K. Andersen, 1912)

*1912. *Petalia major* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): 547. Publication date: 1 November 1912. Type locality: Cameroon: Ja River [ca. 03 00 N 13 00 E]. [Goto Description]. Holotype: NHMUK 1909.10.2.49: ad ♀, skull and alcoholic. Collected by: George Latimer Bates Esq. Collection date: 23 January 1906. - Etymology: From the Latin "*maior*" (see Kozhurina, 2002: 16).

1917. *Nycteris avakubia* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 426, fig 3. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Avakubi [01 18 N 27 32 E]. [Goto Description]. Holotype: AMNH 49403: ad ♂, skull and alcoholic. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: September 1913; original number: 2623.

1917. *Nycteris major:* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 427. Publication date: 29 September 1917. - Comments: The specimens assigned to this species by Allen (1917), however, belong to *Nycteris macrotis* (see Koopman, 1965). (Name Combination, Current Combination).

TAXONOMY:
Includes *avakubia* J.A. Allen, 1917 (see Koopman, 1965; Van Cakenberghe and De Vree, 1985; Simmons, 2005: 393).

arge species group (Van Cakenberghe and De Vree, 1985; Simmons, 2005: 393).

COMMON NAMES:
Czech: rýhonos kamerunský. English: Ja Slit-faced Bat, Dja Slit-faced Bat, Large Slit-faced Bat. French: Nyctère de Ja. German: Dja-Schlitznasenfledermaus, Dja Schlitznasen-Fledermaus.

SIMILAR SPECIES:
Eisentraut (1956b: 517) indicated that the claws of *N. major* are more robust than those of *N. arge*.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence in Central Africa, natural history, and threats. If the species is found to range more widely in Central Africa it is likely to meet the criteria for Least Concern, as the extent and quality of its habitat are probably not declining at a rate sufficient to justify listing in a higher category (Mickleburgh *et al.*, 2008bi; IUCN, 2009; Mickleburgh *et al.*, 2019j).

Assessment History
Global
2018: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2019j). 2008: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2008bi; IUCN, 2009). 2004: VU A4c ver 3.1 (2001) (Mickleburgh *et al.*, 2004cg; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The species appears to need rather large trees, and is presumably threatened by deforestation resulting from logging activities and the conversion of forest to agricultural use (Mickleburgh *et al.*, 2008bi; IUCN, 2009; Mickleburgh *et al.*, 2019j).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bi) [in IUCN (2009)] and Mickleburgh *et al.* (2019j) report that although there appear to be no direct conservation measures in place, it has been recorded from the Tai National Park in Côte d'Ivoire. Further studies are needed into the distribution, natural history and threats to this somewhat enigmatic species. There is a need to monitor to presence of this species at its known localities.

GENERAL DISTRIBUTION:
Nycteris major is distributed in West and Central Africa, where it has been patchily recorded from Guinea, Liberia (at Voinjama) and Côte d'Ivoire in the west, and from Cameroon and the Democratic Republic of the Congo in Central Africa (at Avakubi), with the southern-most record from northern Zambia (close to the border with the Democratic Republic of the Congo).

Native: Benin (Capo-Chichi *et al.*, 2004: 162); Cameroon (Simmons, 2005: 393); Central African Republic; Congo (The Democratic Republic of the) (Simmons, 2005: 393); Côte d'Ivoire (Simmons, 2005: 393); Guinea; Liberia (Simmons, 2005: 393); Nigeria (Tanshi *et al.*, 2022a: 317); Zambia (Van Cakenberghe and De Vree, 1985; Simmons, 2005: 393; Monadjem *et al.*, 2010d: 548).

MOLECULAR BIOLOGY:
Karyotype
Ngene *et al.* (2025: 11) reported 2n = 40 and FN = 79 (♂) or FN = 80 (♀) for Nigerian bats.

PREDATORS:
Demeler (1981: 133) found remains of *N. major* in pellets of *Bubo africanus* (Temminck, 1821) in the Yankari Game Reserve (Nigeria). However, as *N. macrotis* was often mis-identified as *N. major* and the latter species was not yet reported from that area, the bat's identification still needs to be confirmed.

POPULATION:
Structure and Density
This appears to be an extremely rare species, which is only known from a dozen or so specimens. It is not difficult to catch and efforts have been made to locate more specimens (Mickleburgh *et al.*, 2008bi; IUCN, 2009; Mickleburgh *et al.*, 2019j).

Trend
2018: Unknown (Mickleburgh *et al.*, 2019j). 2008: Unknown (Mickleburgh *et al.*, 2008bi; IUCN, 2009).

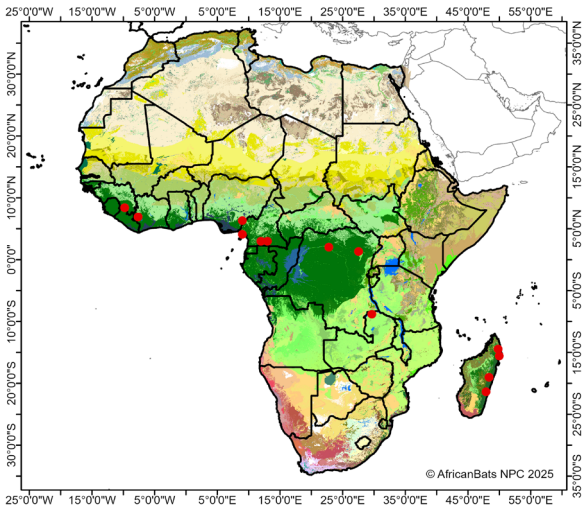

Figure 162. Distribution of *Nycteris major*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Liberia, Madagascar, Nigeria, Zambia.

Nycteris nana (K. Andersen, 1912)

*1912. *Petalia nana* K. Andersen, Ann. Mag. nat. Hist., ser 8, 10 (59): 547. Publication date: 1 November 1912. Type locality: Congo: [Rio Muni ?] Benito River [ca. 01 31 N 09 52 E]. [Goto Description]. Holotype: NHMUK 1900.2.5.46: ad ♂, skull and alcoholic. Collected by: George Latimer Bates Esq.

1926. *Nycteris nana:* Cabrera and Ruxton, Ann. Mag. nat. Hist., ser 9, 17: xxx. (Name Combination, Current Combination).

1936. *Nycteris nana tristis* G.M. Allen and Lawrence, Bull. Mus. comp. Zool., 79 (3): 47. Publication date: 30 January 1936. Type locality: Kenya: W Nyanza: Kakamega district: Kaimosi [00 08 N 34 51 E, 2 130 m]. [Goto Description]. Holotype: MCZ 31156: ad ♀, skin and skull. Collected by: Professor Arthur Loveridge; collection date: 13 February 1934. See Helgen and McFadden (2001: 142). (Name Combination).

1939. *Nycteris nana nana:* G.M. Allen, Bull. Mus. comp. Zool., 83: 70. (Name Combination).

2019. *Nycteris nana 1:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1023. Publication date: 20 August 2019.

2019. *Nycteris nana 2:* Demos, Webala, Kerbis Peterhans, Goodman, Bartonjo and Patterson, J. Zool. Syst. Evol. Res., 57 (4): 1023. Publication date: 20 August 2019.

2020. *Nycterus nana:* Shchelkanov, Dunaeva, Moskvina, Voronova, Kononova, Vorobyeva, Galkina, Yanovich, Gadzhiev and Shestopalov, S. Russia: ecol., dev., 15 (3): 23. Publication date: 27 August 2020. (Name Combination, Lapsus).
? *Nycteris cf. nana DMR-2017*
? *Nycteris nana complex sp. 1 TD-2019*
? *Nycteris nana complex sp. 2 TD-2019*

TAXONOMY:
Includes *tristis* Allen and Lawrence, 1936 (Koopman, 1975; Van Cakenberghe and De Vree, 1985; Simmons, 2005: 393).

arge species group (Van Cakenberghe and De Vree, 1985; Simmons, 2005: 393).

COMMON NAMES:
Chinese: 侏凹脸蝠. Czech: rýhonos drobný. English: Dwarf Slit-faced Bat. French: Nyctère naine. German: Kleinste Schlitznasen-Fledermaus, Zwerg-Schlitznasenfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bj; IUCN, 2009; Monadjem *et al.*, 2017av).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017av). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bj; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004cc; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known, but it seems likely to be locally threatened by deforestation in parts of its range (Mickleburgh *et al.*, 2008bj; IUCN, 2009; Monadjem *et al.*, 2017av).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bj) [in IUCN (2009)] and Monadjem *et al.* (2017av) report that it is not known if the species is present within any protected areas. Further studies are needed into the distribution, general ecology and threats to this species.

GENERAL DISTRIBUTION:
Nycteris nana has been widely recorded in West and Central Africa, with some records from East Africa. It ranges from Côte d'Ivoire and Ghana in the west, through south Cameroon and Equatorial Guinea (Rio Muni), to the Democratic Republic of the Congo, Rwanda and Burundi, to Uganda and western Kenya. It ranges as far south as northern Angola. Generally, a lowland species, but can be found up to 2,100 m asl.

A record from Tanzania, represents *intermedia* (J. Fahr *pers. comm.* in Simmons, 2005: 393).

Native: Angola (Crawford-Cabral, 1989; Simmons, 2005: 393; Monadjem *et al.*, 2010d: 548); Cameroon; Central African Republic; Congo (The Democratic Republic of the) (Van Cakenberghe and De Vree, 1985; Monadjem *et al.*, 2010d: 548); Côte d'Ivoire (Simmons, 2005: 393); Equatorial Guinea (Simmons, 2005: 393); Ghana; Kenya (Simmons, 2005: 393); Rwanda; Sudan (Simmons, 2005: 393); Togo; Uganda.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Verschuren (1955) reported on an albino specimen caught in a hollow tree in the DRC.

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 2.10 to 3.36 mm in length, smaller than that of *N. arge*, the shaft is slender, parallel-sided and essentially straight, the base is expanded and rounded and in lateral profile is often angled ventrally, while the tip is simple, with only a small expansion (Thomas *et al.*, 1994: 20).

POPULATION:
Structure and Density
It is considered to be a rather rare bat, colony sizes tend to be small (Mickleburgh *et al.*, 2008bj; IUCN, 2009; Monadjem *et al.*, 2017av).

Trend
2016: Unknown (Monadjem *et al.*, 2017av). 2008: Unknown (Mickleburgh *et al.*, 2008bj; IUCN, 2009).

PARASITES:
HAEMOSPORIDA
Schaer *et al.* (2015a: 381) found *Nycteria* cf. *houini* in *N. nana* from South Sudan. Landau *et al.* (2012: 142) and Perkins and Schaer (2016: Suppl.) mentioned the parasite as *Nycterida houini* Rosin, Landau and Hugot, 1978, and also reported it from the Republic of Congo and Gabon.

VIRUSES:
Reoviridae
Orbivirus
Fomede virus
Reported in the CDC's Arbovirus Catalogue, to have been isolated in 1978 from the Republic of Guinea, from the brain and internal organs of *N.* cf. *nana*. Reported by de Jong *et al.* (2011: 11).

Chobar Gorge virus was mentioned by Luis *et al.* (2013: Suppl.) and Willoughby *et al.* (2017: Suppl.).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Burundi, Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Gabon, Ghana, Kenya, South Sudan, Uganda.

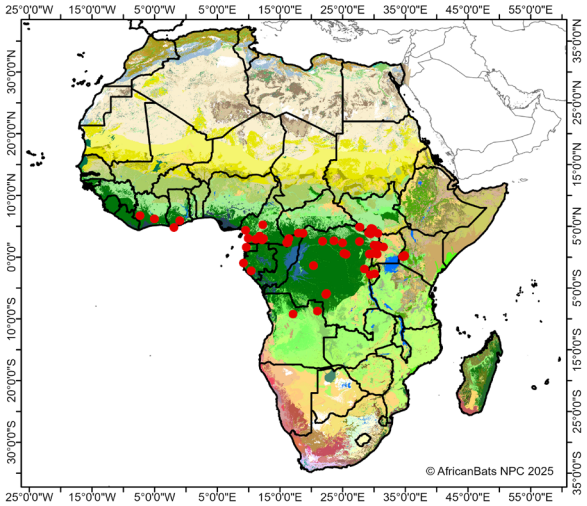

Figure 163. Distribution of *Nycteris nana*.

Nycteris parisii (de Beaux, 1924)

*1924. *Petalia parisii* de Beaux, Atti Soc. ital. Sci. nat., 62: 254 (for 1923). Publication date: February 1924. Type locality: Somalia: Balli [=Ballei Uen] [00 42 N 43 04 E]. [Goto Description]. Holotype: [Unknown] N 1449: ♀, skull and alcoholic. Collection date: 6 April 1922. See De Beaux (1924: 254), Allen (1939a: 70). - Etymology: In honour of Dr. Bruno Parisi, former head of the zoological section (1921 - 1927) and director (1928 - 1951) of the Museo Civico di Storia Naturale di Milano (see De Beaux, 1924: 255; Lanza *et al.*, 2015: 250).
1930. *Nicteris parisii:* Zammarano, Le colonie Italiane, 146. (Name Combination).
1939. *Nycteris parisii:* G.M. Allen, Bull. Mus. comp. Zool., 83: 70. Publication date: February 1939. (Name Combination, Current Combination).
1952. *Nycteris benuensis* Aellen, Mém. Soc. neuchât. Sci. nat., 8: 53. Type locality: Cameroon: Rei Bouba [ca. 08 37 N 14 09 E]. [Goto Description]. Holotype: MHNC 1481a: ad ♂. Collected by: MSS Cameroun; collection date: 16 September 1947. Paratype: MHNG 1326.002: ad. Collected by: Dr. Villy Aellen; collection date: 16 September 1947; original number: 1481b-514.
1971. *N[ycteris] p[arisii] benuensis:* Hayman and Hill, Mammals of Africa: Chiroptera, 18. (Name Combination).
1971. *N[ycteris] p[arisii] parisii:* Hayman and Hill, Mammals of Africa: Chiroptera, 18. (Name Combination).
2015. *[Nycteris] parissi:* Kaipf, Rudolphi and Meinig, NABU - Biodiversity Assessment in Kafa, Ethiopia, 13. (Lapsus).

TAXONOMY:
Included in *woodi* by Van Cakenberghe and De Vree (1985), Koopman (1993a: 162). Thomas *et al.* (1994: 22) elevated it to species rank (Simmons, 2005: 393).

Rosevear (1965: 173) included *N. parisii* in the *aethiopica* group. Included in the *macrotis* group (Simmons (2005: 393) based on Thomas *et al.* (1994: 22) being closely related to *N. macrotis*.

Simmons (2005: 393) recognises one subspecies *benuensis* Aellen, 1952.

COMMON NAMES:
Czech: rýhonos somálský. English: Parisi's Slit-faced Bat, Balli Slit-faced Bat, Parissi's Slit-faced Bat. French: Nyctère de Parisi. German: Parisis Schlitznasen-Fledermaus. Italian: Nitterìde di Parìsi, Nicterìde di Parìsi.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status (Mickleburgh *et al.*, 2008ap; IUCN, 2009; Mickleburgh *et al.*, 2019h).

Assessment History
Global
2018: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2019h). 2008: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2008ap; IUCN, 2009). 2004: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2004bf; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Mickleburgh *et al.*, 2008ap; IUCN, 2009; Mickleburgh *et al.*, 2019h).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ap) [in IUCN (2009)] and Mickleburgh *et al.* (2019h) report that it is not known if the species is present within any protected areas. Further studies are needed into the distribution, abundance, general ecology and threats to this species.

GENERAL DISTRIBUTION:
Nycteris parisii has been recorded from southern Somalia, south Ethiopia and from northern Cameroon, close the border with Nigeria. It is a low elevation species.

Nycteris parisii parisii may be distributed in East Africa and *N. p. benuensis* in West Africa.

Native: Cameroon (Aellen, 1952; Simmons, 2005: 393); Ethiopia (Hill, 1975; Simmons, 2005: 393); Somalia (Varty and Hill, 1988; Simmons, 2005: 393); Togo? (Amori *et al.*, 2016: 217).

DETAILED MORPHOLOGY:
Baculum
The shaft is long, parallel-sided and essentially straight, thickening towards the base, the base is expanded, in lateral profile it is angled ventrally, while the tip is expanded and trifid with three variably developed processes (Thomas *et al.*, 1994: 21).

POPULATION:
Structure and Density
The abundance of this species is not known, and only a few specimens have ever been collected. It was last recorded in the 1980s. Presumably this is a consequence of limited survey effort within the species known range (Mickleburgh *et al.*, 2008ap; IUCN, 2009; Mickleburgh *et al.*, 2019h).

Trend
2018: Unknown (Mickleburgh *et al.*, 2019h).
2008: Unknown (Mickleburgh *et al.*, 2008ap; IUCN, 2009).

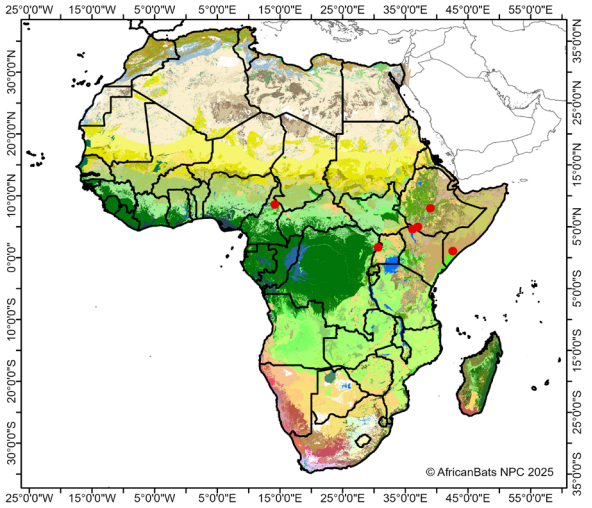

Figure 164. Distribution of *Nycteris parisii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo (Democratic Republic of the), Ethiopia, Somalia.

Nycteris thebaica E. Geoffroy St.-Hilaire, 1818

*1818. *Nycteris Thebaicus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 119, pl 1, No 2. Publication date: 1818. Type locality: Egypt: Qena province: Thebes (near Luxor) [ca.25 41 N 32 39 E]. [Goto Description]. Holotype: MNHN ZM-MO-1997-1800: ad ♀, skin only. Collected by: Etienne Geoffroy-Saint-Hilaire. Number 172 in Rode (1941: 235), who also mentioned number MNHN 142. Previously mentioned as MNHN 889. Paratype: MNHN ZM-AC-1880-974: complete skeleton. Paratype: MNHN ZM-AC-A6954: skull only. - Etymology: From the masculine Latin adjective *thēbàicus*, meaning "native or belonging to Thebes", the ancient capital of Upper Egypt, on the site of modern Luxor, the type locality of the species (see Lanza *et al.*, 2015: 254). (Current Combination).

1820. *Nycteris Geoffroyi* Desmarest, Encyclopédie Méthodique, (Zoologie, Mammalogie), 1: 127. Publication date: 1820. Type locality: Senegal: 40 mi (= 60 km) east of Podor. [Goto Description]. - Comments: Included in *macrotis* by Kock (1969a: 93) [although with a question mark] and Meester *et al.* (1986: 35).

1829. *Nycteris affinis* A. Smith, Zool. Journ., 4 (16): 434. Publication date: May 1829. Type locality: South Africa: E Cape province: Grahamstown [33 17 S 26 31 E]. [Goto Description]. - Comments: Type locality originally as "South Africa", restricted to "Grahamstown, eastern Cape Province, South Africa" by Roberts (1951: 69): see Kock (1969a: 98), Meester *et al.* (1986: 35), Gray *et al.* (1999: 2).

1829. *Nycteris Capensis* A. Smith, Zool. Journ., 4 (16): 434. Publication date: May 1829. Type locality: South Africa: SW Cape province: Swellidam [34 01 S 20 26 E]. [Goto Description]. Lectotype: NHMUK 1863.2.21.6: ad ♂, skin only. Collected by: A. Smith. Paralectotype: RMNH MAM.35900: ad, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters. The RMNH catalog mentions this specimen as a syntype, but as the NHMUK specimen is designated as a lectotype, this specimen is to be considered a paralectotype. - Comments: The type locality was originally mentioned as "Interior of South Africa, as well as upon the Eastern Coase", and restricted to "Swellidam, SW Cape Province, South Africa" by Roberts (1951: 69): see Kock (1969a: 98), Meester *et al.* (1986: 35), Gray *et al.* (1999: 2). Ansell and Dowsett (1988: 31) mention the locality as "Swellendam"). Considered a valid subspecies by Taylor (1998: 33).

1834. *Nycteris thebaica:* A. Smith, S. Afr. Quart. J., 2: 59. (Current Spelling).

1840. *N[ycteris] albiventer* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 1: 439. Type locality: Sudan: Northern province: Dongola [19 10 N 30 27 E]. [Goto

Description]. - Comments: Type locality originally given as "Nubia" (see Kock, 1969a: 98), restricted to Dongola, Northern Province, Sudan by Koopman (1975): see Gray *et al.* (1999: 2).

1840. *N[ycteris] discolor* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 1: 440. Type locality: South Africa: Ecklon. [Goto Description]. - Comments: Allen (1939a: 68) mentioned the type locality as "Südspitze von Afrika". Kock (1969a: 98), Meester *et al.* (1986: 35) mention "Southern tip of Africa; Knysna, fide Roberts (1951: 69).").

1852. *Nycteris fuliginosa* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 46, pl 10. Publication date: 1852. Type locality: Mozambique: 12 mi (19 km) NW Quellimane: Boror [17 53 S 36 51 E]. [Goto Description]. Syntype: NHMUK 1858.6.18.15: ad ♀. See Turni and Kock (2008: 27). Syntype: NHMUK 1907.1.1.337: ad ♀, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters. See Turni and Kock (2008: 27). Syntype: RMNH MAM.35901: ad ♂, mounted skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: March 1846. The RMNH catalog mentions two numbers: 35901.a (skull + loose bones) and 35901.b (mouned skin). Syntype: ZMB 392: ad ♂, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: March 1846. See Turni and Kock (2008: 27). Syntype: ZMB 3954: ad ♂, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: March 1846. See Turni and Kock (2008: 27). Syntype: ZMB 562: ad ♀, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: March 1846. See Turni and Kock (2008: 27).

1861. *Nycteris labiata* Heuglin, Nov. Act. Acad. Cæs. Leop.-Carol., 29 (8): 4, 5. Publication date: 1861. Type locality: Eritrea: Bogos: Cheren [=Keren] [ca. 15 45 N 38 20 E]. [Goto Description]. Syntype: SMNS 980a: ad ♂, alcoholic (skull not removed). Collected by: Martin Theodor von Heuglin; collection date: 1861. See Dieterlen *et al.* (2013: 294). Syntype: SMNS 980b: sad ♂, alcoholic (skull not removed). Collected by: Martin Theodor von Heuglin; collection date: 1861. See: Dieterlen *et al.* (2013: 294). Syntype: ZMB 2794a: ♂. Collected by: Martin Theodor von Heuglin; collection date: 1852. Formerly SMNS, see Turni and Kock (2008). Syntype: ZMB 2794b: ♂. Collected by: Martin Theodor von Heuglin; collection date: 1852. Syntype ex SMNS, see Turni and Kock (2008: 27).

1866. *Plecotus æthiopicus* Heuglin and Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 54 (1) 10: 546. Type locality: Sudan: Bahr el Abiat (White Nile) [ca. 14 00 N 33 00 E]. [Goto Description]. - Comments: Meester *et al.* (1986: 35) mention Fitzinger only as author. Nomen nudum (see Allen, 1939a: 68). Included in *macrotis* by Kock (1969a: 93), but rejected as nomen nudum.

1868. *Nycteris Geoffroyi Var. Senegalensis* Hartmann, Z. Gesel. f. Erdk., 3 (28/29): 44. Type locality: Sudan: Sennaar [15 35 N 33 38 E, 425 m]. [Goto Description].

1871. *Nycteris angolensis* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 903 , fig 5 (for 1870). Type locality: Angola: Biballe and Rio Coroca: Caconda [13 42 S 15 05 E, 1 900 m]. [Goto Description]. Syntype: NHMUK 1879.1.21.2. Syntype: ZMB 3633: juv ♂, skull and alcoholic. From Rio Corvea, Angola; ex Lisbon Museum; see Turni and Kock (2008). Syntype: ZMB 3637: ♂, skull and alcoholic. Collected by: José Alberto de Oliveira Anchieta. Ex Lisbon Museum; this specimen was collected at Caconda, Biballe (see Turni and Kock (2008)). Peters (1871: 904) mentions Anchieta as collector for the type specimen. - Comments: Type locality restricted by Hill and Carter (1941): see Gray *et al.* (1999: 2). The publication covers a meeting held on 22 December 1870.

1871. *Nycteris damarensis* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 905, fig 7 (for 1870). Type locality: Namibia: Damaraland: Otjimbingue [22 15 S 16 10 E]. [Goto Description]. Syntype: NHMUK 1838.2.8.4: ad, skin and skull. Collected by: Captain Alexander; original number: 1079. Syntype: NRM |TS539|. See Turni and Kock (2008: 27). Syntype: ZMB 3298: ♂, skull and alcoholic. Collected by: Missionary Hahn. See Turni and Kock (2008: 27). Syntype: ZMB 3887: ad ♂, skull and alcoholic. Collected by: Higgins. See Turni and Kock (2008: 27) [missing]. - Comments: Part of the original series is in the NRM (see Turni and Kock (2008: 27). The publication covers a meeting held on 22 December 1870. Peters (1871: 905) also mentions that the name *damarensis* was already used in the British Museum and in the Catalogue of Mammalia from 1843.

1881. *Nycteris Revoilii* Robin, Bull. Soc. Philom. Paris, (7) 5: 90. Type locality: Somalia: north of 10 ° N. [Goto Description]. Holotype: MNHN ZM-MO-1881-4: ad ♂, alcoholic (skull not removed). Collected by: Georges Emmanuel Joseph Révoil. Number 174 in Rode (1941: 236). Paratype: MNHN ZM-MO-1881-1: ad ♂, alcoholic (skull not removed). Collected by: Georges Emmanuel Joseph Révoil. Number 174a in Rode (1941: 236). Paratype: MNHN ZM-MO-1881-3: ad ♂, alcoholic (skull not removed). Collected by: Georges Emmanuel Joseph Révoil. Number 174b in Rode (1941: 236). Cotype: MCZ 14929: ♀, alcoholic (skull not removed). Collected by: Georges Emmanuel Joseph Révoil. - Comments: Type locality originally "Somalia", restricted to "Somalia, north of 10 °N" by Moreau *et al.* (1946: 399): see Gray *et al.* (1999: 2). Allen (1931: 235) mentions a "cotype" in MCZ (14929), collected by Revoil in Somaliland in 1880.

1900. *Nycteris thebaica var. angolensis:* Seabra, J. Sci. mat. phys. nat., ser 2, 6 (22): 18. (Name Combination).

TAXONOMY:

Figure 165. *Nycteris thebaica* (SMG-15760) caught at Marloth Park, Mpumalanga, South Africa.

Meester *et al.* (1986) state that the subspecies classification of *thebaica* is uncertain. Hayman and Hill (1971), while acknowledging that the species may include valid subspecies, do not attempt to recognize any. Kock (1969a), however, lists seven subspecies, and Koopman (1975), while not providing a complete synonymy of the species, appears to come to broadly similar conclusions to Kock concerning those names that he does consider. Simmons (2005: 393) recognises seven subspecies - *adana* K. Andersen, 1912; *angolensis* Peters, 1870; *brockmani* K. Andersen, 1912; *capensis* A. Smith, 1829; *damarensis* Peters, 1870; *labiata* Heuglin, 1861; and *najdiya* Nader and Kock, 1982.

Van Cakenberghe and De Vree (1999a) suggest that the status of *brockmani* and *damarensis* remains unclear as these forms may represent distinct species (Harrison and Bates, 1991; Gray *et al.*, 1999).

thebaica species group (Van Cakenberghe and De Vree, 1999a; Simmons, 2005: 393).

COMMON NAMES:
Afrikaans: Gewone-spleetneusvlermuis, Egiptiese spleetneusvlermuis, Kaapse Langoorvlermuis. Arabian: Khafash Teiba, Khaffash. Castilian (Spain): Rinolofo egipcio. Chinese: 非洲凹脸蝠. Czech: rýhonos egyptský, šerowec tébský, dutonosec, netopýr koptový, nykteris egyptská. Dutch: Thebaanse spleetneusvleermuis. English: Egyptian Slit-faced Bat, Common Slit-faced Bat, Geoffroy's Nycteris, Cape Long-eared Bat, Aden Slit-faced bat. French: Nyctère de la Thébaïde, Nyctère égyptienne. German: Großohrrhohlnase, Ägyptische Schlitznasen-Fledermaus, Stirngrubenfledermaus. Hebrew: לילן, leilan, Leylan. Italian: Nitterìde tebàna, Nicterìde tebàna, Nitterìde di Tèbe, Nicterìde di Tèbe. Malawian: Nanthuthu. Portuguese: Morcego orelhudo do Egipto. Kiluba (DRC): Kasusu. Yao (Malawi): Liputiputi (applied to all small bats).

ETYMOLOGY OF COMMON NAME:
So named because they were first described from tombs in Thebes, Egypt (see Taylor, 2005).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
N. thebaica was found in upper Pleistocene samples at Border Cave, South Africa (Avery, 1991: 6).

Butler (1984: 185) reported on a distal end of a humerus found at Chamtwara (Kenya).

CONSERVATION STATUS:
Global Justification
This species has a large range and faces no major threats, hence is listed as Least Concern LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bk; IUCN, 2009; Monadjem *et al.*, 2017aw).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017aw). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bk; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004ce; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016d). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
Habitat destruction and degradation affect the species. Roost disturbance and degradation are the main threats in the Mediterranean region. These are not considered major threats at present (Mickleburgh *et al.*, 2008bk; IUCN, 2009; Monadjem *et al.*, 2017aw).

In the Limpopo province, South Africa, Toussaint and McKechnie (2012: 1138) indicate that the cool baobab tree cavities appear to be critical for the presence of *N. thebaica* in that area and may buffer this species from future increases in extreme maximum ambient temperatures.

Aerial hawking and water stress are believed to be the major risk factors linked to climatic change (Sherwin *et al.*, 2012: 174).

Collinson *et al.* (2015: 311) report on two roadkills in the Greater Mapungubwe Transfrontier Conservation Area (GMTFCA), South Africa.

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bk) [in IUCN (2009)] and Monadjem *et al.* (2017aw) report that it may occur within some protected areas. No specific conservation measures are known. Protection of the roost sites is required and also legal protection of the species should be improved. Further research is required on the population size and trends.

GENERAL DISTRIBUTION:
Nycteris thebaica is broadly distributed across savanna and riparian zones. Mostly found in sub-Saharan Africa; also found in Morocco, Libya, Egypt (primarily down the Nile River valley, but also into Sinai) and the Middle East (Israel, Palestine and Jordan). Recorded form the islands of Unguja [=Zanzibar] and Pemba [see Simmons (2005: 393), although not from the latter by O'Brien (2011: 289)]. Elevation from sea level to 2,000 m.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,704,632 km^2 (covering 27 % of the total surface). In South Africa, its distribution is mainly affected by the minimum temperature of the coldest month (Babiker Salata, 2012: 49).

Corbet (1984: 8) states that the inclusion of Corfu (Greece) in the range could be the result of a vagrant specimen from N Africa (for details see Van Cakenberghe and De Vree, 1999a).

Native: Angola (Crawford-Cabral, 1989; Cotterill, 2004a: 261; Monadjem *et al.*, 2010d: 548); Benin (Simmons, 2005: 393); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 548); Burkina Faso (Simmons, 2005: 393; Kangoyé *et al.*, 2015a: 617); Burundi; Cameroon; Central African Republic; Chad; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 548); Côte d'Ivoire; Djibouti (Pearch *et al.*, 2001: 397; Simmons, 2005: 393); Egypt (Simmons, 2005: 393); Eritrea; Swaziland (Monadjem, 2001, Monadjem, 2006b; Simmons, 2005: 393; Monadjem *et al.*, 2010d: 549, Monadjem *et al.*, 2021: 5); Ethiopia (Lavrenchenko *et al.*, 2004b: 133); Gambia; Ghana (Simmons, 2005: 393); Guinea (Konstantinov *et al.*, 2000: 144; Simmons, 2005: 393; Decher *et al.*, 2016: 264); Guinea-Bissau; Israel (Simmons, 2005: 393); Jordan (Al-Omari *et al.*, 2000: 5); Kenya (Simmons, 2005: 393); Libyan Arab Jamahiriya; Malawi (Ansell and Dowsett, 1988: 31; Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 548); Mali (Simmons, 2005: 393); Morocco (Simmons, 2005: 393; Benda *et al.*, 2010a: 157; El Ibrahimi and Rguibi Idrissi, 2015: 358; Dbiba *et al.*, 2025: 6); Mozambique (Smithers and Lobão Tello, 1976; Lopes and Crawford-Cabral, 1992; Monadjem *et al.*, 2010d: 548; Monadjem *et al.*, 2010c: 382); Namibia; Niger (Simmons, 2005: 393; Monadjem *et al.*, 2010d: 548); Nigeria (Simmons, 2005: 393); Palestinian Territory, Occupied; Rwanda; Saudi Arabia; Senegal (Simmons, 2005: 393); Sierra Leone; Somalia (Simmons, 2005: 393); South Africa (Simmons, 2005: 393; Monadjem *et al.*, 2010d: 549); Sudan; Tanzania (Stanley and Goodman, 2011: 43); Togo (Amori *et al.*, 2016: 218); Uganda (Kityo and Kerbis, 1996: 60); Yemen; Zambia (Ansell, 1969; Ansell, 1973; Ansell, 1978; Ansell, 1986; Monadjem *et al.*, 2010d: 549); Zimbabwe (Monadjem *et al.*, 2010d: 550).

Presence uncertain: Lebanon; Lesotho; Liberia; Mauritania.

Bates *et al.* (2013: 338) reject the presence of *N. thebaica* in the Republic of Congo as the locality (Kemo) mentioned by Pousargues (1896: 259) and Van Cakenberghe and De Vree (1999a: 143) is actually located in the Central African Republic.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Schoeman and Jacobs (2002: 157) mention the following wing parameters for 8 specimens from the Algeria Forestry Station (RSA): Fa: 48.2 ± 0.8 mm, Wing area: 155.4 ± 7.4 cm^2, Wing span: 28.7 ± 1.1 cm, Wing loading: 8.3 ± 0.9 N/m^2, and aspect ratio: 5.3 ± 0.3.

Four piebald (all-white fur/skin patches, eyes always normally coloured) specimens were reported from a mine in Tanzania (Howell, 1980a; Lucati and López-Baucells, 2016: Suppl.).

Shockney and Rummel (2025: 6) mention the pelage density for this species to be significant on both the dorsal and ventral sides of all the wing parts (proximal and distal arm, forearm, plagiopatagium, propatagium).

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 2.49 to 2.97 mm in length, the shaft is slender and parallel-sided, the base is expanded, in lateral profile it is usually angled ventrally, while the tip is simple with a small expansion (Thomas *et al.*, 1994: 22).

Brain

From specimens collected in Bénin, Amrein *et al.* (2007) reported that proliferating cells, detected with Ki-67 and MCM2, in the subgranular layer of the dentate gyrus was found to be absent. Amrein *et al.* (2007) also reported moderate to ample proliferating cells (Ki-67 positive cells) and migrating young neurons (DCX positive cells) in the rostral migratory stream. Amrein *et al.* (2007) could not detect any antigen in the antibody against DCX, and no NeuroD was detected in the hippocampal granule cells.

Reproduction system
Carter and Enders (2016: 284) found that *N. thebaica* has an extensive smooth chorioallantois, and its luminal epithelium is incomplete.

Gastro-intestinal tract (GIT)
Aylward *et al.* (2019: 1108) reported for six specimens an average weight of 10.17 ± 1.71 g and a GIT of 0.61 ± 0.14 g (6.02 ± 1.31 %).

FUNCTIONAL MORPHOLOGY:
Zhuang *et al.* (2012: 1) showed that the pit in the noseleaf of *Nycteris thebaica* has an effect on focusing the acoustic near field as well as shaping the radiation patterns and therefore enhancing the directionality.

Toussaint *et al.* (2012) investigated the patterns of heterothermy exhibited by *N. thebaica* during the austral winter in a tropical semi-arid environment. They expected that it would use pronounced heterothermy during the warm, dry winter months, but found this not to be the case. As possible reasons for this, they suggest the relatively high risk of predation, the communal roosting, the species' reproduction cycle (although they find this highly unlikely as the results for both sexes were similar), and the relatively long nightly foraging period.

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 6.3 Pa, aspect ratio 5.5 and tip shape index of 3.62 for a wingspan of 31 cm and a wing area of 171 cm^2 and a body mass of 11 g.

SEXUAL DIMORPHISM:
In Swaziland, Monadjem (2001: 49) found that females were heavier and had longer forearms than males.

ECHOLOCATION:
Schoeman and Waddington (2011: 291) mention a F_{peak}: 90.3 ± 0.7 kHz and a duration of 1.7 ± 0.1 ms for specimens from Durban, South Africa. Davies *et al.* (2013b: Table S8) report a F_{peak}: 88.23 kHz (55.97 - 75.5 kHz). However, also in the Durban area, Naidoo *et al.* (2011: 23) mention a F_{peak}: 65.8 ± 20.1 kHz, and a duration of 1.7 ± 1.0 ms. From the Algeria Forestry Station (RSA), Schoeman and Jacobs (2002: 157) report the type of call to be "Low duty echolocation dominated by frequency modulated calls", with F_{peak}: 77.4 ± 2.7 kHz, and a low intensity. Parker and Bernard (2018: 57) recorded one call at the Mapungubwe National Park (RSA): F_{char}: 62.50 kHz, F_{max}: 83.40 kHz, F_{min}: 62.40 kHz, F_{knee}: 63.10 kHz, duration: 1.68 ms and 11.63 calls/sec.

Although very common in their study area in Swaziland, Monadjem *et al.* (2017c: 181) were unable to detect this species using an Anabat Express Detector due to its whispering (low db) calls. Even at distances of 0.1 m, they could not detect a call.

For Morocco, Disca *et al.* (2014: 226) recorded the following information: call type: FM multi H, F_{start}: 137.0 ± 1.2 kHz, F_{end}: 19.6 ± 0.5 kHz, F_{peak}: 84.5 ± 3.9 kHz, $F_{max\ all\ harmonics}$: 27.9 ± 0.2 kHz, $F_{max\ first\ harmonic}$: 56.1 ± 0.7 kHz, $F_{max\ third\ harmonic}$: 105.4 ± 3.2 kHz, bandwidth: 117.4 ± 1.5 kHz, duration: 2.4 ± 0.3 ms. This information is based on one single sequence they were not able to identify in hand.

Hackett *et al.* (2016: 223) reported the following values for 13 calls from Israel: Pulse duration: 1.35 ± 0.13 ms, F_{start}: 78.45 ± 3.08 kHz, F_{end}: 63.20 ± 1.99 kHz, F_{peak}: 70.18 ± 2.00 kHz.

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats): F_{peak}: 70.18 kHz, F_{start}: 78.45 kHz, F_{end}: 63.2 kHz, Band width: 15.25 kHz, and duration: 1.35 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 1 *Nycteris thebaica* call from the Kruger Park (RSA): F_{min}: 62.4 kHz, Duration: 1.7 ms, F_{max}: 83.4 kHz, F_{knee}: 63.1 kHz, F_{char}: 42.1 kHz.

Barclay and Jacobs (2022: 139) [referring to Fenton *et al.* (1983)] mention that *N. thebaica* responded more to the sounds of flapping wings of potential prey, than to their echolocation calls.

MOLECULAR BIOLOGY:
Karyotype
Both Peterson and Nagorsen (1975) and Rautenbach *et al.* (1993) reported $2n$ = 42, FN = 78, BA = 38, with a submetacentric X chromosome, and a metacentric Y chromosome.

An Ethiopian female studied by Tolera *et al.* (2021: 126) had 2n = 42 and FN either 78 or 80, depending on whether the X chromosome is either acrocentric or bi-armed. With the

exception of the acrocentric (X?) pair, all others are bi-armed.

HABITAT:
This species has a wide distribution and is found in most habitats throughout its range.

Cooper-Bohannon *et al.* (2016: Table S2) indicate that - in southern Africa - it occurs primarily in Savanna (63 %) areas, followed by SW arid (18 %) and Afromontane (10 %) habitats.

Based on the study of stable isotope ratios of carbon, nitrogen and hydrogen, Voigt *et al.* (2013: 755) suggest that *N. thebaica* might potentially be a migratory bat species, as far as elevational migration along the slopes of Mount Kilimanjaro is concerned. However, they also point out that the very low wing loading and aspect ratio is atypical for a migratory species, and therefore still categorize it as a sedentary species. Foord *et al.* (2018: 5), furthermore, indicate that *N. thebaica* moves less than one km per night between its roost and foraging sides.

HABITS:
In Swaziland male *N. thebaica* exhibit less roost site fidelity than females: there is greater roost movement in males than females (Monadjem, 2006b).

Stanley *et al.* (2007b: 209) report on a specimen in a Victor Rat trap, because it probably chased insects attracted to the bait used in the trap.

Thomas and Jacobs (2013: 125) found that, at De Hoop Nature Reserve (South Africa), *N. thebaica* emerged significantly earlier during mid-summer than during early and late summer. They also reported that bats feeding on Lepidoptera (*N. thebaica* and *Rhinolophus capensis*) emerged earlier than bats feeding on Diptera (*Tadarida aegyptiaca*).

ROOST:
Roosting in caves, mine audits and various other hollow sites (Churchill *et al.*, 1997), road culverts (Monadjem, 1998a; 2001; 2006b), under houses (LaVal and LaVal, 1980; Seamark and Bogdanowicz, 2002). Avery *et al.* (1990: 7) indicate that cool and moist caves or cave-like structures are used as daytime roosts. Howell (1980b: 26) reported that observed 300 *N. thebaica* individuals in short side pasages in the twilight zone of an abandoned kaolin mine in the Pugu Forest (Tanzania), where the humidity was 80 - 85 %. The same mine - but deeper inside - also housed about 500 000 *Hipposideros ruber* and 172 000 *Triaenops afer* bats.

Webala *et al.* (2022: 2) reported on several groups of *N. thebaica* specimens in Kenya using pit latrines as day or (possibly) night roosts and also as maternity roost.

In Swaziland, Monadjem *et al.* (2015: 15) found that roost switching occurs frequently, with more transitions to roosts where large numbers of bats were staying. They also found that moving to another roost was related to the distance of the new roost from the original one.

MIGRATION:
The species is not known to undergo migration (Monadjem, 2006a), and Laycock (1973) and Wingate (1983) suggest that *N. thebaica* does not have any homing ability. Monadjem (2006b) states that bat numbers vary greatly with season, suggesting that some movement is taking place. Monadjem (2006b) also reported that a banded female in Swaziland was discovered 107 km from where it was originally banded.

DIET:
Casual observations in Israel (Makin, 1979), Sudan (McLellan, 1986) and Namibia (Felten, 1956) reported that scorpions formed a stable part of *N. thebaica* diet. Yerbury and Thomas, 1895) examined cull-parts in Arabia, identifying various species of Orthoptera. Whereas Chapman (1958, in Tanzania), Roer (1975, in Namibia), and LaVal and LaVal (1980, in South Africa) found that Orthoptera, Lepidoptera, and Coleoptera were the primary prey orders consumed by *N. thebaica*. LaVal and LaVal (1980) presented results for early autumn (April), mid-winter (July), spring (November), and summer (January to March), listing a monthly breakdown of all prey orders consumed and finding that Orthoptera predominated in the study. In Zimbabwe, Fenton (1975) combined the results of his wet season collection (November 1969 to March 1970), finding only Orthoptera and Lepidoptera wings. Fenton *et al.* (1977a) and Fenton and Thomas (1980) examined the faeces of *N. thebaica* in Zimbabwe, and found that in the wet season (January and February 1976) Lepidoptera, Diptera and Coleoptera formed the bats' diet, while in the dry season (June 1977) he found only Lepidoptera (100 percent volume). In Zambia, Whitaker and Black (1976) examined the stomach contents of 33 *N. thebaica* which they separated into summer (November to March) and winter (May to September) categories. They found similar prey orders in *N. thebaica* diet, but also found many wingless insects.

At Farm Laatstgevonden, South Africa, Taylor *et al.* (2012b: 62) found the following prey groups: Lepidoptera (31.5 %), Coleoptera (24.75 %),

Hemiptera (19.5 %), Orthoptera (12.75 %), and other (11.5 %).

Bowie *et al.* (1999) at Mkuzi Game Reserve, KwaZulu Natal, South Africa, found that the diet consisted mainly of non-volant prey, primarily orthopterans and arachnids.

Feldman *et al.* (2000), in Israel, found they fed on Lepidoptera and Diptera.

Seamark and Bogdanowicz (2002) showed that prey eaten by *N. thebaica* varies significantly by order but not by season, and there was a significant interaction between the prey category and season, suggesting that these two factors are not independent from each other. Coleoptera (49.6 %) in the culled parts, (calculated as percent composition) dominated in spring (September-November), Orthoptera (38.8 %) in summer (December-February), Hemiptera (42.8 %) in autumn (March-May) and Lepidoptera (36.3 %) in winter (June-August). The diet also included a frog and small fish. Sometimes, geckos are taken too, but in general, vertebrate prey is rarely eaten (Happold and Happold, 2023: 111).

From the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) reported the following prey groups based on 51 faecal pellets from 8 bats (in volume percent): Lepidoptera (34.9 ± 27.3), Orthoptera (23.5 ± 19.6), Coleoptera (21.3 ± 17.6), Arachnida (13.5 ± 27.4), Diptera (3.8 ± 10.6), Hymenoptera (1.6 ± 4.6), and Hemiptera (1.5 ± 4.5).

Weier *et al.* (2019c: 6) examined droppings from this species in the Levubu region (Limpopo, RSA) and found DNA sequences of *Cryptophlebia peltastica* (Meyrick, 1921) (Lepidoptera) and *Nezara viridula* (Linnaeus, 1758) (Hemiptera).

Using Next Generation Sequencing (NGS), (Taylor *et al.* (2017b: 243, 252 - 254) reported on the 28 food items found in faecal pellets in the Limpopo province (RSA): Lepidoptera (occurred in 100 % of analysed pellets - *Toxocampinae tathorhynchus* + *Eutelia polychorda* + *Acanthovalva inconspicuaria* + *Isturgia roraria* + *Scopula rufisalsa* + *Hyblaea puera* + *Sena* sp. + *Sena prompta* + *Enmonodia capensis* + *Leucania BioLep10* + *Pandesma robusta* + *Pericyma atrifusa* + *Argyrogrammatini* sp. + *Thysanoplusia indicator* + *Tycomarptes* sp. + *Garella nilotica* + *Maurilia arcuata* + *Phycitinae* sp. + *Arotrura JFL201* + unmatched), Blattodea (50 % - *Pycnoscelus* + unmatched), Orthoptera (33 %), Coleoptera (17 % - *Cybister tripunctatus* + unmatched); Hemiptera (17 % - *Macrorhaphis acuta* + *Nezara viridula*); Orthoptera (Tettigoninae sp.).

PREDATORS:
Perrin (1982: 16) and Avery *et al.* (2005: 1054) found this species in pellets from *Tyto alba* (Scopoli, 1769) in South Africa.

Mikula *et al.* (2016: Supplemental data) and Malan *et al.* (2022: 67) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure
Monadjem (2001: 50) mentions that sex ratio was highly skewed with adult females outnumbering adult males by 2.8:1, even though the sex ratio of juveniles was 1:1. Sex ratios of adults varied seasonally, being highly skewed in July/August, October and December. Monadjem (2001: 50) suggests that this might be due to the females being resident and males joining them in late summer to mate.

Density
Fairly common through most of its range. However, an uncommon species in the Mediterranean region. In Morocco only three small colonies (usually 10 to 30 and occasionally up to 100 individuals) are known (Stéphane Aulagnier *pers. comm.* 2007 in Mickleburgh *et al.*, 2008bk; IUCN, 2009; Monadjem *et al.*, 2017aw).

Trend
2016: Unknown (Monadjem *et al.*, 2017aw).
2008: Unknown (Mickleburgh *et al.*, 2008bk; IUCN, 2009).

LIFESPAN:
In Swaziland, Monadjem (2006b) found that for both males and females, survivorship was low in the first year, but increased thereafter. While 15 % of females and 10 % of males banded as juveniles in 1998 and 1999 survived to three years of age. Monadjem (2006a) reported the age of *N. thebaica* in Swaziland to reach at least 7 to 8 years. Monadjem *et al.* (2015) studied the effect of time, age and sex class and climatic variables on survival from 1450 marked individuals from 16 roosts over a 10-year period. They found that the annual survival rate was highest in adult males and lowest in juvenile females. Climatological factors did not seem to have an influence.

ACTIVITY AND BEHAVIOUR:
Female *N. thebaica* in Eswatini appear to be resident year-round in the culverts, which

suggests that males join females in late summer for the purpose of mating (Monadjem, 2001). Lindeque (1987) describes the inflight behaviour of mating, where the active pursuit of the female by the male bat can be equated to courtship phase, with the butting phase inducing the female bat to hover and allowing the male to copulate, the brief frontal approach and head-neck biting by the male could be relict of some incomplete behaviour sequence.

Korine *et al.* (2015: 5) mention that the activity of *N. thebaica* could be underestimated because of the whispering nature of its echolocation calls.

REPRODUCTION AND ONTOGENY:
Martin and Bernard (2000: 32) mention that the corpus luteum is only present for the first half of pregnancy, and is subsequently completely regressed (Badwaik and Rasweiler, 2000: 276).

Bernard (1982a) [in Krutzsch (2000: 114)] indicated that this species is monoestrous in the subtropical, temperate regions of South Africa with a longer than usual gestation of five months and a three-month anoestrus. Male and female cycles are synchronized; spermatogenesis commences in late summer and the epididymides contain mature sperm from autumn to summer (see Bernard, 1976).

In Malawi, females are in reproductive synchrony, give birth at the end of the dry season and lactate their young for at least 1.5 months (Happold and Happold, 1990b: 566).

A pregnant female was collected on 22 July 1992 in the West Usambara Mountains (Tanzania) (Stanley and Goodman, 2011: 43).

Pregnant females were collected by Pakenham (1984: 29) on 4 November on Zanzibar.

MATING:
Mating system is not known (Monadjem, 2001).

PARASITES:
BACTERIA
Four out of 49 specimens tested at Mlawula (Swaziland) by Dietrich *et al.* (2016b: 3) tested positive for *Bartonella* and one was positive for *Rickettsia*.

Dietrich *et al.* (2016a: 4) found *Leptospira* in the urine of a bat from South Africa, and *Coxiella* in its faeces. For the RSA, these bacteria were further identified as *Leptospira borgpetersenii*, whereas in bats from Swaziland sequences belonging to *L. interrogans* were found.

Federici *et al.* (2022: 5) [referring to Dietrich *et al.* (2016a)] mentions Proteobacteria *Burkholderia, Helicobacter* and *Bartonella*.

FUNGI
Brennan *et al.* (2015: 145) found no antibodies against *Pseudogymnoascus destructans* (White-nose syndrome) in blood samples from bats from Botswana.

PROTOZOA
Schaer *et al.* (2015a: 381) found *Nycteria* sp. parasites in *N. thebaica* from South Sudan. Garnham and Heisch (1953: 357) described *Nycteria medusiformis* from a "*Nycteris capensis*".

24 of the 36 southern African *N. thebaica* specimens reported by Clément *et al.* (2019a: 5) were infected by *Trypanosoma* cf. *livingstonei*_likeA, likeB (5), likeC (5), likeD, likeE, likeF, likeG, likeI, likeJ, likeK (3), likeL, likeM, likeN (2). Based on otder references, Babyesiza *et al.* (2025: 4) reported *T. livingstonei* in bats from Uganda.Austen and Barbosa (2021: 7) also mentions the presence of *Trypanosoma (Megatrypanum) heybergi* from "*Nycteris capensis*" in the DRC.

NEMATODA
Spiruridae
An infection by *Spirura nycterisi* Khalil, 1975 in Tanzania was reported by Peralta-Rodríguez *et al.* (2012: 1006).

DIPTERA
Streblidae
Raymondia alulata Speiser, 1908, for which *N. thebaica* is the typical host, occurs in many parts of southern Africa from the Cape northwards to the Kaokoveld in Namibia and eastwards to Bukawayo in Zimbabwe (Haeselbarth *et al.*, 1966: 102). Shapiro *et al.* (2016: 249) reported it for the first time from Swaziland. *Raymondia hardyi* Fiedler, 1954 from South Africa (Shapiro *et al.*, 2016: 254). *Raymondia planiceps* Jobling, 1930 (Haeselbarth *et al.*, 1966: 102). *Raymondia seminuda* Jobling, 1954 from southern Botswana (Haeselbarth *et al.*, 1966: 103; Shapiro *et al.*, 2016: 255).

Nycteribiidae
Eucampsipoda africana Theodor, 1955 was repoted by Pawęska *et al.* (2021: 5) in the RSA.

Nycteribia scissa rhodesiensis Theodor, 1957 from Zimbabwe and Malawi (Haeselbarth *et al.*, 1966: 108). *Penicillidia fulvida* (Bigot, 1885) (Haeselbarth *et al.*, 1966: 114; Verrett *et al.*, 2022: 8).

Dick *et al.* (2023) mentioned the flies have been found on *Nycteris thebaica*: *Cyclopodia greeffi greeffi* Karsch, 1884, *Basilia (Tripselia) blainvillii blainvillii* (Leach, 1817), *Nycteribia schmidlii scotti* Falcoz, 1923, *Penicillidia (Penicillidia) fulvida* (Bigot, 1885) and *Penicillidia (Penicillidia) pachymela* Speiser, 1901. *Phthiridium rhodesiense* (Theodor, 1957) has also been found on *Nycteris thebaica capensis* and *Penicillidia (Penicillidia) fulvida* (Bigot, 1885) on *Nycteris thebaica* clade 4.

HEMIPTERA
Polyctenidae
Eoctenes nycteridis (Horváth, 1910) was reported from the DRC and Egypt by Szentiványi *et al.* (2022: 5) [referring to Anciaux de Faveaux (1965)].

SIPHONAPTERA
Pulicidae
Echidnophaga aethiops Jordan and Rothschild, 1906 described from Klipfontein, Namaqualand, South Africa and also found in Namibia, Botswana, Tanzania, Kenya and Somalia (Haeselbarth *et al.*, 1966: 135).

Ischnopsyllidae
Oxparius isomalus (Waterston, 1915) locality not stated (Haeselbarth *et al.*, 1966: 188).

ARACHNIDA
Argasidae
Sándor *et al.* (2021a: 4) reported the presence of *Chiropterargas boueti* (Roubaud and Colas-Belcour, 1933) and *Chiropterargas confusus* (Hoogstraal, 1955).

Laelapidae
Metaspinolaelaps aelleni Till ([May] 1958) was described from *Nycteris thebaica capensis* from Zululand. Till (1960: 223) suggests that this possibly might be a synonym of *Bewsiella fledermaus* Domrow, [March] 1958, but this view doesn't seem to be followed (e.g., https://en.wiki2.org/wiki/Metaspinolaelaps).

Macronyssidae
Steatonyssus longipes Radovsky and Yuker, 1953 was described from an Egyptian slit-faced bat (Negm *et al.*, 2018: 728).

Trombiculidae
Vercammen-Grandjean and Fain (1958: 24) mention the presence of *Trombigasta (Trombigastia) mounti* (Radford, 1954) on "*N. capensis damarensis*" in Asmara, Eritrea. Stekolnikov (2018a: 50, 119, 160, 173) reported *Whartonia oweni* Vercammen-Grandjean and Brennan, 1957, *Trombigastia mounti* (Radford, 1954) (from "*N. thebaica damarensis*"), *Microtrombicula minutissima* (Oudemans, 1910) (from "*N. thebaica capensis*"), *Microtrombicula tanzaniae* Goff, 1982.

VIRUSES:
Astroviridae
Four out of 14 Mozambican bats tested by Hoarau *et al.* (2018: 2) were positive for this group of viruses. In Egypt, El Taweel *et al.* (2020: 5) found bats infected by viruses of the genus Mamastrovirus.

Bats carrying viruses of this family were also reported from Mozambique by Hoarau *et al.* (2021: Suppl.).

Dorrestein *et al.* (2024:9) reported that astroviruses found in *Nycteris thebaica* resolved into two very different positions across the virus phylogeny tree: one clustered within the Molossids and another as basal to the Yinpterochiropteran clade.

Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested between 1986 and 1999, for antibody to SARS-CoV in sera in six individuals from Limpopo Province, South Africa, none were tested positive (0/6). Hoarau *et al.* (2021: Suppl.) reported on bats from Mozambique testing positive for viruses of this family.

Hantaviridae
In Zambia, Sarii *et al.* (2024: 14) found *Nycteris thebaica* to be seropositive for Robina virus.

Paramyxoviridae
Mortlock *et al.* (2015: 1841) reported that one out of twelve examined South African *N. thebaica* specimens tested positive for *Paramyxovirus* sequences.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Duvenhage Virus
In 1986, Foggin (1988) recovered the Duvenhage (DUVV) virus from a *Nycteris thebaica* in Zimbabwe (see Paweska *et al.*, 2006; Hayman *et al.*, 2011a: 88; van Eeden *et al.*, 2011: 67). Markotter *et al.* (2013: 1000) report on antibodies for DUVV that were recovered from bats from Swaziland. Kuzmin and Rupprecht (2015: 71) [referring to Markotter *et al.* (2013)] indicate that *N. thebaica* might be a regionally important host for DUVV.

Rabies
Oelofsen and Smith (1993) tested 12 individual brains, from three localities by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), none were tested positive.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burkina Faso, Cameroon, Central African Republic, Congo (Democratic Republic of the), Djibouti, Egypt, Eritrea, Eswatini, Ethiopia, Ghana, Guinea, Kenya, Malawi, Mali, Morocco, Mozambique, Namibia, Niger, Nigeria, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Uganda, Zambia, Zimbabwe.

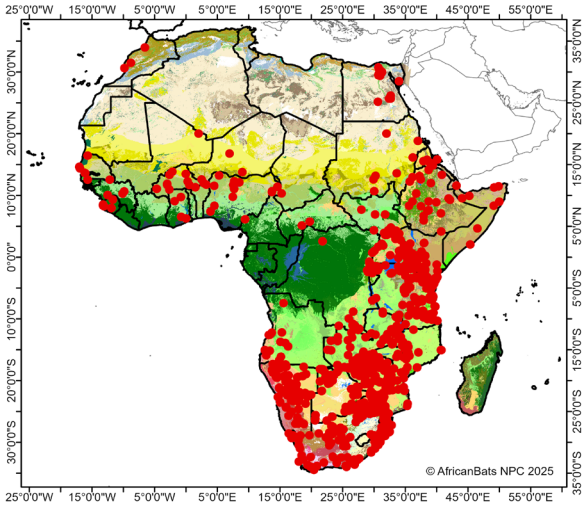

Figure 166. Distribution of *Nycteris thebaica*.

Nycteris woodi K. Andersen, 1914

*1914. *Nycteris woodi* K. Andersen, Ann. Mag. nat. Hist., ser 8, 13 (78): 563. Publication date: 1 June 1914. Type locality: Zambia: Chilanga [15 33 S 28 11 E, 4 100 ft]. [Goto Description]. Holotype: NHMUK 1914.4.22.2: ad, skin and skull. Collected by: Rodney Carrington Wood Esq. Collection date: November 1913. - Etymology: In honour of Rodney C. Wood, a well-known naturalist, who collected the original specimens at Chilanga, near Lusaka, Zambia (see Smithers, 1983: 118; Taylor, 2005). (Current Combination).
1946. *Nycteris woodi sabiensis* Roberts, Ann. Transv. Mus., 20 (4): 304. Type locality: Zimbabwe: Melsetter district: Sabi River: Birchenough Bridge [19 54 S 32 14 E]. [Goto Description]. Holotype: TM 8578: ad ♀, skin and skull. Collected by: A.G. White; collection date: 11 January 1938. (Name Combination).
1946. *Nycteris woodi woodi:* Roberts, Ann. Transv. Mus., 20 (4): 304. (Name Combination).
2018. *Nycteris woodii:* Parker and Bernard, Mammalia, 83 (1): 53. Publication date: 14 April 2018. (Lapsus).

TAXONOMY:
Van Cakenberghe and De Vree (1985) included *parisii* and *benuensis*. Thomas *et al.* (1994) elevated *parisii* to full species rank, followed by Simmons (2005: 393), who included *benuensis* as a subspecies of *parisii*.

Simmons (2005: 394) recognised one subspecies *sabiensis* Roberts, 1946.

COMMON NAMES:
Afrikaans: Wood se spleetneusvlermuis, Wood-spleetneusvlermuis, Woodse Langoorvlermuis. Czech: rýhonos jihoafrický. English: Wood's Slit-faced Bat, Wood's Long-eared Bat. French: Nyctère de Wood. German: Woods Schlitznasen-Fledermaus. Malawian: Liputiputi, Ndemiya, Namzeze.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, it occurs in some protected areas, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008ab; IUCN, 2009; Monadjem *et al.*, 2017w).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017w). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008ab; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004ap; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: NT B1ab(ii,iii,iv, v) ver 3.1 (2001) (Schoeman *et al.*, 2016b). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
It is possibly locally threatened in parts of its range by habitat loss (particularly through conversion of land to cotton farming), pesticide use, and disturbance of roosting sites (Mickleburgh *et al.*, 2008ab; IUCN, 2009; Monadjem *et al.*, 2017w).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ab) [in IUCN (2009)] and Monadjem *et al.* (2017w) report that it has been recorded from some protected areas (e.g., Kruger National Park, South Africa). Additional studies are needed into the distribution, natural history and possible threats to this poorly known species.

GENERAL DISTRIBUTION:
Nycteris woodi has been recorded from Zimbabwe, South Africa, to Zambia, north-west Mozambique and Malawi. It may range into southwestern Tanzania, however, it has yet to be recorded in this country. It is generally a lowland species. South of 8° S, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 308,190 km^2.

Native: Malawi (Happold *et al.*, 1988; Ansell and Dowsett, 1988: 30; Monadjem *et al.*, 2010d: 550); Mozambique (Simmons, 2005: 394; Monadjem *et al.*, 2010d: 550); South Africa (Simmons, 2005: 394; Monadjem *et al.*, 2010d: 550); Zambia (Ansell, 1967; Ansell, 1986; Simmons, 2005: 394; Monadjem *et al.*, 2010d: 550); Zimbabwe (Cotterill, 2004a: 261; Monadjem *et al.*, 2010d: 550).

Presence uncertain: Tanzania (Simmons, 2005: 394).

DETAILED MORPHOLOGY:
Baculum
The baculum ranges from 2.49 to 2.73 mm in length, the shaft is straight and parallel-sided, the base is expanded, in lateral profile it is angled ventrally, while the tip is simple and unexpanded, unlike *N. macrotis* and *N. parisii* (Thomas *et al.*, 1994:21).

ECHOLOCATION:
See Taylor (1999b).

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 42, FN = 78, BA = 38, a metacentric X chromosome, and an acrocentric Y chromosome, for a specimen from South Africa.

POPULATION:
Structure and Density
The abundance of this species is not well known. It has been recorded in colonies of a few dozen individuals, otherwise animals have been recorded individually (Mickleburgh *et al.*, 2008ab; IUCN, 2009; Monadjem *et al.*, 2017w).

Trend
2016: Decreasing (Monadjem *et al.*, 2017w).
2008: Decreasing (Mickleburgh *et al.*, 2008ab; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Although data were inconclusive, Happold and Happold (1990b: 566) indicate that young were born early in the wet season in Malawi.

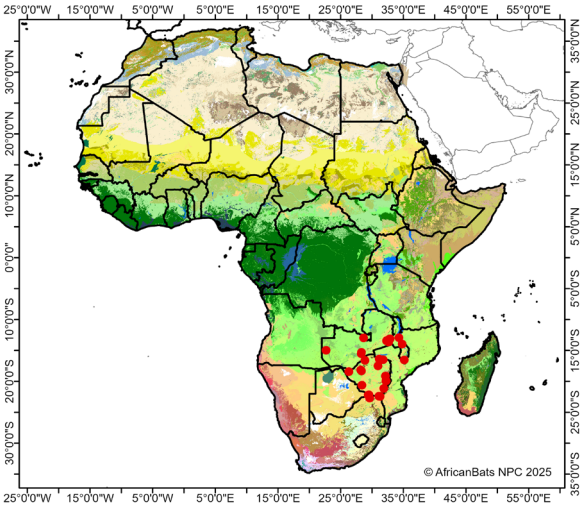

Figure 167. Distribution of *Nycteris woodi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Malawi, Mozambique, South Africa, Tanzania, Zambia, Zimbabwe.

INFRAORDER VESPERTILIONIFORMACEI Van Cakenberghe, Kearney and Seamark, 2007

*2007. *VESPERTILIONIFORMACEI* Van Cakenberghe, Kearney and Seamark, African Chiroptera Report. Publication date: July 2007. - Comments: The name of the Infraorder is based on *Vespertilio* Linnaeus, 1758 (type of VESPERTILIONIDAE Gray, 1821). (Current Combination).
? *Yangochiroptera*

TAXONOMY:
Currently two superfamily is known from within the Infraorder VESPERTILIONIFORMACEI for Africa: **MOLOSSOIDEA** Gervais, 1856; **VESPERTILIONOIDEA** Gray, 1821.

COMMON NAMES:
Czech: netopýrotvaří, netopýři.

Superfamily MOLOSSOIDEA Gervais, 1856

*1856. *Molossoidae* Gervais. (Current Combination).
1998. *Molossoidea:* Simmons, Interfamilian relationships in bats, 11. - Comments: Originally included the families Molossidae Gervais, 1855 and Antrozoidae Simmons, 1998 [= Antrozoinae Miller, 1897]. Considered a synonym of Molossidae by Jackson and Groves (2015: 257).

Family MOLOSSIDAE Gervais, 1856

*1856. *Molossidae* Gervais, in: F. Comte de Castelnau, Exped. Partes Cen. Am. Sud., Zool, (Sec 7), Vol 1, pt 2 (Mammifères): 53 footnote. Publication date: 23 July 1856. - Comments: Type genus: *Molossus* E. Geoffroy St. Hillaire, 1805. - Etymology: The name of the family is derived from the Greek "*molossus*", a kind of dog used by Greek shepherds, in ancient times (see Taylor, 2005). (Current Combination).
1866. *Molossi* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 1865: 258. - Comments: Type genus: *Molossus* E. Geoffroy, 1805. Originally included the genera *Dysopes* Illiger, 1811 [= *Molossus* É. Geoffroy, 1805]; *Molossus* É. Geoffroy, 1805; *Promops* Gervais, 1855; *Mormopterus* Peters, 1865; *Nyctinomus* É. Geoffroy, 1818 [= *Tadarida* Rafinesque, 1814]; and *Chiromeles* [= *Cheiromeles*] Horsfield, 1824 (see Jackson and Groves, 2015: 257).
1866. *Molossina* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 93. Publication date: 1 February 1866. - Comments: Type genus: Molossus E. Geoffroy, 1805. Proposed as tribe and originally included the genera *Molossus* É. Geoffroy, 1805; *Promops* Gervais, 1855 and *Nyctinomus* É. Geoffroy, 1818 [= *Tadarida* Rafinesque, 1814] (see Jackson and Groves, 2015: 257).
1869. *Gymnorhinidæ* Fatio, Faune des Vertébrés de la Suisse.
1872. *Molossidae* Gill, Smiths. Misc. Coll., 11 (1): 17. - Comments: Type genus: *Molossus* E. Geoffroy, 1805. Originally included the genus *Molossus* É. Geoffroy, 1805 (see Jackson and Groves, 2015: 257). (Current Combination).
1889. *Gymnuridae* Ameghino, Actas Acad. Nac. Ciencias, Argentine e Cordoba, p 351. - Comments: See Taylor (1934).
1893. *Molossini* Winge, Samling af Afhandlinger. E Museo Lundii, 2 (1): 24. - Comments: Type genus: *Molossus* E. Geoffroy, 1805. Proposed as tribe(?) and originally included the genera *Mystacina* J. Gray, 1843; *Nyctinomus* É. Geoffroy, 1818 [= *Tadarida* Rafinesque, 1814]; *Chiromeles* [= *Cheiromeles*] Horsfield, 1824; and *Molossus* É. Geoffroy, 1805 (see Jackson and Groves, 2015: 257).
1952. *Mollossidae:* Srivastava, Proc. zool. Soc. Bengalen, 5 (2): 121. Publication date: September 1952. (Lapsus).
1961. *Mollosidae:* Siddiqi, Biologia, 7 (1/2): 117. (Lapsus).

TAXONOMY:
Koopman (1993a: 232) mentioned Gervais, 1856, whereas Corbet and Hill (1992: 156) and Peterson *et al.* (1995: 142) mentioned Gill 1872: 17 as author for this family.

Revised by Freeman (1981b). For a very different arrangement see Legendre (1984). See also Lamb *et al.* (2011).

Pavlinov *et al.* (1995: 90) recognise two subfamilies: Cheiromelinae and Tadaridinae.

Most recent authors (Hoofer and Van Den Bussche, 2003: 2; Simmons, 2005; Lamb *et al.*, 2011: 1) accept that the Molossidae consists of two subfamilies: Molossinae and Tomopeatinae. The latter subfamily used to be assigned to the Vespertilionidae, but Hoofer and Van Den Bussche (2003: 2) clearly indicate that this subfamily belongs to the Molossidae. Representatives of this subfamily only occur in South America and are therefore not included here.

Based on 102 morphological characters from the skull, dentition, postcrania, external morphology, tongue, and penis, Gregorin and Cirranello (2015: 2) distinguish two clades within the Molossidae, both of which include taxa from the Old and the New World: One clade is comprised of *Mormopterus, Platymops, Sauromys, Neoplatymops, Molossops, Cynomops, Cheiromeles, Molossus*, and *Promops*, whereas the second includes *Tadarida, Otomops, Nyctinomops, Eumops, Chaerephon*, and *Mops*. The relation of *Myopterus* to these two clades remains unclear. They also found that genera such as *Tadarida, Chaerephon* and *Molossops sensu lato* do not appear to be monophyletic.

Ammerman *et al.* (2012: 12) distinguish 16 - 17 genera, including 110 species worldwide.

Currently (Simmons and Cirranello, 2024b) recognized genera within the family MOLOSSIDAE: *Austronomus* Troughton, 1941; *Cabreramops* Ibãñez, 1980; *Cheiromeles* Horsefield, 1824; *Cynomops* Thomas,1920; *Eumops* Miller, 1906; *Micronomus* Throughton, 1944; *Molossops* Peters, 1866; *Molossus* E.

Geoffroy, 1805; ***Mops*** Lesson, 1842; ***Mormopterus*** Peters, 1865; ***Myopterus*** E. Geoffroy, 1818; *Neoplatymops* Peterson, 1965; *Nyctinomops* Miller, 1902; ***Otomops*** Thomas, 1913; *Ozimops* Reardon, McKenzie and Adams, 2014; ***Platymops*** Thomas, 1906; *Promops* Gervais, 1856; ***Sauromys*** Roberts, 1917; *Setirostris* Reardon, McKenzie and Adams, 2014; ***Tadarida*** Rafinesque, 1814 and *Tomopeas* Miller, 1900..

COMMON NAMES:
Castilian (Spain): Murcielagos cola de raton o de cola libre. Czech: morousovití, netopýři buldočí, tadaridovití. Dutch: Buldogvleermuizen. English: Free-tailed Bats, Wrinkled-lipped Bats, Bulldog Bats, Mastiff Bats, Bonneted Bats, Wolf-dog Bats. Finnish: Doggilepakot. French: Molossidés, Chauves-souris à queue libre, Molosses. German: Bulldoggfledermäuse, Bulldogg-Fledermäuse. Italian: Molòssidi. Norwegian: Buldoggflaggermus, foldeleppede flaggermus. Russian: Свободнохвостые, Бульдоговые. Tanoboase (Ghana): afrifraa, frede frede. Ukrainian: Молоссові [= Molossovi]. Vietnamese: Họ dơi thò đuôi.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Lavocat (1961) found an indetermined Molossid species from the Mio-Pliocene at Beni Mellal. While Butler (1978: 66) found four indetermined species from the early Pleistocene at Olduvai, Avery (1991: 6) found the remains of two different sized molossids in the upper Pleistocene at Border Cave, South Africa.

Shi and Rabosky (2015: 1532) report that the approximate fossil date for the Molossidae is 37.2 million years ago. The family-level stem ages/crown ages are respectively 53.8 and 45.2 mya. Ammerman *et al.* (2012: 12) indicate that the split between the Old and New World Molossid bats took place about 29 Mya.

MOLECULAR BIOLOGY:
Karyotype
Across the family, the 2*n* value varies between 34 and 52 (Sotero-Caio *et al.*, 2017: 5).

HABITS:
Rainho *et al.* (2023: 7) assigned the molossid bats occurring in the Meru county (Kenya) to two high-flying guilds: one containing *Otomops harrisoni* and flying at an approximate altitude of 15 - 550 m and all the others in a guild flying between 5 and 100 of altitude.

ROOST:
López-Baucells *et al.* (2018: 30) investigated roost selection by molossid bats in rural Madagascar and found that they predominantly roosted in modern public buildings (e.g., schools, offices and libraries), built with cement and bricks. Small, traditional housed made from mud and wood were much less used by molossids but housed small colonies of vespertilionids. Very similar results were reported by Lunn *et al.* (2024b: 1) from Kenya, where modern-build styles and triangular roofing were found to be building-level predictors of bat occupancy and the proportion of modern buildings a landscape predictor of bat occupancy.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention unidentified Molossidae to be taken by Grey kestrels (*Falco ardosiaceus* Vieillot, 1823) and Dickinson's kestrel (*Falco dickinsoni* Sclater, 1864), Red-necked falcon (*Falco ruficollis* Daudin, 1800), Eastern chanting goshawk (*Melierax poliopterus* Cabanis, 1868) [the latter three preying on "*Tadarida*" sp, where they also include *Mops* and *Chaerephon*].

PARASITES:
HEMIPTERA
Cimicidae
Crassicimex sexualis Ferris and Usinger, 1957 described from a single female taken 50 miles SE of Torit, Uganda (Haeselbarth *et al.*, 1966: 12, host referenced as a *Tadarida* sp.).

SIPHONAPTERA
Ischnopsyllidae
Araeopsylla scitula (Rothschild, 1909) found in southern Africa Cape Province, Lesotho, Natal, Transvaal and Botswana, where it has been collected from Free-tailed bats which are its true host (Haeselbarth *et al.*, 1966: 189). *Lagaropsylla* Jordan and Rothschild, 1921 almost all records of hosts are from Free-tailed Bats (Haeselbarth *et al.*, 1966: 190). *Lagaropsylla hoogstraali* Smit, 1957 from Sudan host recorded as a molossid (Haeselbarth *et al.*, 1966: 190). *Lagaropsylla idea* Smit, 1957 recorded mainly from free-tailed bats, with distributions in tropical Africa (Haeselbarth *et al.*, 1966: 190). *Lagaropsylla oblique* Smit 1957 known to infest molossid species from Sierra Leone, Cameroon and the Congo (Haeselbarth *et al.*, 1966: 191). *Lagaropsylla tauffliebi* Smit 1962 a series was taken from a free-tailed bat (*Tadarida* sp.) near Bangui, Central African Republic (Haeselbarth *et al.*, 1966: 191; host referenced as a *Tadarida* sp.).

VIRUSES:
Gutiérrez-Guerrero *et al.* (2020: Suppl. Fig 3A) report that worldwide 40 % of the species

belonging to this family are confirmed viral carriers.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: "Africa", Angola, Cameroon, Congo (Democratic Republic of the), Egypt, Ethiopia, Ghana, Guinea, Guinea-Bissau, Kenya, Madagascar, Mozambique, Namibia, Senegal, South Africa, South Sudan, Tanzania, Togo, Uganda, Zambia, Zimbabwe.

Subfamily Molossinae Gervais, 1856

*1856. *Molossinae* Gervais, in: F. Comte de Castelnau, Exped. Partes Cen. Am. Sud., Zool, (Sec 7), Vol 1, pt 2 (Mammifères): 53 footnote. Publication date: 23 July 1856. - Comments: Type genus: *Molossus* E. Geoffroy St. Hilaire, 1805. (Current Combination).

1866. *Molossina* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 93. Publication date: 1 February 1866. - Comments: Type genus: Molossus E. Geoffroy, 1805. Proposed as tribe and originally included the genera *Molossus* É. Geoffroy, 1805; *Promops* Gervais, 1855 and *Nyctinomus* É. Geoffroy, 1818 [= *Tadarida* Rafinesque, 1814] (see Jackson and Groves, 2015: 257).

1984. *Cheiromelinae* Legendre, Rev. suisse Zool., 91 (2): 425. Publication date: June 1984. - Comments: Type genus: *Cheiromeles* Horsfield, 1824. Pavlinov *et al.* (1995: 90) recognise this as a subfamily, but see R(3345: 432) and Jackson and Groves (2015: 257).

1984. *Molossinae:* Legendre, Rev. suisse Zool., 91 (2): 399, 425. Publication date: June 1984. - Comments: Type genus: *Molossus* E. Geoffroy, 1805. Originally included the genera *Molossus* É. Geoffroy, 1805; *Eumops* Miller, 1906; *Molossops* Peters, 1865 [including the subgenera *Cynomops* Thomas, 1920 and *Neoplatymops* Peterson 1965]; *Myopterus* É. Geoffroy, 1818 and *Promops* Gervais, 1855 (see Jackson and Groves, 2015: 258).

1984. *Tadaridinae:* Legendre, Arch. Zool. Mus., Moscow State Univ., 91 (2): 399, 426. - Comments: Type genus: *Tadarida* Rafinesque, 1814. Originally included the genera *Tadarida* Rafinesque, 1814; *Mormopterus* Peters, 1865a; *Nyctinomops* Miller, 1902; *Otomops* Thomas, 1913; and *Rhizomops* Legendre, 1984 [= *Tadarida* Rafinesque, 1814 (see Jackson and Groves, 2015: 257). (Lapsus).

1995. *Tadarinae:* Peterson, Eger and Mitchell, Faune de Madagascar, 84: 143. (Lapsus).

TAXONOMY:
Bronner *et al.* (2003) state that the genera *Mops* and *Chaerephon* have often been included as subgenera of *Tadarida* (Ellerman *et al.*, 1953; Hayman and Hill, 1971; Swanepoel *et al.*, 1980; Meester *et al.*, 1986; Corbet and Hill, 1992). Roberts (1951) elevated these taxa to generic rank, an approach followed by Freeman (1981b), Koopman (1982, 1993a) and Simmons (2005). In southern Africa, *Mops* is therefore represented by two species (*M. midas* and *M. condylurus*); *Chaerephon* by five (*C. bivittata, C. ansorgei, C. nigeriae, C. chapini* and *C. pumilus*); and *Tadarida* by four (*T. aegyptiaca, T. lobata, T. ventralis* and *T. fulminans*). Other African genera are *Mormopterus, Myopterus, Otomops, Platymops* and *Sauromys* (Lamb *et al.*, 2011: 2), with *Myopterus, Platymops* and *Sauromys* being endemic to mainland Africa.

Ammerman *et al.* (2012: 23) suggest that this subfamily should be subdivided into four tribes: Molossini containing the New World taxa (*Molossus, Eumops, Molossops, Cynomops, Neoplatymops, Nyctinomops*, and *Promops*), tribe Tadarini containing Old World taxa (*Tadarida, Chaerephon, Mops, Platymops, Sauromys, Myopterus*, and *Otomops*), tribe Cheiromelini, and tribe Mormopterini.

Based on five nuclear sequence markers, Napier (2013) found strong support for the monophyly of the combined genera *Chaerephon* and *Mops* (with the exception of *C. jobimena*). There was no support for monophyly of either of these genera, suggesting that both should be combined in a single genus. Her study also suggests that a new species of *Otomops* should be names from northeast Africa and Arabia.

COMMON NAMES:
Czech: praví morousi. English: Free-tailed Bats, Wrinkled-lipped Bats, Bulldog Bats, Mastiff Bats, Bonneted Bats, Wolf-dog Bats. French: Molosses.

PARASITES:
ACARI
Rosensteiniidae
Fain (1979: 124) reported a "*Tadarida* sp." parasitised by *Nycferiglyphus tadaridae* Fain, 1963.

Genus ***Mops*** Lesson, 1842

*1842. *Mops* Lesson, Nouv. Tabl. Regn. Anim. Mammifères, 18. Publication date: 1842. - Comments: Type species: *Mops indicus* Lesson, 1842 (=*Molossus mops* de Blainville, 1840; Genotype *Mops indicus* Lesson = *Dysopes mops* F. Cuvier; listed in synonymy of *Nyctinomus* by Miller, 1907, Bull. U.S. Nat. Mus., 57, p. 251; but listed as a genus with distinct characters by Thomas, 1913, J. Bombay Nat. Hist. Soc., 22, p. 91). - Etymology: From the masculine German substantive *Mops*, meaning "pug", a small companion dog resembling a bulldog,

corresponding to the French "carlin" and the Italian "carlino"; the name refers to the wrinkled lips characteristic of the genus *Mops* and the family Molossidae. According to one seemingly erroneous interpretation, from the Malaysian substantive *mòps*, meaning "bat" (see Lanza *et al.*, 2015: 293). (Current Combination).

1907. *Chaerephon:* Andersen. (Name Combination).

1951. *Tadarida (Chaerephon):* Ellerman and Morrison-Scott. (Name Combination).

TAXONOMY:

Formerly included in *Tadarida*; for synonyms see Freeman (1981b: 158). See also Legendre (1984). Harrison and Bates (1991: 64), Ansell and Dowsett (1988: 45), Corbet and Hill (1992: 157), Grubb *et al.* (1998: 93) and Horáček *et al.* (2000: 137), who include *Mops* as subgenus in *Tadarida*. A key for the species traditionally assigned to *Mops* is provided by Dunlop (1999: 1, Mammalian Species, 615), whereas a key for the species traditionally assigned to *Chaerephon* is provided by Bouchard (1998: 1, Mammalian Species, 574).

In their molecular phylogeny study, Lamb *et al.* (2010: 204; 2011: 9) found strong support for the monophyly of the *Chaerephon* + *Mops* taxa (about 17.2 Mya old), but not for either of the genera separated. They also found some indications that certain *Mops* species are ancestral and *Chaerephon* species more derived. Their results suggest that *Chaerephon* should not be considered a subgenus of *Tadarida*, nor a genus on itself. They suggest combining *Chaerephon* (except *Chaerephon jobimena*) together with *Mops* into a single genus pending a more complete study.

Ammerman *et al.* (2012: 20) also found support for a *Mops* - *Chaerephon* clade, which resulted in paraphyly of *Chaerephon*, and confirm again that *Chaerephon* is distinct from *Tadarida*. A further morphological study by Gregorin and Cirranello (2015: 10) confirmed the paraphyly of *Chaerephon* but was unable to resolve the relationships within the genus.

The morphological study by Gregorin and Cirranello (2015: 10) was unable to resolve the relations within the genus *Mops*, but it supports the monophyly of the genus.

Simmons and Cirranello (2020) included "*Chaerephon*" in the list of synonyms for *Mops*, but did not assign it to as subgenus, as they do for the species traditionally assigned to the genus *Mops*. For convenience reasons, however, we tentatively retain *Chaerephon* as a subgenus.

Currently, Simmons and Cirranello (2024b) do not recognize subgenera, but these are retained here. They do recognize the following species in the genus *Mops*:

Mops Lesson, 1842: ***condylurus*** (A. Smith, 1833); ***congicus*** J. A. Allen, 1917; ***demonstrator*** (Thomas, 1903); ***leucostigma*** G. M. Allen, 1918; ***midas*** (Sundevall, 1843); *mops* (de Blainville, 1840) – western Malaysia, Sumatra, Borneo perhaps Java (Simmons, 2005: 443); ***niangarae*** J. A. Allen, 1917; ***niveiventer*** Cabrera and Ruxton, 1926; *sarasinorum* (A. Meyer, 1899) – Sulawesi (Indonesia) and adjacent small islands, Philippines (Simmons, 2005: 443); ***trevori*** J. A. Allen, 1917.

Xiphonycteris Dollman, 1911: ***bakarii*** Stanley, 2008; ***brachypterus*** (Peters, 1852); ***nanulus*** J. A. Allen, 1917; ***petersoni*** (El Rayah, 1981); ***spurrelli*** (Dollman, 1911); ***thersites*** (Thomas, 1903).

No subgenus assigned: ***aloysiisabaudiae*** (Festa, 1907); ***ansorgei*** Thomas, 1913; ***atsinanana*** Goodman, Buccas, Naidoo, Ratrimomanarivo, Taylor and Lamb, 2010; ***bemmeleni*** (Jentink, 1879); ***bivittatus*** (Heuglin, 1861); *bregullae* (Felten, 1964) – Vanuatu, Fiji Isls (Simmons, 2005: 433); ***chapini*** J. A. Allen, 1917; ***gallagheri*** (Harrison,1975); *jobensis* (Miller, 1902) – Seram (Moluccas), Yapen Isl (Indonesia), New Guinea, northern and central Australia (Simmons, 2005: 434); ***jobimena*** Goodman and Cardiff, 2004; *johorensis* (Dobson, 1873) – western Malaysia, Sumatra (Indonesia) (Simmons, 2005: 433); ***leucogaster*** A. Grandidier, 1870; ***major*** (Trouessart, 1897); ***nigeriae*** Thomas, 1913; *plicatus* (Buchannan, 1800) – India and Sri Lanka to southern China, Hong Kong, Cambodia and Vietnam, southeast through Malyasia to the Philippines, Borneo and Lesser Sunda Isls, Hainan (China), Cocos Keeling Isl (Indian Ocean) (Simmons, 2005: 434); ***pumilus*** (Cretzschmar, 1830-1831); ***pusillus*** (Miller, 1902); ***russatus*** J. A. Allen, 1917; ***shortridgei*** (Thomas, 1926); *solomonis* (Troughton, 1931) – Solomon Isls (Simmons, 2005: 435); ***tomensis*** (Juste and Ibañez, 1993).

Additionally, there is the extinct African ***†rusingae*** Arroyo-Cabrales, Gregorin, Schlitter and Walker, 2002.

COMMON NAMES:

Czech: velcí morousi. English: Mops Bats, Greater Free-tailed Bats, Mops Free-tailed Bats. French: Tadarides. Italian: Pipistrèllo carlìno.

SEXUAL DIMORPHISM:
El-Rayah (1980: 163) confirmed the sexual dimorphism in the premolar size reported earlier: in males the first lower premolar is larger at the base than the second lower premolar, whereas in females this is the opposite.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Burundi, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Ghana, Kenya, Madagascar, Malawi, Namibia, South Africa, South Sudan, Tanzania, The Gambia, Uganda, Zambia, Zimbabwe.

Subgenus *Mops (Chaerephon)* Dobson, 1874

1874. *Chœrephon:* Dobson, J. Asiatic Soc. Bengal, 431. - Comments: "Incorrect subsequent spelling", see Jackson and Groves (2015: 259), who indicated that "this spelling does not appear to have [been] subsequently used", although Bræstrup (1935b: 94) and Roberts (1932a: 17; 1935: 245) a.o. used *Choerephon*. Most authors (including Jackson and Groves, 2015: 259) assign this spelling to another publication by Dobson (Dobson, 1878), but this was actually the original spelling. - Phonetics: keer'-ef-on.

*1874. *Nyctinomus (Chaerephon)* Dobson, J. Asiatic Soc. Bengal, 43 (2): 144. Publication date: 17 October 1874. - Comments: Type species: *Molossus (Nyctinomus) johorensis* Dobson, 1873. Not *Chaerephon* Godman in Godman and Salvin, 1900 (Insecta, Lepidoptera, Hesperiidae) (see Jackson and Groves, 2015: 258). - Etymology: From the Greek "*chaerephon*" meaning joyful-sounding. Flannery (1990: 370; 1995a: 404) refers to it as "a proper name, significance unknown". Dobson (1874) in Bouchard (1998: 4) and Lanza *et al.* (2015: 268) indicate that it refers to the friend of Socrates who is depicted as "*Χαιρεφῶν*" ("Chaerephon the bat") in Aristophanes' comedy, *Aves*, maybe alluding to his nocturnal habits or bony appearance or as suggested by Plato in Apology, to his sudden, excitable nature.

1914. *Nyctinommus:* Alluaud and Jeannel, in: Jeannel and Racovitza, Arch. Zool. exp. gen., 53: 373. Publication date: 7 March 1914. (Lapsus).

1917. *Chærephon (Lophomops)* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 460, text-fig 9 - 11. Publication date: 29 September 1917 [Goto Description]. - Comments: Type species: *Chærephon (Lophomops) chapini* J.A. Allen, 1917, by original designation (see Jackson and Groves, 2015: 259).

1938. *Lephomops:* Frechkop, Exploration du Parc National Albert, 48. - Comments: Reported as subgenus of *Chaerephon* by Frechkop (1938: 48), but clearly a lapsus, as furtheron (p. 53) the correct *Lophomops* is used. (Lapsus).

1962. *Tadarida (Chaerophoron):* Taufflieb, Bull. Inst. Rech. Sci. Congo, 1: 112. (Lapsus).

1965. *Nyctinimus:* Koopman, Am. Mus. Novit., 2219: 21. Publication date: 22 June1965. (Lapsus).

2004. *Chaeraphon:* Okafor, Igbinosa and Ezenwaji, Anim. Res. Int., 1 (1): 64. Publication date: April 2004. (Lapsus).

2017. *Chaereophon:* Weiss, Dabrowski, Kurth, Leendertz and Leendertz, Virology J., 14 (181): 1. Publication date: 18 September 2017. (Lapsus).

? *Mops (Chaerephon):* (Current Combination).

TAXONOMY:
Formerly included in *Tadarida*; see Freeman (1981b: 60, 133, 150); see also Legendre (1984). Harrison and Bates (1991: 62) and Ansell and Dowsett (1988: 45), Corbet and Hill (1992: 157), Grubb *et al.* (1998: 93) and Horáček *et al.* (2000: 137) include *Chaerephon* in *Tadarida*. A key is provided by Bouchard (1998: 1, Mammalian Species, 574).

Nyctinomus is considered a valid genus by McFarland (1998: 34), but included in *Tadarida* by Koopman (1993a: 240), Grubb *et al.* (1998: 93), or included in *Chaerephon* by Simmons (2005), or in *Mormopterus* by Jacobs and Fenton (2002, Mammalian Species, 703: 1). Grubb *et al.* (1998: 93) also indicate that Mahoney and Walton (1988a: 148 - 149) considered that *Nyctinomus* was dated from 1813 and was therefore the prior name for the genus *Tadarida* Rafinesque, 1814. Their case is unconvincing, and Grubb *et al.* (1998) do not think it desirable to change the long established usage of *Tadarida*. However, since *Chaerephon* Dobson, 1874 is clearly more recent it might be that *Nyctinomus* should be used instead of *Chaerephon*.

Simmons and Cirranello (2020) include "*Chaerophon*" Dobson, 1874 in the list of synonyms of "*Mops*" Lesson, 1842, but they do not mention any of the *Chaerephon* species in their listing.

In their molecular phylogeny study, Lamb *et al.* (2010: 204; 2011: 9) found strong support for the monophyly of the *Chaerephon* + *Mops* taxa (about 17.2 Mya old), but not for either of the genera separated. They also found some indications that certain *Mops* species are ancestral and *Chaerephon* species more derived. Their results suggest that *Chaerephon* should not be considered a subgenus of *Tadarida*, nor a

genus on itself. They suggest combining *Chaerephon* (except *Chaerephon jobimena*) together with *Mops* into a single genus pending a more complete study.

Ammerman *et al.* (2012: 20) also found support for a *Mops* - *Chaerephon* clade, which resulted in paraphyly of *Chaerephon*, and confirm again that *Chaerephon* is distinct from *Tadarida*. A further morphological study by Gregorin and Cirranello (2015: 10) confirmed the paraphyly of *Chaerephon* but was unable to resolve the relationships within the genus.

Simmons and Cirranello (2020) include all the "*Chaerephon*" species in the genus *Mops*.

Benda *et al.* (2025: 81) tentatively follow the traditional view and consider *Chaerephon* a valid genus until this phylogenetic question is resolved.

Currently recognized species of the subgenus *Chaerephon*: ***aloysiisabaudiae*** (Festa, 1907); ***ansorgei*** Thomas, 1913; ***atsinanana*** Goodman, Buccas, Naidoo, Ratrimomanarivo, Taylor and Lamb, 2010; ***bemmeleni*** (Jentink, 1879); ***bivittatus*** (Heuglin, 1861); *bregullae* (Felten, 1964) – Vanuatu, Fiji Isls (Simmons, 2005: 433); ***chapini*** J. A. Allen, 1917; *jobensis* (Miller, 1902) – Seram (Moluccas), Yapen Isl (Indonesia), New Guinea, northern and central Australia (Simmons, 2005: 434); ***jobimena*** Goodman and Cardiff, 2004; *johorensis* (Dobson, 1873) – western Malaysia, Sumatra (Indonesia) (Simmons, 2005: 433); ***leucogaster*** A. Grandidier, 1870; ***major*** (Trouessart, 1897); ***nigeriae*** Thomas, 1913; *plicatus* (Buchannan, 1800) – India and Sri Lanka to southern China, Hong Kong, Cambodia and Vietnam, southeast through Malyasia to the Philippines, Borneo and Lesser Sunda Isls, Hainan (China), Cocos Keeling Isl (Indian Ocean) (Simmons, 2005: 434); ***pumilus*** (Cretzschmar, 1830-1831); *pusillus* (Miller, 1902); ***russatus*** J. A. Allen, 1917; *solomonis* (Troughton, 1931) – Solomon Isls (Simmons, 2005: 435).

For convenience reasons, however, we tentatively retain *Chaerephon* as a subgenus.

COMMON NAMES:
Czech: malí morousi, příšerecové. English: Wrinkle-lipped Bats, Lesser Free-tailed Bats, Lesser Mastiff Bats. French: Tadarides. Italian: Cherefónti.

BIOGEOGRAPHY:
Taylor *et al.* (2009) investigated patterns in mitochondrial DNA (cytochrome *b* and D-loop) variation in *Chaerephon* spp. specimens from southern Africa and Madagascar, including individuals from Madagascar with distinct phenotypic characters and identified as *C. leucogaster* and *C. pumilus*. Taylor *et al.* (2009) found southern African populations of *C. pumilus* to be paraphyletic, Malagasy *C. leucogaster* to be nested within *C. pumilus* sensu lato, and Malagasy *C. pumilus* forming a sister group to a complex of African *C. pumilus* and Malagasy *C. leucogaster* clades. Goodman *et al.* (2010a) including *C. pusillus* samples from the Comoros (all four islands) and Aladabra, found that on Mayotte and Madagascar individuals that can phenotypically be assigned to *C. leucogaster* and *C. pumilus* sensu lato, are known to occupy the same day roost sites. Morphological and molecular genetics data indicate they act as a good biological species. The individuals from the Comoros and Aldabra formed a monophyletic group, which shows morphological similarity. Comorian individuals, classically assigned to *C. pumilus*, are best considered distinct from African and Madagascan populations, and represent the same taxon occurring in the western Seychelles under the name *C. pusillus*.

PARASITES:
BACTERIA
Di Cataldo *et al.* (2020: 2) examined 11 Nigerian *Chaerephon* sp. bats and found 4 (36 %) to be infected by hemoplasma bacteria.

NEMATODA
Durette-Desset and Chabaud (1975: 317) described *Molinostrongylus bauchoti* from a Madagascan bat belonging to this genus.

ACARI
Trombiculidae
Stekolnikov (2018a: 154) mentioned *Microtrombicula intranasalis* Vercammen-Grandjean, 1965 from *Chaerephon* sp.

VIRUSES:
Of the 13 *Chaerephon* sp. specimens from Kisumu, Kenya, one tested positive for *Adenovirus*, one for *Rhabdovirus* and five for *Polyoma virus* (Conrardy *et al.*, 2014: 259). Of the 16 specimens from Moi University, one tested positive for *Adenovirus*, one for *Paramyxovirus* and two for *Polyomavirus*.

Adenoviridae
Conrardy *et al.* (2014) detected an adenovirus in two individuals out of 35 sampled in Kenya. This virus groups within the *Mastadenovirus* genus.

Coronaviridae - Coronaviruses
SARS-CoV
During February 2008 in Ghana, six fecal samples were tested negative for coronavirus

(CoV) RNA by Pfefferle *et al.* (2009) [as *Chaerephon spp.*]. Tong *et al.* (2009) tested several bats collected in Kenya in 2006 positive for the presence of coronavirus RNA in fecal samples (genus *Betacoronavirus*, subgenus *Sarbecovirus*; see Markotter *et al.*, 2020: 5).

Hu *et al.* (2015: 5) indicate that in Ghana, Kenya and Nigeria novel betacoronaviruses related to SARS-CoV have been detected.

12 of the 113 Kenyan specimens tested by Tao *et al.* (2017: Suppl.) were positive for CoV (10.6 %).

Flaviviridae
Pegivirus (BPgV)
1 out of 3 Kenyan *Chaerephon* sp specimens was infected by clade K type *Pegivirus* (Quan *et al.*, 2013: Table S5).

Raulino *et al.* (2022: 256) found antibodies against Dengue virus.

Paramyxoviridae
Conrardy *et al.* (2014) detected a paramyxovirus in one out of 35 individuals sampled in Kenya. This virus groups with Morbillivirus-related viruses.

Polyomaviridae
Orthopolyomavirus (BPyV)
DNA of two novel polyomaviruses were detected from fecal/oral swabs from *Chaerephon* sp specimens from Kenya (Tao *et al.*, 2012).

Rhabdoviridae
Conrardy *et al.* (2014) detected a rhabdovirus in one out of 35 individuals sampled in Kenya. This virus groups with the *Tupavirus* genus, with a near identical sequence detected in *Miniopterus africanus*.

Togavirida
Raulino *et al.* (2022: 256) found antibodies against Chikungunya virus and O'nyong nyong virus.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Benin, Burkina Faso, Cameroon, Congo (Democratic Republic of the), Kenya, Madagascar, Mayotte, Sierra Leone, South Sudan, Tanzania, Uganda.

See Simmons (2005).

COMMON NAMES:
Czech: morous vévodský. English: Duke of Abruzzi's Wrinkle-lipped Bat, Abruzzi's Wrinkle-lipped Bat, Duke of Abruzzi's Free-tailed Bat. French: Tadaride du Duc des Abruzzes, Molosse du Duc des Abruzzes. German: Fürst von Abruzzen Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bn; IUCN, 2009; Monadjem *et al.*, 2017ax).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon aloysiisabaudiae*] (Monadjem *et al.*, 2017ax). 2008: LC ver 3.1 (2001) assessed as *Tadarida aloysiisabaudiae* (Mickleburgh *et al.*, 2008bn; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004bi; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is threatened by deforestation of its habitat by logging activities (Mickleburgh *et al.*, 2008bn; IUCN, 2009; Monadjem *et al.*, 2017ax).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bn) [in IUCN (2009)] and Monadjem *et al.* (2017ax) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further studies are needed into the distribution, natural history and threats to this species.

GENERAL DISTRIBUTION:
Mops aloysiisabaudiae has been patchily recorded in West and Central Africa. It ranges from Côte d'Ivoire and Ghana in the west, through Cameroon and northern Central Africa, to southern Sudan and western Uganda. It is known from around 50 localities (mostly single specimens).

Native: Cameroon; Central African Republic; Congo (The Democratic Republic of the); Côte d'Ivoire (Beaucournu and Fahr, 2003: 175); Gabon; Ghana; Guinea (Mamba *et al.*, 2020: 134), Nigeria (Tanshi *et al.*, 2019: 14788); Sudan; Uganda.
Presence uncertain: Ethiopia (Simmons, 2005).

MOLECULAR BIOLOGY:
Karyotype
Smith *et al.* (1986) reported 2*n* = 48, FN = 66, BA = 20, a submetacentric X chromosome and an acrocentric Y chromosome.

POPULATION:
Structure and Density
This high-flying species is rarely captured. It is found in relatively small groups (Mickleburgh *et al.*, 2008bn; IUCN, 2009; Monadjem *et al.*, 2017ax).

Trend
2016: Decreasing (Monadjem *et al.*, 2017ax).
2008: Decreasing (Mickleburgh *et al.*, 2008bn; IUCN, 2009).

VIRUSES:
Reoviridae
Weiss *et al.* (2017: 1) isolated a new virus belonging to the subfamily Spinareovirinae: Taï Forest reovirus (TFRV) (tentatively assigned to the genus *Coltivirus*) from a bat in Côte d'Ivoire. This was the first bat-borne reovirus in Africa (Weiß, 2013: 65).

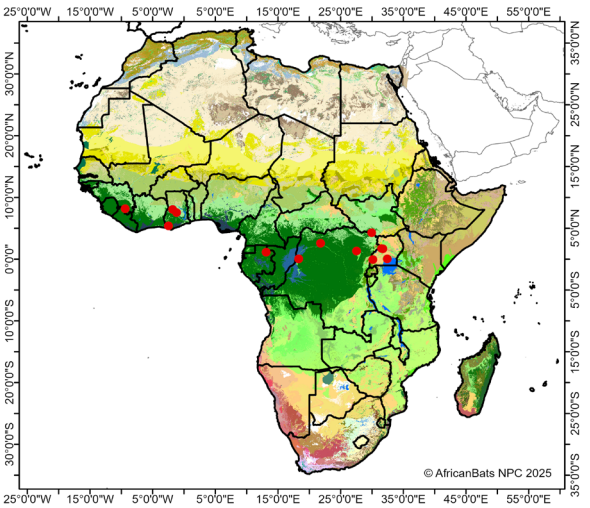

Figure 168. Distribution of *Mops (Chaerephon) aloysiisabaudiae*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Congo (Democratic Republic of the), Côte d'Ivoire, Gabon, Ghana, Guinea, Uganda.

Mops (Chaerephon) ansorgei (Thomas, 1913)

*1913. *Nyctinomus ansorgei* Thomas, Ann. Mag. nat. Hist., ser 8, 11 (63): 318. Publication date: 1 March 1913. Type locality: Angola: Malange [=Malanje] [09 32 S 16 20 E, 1 150 m]. [Goto Description]. Holotype: NHMUK 1910.4.8.4: ad ♂. Collected by: Dr. William John Ansorge; collection date: 17 February 1909; original number: 5. - Etymology: In honour of Dr. William John Ansorge (1850 - 1913), a collector of zoological specimens, who collected the type specimen of this species in Malange, northern Angola (see Taylor, 2005; Lanza *et al.*, 2015: 271).
1946. *Nyctinomus rhodesiae* Roberts, Ann. Transv. Mus., 20 (4): 307. Type locality: Zimbabwe: Bindura district: Masembura Native Reserve: Chikupo caves [17 24 S 31 20 E]. [Goto Description]. Holotype: TM 9977: ad ♂, skin and skull. Collected by: H.B. Masterson; collection date: 10 July 1945.
1967. *Tadarida bivittata:* Ansell, Arnoldia Rhod., 2 (38): 25. - Comments: Not of Heuglin, 1861.
1989. *Chaerophon ansorgei:* Fenton, Can. J. Zool., 67 (8): 2034. Publication date: 1 August 1989. (Lapsus).
2020. *Mops ansorgei:* Simmons and Cirranello, BatNames.org. (Current Combination).
? *Chaerephon ansorgei:* (Name Combination).
? *Mops (Chaerephon) ansorgei:* (Current Combination).
? *Tadarida (Chaerephon) ansorgei:* (Name Combination).
? *Tadarida ansorgei:* (Name Combination).

TAXONOMY:
Distinct from *bivittata*; see Eger and Peterson (1979: 1889), who revised it.

COMMON NAMES:
Afrikaans: Ansorge se losstertvlermuis, Ansorge-losstertvlermuis. Chinese: 安氏犬吻蝠. Czech: morous Ansorgeův. English: Ansorge's Wrinkle-lipped Bat, Ansorge's Free-tailed Bat. French: Tadaride d'Ansorge, Molosse d'Ansorge, Molosse d'Afrique du Sud. German: Ansorges Bulldoggfledermaus. Italian: Cherefónte di Ansòrge. Portuguese: Morcego de cauda livre de Ansorge.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Hildebrand *et al.* (2010: 281) recorded this species from the Koka site in southern Ethiopia.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, it is likely to occur in a number of protected areas, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008ac; IUCN, 2009; Monadjem *et al.*, 2017v).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon ansorgei* (Monadjem *et al.*, 2017v). 2008: LC ver 3.1 (2001) [assessed as *Tadarida ansorgei*] (Mickleburgh *et al.*, 2008ac; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004al; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016aa). 2008: LC ver 3.1 (2001) (Friedmann and Daly, 2004). 1986 - Indeterminate (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species. In parts of West Africa, some populations may be threatened by overharvesting for subsistence food (Mickleburgh *et al.*, 2008ac; IUCN, 2009; Monadjem *et al.*, 2017v).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ac) [in IUCN (2009)] and Monadjem *et al.* (2017v) report that in view of the species wide range it is presumably present in many protected areas (including Comoe National Park, Côte d'Ivoire). No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Mops ansorgei is widely distributed over much of sub-Saharan Africa. It ranges from northeastern Côte d'Ivoire in the west, through much of the northern part of West and Central Africa (north of the Congo basin), to Ethiopia and East Africa, from here southwards as far as northeastern South Africa. It has been recorded between 400 and 2,000 m asl.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 673,792 km^2.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 541; Taylor *et al.*, 2018b: 62); Cameroon (Eisentraut, 1968: 171 - 1st record from West Africa); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 541); Côte d'Ivoire; Ethiopia; Mozambique (Monadjem *et al.*, 2010d: 541: Monadjem *et al.*, 2010c: 382); Nigeria (Tanshi *et al.*, 2022a: 314); South Africa (Monadjem *et al.*, 2010d: 541); Sudan; Uganda (Kityo and Kerbis, 1996: 63); Zambia (Ansell, 1978: Monadjem *et al.*, 2010d: 541); Zimbabwe (Cotterill, 2004a: 261: Monadjem *et al.*, 2010d: 541).

Presence uncertain: Namibia.

ECHOLOCATION:
Jacobs (1996) and Fenton and Bell (1981) reported a F_{max}: 28 kHz for individuals at Sengwa in Zimbabwe.

Taylor (2000: 67) reported call details as: long duration (15 ms), multi-harmonic (up to two), narrow bandwidth (16 - 28 kHz) shallow-FM calls, with low dominant frequency of 18 kHz, in a field guide to bats of Southern Africa.

For "*Chaerephon ansorgei*" from Mozambique, Taylor *et al.* (2013b: 18) reported the following parameters for 3 calls: F_{max}: 23.1 ± 3.5 (20.1 - 27.0) kHz, F_{min}: 186. ± 1.5 (16.9 - 19.8) kHz, F_{knee}: 21.5 ± 1.4 (19.9 - 22.6) kHz, F_{char}: 19.8 ± 1.1 (18.5 - 20.5) kHz, duration: 10.6 ± 1.2 (9.4 - 11.9) ms. And for 12 calls from Waterberg, South Africa: F_{max}: 22.1 ± 1.53 (19.5 - 243) kHz, F_{min}: 18.5 ± 0.92 (17.5 - 20.0) kHz, F_{knee}: 20.1 ± 1.05 (18.9 - 21.8) kHz, F_{char}: 19.0 ± 0.94 (17.8 - 20.5) kHz, duration: 6.4 ± 1.51 (4.5 - 9.3) ms.

At Farm Welgevonden (RSA), Taylor *et al.* (2013a: 556) report a F_{knee} value of 20 (19 - 22) kHz.

In the Soutpansberg area (RSA), Linden *et al.* (2014: 40) mentioned the following characteristics for *C.* cf. *ansorgei*: F_{min}: 17 - 20 kHz, F_{char}: 18 - 21 kHz, F_{knee}: 19 - 23, slope: 24 - 212 OPS, duration: 4 - 12 ms.

20 calls from the Mapungubwe National Park (RSA) were recorded by Parker and Bernard (2018: 57): F_{char}: 18.21 ± 1.01 kHz, F_{max}: 20.92 ± 3.39 kHz, F_{min}: 17.59 ± 1.03 kHz, F_{knee}: 19.38 ± 1.49 kHz, duration: 10.07 ± 3.03 ms with 2.47 ± 1.43 calls/sec.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 18.21 ± 1.01 kHz, F_{max}: 20.92 ± 3.39 kHz, F_{min}: 17.59 ± 1.03 kHz.

Weier *et al.* (2020: Suppl.) reported on 12 calls from the Okavango River Basin with the following characteristics: F_{max}: 19.68 ± 0.53 kHz, F_{min}: 18.35 ± 3.33 kHz, F_{knee}: 19.49 ± 0.45 kHz, F_{char}: 19.19 ± 0.26 kHz, slope: 6.26 ± 9.90 OPS, duration: 5.99 ± 3.52 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 10 bats: F_{max}: 22.28 ± 1.52 kHz, F_{min}: 20.28 ± 3.04 kHz, F_{knee}: 21.79 ± 1.19 kHz, F_{char}: 20.9 ± 0.99 kHz, slope: -226.44 ± 1751.57 OPS, duration: 7.8 ± 3.63 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 15 *Chaerephon ansorgei* calls from the Kruger Park (RSA): F_{min}: 18.8 ± 1 (17.6 - 20.4) kHz, duration: 6.7 ± 2.3 (3.8 - 10.9) ms, F_{max}: 22.4 ± 1.8 (19.5 - 26.3) kHz, F_{knee}: 19.8 ± 1.1 (18.5 - 21.6) kHz, F_{char}: 19.4 ± 1.0 (18.2 - 21.0) kHz.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

58 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 17 - 20 kHz, F_{max}: 19 - 27 kHz, F_{char}: 17 - 21 kHz, F_{knee}): 18 - 22 kHz and duration 4 - 12 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 18.21 ± 1.01 kHz, F_{max}: 20.92 ± 3.39 kHz and F_{min}: 17.59 ± 1.03 kHz.

Molecular Biology:

Karyotype

Smith *et al.* (1986) and Rautenbach *et al.* (1993) agreed on $2n = 48$, and the Y chromosome being acrocentric. However, Smith *et al.* (1986) reported FN = 66, BA = 20, and a subtelocentric X chromosome, whereas Rautenbach *et al.* (1993) reported for specimens from South African, FN = 68, BA = 22, and a submetacentric X chromosome.

Roost:

Happold and Happold (2023: 118) mention that - in NE DRC - these bats roost in groups of up to 40 individuals with about equal numbers of males and females, whereas in Zimbabwe the groups can add up to several hundreds, with males generally outnumbering the females.

Predators:

Mikula *et al.* (2016: Supplemental data) mention the Southern yellow-billed hornbill (*Tockus leucomelas* Lichtenstein, 1842) as diurnal avian predator.

Population:

Structure and Density

It appears to be generally uncommon, although colonies may contain hundreds of bats (Mickleburgh *et al.*, 2008ac; IUCN, 2009; Monadjem *et al.*, 2017v).

Trend

2016: Stable (Monadjem *et al.*, 2017v). 2008: Stable (Mickleburgh *et al.*, 2008ac; IUCN, 2009).

Reproduction and Ontogeny:

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned lactating females in November-January and April.

Parasites:

SIPHONAPTERA

Ischnopsyllidae

Lagaropsylla anciauxi Smit, 1957 from Katanga, Congo (Haeselbarth *et al.*, 1966: 190).

Distribution based on voucher specimens:

Angola, Cameroon, Congo (Democratic Republic of the), Ethiopia, Kenya, Malawi, Mozambique, Nigeria, Rwanda, South Africa, South Sudan, Uganda, Zimbabwe.

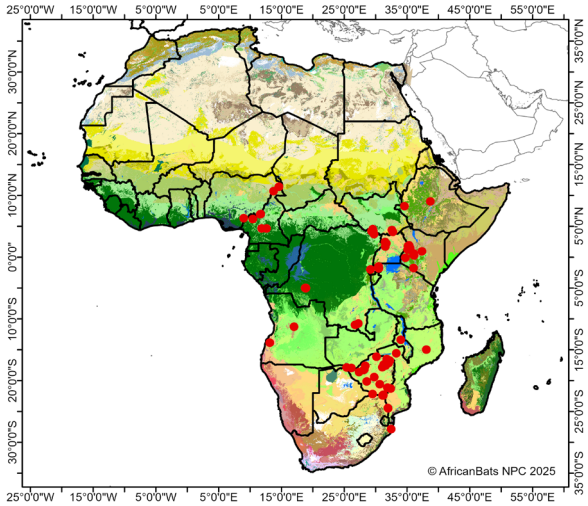

Figure 169. Distribution of *Mops (Chaerephon) ansorgei*.

Mops (Chaerephon) atsinanana (Goodman, Buccas, Naidoo, Ratrimomanarivo, Taylor and Lamb, 2010)

*2010. *Chaerephon atsinanana* Goodman, Buccas, Naidoo, Ratrimomanarivo, Taylor and Lamb, Zootaxa, 2551: 21, figs 34, 6A, 7. Publication date: 28 July 2010. Type locality: Madagascar: Fianarantsoa: Farafangana: Collèges d'Enseignement Général (CEG) Fenoarivo [22 49.275 S 47 49.860 E, 10 m]. Holotype: FMNH 185259: ad ♀, skull and alcoholic. Collected by: Fania H. Ratrimomanarivo; collection date: 26 April 2005. Paratype: FMNH 185260. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185261. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185262. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185263. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185264. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185265. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185266. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185267. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). Paratype: FMNH 185268. Same locality as the type specimen (see Goodman *et al.*, 2010a: 21). - Etymology: The name *atsinanana* is derived from the Malagasy word meaning "from the east" (see Goodman *et al.*, 2010a: 23).
2020. *Mops atsinanana:* Simmons and Cirranello, BatNames.org. (Current Combination).
? *Chaerephon pumilus:*
? *Mops (Chaerephon) atsinanana:* (Current Combination).

TAXONOMY:
Based on mitochondrial markers, Goodman *et al.* (2022: 1904) state that *C. atsinanana* is poorly differentiated from *C. leucogaster*.

COMMON NAMES:
English: Malagasy eastern Free-tailed Bat, Madagascar Free-tailed Bat. French: Molosse de l'est malgache

CONSERVATION STATUS:
Global Justification
This species is known from numerous sites in the eastern portion of the island, particularly in synanthropic settings, where it can be very common (Goodman *et al.*, 2010a; Goodman and Ramasindrazana, 2013).

Assessment History
Global
2016: LC ver. 3.1 (2001) [assessed as *Chaerephon atsinanana*] (Goodman, 2017e).

Regional
None known.

MAJOR THREATS:
Goodman (2017e) report that none are known.

CONSERVATION ACTIONS:
On Madagascar, it has not been recorded from any protected areas, but it has been recorded from houses close to protected areas as "*Chaerephon pumilus*" (Mickleburgh *et al.* (2008dr) [in IUCN (2009)]). While Goodman (2017e) make no suggestions for conservation action.

GENERAL DISTRIBUTION:
Mops atsinanana is known from numerous localities across the eastern half of Madagascar from near sea level to over 1,100 m (see Goodman *et al.*, 2010a: 26).

In Madagascar, the species is restricted to the humid areas of the island (in the north and east)

and can be found up to 1,300 m asl. Its southernmost range in Madagascar is not well understood and it has not been recorded south of Moramanga (Goodman and Cardiff, 2004).

Garbutt (2022: 95) mention the range in eastern Madagascar approximately from Farafangana to Toamasina and Makira, Anjanaharibe-Sud and Marojejy.

Native: Madagascar (Goodman *et al.*, 2010a: 26).

BIOGEOGRAPHY:
Mops atsinanana is common in the mesic eastern portion of Madagascar, across an elevational range from near sea level to 1,100 m a.s.l. (Lamb *et al.*, 2012: 19).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 60) found that the triangular shaped baculum of this species could be subdivided into three morphotypes: morphotype A is more rounded than the flattened morphotype B, and morphotype C is similar to B, but with an indentation in the proximal base. The shaft curvature is more pronounced in types B and C as compared to type A. In all morphotypes, the distal portions are similar, gradually tapering from the midshaft towards a blunt tip. Length: 0.90 ± 0.066 (0.78 - 1.00) mm, width: 0.34 ± 0.056 (0.26 - 0.46) mm.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Taylor *et al.* (2012a)] mention a wing loading value of 10.3 Pa and an aspect ratio of 8.4.

MOLECULAR BIOLOGY:
Genetics
See Goodman *et al.* (2010a).

Napier (2013) hypothesized that this species should show relatively low levels of intraspecific genetic structure as bats are strong fliers and are able to traverse the riverine and mountain barriers. However, she needed to reject this hypothesis as genetic distances of up to 8.14 % were found. She furthermore suggests that these differences are consistent with the existence of female philopatry.

HABITAT:
Goodman *et al.* (2010a: 26) report that all of the sites where this species is found, are in urban or at least rural areas and outside of natural forest. They were also unable to find a natural day-roost of this species. A further analysis by Lamb *et al.* (2012: 29) indicated that the predicted distribution pattern was rather patchy and limited to the Madagascar Lowland Forests ecoregion and furthermore strongly associated with human population centres and transport routes.

ROOST:
Wilkinson *et al.* (2012: 160) and Garbutt (2022: 95) indicate that synanthropic structures (including houses and churches) are the typical roosts for this species on Madagascar.

DIET:
The faeces of five specimens examined by Rasoanoro *et al.* (2015: 64) contained the following volume percentages of prey: Coleoptera: 44.0 ± 5.08, Diptera: 8.3 ± 4.15, Hemiptera: 3.1 ± 1.36, Homoptera: 19.0 ± 4.42, Hymenoptera: 0.3 ± 0.31, and Lepidoptera: 25.4 ± 1.86.

Goodman *et al.* (2023b: 238) [referring to Falimiarintsoa (2022)] mention fecal pellets of 21 bats to contain: Odonata (24.6 %), Hemiptera (19.0 %), Coleoptera (18.4 %), Lepidoptera (15.3 %), Diptera (10.7 %), Hymenoptera (9.3 %), and Ephemeroptera (2.7 %). They point out that the high percentage of Odonata is exceptional

Kemp *et al.* (2018: Suppl.) used DNA metabarcoding to detect insect pest species in the diet of these bats and found the following prey orders (in descending order): Coleoptera, Ephemeroptera, Lepidoptera (*Meyrickiella homosema* (Meyrick, 1887), *Leguminivora* sp., *Mythimna* sp., *Cydia choleropa* (Meyrick, 1913)), Diptera (*Simulium lineatum* (Meigen, 1804), *Culex* MBI-27, *Anopheles squamosus* Theobald, 1901, *Culex annulioris* Theobald, 1901), Orthoptera, Trichoptera, Blattodea, Hemiptera, Sarcoptiformes, Trombidiformes, Odonata, Siphonaptera, Hymenoptera.

POPULATION:
Structure and Density
There are no estimates of its population in Madagascar, but it is thought to be locally common in the eastern zone (Mickleburgh *et al.*, 2008dr; IUCN, 2009, as *C. pumilus*). Not estimated but can be common as a synanthropic species in villages and towns of eastern Madagascar (Goodman, 2017e). Based on inference from genetic data, this species has witnessed a recent population expansion (Lamb *et al.*, 2012).

Trend
2016: Increasing (Goodman, 2017e).

REPRODUCTION AND ONTOGENY:
Goodman *et al.* (2023b: 238) report on 14 females collected at Sarahandrano between 30

April and 2 May 2021. Eleven of these did not show any signs of recent breeding activity, whereas three had large nipples. Of the eleven males, nine had abdominal testes and two had slightly descended testes.

PARASITES:
SIPHONAPTERA
Ischnopsyllidae
Duchemin *et al.* (2022: 1077) mentioned the presence of *Lagaropsylla consularis* Smit, 1957.

VIRUSES:
Wilkinson *et al.* (2012: 160) tested 20 individuals from the Madagascar using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids.

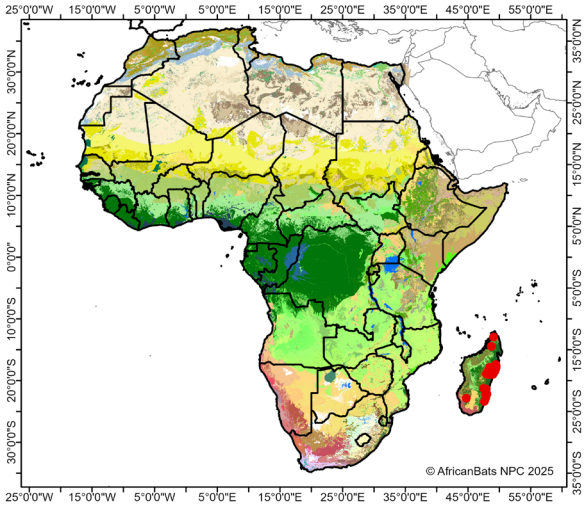

Figure 170. Distribution of *Mops (Chaerephon) atsinanana*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Mops (Chaerephon) bemmeleni (Jentink, 1879)

*1879.	*Nyctinomus Bemmeleni* Jentink, Notes Leyden Mus., 1 (1): 125. Publication date: April 1879. Type locality: "Africa": "Liberia ??". [Goto Description]. Holotype: RMNH MAM.21649: ad ♀, skull and alcoholic. Collection date: 1875. The RMNH catalog mentions two numbers: 21649.a (skull + loose bones) and 21649.b (wet specimen). - Comments: The type locality was originally mentioned as "Liberia", but see Kuhn (1965: 327), who doubts this, since the type specimen had come from a zoo. - Etymology: In honour of Mr. A.A. van Bemmelen, director of the Zoological Gardens at Rotterdam, who presented the type specimen to the museum (see Jentink, 1879b: 127).
1897.	*[Nyctinomus (Nyctinomus)] Vemmeleni:* Trouessart, Catalogus Mammalium tam viventium quam fossilium, nov ed 1, pt 1: 146. Publication date: 1897. (Lapsus).
1903.	*Nyctinomus cisturus* Thomas, Ann. Mag. nat. Hist., ser 7, 12 (71): 502. Publication date: 1 November 1903. Type locality: South Sudan: Equatoria province: 25 mi (37.5 km) N Gondokoro: Mangala (=Mongalla) [05 10 57 N 31 45 00 E, 466 m]. [Goto Description]. Holotype: NHMUK 1902.7.4.4: ad ♂. Collected by: W.L.S. Loat Esq. Original number: 2805. Presented/Donated by: W.L.S. Loat Esq.
1989.	*Chaerophon bemmeleni:* Fenton, Can. J. Zool., 67 (8): 2034. Publication date: 1 August 1989. (Lapsus).
2020.	*Mops bemmeleni* Simmons and Cirranello, BatNames.org. (Current Combination).
?	*Chaerephon bemmeleni:* (Name Combination).
?	*Mops (Chaerephon) bemmeleni:* (Current Combination).
?	*Tadarida bemmeleni cistura:* (Name Combination).
?	*Tadarida bemmeleni:* (Name Combination).

TAXONOMY:
Includes *cisturus*; see Koopman (1975: 425).

The data used by Herkt *et al.* (2017: Appendix S9) support the idea that *bemmeleni* includes more than one species. However, genetic tests to confirm this are not yet available, but material from the small overlapping area can clearly be allocated to the ssp. *cisturus*, rendering a large geographic gap between occurrence records of either population: one in West and western Central Africa (*bemmeleni*) and one in East Africa (*cisturus*).

COMMON NAMES:
Chinese: 腺尾犬吻蝠. Czech: morous liberijský. English: Gland-tailed Wrinkle-lipped Bat, Van Bemmelen's Wrinkle-lipped Bat, Gland-tailed Free-tailed Bat. French: Tadaride à glande caudale, Molosse à glandes caudales. German: Schwanzdrüsen-Bulldoggfledermaus, Bemmelens Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, it occurs in a number of protected areas, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008am; IUCN, 2009; Monadjem *et al.*, 2017ai).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon bemmeleni* (Monadjem *et al.*, 2017ai). 2008: LC ver 3.1 (2001) [assessed as "*Tadarida bemmeleni*"] (Mickleburgh *et al.*, 2008am; IUCN, 2009). 2004: LC ver 3.1 (2001)

(Mickleburgh *et al.*, 2004ba; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The species is threatened by habitat loss, largely through logging activities and the conversion of land to agricultural use (Mickleburgh *et al.*, 2008am; IUCN, 2009; Monadjem *et al.*, 2017ai).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008am) [in IUCN (2009)] and Monadjem *et al.* (2017ai) report that it is present in Meru National Park, Kenya, and is presumably present in several more protected areas. Further studies are needed into the taxonomy, natural history, threats and distribution of this species.

GENERAL DISTRIBUTION:
Mops bemmeleni is widely distributed in Africa from Sierra Leone in the west, then patchily through West and Central Africa to southern Sudan, Uganda, Kenya and Tanzania in the east. It has been recorded up to 1,700 m asl on Mount Nimba along the border of Côte d'Ivoire and Guinea (J. Fahr, *pers. comm.*, 2004 in Mickleburgh *et al.*, 2008am in IUCN, 2009).

Native: Cameroon; Congo (The Democratic Republic of the); Côte d'Ivoire; Guinea; Kenya (Start, 1969; as "*Tadarida cistura*"); Liberia; Rwanda; Sierra Leone; Sudan; Tanzania; Uganda.

Presence uncertain: Burkina Faso; Central African Republic; Chad; Ethiopia; Guinea-Bissau; Mali; Nigeria; Senegal.

MOLECULAR BIOLOGY:
Karyotype
Nagorsen *et al.* (1976: 10) reported 2*n* = 48, FN = 54, BA = 8, a submetacentric X chromosome and an acrocentric Y chromosome.

POPULATION:
Structure and Density
The abundance of *Mops bemmeleni* is unclear, in parts of the range it seems to be a rare species that is found in small colonies consisting of a few individuals. In East Africa this species exhibits a clumped distribution, yet is relatively abundant locally (Webala *et al.*, 2004).

Trend
2016: Unknown (Monadjem *et al.*, 2017ai). 2008: Unknown (Mickleburgh *et al.*, 2008am; IUCN, 2009).

PARASITES:
Lainson and Naiff (2000: 128) and Duszynski (2002: 21) indicate that *M. bemmeleni* is the type host for *Eimeria levinei* Bray, 1958 (Apicomplexa).

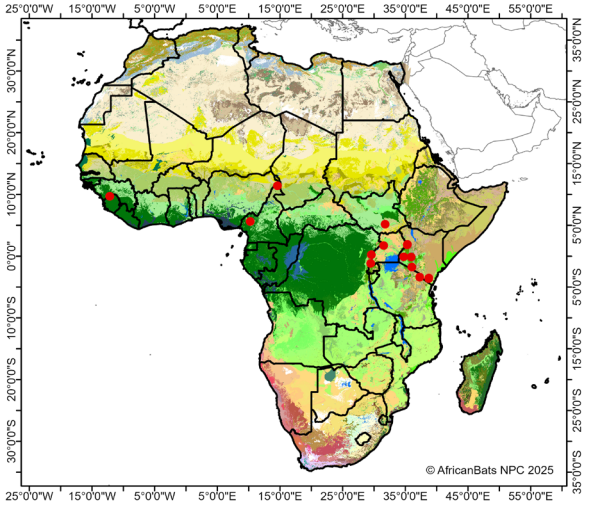

Figure 171. Distribution of *Mops (Chaerephon) bemmeleni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Cameroon, Congo (Democratic Republic of the), Kenya, Liberia, Sierra Leone, South Sudan, Tanzania, Uganda.

Mops (Chaerephon) bivittatus (Heuglin, 1861)

*1861. *Nyctinomus bivittatus* Heuglin, Nov. Act. Acad. Cæs. Leop.-Carol., 29 (8): 4, 13. Publication date: 1861. Type locality: Eritrea: Kérén [ca. 15 45 N 38 20 E]. [Goto Description]. Syntype: RMNH MAM.35876.a: ad. Collected by: Martin Theodor von Heuglin; collection date: 1861. Syntype: RMNH MAM.35876.b: ad ♀. Collected by: Martin Theodor von Heuglin; collection date: 1861. Syntype: ZMB 2792a: skull and alcoholic. Collected by: Theodor Von Heuglin. Formerly SMNS, from "Abyssinia, Bogos[land]". See Turni and Kock (2008: 72). Syntype: ZMB 2792b: skull and alcoholic. Collected by: Theodor Von Heuglin. Formerly SMNS, from "Abyssinia, Bogos[land]". See Turni and Kock (2008: 72). Lectotype: SMNS 981: ad ♂, skull and alcoholic. Collected by: Martin Theodor von Heuglin; collection date: 1861. Dieterlen *et al.* (2013: 294) indicated this specimen to be the lectotype, referring to ICZN article 74.6, which would indicate that this status was established by Dobson (1878), who called specimen this "'type". However, Dobson (1878: 426) presents the measurements of an adult male, which he called the "type", but since there are two adult males (981 and 981b), it is not clear which of these two specimens was referred to by Dobson (1878). Paralectotype: SMNS 981a: ad ♀, skull and alcoholic. Collected by: Martin Theodor von Heuglin; collection date: 1861. See Dieterlen *et al.* (2013: 294). Paralectotype: SMNS 981b: ad ♂, skull and alcoholic. Collected by: Martin Theodor von Heuglin; collection date: 1861. See Dieterlen *et al.* (2013: 294), but see also note above. -

Etymology: From the masculine scientific Latin adjective *bivittàtus*, meaning "bivittate", as the species is provided with two narrow longitudinal stripes on and behind the head (see Lanza *et al.*, 2015: 273).

1967. *Tadarida bivittata:* Ansell, Arnoldia Rhod., 2 (38): 29. (Name Combination).
1999. *Chaerephon bivitattus:* Taylor, Acta Chiropt., 1 (2): 199. (Lapsus).

2016. *Chaerophon bivittattus:* Simmons, Seiffert and Gunnell, Am. Mus. Novit., 3857: 43. Publication date: 9 May 2016. (Lapsus).
2020. *Mops bivittatus:* Simmons and Cirranello, BatNames.org. (Current Combination).
2025. *Chaerephon bibittatus:* King, Loeffler, Rosenberger, Wagner, Chhaya, DeLeon, Curtis, Eiting, Santana and Smith, Anat. Rec., xxx (x): 4. Publication date: 6 October 2025. (Lapsus).
? *Chaerephon bivittatus:* (Name Combination).
? *Mops (Chaerephon) bivittatus:* (Current Combination).
? *Tadarida bivittata bivittata:* (Name Combination).

Taxonomy:
Revised by Eger and Peterson (1979).

Common Names:
Afrikaans: Gevlekte losstertvlermuis. Chinese: 斑犬吻蝠. Czech: morous skvrnitý. English: Spotted Wrinkle-lipped Bat, Spotted Free-tailed Bat, Spotted Gland-tailed Bat. French: Tadaride tachetée, Molosse tacheté. German: Gefleckte Bulldoggfledermaus, zweistreifige Doggengrämler. Italian: Cherefónte bivittàto. Portuguese: Morcego de cauda livre malhado.

Etymology of common name:
So named because of the tiny white, and sometimes barely discernible, flecks on the upper parts of the body (see Taylor, 2005).

Conservation status:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008ad; IUCN, 2009; Monadjem *et al.*, 2017x).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon bivittatus*] (Monadjem *et al.*, 2017x). 2008: LC ver 3.1 (2001) [assessed as "*Tadarida bivittata*"] (Mickleburgh *et al.*, 2008ad; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessed as "*Chaerephon bivittata*"] (Mickleburgh *et al.*, 2004an; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

Major threats:
There appear to be no major threats to this species as a whole (Mickleburgh *et al.*, 2008ad; IUCN, 2009; Monadjem *et al.*, 2017x).

Conservation actions:
Mickleburgh *et al.* (2008ad) [in IUCN (2009)] and Monadjem *et al.* (2017x) report that there appear to be no direct conservation measures in place. It is presumably present in some East African protected areas. Further studies are needed into the abundance, distribution and natural history of this bat.

General distribution:
Mops bivittatus is an East African species ranging from Eritrea and Ethiopia in the north, through southern Sudan, Uganda, Kenya and eastern Tanzania, to Zambia, Zimbabwe and Mozambique in the south.

Native: Eritrea; Ethiopia; Kenya; Malawi (Monadjem *et al.*, 2010d: 541); Mozambique (Crawford-Cabral, 1989; Simmons, 2005); Sudan; Tanzania; Uganda; Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 541); Zimbabwe (Ansell, 1986; Monadjem *et al.*, 2010d: 541).

Functional morphology:
King *et al.* (2025) investigated the olfactory system of this species.

Molecular Biology:
Karyotype
Peterson and Nagorsen (1975) reported 2*n* = 48, FN = 54, BA = 8, a metacentric X chromosome, and an acrocentric Y chromosome for specimens from Kenya and Zimbabwe.

Population:
Structure and Density
Although there is little information on the abundance of this species, it is common in collections suggesting that it is easily found (Mickleburgh *et al.*, 2008ad; IUCN, 2009; Monadjem *et al.*, 2017x).

Trend
2016: Stable (Monadjem *et al.*, 2017x). 2008: Stable (Mickleburgh *et al.*, 2008ad; IUCN, 2009).

PARASITES:
Beaucournu and Kock (1996) mentioned the first record for the flea *Lagaropsylla anciauxi* Smit, 1957 on this bat.
Hastriter (2016: 15) described the flea *Araeopsylla smiti* from a *M. bivittatus* collected at Maji Moto, Kenya.

Copeland *et al.* (2011: 363) reported the rediscovery of the "terrible hairy fly" (*Mormotomyia hirsuta* (after 62 years) in guano produced by "*Chaerephon* cf. *bivittatus*" and *Tadarida aegyptiaca* at Ukasi Hill, Kenya.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Congo (Democratic Republic of the), Eritrea, Ethiopia, Kenya, Malawi, Mozambique, South Sudan, Tanzania, Uganda, Zambia, Zimbabwe.

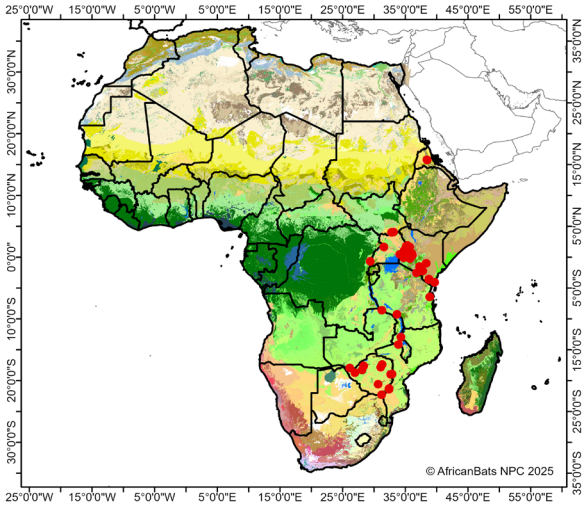

Figure 172. Distribution of *Mops (Chaerephon) bivittatus*.

Mops (Chaerephon) chapini (J.A. Allen, 1917)

*1917. *Chærephon (Lophomops) chapini* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 460, 461, text-fig 9. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Faradje [03 44 N 29 43 E]. [Goto Description]. Holotype: AMNH 48841: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 11 November 1912; original number: 1971.
1938. *Chærephon lancasteri* Hayman, Ann. Mag. nat. Hist., ser 11, 1 (4): 383. Publication date: 1 April 1938. Type locality: Zambia: Loangwa Valley: Lundazi district: Lunzi River [ca. 11 S 33 E]. [Goto Description]. Holotype: NHMUK 1937.12.8.25: ad ♂, skin and skull. Collected by: D. Gordon Lancaster; collection date: August 1936; original number: 724. Notes: caught in hole in tree. - Comments: Kock (1969a: 140) situates the Lunzi river in Zambia, rather than in Zimbabwe.

TAXONOMY:
Included in *pumilus* by Kock (1969a: 139). See Fenton and Eger (2002).

COMMON NAMES:
Afrikaans: Bleek losstertvlermuis. Chinese: 查平犬吻蝠. Czech: morous chocholatý. English: Long-crested Free-tailed Bat, Chapin's Wrinkle-lipped Bat, Long-crested Wrinkle-lipped Bat, Crested Wrinkle-lipped Bat, Chapin's Free-tailed Bat, Pale Free-tailed Bat, Long-crested Gland-tailed Bat, Crested Free-tail Bat. French: Tadaride de Chapin, Molosse à crinière, Molosse pâle. German: Chapins Bulldoggfledermaus.

ETYMOLOGY OF COMMON NAME:
Named after Mr. James P. Chapin, co-organiser of the American Museum expedition to the former Belgian Congo that resulted in the discovery of the species (Taylor, 2005).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
No fossils are known (Fenton and Eger, 2002).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, it occurs in a number of protected areas, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008ae; IUCN, 2009; Monadjem *et al.*, 2017y).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon chapini*] (Monadjem *et al.*, 2017y). 2008: LC ver 3.1 (2001) [assessed as "*Tadarida chapini*"] (Mickleburgh *et al.*, 2008ae; IUCN, 2009). 2004: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2004ag; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this widespread species as a whole. It may be threatened in parts of its range through habitat loss and degradation (e.g., in northern Zimbabwe and parts of Zambia) (Mickleburgh *et al.*, 2008ae; IUCN, 2009; Monadjem *et al.*, 2017y).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ae) [in IUCN (2009)] report that it has been recorded from Kruger National Park in South Africa, and from Mole National Park in Ghana and Comoe. Monadjem *et al.* (2017y) makes no recommendations for conservation actions.

GENERAL DISTRIBUTION:
Mops chapini has been widely recorded over much of sub-Saharan Africa. It has been collected from Côte d'Ivoire and Ghana in West Africa, southern Sudan, northeastern Democratic Republic of the Congo, Ethiopia, Uganda and Kenya, ranging south into southern Democratic Republic of the Congo and Congo, Angola, Zimbabwe, Zambia, Botswana and Namibia.

Native: Angola (Monard, 1935; Crawford-Cabral, 1989; Hill and Carter, 1941; Monadjem *et al.*, 2010d: 541); Botswana (Monadjem *et al.*, 2010d: 541); Cameroon (Bol A Anong *et al.*, 2011: 46; Bakwo Fils *et al.*, 2014: 3); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Fenton and Eger, 2002: 2; Monadjem *et al.*, 2010d: 541); Ethiopia; Ghana; Kenya (Fenton and Eger, 2002: 2); Namibia (Monadjem *et al.*, 2010d: 541); Sudan (Fenton and Eger, 2002: 2); Uganda; Zambia (Ansell, 1969; Monadjem *et al.*, 2010d: 541); Zimbabwe (Monadjem *et al.*, 2010d: 541).

Bates *et al.* (2013: 338) reject the occurrence of *M. chapini* in the Republic of Congo as the "Marine Park Nature Reserve" was erroneously located in that country in ACR (2012) rather than in the DRC. The record from Cameroon is probably doubtful (Jakob Fahr, pers. comm.).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Fenton and Eger (2002).

DENTAL FORMULA:
Esquivel *et al.* (2021: Suppl.) examined three skulls, of which one had extra teeth (polyodontia).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Fenton and Eger (2002).

DETAILED MORPHOLOGY:
Other
For a description of the crania, teeth, ears and tragus see Fenton and Eger (2002).

SEXUAL DIMORPHISM:
Sexual dimorphism in the structure of interaural crest, with females having a small crest (3 - 5 mm) and males a long, bicolored one (12 - 15 mm) (Fenton and Eger, 2002). Krutzsch (2000: 128) pointed out that this crest is also odoriferous in the breeding male.

ECHOLOCATION:
Jacobs (1996) and Fenton and Bell (1981) reported a F_{max}: 27 kHz for individuals at Sengwa in Zimbabwe.

In Benin, Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 48, FN = 64, BA = 18, a subtelocentric X chromosome, and an acrocentric Y chromosome, for specimens from Namibia and Zimbabwe.

HABITAT:
See Fenton and Eger (2002).

HABITS:
See Fenton and Eger, 2002).

Fenton and Griffin (1997: 248) recorded echolocation calls from "*Tadarida chapini*" at altitudes between 0 and 450 m above a *Brachystegia* woodland in Zimbabwe.

ROOST:
See Fenton and Eger (2002).

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure and Density
In general there is little information on the abundance of this species over its range (Mickleburgh *et al.*, 2008ae; IUCN, 2009; Monadjem *et al.*, 2017y). It can be common in northwestern Zimbabwe, but it is not regularly recorded. The species is found in small colonies, with a single observation of a small group of breeding females.

Trend
2016: Unknown (Monadjem *et al.*, 2017y). 2008: Unknown (Mickleburgh *et al.*, 2008ae; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
See Fenton and Eger, 2002).

REPRODUCTION AND ONTOGENY:
See Fenton and Eger (2002).

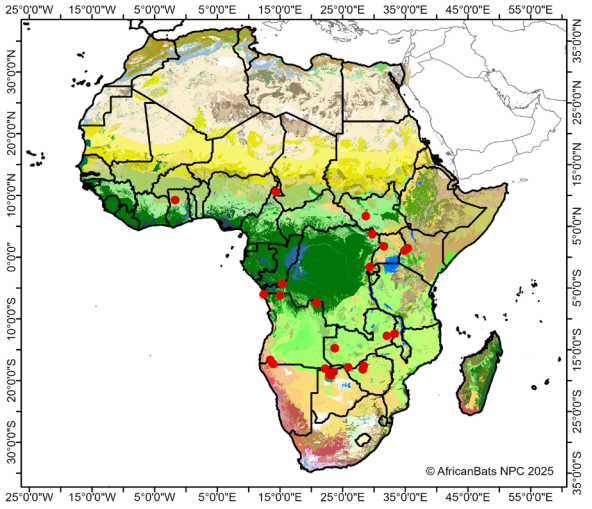

Figure 173. Distribution of *Mops (Chaerephon) chapini*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Botswana, Cameroon, Congo (Democratic Republic of the), Ethiopia, Ghana, Kenya, Namibia, Rwanda, South Sudan, Uganda, Zambia, Zimbabwe.

Mops (Chaerephon) jobimena (Goodman and Cardiff, 2004)

*2004. *Chaerephon jobimena* Goodman and Cardiff, Acta Chiropt., 6 (2): 230, fig 2, 3, 4. Type locality: Madagascar: Antsiranana province: Ankarana special reserve, 2.6 km E Andrafiabe: Andrafiaba cave, in forest near [12 55.9 S 49 03.4 E, ca. 50 m]. [Goto Description]. Holotype: FMNH 169716: ad ♂, skin and skeleton and skull and tissue. Collected by: Steven M. Goodman; collection date: 23 January 2001; original number: SMG 11932. See Goodman and Cardiff (2004: 230). - Etymology: From the northern dialects of Malagasy, with "*joby*" meaning dark or black and "*mena*" red. The combination refers to the two color morphs of this species (see Goodman and Cardiff, 2004: 230).
2020. *Mops jobimena:* Simmons and Cirranello, BatNames.org. (Current Combination).
? *Mops (Chaerephon) jobimena:* (Current Combination).

TAXONOMY:
Lamb *et al.* (2011: 9) and Goodman *et al.* (2022: 1904) indicate that, although morphologically similar to other "*Chaerephon*" taxa, *jobimena* is genetically more similar to *Tadarida aegyptiaca*, and probably should be assigned to the latter genus.

COMMON NAMES:
Czech: morous malgašský. English: Malagasy western Free-tailed bat, Black and Red Free-tailed Bat, Bicoloured free-tailed bat. French: Tadaride rouge ou noir, Molosse de l'ouest malgache. German: Variable Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) because although it appears to be rather rare in the few areas where it is known to occur, it is widespread and its population status may not be related to the amount or state of native forest. Additional information are needed on its propensity for roosting in large colonies in synanthropic settings as this will be crucial to a better understanding of its conservation status (Andriafidison *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017bz).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon jobimena*] (Monadjem *et al.*, 2017bz). 2008: LC ver 3.1 (2001) [assessed as "*Tadarida jobimena*"] (Andriafidison *et al.*, 2008l; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
The threats to this species are not well known, but it is probably hunted in the south of Madagascar for food (Andriafidison *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017bz).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008l) [in IUCN (2009)] and Monadjem *et al.* (2017bz) report that this species

is known from in or near to four protected areas, but is never as common or as abundant as other sympatric molossid species (Goodman and Cardiff, 2004; Goodman *et al.*, 2005a) and its conservation status should be reviewed in the future when new data are available. In particular, information on its propensity to dwell in buildings is needed.

GENERAL DISTRIBUTION:
Mops jobimena is endemic to Madagascar where it is found from the north-west to the south-west of the island. It is known to occur in areas with dry deciduous or spiny forest from 50 to 870 m above sea level (Goodman and Cardiff, 2004; Goodman *et al.*, 2005a). Although further surveys may reveal that this species is more widespread than currently known, it has yet to be recorded from some sites with extensive limestone caves, from where it would be expected based on habitat preference and distribution (Goodman and Cardiff, 2004; Goodman *et al.*, 2005a; Cardiff, 2006).

Native: Madagascar (Goodman and Cardiff, 2004; Goodman *et al.*, 2005a; Cardiff, 2006).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 61) report the following shape for the baculum of this species: the proximal portion is notably expanded. Its size decreases slightly in the mid-shaft portion, then more notably distally. The distal tip tapers to a rounded point. Length: 1.16 mm, width: 0.37 mm.

HABITAT:
Dammhahn and Goodman (2013: 108) indicate that this species' foraging habitat consists of open areas and the area above the forest canopy.

ROOST:
M. jobimena roosts in caves and hollow baobab trees, as well as in synanthropic sites. Colonies can count up to 1,200 bats in caves and 40 in buildings (Garbutt, 2022: 95).

POPULATION:
Structure and Density
The population and local abundance of this species are not known, but at Ankarana the recorded roost is 1,200 individuals (S. G. Cardiff *pers. obs.*, in Andriafidison *et al.*, 2008l [in IUCN, 2009]; Monadjem *et al.*, 2017bz). Forty individuals were recorded from a house roughly 10 km from Parc National de Namoroka (A. F. Kofoky *pers. obs.*, in Andriafidison *et al.*, 2008l [in IUCN, 2009]; Monadjem *et al.*, 2017bz).

Trend
2016: Unknown (Monadjem *et al.*, 2017bz).
2008: Unknown (Andriafidison *et al.*, 2008l; IUCN, 2009).

PARASITES:
Hastriter (2016: 9) described the flea *Araeopsylla goodmani* from a male *M. jobimena* collected at Isalo, 3.8 km NW Ranohira, along Namaza River, Madagascar.

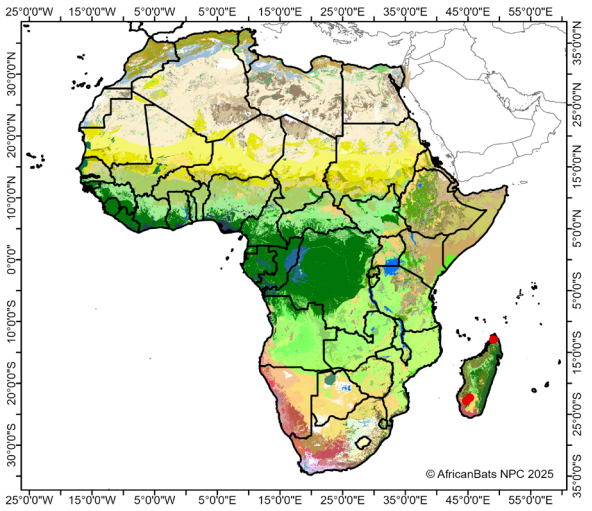

Figure 174. Distribution of *Mops (Chaerephon) jobimena*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Mops (Chaerephon) leucogaster (A. Grandidier, 1869)

*1869. *Nyctinomus leucogaster* A. Grandidier, Rev. Mag. Zool., ser 2, 21: 337. Publication date: September 1869. Type locality: Madagascar: Mahab (?Mahabo) and Ménabé (E of Morondava) [20 23 S 44 40 E, 50 m]. [Goto Description]. Neotype: FMNH 176137: ad ♂, skull and alcoholic. Collected by: H. Vola Razakarivony; collection date: 11 November 2002. - Comments: Ratrimomanarivo *et al.* (2009a: 28) mention "The only specimen possibly fitting the details of the Grandidier type is MCZ 45094, which is in poor condition and the original specimen label bears the following information: 'Cote Ouest' [= west coast], '*Nyctinomus pumelus* [sic]', 'collection Grandidier', and '1901'. Based on numerous characters, including aspects of external, cranial, and dental measurements as well as pelage and soft part coloration, this animal is referable to *C. leucogaster*. However, the collection details are too ambiguous to clearly conclude that this specimen can be considered the type of *C. leucogaster* described by Grandidier (1869) and, further, the skull is considerably damaged." They also select a neotype (FMNH 176137): "collected in the Menabe Region of western coastal Madagascar, specifically at Belo sur Mer (20°44.139'S, 44°00.266'E) at 10 m above sea level on 11 November 2002 by Vola Razakarivony. This site is approximately 80 km southwest of Mahabo. The animal is an adult male, the body was preserved in formalin and subsequently transferred to 70% ethanol, the skull has been extracted, cleaned,

and is in excellent condition.". - Etymology: From the Greek "*leugos*" and "*gaster*" meaning white-bellied (see Kozhurina, 2002: 16).

1908. *Chœrephon websteri* Dollman, Ann. Mag. nat. Hist., ser 8, 2 (12): 546. Publication date: 1 December 1908. Type locality: Nigeria: N Nigeria, on Bénoué river: Yola [09 12 N 12 29 E]. Holotype: NHMUK 1908.10.6.8: ad ♀, skin and skull. Collected by: G.W. Webster; collection date: 27 July 1908; original number: 11.

1917. *Chærephon (Lophomops) cristatus* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 463, text-fig 10 A, B. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Kinshasa province: near mouth of Congo River: Boma [05 50 S 13 03 E]. [Goto Description]. Holotype: AMNH 48844: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 26 January 1915; original number: 2628.

1917. *Chærephon frater* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 456. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Kinshasa province: near Boma: Malela [05 57 S 12 38 E, 30 m]. [Goto Description]. Holotype: AMNH 49275: ad ♀, skull and alcoholic. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 8 July 1915; original number: 2613. Topotype: MCZ 17219: ♀, alcoholic (skull not removed). Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 8 July 1915. Topotype: MCZ 17221: ♀, alcoholic (skull not removed). ? *Tadarida leucogaster websteri:* (Name Combination).

? *Tadarida leucogaster:* (Name Combination).

? *Tadarida pumila frater:*

? *Tadarida websteri:* (Name Combination).

Taxonomy:

Included in *pumilus* by Koopman (1993a: 233), Bouchard (1998: 1).

Considered a valid species in the genus *Tadarida (Chaerephon)* by Peterson *et al.* (1995: 152) and Russ *et al.* (2001). Considered a valid species in the genus *Chaerephon* by Hutson *et al.* (2001: 33), Goodman and Cardiff (2004: 227), Lavrenchenko *et al.* (2004b: 141), and Simmons (2005).

Russ *et al.* (2001) distinguish it from *M. pumilus* on smaller size and different echolocation calls. Ammerman *et al.* (2012: 23) indicate that the separation between *leucogaster* and *pumilus* took place less than 2 million years ago.

Based on mitochondrial markers, Goodman *et al.* (2022: 1904) state that *leucogaster* is poorly differentiated from *C. atsinanana*.

Common Names:

Czech: morous bělobřichý. English: Grandidier's lesser Free-tailed bat, Grandidier's Free-tailed Bat, Madagascan white-bellied Free-tailed Bat. French: Tadaride de Madagascar à ventre blanc, Tadaride à ventre blanc, Petite tadaride de Madagascar, Molosse de Grandidier. German: Grandidiers Bulldoggfledermaus.

Conservation Status:

Global Justification

Assessed by Mickleburgh *et al.* (2014b) as part of *Chaerephon pumilus*.

Assessment History

Global

2014: LC ver. 3.1 (2001) as a synonym of *Chaerephon pumilus* (Mickleburgh *et al.*, 2014b). DD ver 2.3 (1994).

Regional

None known.

General Distribution:

Ethiopia to Ghana, Nigeria, Cameroon (Bol A Anong *et al.*, 2011: 46; Bakwo Fils *et al.*, 2014: 4; Waghiiwimbom *et al.*, 2019b: 6 [as "*Chaerephon nigri*"]), Congo (Bates *et al.*, 2013: 336), Congo

(Democratic Republic of the Congo?), Mali, Madagascar (Russ *et al.*, 2001), Nosy Be and Nosy Komba (Rakotonandrasana and Goodman, 2007: 6).

O'Brien (2011: 288) reports it further from the Comoros, and the Tanzanian islands of Pemba, Unguja [=Zanzibar], and Mafia.

BIOGEOGRAPHY:
Mops leucogaster is found across an elevational range of 0 - 920 m a.s.l., and is confined almost exclusively to the more extensive and drier western portion of Madagascar (Lamb *et al.*, 2012: 19).

GEOGRAPHIC VARIATION:
Tidière *et al.* (2022: 11) found some mitochondrial discordance in the animals from Mayotte. Some specimens showed ambiguous morphological traits. They were found to have $_{mt}$DNA haplotypes, but grouped with the *pusillus* microsatellite-cluster, suggesting that hybridization between the two species has occurred.

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 61) describe the baculum of *M. leucogaster* as "Eiffel tower shaped", with a bifurcated proximal tip that tapers abruptly to a distal point; length: 0.78 ± 0.072 (0.65 - 0.89) mm, width: 0.47 ± 0.055 (0.37 - 0.58) mm.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Ramasindrazana and Goodman (2011) and Taylor *et al.* (2012a)] mention a wing loading value of 9.6 Pa, aspect ratio 8.1 for a wingspan of 27 cm and a wing area of 87 cm^2 and a body mass of 9 g.

MOLECULAR BIOLOGY:
Karyotype
From Ethiopia, Tolera *et al.* (2021: 125) reported *2n* = 48 and FN = 54. The autosomal chromosomes include four pairs of metacentrics and 19 pairs of acrocentrics; the X chromosome is metacentric and the Y chromosome is acrocentric.

HABITAT:
Lamb *et al.* (2012: 29) indicate that the highly suitable habitat for this species was associated with low annual rainfall, high mean annual temperature, and high human influence. Dammhahn and Goodman (2013: 108) indicate that this species' foraging habitat consists of open areas and the area above the forest canopy.

ROOST:
Ravelomanantsoa *et al.* (2019: 111) indicated that *Mops leucogaster* uses human constructions for roosting. Occasionally found in natural roosts under bark of dead trees (Garbutt, 2022: 96).

DIET:
Rocha *et al.* (2019: 188) found the paddy swarming armyworm (*Spodoptera mauritia*, Lepidoptera) in faecal samples of *Mops leucogaster*.

Tomita (2025: Suppl.) reported the sugarcone cicada (*Yanga guttulata* (Signoret, 1860)) as a prey item.

PREDATORS:
Goodman *et al.* (2015c: 78) found the remains of four individuals in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar. Razakaratrimo *et al.* (2019: 117) indicate that these bats are much more taken as prey during the wet season than during the dry season.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

Montade *et al.* (2024: 7) [referring to Lamb *et al.* (2012)] indicated that this species encountered a reduction in population size during the late Holocene.

REPRODUCTION AND ONTOGENY:
Nine females collected in December (?) at Ankajely (Madagascar) were all pregnant with embryos (crown-rump length 15 - 23 mm) (Goodman *et al.*, 2025: 214). Two males had large scrotal testes and well developed epididymides.

PARASITES:
BACTERIA
Gomard *et al.* (2016: 5) found 1 out of 94 tested bats to be positive for *Leptospira*.

SIPHONAPTERA
Ischnopsyllidae
Lagaropsylla consularis Smit, 1957 from Ethiopia, Kenya, Uganda, Congo and Congo (Democratic Republic of), Angola, Zimbabwe and

Mozambique (Haeselbarth *et al.*, 1966: 190, host referred to as "*Tadarida frater*").
Duchemin *et al.* (2022: 1077) reported the presence of *Lagaropsylla idae* Smit, 1957.

VIRUSES:
Astroviridae
Hoarau *et al.* (2021: Suppl.) reported these viruses from swab samples.

Paramyxoviridae
Specimens from this species tested by Wilkinson *et al.* (2014: 8270) were found to be positive for paramyxoviruses. Mélade *et al.* (2016b: 4) tested 94 Madagascan specimens, of which 6 were found positive for paramyxoviruses.

Rhabdoviridae
Mélade *et al.* (2016a: 6) tested 28 bats for *Duvenhage lyssavirus* and found seroreactivlty in nine of them.

UTILISATION:
See Goodman *et al.* (2008d).

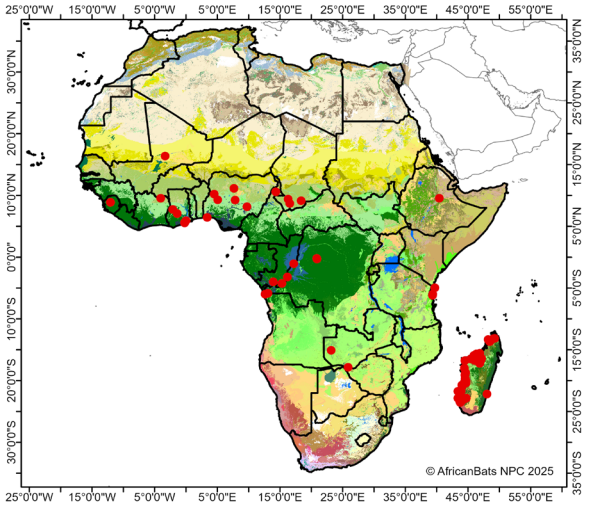

Figure 175. Distribution of *Mops (Chaerephon) leucogaster*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Ethiopia, Ghana, Madagascar, Mali, Nigeria, Sierra Leone, Tanzania, Zambia.

Mops (Chaerephon) major (Trouessart, 1897)

*1897. *[Nyctinomus (Nyctinomus) pumilus] Var. Major* Trouessart, Catalogus Mammalium tam viventium quam fossilium, nov ed 1, pt 1: 146. Publication date: 1897. Type locality: Sudan: N Sudan: 5th Cataract of the Nile [18 32 N 33 41 E]. [Goto Description]. Holotype: NHMUK 1849.2.8.36: Collected by: Sir Francis Galton. - Comments: Kock (1969a: 148) mentions "Nilus super = 5. Nil-Katarakt, nördlich Berber, Sudan" as original type locality. He also states that de Winton (1901a: 40) changed the type locality in "erster Kakarakt der Nil".). - Etymology: From the Latin "*maior*" (see Kozhurina, 2002: 16).
1901. *Nyctinomus Emini* de Winton, Ann. Mag. nat. Hist., ser 7, 7 (37): 40. Publication date: 1 January 1901. Type locality: Tanzania: "Mosambiro" [=Usambiro] [03 00 S 32 34 E]. [Goto Description]. Holotype: NHMUK 1890.6.8.15: ad ♂, skin and skull. Collection date: 9 September 1889. Notes: Local name - 'Katunke'. - Comments: See Thorn *et al.* (2009: 72).
1917. *Chærephon (Lophomops) abæ* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 464, text-fig 11. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Aba [03 53 N 30 17 E]. [Goto Description]. Holotype: AMNH 48887: ad ♀, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 17 December 1911; original number: 1823.
1967. *Tadarida (Chaerephon) pumila:* Happold, Sudan Notes & Records, 48: 122. - Comments: Preoccupied by *pumilus* Cretzschmar, 1830 (see Simmons, 2005). Attribution to *major* seems strange.
1989. *Chaerophon major:* Fenton, Can. J. Zool., 67 (8): 2035. Publication date: 1 August 1989. (Lapsus).
2020. *Mops major:* Simmons and Cirranello, BatNames.org. (Current Combination).
? *Chaerephon abae:* (Alternate Spelling).

? *Mops (Chaerephon) major:* (Current Combination).
? *Tadarida (Chaerephon) major:* (Name Combination).
? *Tadarida abae:* (Name Combination).
? *Tadarida major:* (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Chinese: 垂耳犬吻蝠. Czech: morous nubijský. English: Large Wrinkle-lipped Bat, Lappet-eared Wrinkle-lipped Bat, Lappet-eared Free-tailed Bat, Giant gland-tailed bat. French: Tadaride à oreillettes, Grand molosse à glandes caudales. German: Stirnlappen-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008ah; IUCN, 2009; Monadjem *et al.*, 2017z).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Chaerephon major*] (Monadjem *et al.*, 2017z). 2008: LC ver 3.1 (2001) [assessed as "*Tadarida major*"] (Mickleburgh *et al.*, 2008ah; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004am; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There are no major threats to this species. Some populations are threatened by general habitat loss and disturbance of old buildings (Mickleburgh *et al.*, 2008ah; IUCN, 2009; Monadjem *et al.*, 2017z).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ah) [in IUCN (2009)] and Monadjem *et al.* (2017z) report that the species has a wide range, and likely occurs in some protected areas, although this needs to be confirmed. No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Mops major is a lowland species is found throughout much of West Africa (including Senegal, Liberia, Côte d'Ivoire, Mali, Burkina, Ghana, Togo, Benin, Niger, and Nigeria), as well as a narrow distribution following the Nile from northern Sudan to Uganda. A second population is known from the east of Lake Victoria in eastern Uganda, western Kenya, and north-western Tanzania. A third, apparently disjunct, population is present in southeastern Kenya and northeastern Tanzania.

The records from Liberia should be re-examined as they may represent a different species, while the record from Malawi is doubtful (J. Fahr *pers. comm.* 2004 in Mickleburgh *et al.*, 2008ah in IUCN, 2009).

Native: Benin (Capo-Chichi *et al.*, 2004: 163); Burkina Faso (Kangoyé *et al.*, 2015a: 617); Cameroon (Bakwo Fils *et al.*, 2014: 4); Congo (The Democratic Republic of the); Côte d'Ivoire; Ghana; Guinea; Kenya; Liberia; Mali; Niger; Nigeria; Senegal; Sudan; Tanzania; Togo; Uganda (Kityo and Kerbis, 1996: 63); Zambia (Monadjem *et al.*, 2010d: 541).

ECHOLOCATION:
From Maroua, Cameroon, Manga Mongombe (2012: 79) and Bakwo Fils *et al.* (2018: 4) reported for 16 calls a call type of FM and the following parameters: F_{max}: 39.3 ± 6.9 (31.9 - 53.1) kHz, F_{min}: 37.4 ± 6.7 (25.9 - 49.0) kHz, F_{mean}: 36.4 ± 6.7 (28.7 - 51.0) kHz, F_{knee}: 38.2 ± 7.3 (29.9 - 53.1) kHZ, F_{char}: 33.7 ± 7.3 (26.2 - 49.0) kHz, and duration: 1.66 ± 0.40 (0.85 - 2.73) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

POPULATION:
Structure and Density
This is a relatively common species, found in fairly small colonies (Mickleburgh *et al.*, 2008ah; IUCN, 2009; Monadjem *et al.*, 2017z).

Trend
2016: Stable (Monadjem *et al.*, 2017z). 2008: Stable (Mickleburgh *et al.*, 2008ah; IUCN, 2009).

PARASITES:
ARACHNIDA
Macronyssidae
Budinski and López-Baucells (2023: 154) mentioned this species as host for *Chelanyssus aethiopicus* (Hirst, 1921).

SIPHONAPTERA
Beaucournu and Kock (1996) reported the first record for the flea *Lagaropsylla anciauxi* Smit, 1957 on "*Tadarida major*" from Burkina Faso.

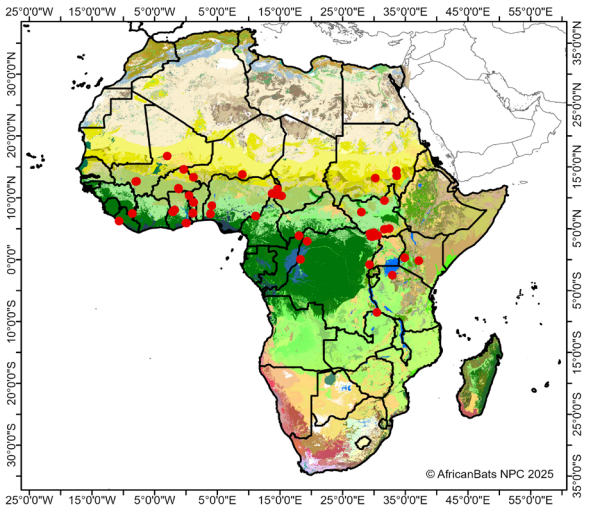

Figure 176. Distribution of *Mops (Chaerephon) major*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Burkina Faso, Cameroon, Central African Republic, Congo (Democratic Republic of the), Ghana, Kenya, Liberia, Mali, Niger, Nigeria, South Sudan, Sudan, Tanzania, Togo, Uganda, Zambia, Zimbabwe.

Mops (Chaerephon) nigeriae (Thomas, 1913)

*1913. *Chærephon nigeriæ* Thomas, Ann. Mag. nat. Hist., ser 8, 11 (63): 319. Publication date: 1 March 1913. Type locality: Nigeria: Northern region: Zaria province [ca. 11 01 N 07 44 E]. [Goto Description]. Holotype: NHMUK 1911.3.22.1: ad ♀. Collected by: A.C. Francis Esq. Presented/Donated by: A.C. Francis Esq. - Etymology: From the genitive scientific Latin feminine substantive *nigèriae*, meaning "from Nigeria", as the species was described from a Nigerian specimen (see Lanza *et al.*, 2015: 277).
1957. *Tadarida (Chearephon) spillmani:* Ansell, Ann. Mag. nat. Hist., ser 12 (10): 539. (Lapsus).
1988. *Tadarida chaeraphon nigeriae:* Okafor, Misc. Zool., 12: 11. (Lapsus).

? *Tadarida nigeriae:* (Name Combination).

TAXONOMY:

Figure 177. *Mops (Chaerephon) nigeriae* (ECJS-77/2009) caught in the Okavango, Botswana.

See Willis *et al.* (2002, Mammalian Species, 710).

This may be a complex of two distinct species, with *Mops nigeriae* in the north of the known distribution and *M. spillmanni* in the south. We follow Simmons (2005) in currently recognizing *spillmanni* Monard, 1933 as a subspecies of *M. nigeriae*.

Herkt *et al.* (2017: Appendix S9) found that the localities in the southern part of the distribution area suggest rather different ecological niches than those for the northern part, which would suggest that more than one species might be included.

COMMON NAMES:

Afrikaans: Nigeriese losstertvlermuis. Azande (DRC): Fulo. Czech: morous nigerijský. English: Nigerian Free-tailed Bat, Nigerian Wrinkle-lipped Bat. French: Tadaride du Nigeria, Molosse du Nigéria. German: Nigeria-Bulldoggfledermaus. Italian: Cherefónte nigeriàno.

ETYMOLOGY OF COMMON NAME:

The species was originally described from a specimen from Nigeria (see Taylor, 2005).

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008ai; IUCN, 2009; Monadjem *et al.*, 2017d).

Assessment History

Global

2016: LC ver 3.1 (2001) [assessed as *Chaerephon nigeriae*] (Monadjem *et al.*, 2017d). 2008: LC ver 3.1 (2001) [assessed as "*Tadarida nigeriae*"] (Mickleburgh *et al.*, 2008ai; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004af; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

South Africa: 2004: considered a vagrant not assessed, not recorded in SA (Friedmann and Daly, 2004).

MAJOR THREATS:

There appear to be no major threats to this species (Mickleburgh *et al.*, 2008ai; IUCN, 2009; Monadjem *et al.*, 2017d). The ability of the species to exploit buildings as roosts, and its association with cleared rainforest in Nigeria, suggests that it is relatively resistant to anthropogenic impacts (Willis *et al.*, 2002).

CONSERVATION ACTIONS:

Mickleburgh *et al.* (2008ai) [in IUCN (2009)] and Monadjem *et al.* (2017d) report that in view of the species wide range, it is presumably present in some protected areas. No direct conservation

measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Mops nigeriae is widely distributed over much of sub-Saharan Africa. It ranges from Sierra Leone in the west to Ethiopia in the east, being recorded as far south as Angola, Botswana and Zimbabwe. There are some additional records from the Arabian Peninsula in Yemen and western Saudi Arabia. The species has been found at elevations of up to 1,000 m asl, and possibly occur higher.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,133,308 km^2.

Native: Angola (Crawford-Cabral, 1989; Al-Jumaily, 2002: 55; Monadjem *et al.*, 2010d: 541; Taylor *et al.*, 2018b: 60); Botswana (Archer, 1977; Al-Jumaily, 2002: 55; Monadjem *et al.*, 2010d: 541); Burkina Faso (Kangoyé *et al.*, 2012: 6024; 2015a: 618); Burundi; Cameroon; Central African Republic (Al-Jumaily, 2002: 55); Chad (Al-Jumaily, 2002: 55); Congo; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Al-Jumaily, 2002: 55; Monadjem *et al.*, 2010d: 541); Côte d'Ivoire (Beaucournu and Fahr, 2003: 157; but see Al-Jumaily, 2002); Ethiopia (Al-Jumaily, 2002: 55); Ghana (Al-Jumaily, 2002: 55); Guinea (Al-Jumaily, 2002: 55; Ziegler *et al.*, 2002: 78); Malawi (Happold and Happold, 1997b: 823; Al-Jumaily, 2002: 55); Mali (Al-Jumaily, 2002: 55); Mozambique; Namibia (Al-Jumaily, 2002: 55; Monadjem *et al.*, 2010d: 541); Niger (Al-Jumaily, 2002: 55); Nigeria (Al-Jumaily, 2002: 55); Saudi Arabia (Nader and Kock, 1980); Sierra Leone (Al-Jumaily, 2002: 55); Sudan; Tanzania (Al-Jumaily, 2002: 55); Uganda (Al-Jumaily, 2002: 55); Yemen (Al-Jumaily, 2002: 55; Benda *et al.*, 2011b: 46); Zambia (Ansell, 1957; Ansell and Ansell, 1973; Cotterill, 2004a: 261; Al-Jumaily, 2002: 55; Monadjem *et al.*, 2010d: 541); Zimbabwe (Al-Jumaily, 2002: 55; Monadjem *et al.*, 2010d: 542).

Presence uncertain: Togo (Al-Jumaily, 2002: 55).

ECHOLOCATION:
Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 17 kHz and duration: 10 ms.

Eight calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 16.51 ± 0.57 kHz, F_{min}: 14.11 ± 4.77 kHz, F_{knee}: 16.29 ± 0.54 kHz, F_{char}: 16.12 ± 0.43 kHz, slope: 2.99 ± 9.56 OPS, duration: 6.83 ± 4.45 ms.

In Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 9 calls: Interpulse interval: 136.0 ± 128.2 (37.5 - 465.0) ms; F_{max}: 24.6 ± 3.6 (20.7 - 30.3) kHz; Start slope: -4.0 ± 1.8 (-1.7 - -6.5) kHz/ms; End slope: -2.7 ± 1.9 (0.0 - -5.7) kHz/ms; Ledge duration: 0.4 ± 0.0 (0.4 - 0.5) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

See also Taylor (1999b).

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 48, FN = 62, BA = 16, a submetacentric X chromosome, and an acrocentric Y chromosome, for specimens from Namibia and Zimbabwe

ROOST:
In Zimbabwe, a group of six individuals was noticed leaving a roost under bark, whereas in Botswana a similar roost contained at least 25 animals, and in Zambia, colonies of 30 to 100 individuals were reported (Happold and Happold, 2023: 126).

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure and Density
This species is typically found in small groups of 10 to 15 animals, with maternity roosts being formed of up to 25 bats (Mickleburgh *et al.*, 2008ai; IUCN, 2009; Monadjem *et al.*, 2017d).

Trend
2016: Unknown (Monadjem *et al.*, 2017d). 2008: Unknown (Mickleburgh *et al.*, 2008ai; IUCN, 2009).

PARASITES:
BACTERIA
Bartonellae
Kamani *et al.* (2014: 628) tested 16 Nigerian *C. nigeriae* animals, and found 2 of them testing positive for *Bartonella* DNA. Of the two Nigerian bats examined by Di Cataldo *et al.* (2020: 2), one was infected by hemoplasma bacteria.

HELMINTHS
Okafor *et al.* (2004: 64) investigated the helminth parasite load of 857 *M. nigeriae* specimens from Nigeria and found 658 (76.78 %) of them to be infected by 9 species: Nematodes: *Rictularia*

chaerephoni, Histostrongylus coronatus, Capillaria annulosa Dujardin, 1845, *Cheiropteronema globocephala* Sandground, 1929, *Litosoma pujoli* Bain, 1966; Trematodes: *Posthodendrium panouterus, Castroia nyctali* Gvosdev, 1954; Cestodes: *Hymenolepis kerivoulae* (Prudhoe and Manger, 1969), *Oochoristica agamae* Bayliss, 1919.

ARACHNIDA
Macronyssidae
Orlova *et al.* (2024: 154) mentioned this species as host for *Chelanyssus aethiopicus* (Hirst, 1921).

DIPTERA
Nycteribiidae
16 Nigerian bats examined by Stuckey *et al.* (2017: 22) were parasitized by *Cyclopodia greefi* Karsch, 1884 bat flies.

VIRUSES:
Paramyxoviridae
Ayolabi *et al.* (2021) reported on the presence of Paramyxoviruses (PmV) in these bats from Lagox (Nigeria).

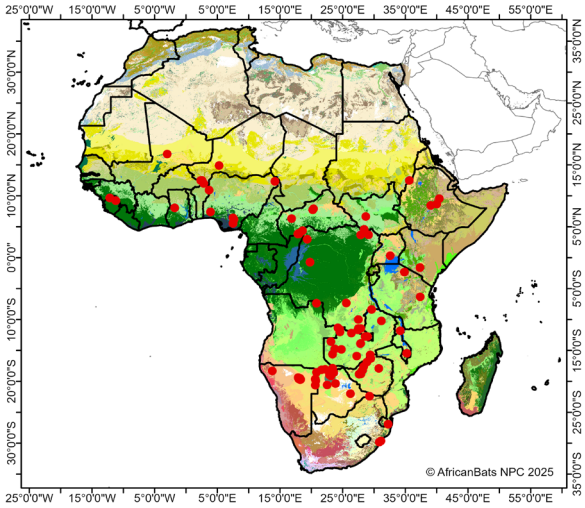

Figure 178. Distribution of *Mops (Chaerephon) nigeriae*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa".

Mops (Chaerephon) nigeriae nigeriae (Thomas, 1913)

*1913. *Chærephon nigeriæ* Thomas, Ann. Mag. nat. Hist., ser 8, 11 (63): 319. Publication date: 1 March 1913. Type locality: Nigeria: Northern region: Zaria province [ca. 11 01 N 07 44 E]. [Goto Description]. - Etymology: From the genitive scientific Latin feminine substantive *nigèriae*, meaning "from Nigeria", as the species was described from a Nigerian specimen (see Lanza *et al.*, 2015: 277).
? *Chaerephon nigeriae nigeriae:* (Name Combination).
? *Mops (Chaerephon) nigeriae nigeriae:* (Current Combination).
? *Tadarida (Chaerephon) nigeriae nigeriae:* (Name Combination).

Mops (Chaerephon) pumilus (Cretzschmar, 1826)

*1826. *Dysopes pumilus* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 69, pl 27a. Type locality: Eritrea: Massawa [15 37 N 39 26 E]. [Goto Description]. Lectotype: SMF 4311: ♀, skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1825. Old catalog II.K.3.a: see Mertens (1925: 20). Paralectotype: RMNH MAM.27334: ad, mounted skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell. - Comments: The publication date of Cretzschmar's work is sometimes indicated as "1826" (as mentioned on the title page), but also as "1827", "1828", "1830-1831". - Etymology: From the masculine Latin adjective *pùmilus*, meaning "of short stature, dwarf or pygmy" as the species is a particularly small African molossid (see Lanza *et al.*, 2015: 282).

1838. *Nyctinomus pusilus:* Lesson, Compléments de Buffon, ed 2, Paris, 1: 328. Publication date: 1838. (Lapsus).

1852. *Dysopes dubius* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 60, pl 15, fig 2. Publication date: 1852. Type locality: Mozambique: South bank of Zambezi River: Sena [17 28 S 35 01 E]. [Goto Description]. Holotype: ZMB 85539: juv, skull only. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. Pullus specimen; see Turni and Kock (2008: 72). - Comments: Preoccupied by *dubius* A. Smith, 1833 (see Simmons, 2005). Allen (1939a: 111) also mentioned *Nyctinomus dubius* A. Smith, 1833 as a separate species. Turni and Kock (2008: 72) state that no other African molossid collected was ever identified with *D. dubius* until Ellerman *et al.* (1953: 68) synonymized it without any comment. Peters´ species description on the *pullus* specimen ZMB 85539 is very questionable, so they conclude that *dubius* is a *nomen dubium*.

1852. *Dysopes limbatus* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 56, pl 14. Publication date: 1852. Type locality: Mozambique: Mozambique Island [15 03 S 40 46 E]. [Goto Description]. Syntype: NHMUK 1907.1.1.704. Syntype: ZMB 537/85520: ad ♂, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008) [skin: ZMB 537 / skull: ZMB 85520]. Syntype: ZMB 538/85519: ad ♀, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008) [skin: ZMB 538 + skull: ZMB 85519]. Syntype: ZMB 539: juv, skin only. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008). - Comments: Peters (1852: 56) mentions "Africa orientalis, Insula Mozambique, Sena at 15° ad 17° Let. Aust.", and Roberts (1951: 98) "Mozambique Island and Sena"). Possibly valid as a subspecies. Considered a valid species by Peterson *et al.* (1995: 159).

1877. *Nyctinomus [(Nyctinomus)] limbatus:* Dobson, Proc. zool. Soc. Lond., 1876, IV: 724. Publication date: April 1877. (Name Combination).

1877. *Nyctinomus [(Nyctinomus)] pumilus:* Dobson, Proc. zool. Soc. Lond., 1876, IV: 723. Publication date: April 1877. (Name Combination).

1878. *Nyctinomus limbatus:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 428. Publication date: 15 June 1878. - Comments: . (Name Combination).

1901. *Nyctinomus gambianus* de Winton, Ann. Mag. nat. Hist., ser 7, 7 (37): 39. Publication date: 1 January 1901. Type locality: The Gambia: "Gambia". [Goto Description]. Holotype: NHMUK 1889.10.7.3.

1904. *Nyctinomus hindei* Thomas, Ann. Mag. nat. Hist., ser 7, 13 (75): 210. Publication date: 1 March 1904. Type locality: Kenya: Fort Hall [=Muranga] [00 43 S 37 09 E, 4 000 ft]. [Goto Description]. Holotype: NHMUK 1903.3.2.4: ad ♂. Collected by: Mrs. Hildegarde Beatrice Hinde; collection date: 1 January 1903; original number: 134. Presented/Donated by: Mrs. Hildegarde Beatrice Hinde. - Comments: Possibly valid as a subspecies. Considered a valid species by Peterson *et al.* (1995: 159). Thomas (1904a: 210) mentions 2 specimens.

1914. *Chaerephon pumilus:* G.M. Allen, Bull. Mus. comp. Zool., 58 (7): 353. Publication date: July 1914. (Name Combination).

1916. *Chaerephon pumilus naivashæ* Hollister, Smiths. Misc. Coll., 66 (1) (2406): 4. Publication date: 10 February 1916. Type locality: Kenya: Naivasha Station [00 43 S 36 26 E]. [Goto Description]. Holotype: USNM 166658: ad ♂, skull and alcoholic. Collected by: John Alden Loring; collection date: 7 August 1909; original number: 6955. Topotype: ROM 36466: ad ♂, skin and skull. Collected by: John George Williams; collection date: 10 July 1965. Topotype: ROM 36467: ad ♀, skin and skull. Collected by: John George Williams; collection date: 17 July 1965. Topotype: ROM 36468: ad ♀, skin and skull. Collected by: John George Williams; collection date: 17 July 1965. Topotype: ROM 36469: ad ♀, skin and skull. Collected by: John George Williams; collection date: 17 July 1965. Topotype: ROM 36470: ad ♂, skin and skull. Collected by: John George Williams; collection date: 17 July 1965. Topotype: ROM 36471: ad ♀, skin and skull. Collected by: John George Williams; collection date: 10 August 1965. Topotype: ROM 36472: ad ♀, skin and skull. Collected by: John George Williams; collection date: 10 August 1965. Topotype: ROM 41842: juv ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41843: juv ♀, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41844:

juv ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41845: juv ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41846: juv ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41847: juv ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41848: juv ♀, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41849: juv ♀, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41850: ad ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41851: ad ♀, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41852: ad ♀, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. Topotype: ROM 41853: ad ♂, alcoholic (skull not removed). Collected by: Randolph Lee Peterson, John George Williams and Robert M. Glen; collection date: 9 August 1967. TAXONOMY:

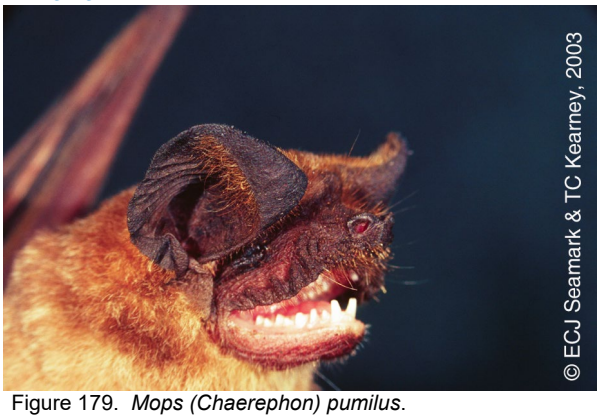

Figure 179. *Mops (Chaerephon) pumilus*.

See Bouchard (1998, Mammalian Species, 574). Formerly included *pusillus*; see Hayman and Hill (1971: 64), but see Goodman and Ratrimomanarivo (2007: 391). The description date is sometimes mentioned as "1830 or 1831" (see Happold and Happold (1997b: 823). Peterson *et al.* (1995: 162) consider *pumilus* not to include most of the forms occurring on Madagascar. Horáček *et al.* (2000: 136) include *pumilus* in the genus *Tadarida*, subgenus *Chaerephon*. Taylor (1999b), Aspetsberger *et al.* (2003: 250; 252) indicate that cryptic species might exist within the genus *Chaerephon* (more specifically in *pumilus*), but find it premature to identify them already. Jacobs *et al.* (2004ar: 17) identified five haplotypes, but indicate they represent only one species.

Naidoo *et al.* (2013c: 134) indicate that southeast African *M. pumilus s.l.* contains several well-supported sympatric genetic lineages (they identified three clades), which exhibit paraphyly with the Malagasy *M. leucogaster*. They were not able to to distinguish these clades based on echolocation characteristics (p. 137) but suggest that these stable sympatric lineages might be the result of female philopatry or roost faithfulness.

Naidoo *et al.* (2016) used cyt *b*, control region, and Rag2 data on a large number of representatives from the *Mops pumilus* species complex from islands in the western Indian Ocean, and eastern and southeastern Africa. They found that *Mops pumilus* s.s. (Eritrea and Yemen) is specifically distinct from the following taxa/samples: *M. pumilus* from southeastern Africa, the syntype of *limbatus*, the holotypes of *elphicki* and *langi*, and the topotype of *naivashae*. They suggest (p. 642) that additional evidence from more variable nuclear markers is necessary to resolve the issue of the number of species present in this complex. The genetic differentiation is probably the result of habitat fragmentation during glacial maxima when the ancestral population was separated over isolated

subtropical forests (Schoeman and Monadjem, 2018: 4).

Benda *et al.* (2023a: 44; 2025: 81) indicate that bats traditionally assigned to "*Chaerephon pumilus*" are currently believed to belong to a complex of several species, which still needs to be resolved. Most sub-Saharan populations would not belong to *Chaerephon pumilus* s.s.

COMMON NAMES:
Afrikaans: Klein losstertvlermuis. Chinese: 小犬吻蝠. Czech: morous malý, tadarida malá. English: Little Free-tailed Bat, Lesser Free-tailed Bat, Little Wrinkle-lipped Bat, White-bellied Free-tailed Bat. French: Petite tadaride, Petit molosse à glandes caudales, Tadaride bornée. German: Kleine Bulldoggfledermaus, Zwerg-Doggengrämler, Sena-Doggengrämler, Gesäumte Doggengrämler. Italian: Cherefónte pigmèo. Kiluba (DRC): Kasusu. Malawian: Liputiputi, Ndemiya, Namzeze. Nyungwe (Malawi): Kalemawalema (not specific). Portuguese: Morcego pequeno de cauda livre.

ETYMOLOGY OF COMMON NAME:
From the Latin "*pumilus*" meaning dwarf, because it is the smallest of the molossids occurring in the (southern African sub)region (see Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, tolerance of a broad range of habitats, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008dr; IUCN, 2009; Mickleburgh *et al.*, 2014b; Mickleburgh *et al.*, 2019m).

Assessment History
Global
2018: LC ver 3.1 (2001) assessed as *Chaerephon pumilus* (Mickleburgh *et al.*, 2019m). 2014: LC ver 3.1 (2001) assessed as "*Chaerephon pumilus*" (Mickleburgh *et al.*, 2014b). 2008: LC ver 3.1 (2001) assessed as "*Tadarida pumila*" (Mickleburgh *et al.*, 2008dr; IUCN, 2009). 2004: LC ver 3.1 (2001) assessed as "*Chaerephon pumila*" (Mickleburgh *et al.*, 2004ah; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016a). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There are no major threats to the species. In some parts of its range, it is threatened from persecution as a pest, especially since it roosts in buildings (Mickleburgh *et al.*, 2008dr; IUCN, 2009; Mickleburgh *et al.*, 2014b; Mickleburgh *et al.*, 2019m).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2014b) and Mickleburgh *et al.* (2019m) reported that due to its wide range it seems probable that this species is present in some protected areas. On Madagascar, it has not been recorded from any protected areas, but it has been recorded from houses close to protected areas. The status of the population on Aldabra need to be clarified with complementary research needed into the conservation status of this population.

GENERAL DISTRIBUTION:
This widespread species is found from Senegal in the west of its range, eastwards to Yemen and southwestern Saudi Arabia, and as far south as South Africa, where Babiker Salata (2012: 49) found that its distribution is strongly associated with the mean temperature of the coldest quarter. It has been recorded from the island of Bioko and the Annobon Islands (Equatorial Guinea), Pemba and Zanzibar (Tanzania).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 809,867 km^2.

Records from Western Cape Province are rejected by Jacobs and Fenton (2001), since these represent *Sauromys petrophilus*.

Records from the Seychelles [Aldabra] (Hutson, 2004a) and the Comoros (Louette, 2004; Goodman, 2007; ACR, 2006, 2007, 2008, 2009, 2010) are rejected by Goodman *et al.* (2010a) since these represent *Mops pusillus*.

Records from Madagascar (Bouchard, 1998; Russ *et al.*, 2001; Goodman and Cardiff, 2004; ACR, 2006, 2007, 2008, 2009,2010) are now assigned to *Mops atsinanana* (Goodman *et al.*, 2010a).

Native:
Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 542; Taylor *et al.*, 2018b: 62); Benin (Capo-Chichi *et al.*, 2004: 164); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 542); Burkina Faso (Kangoyé *et al.*, 2015a: 618); Burundi; Cameroon (Bakwo Fils *et al.*, 2014: 4): Chad; Congo (Bates *et al.*, 2013: 336); Congo (The Democratic Republic of the) (Allen, 1917;

Schouteden, 1944; Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Monadjem *et al.*, 2010d: 542); Côte d'Ivoire; Equatorial Guinea [Annobón, Bioko]; Eritrea; Eswatini (Monadjem *et al.*, 2010d: 543, Monadjem *et al.*, 2021: 5); Ethiopia (Lavrenchenko *et al.*, 2004b: 132; Benda *et al.*, 2020: 2586); Gambia (Emms and Barnett, 2005: 50); Ghana; Guinea; Guinea-Bissau (Monard, 1939; Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 73); Kenya; Liberia (Fahr, 2007a: 104); Malawi (Happold *et al.*, 1988; Ansell and Dowsett, 1988: 46; Monadjem *et al.*, 2010d: 542); Mali (Meinig, 2000: 105); Mozambique (Smithers and Lobão Tello, 1976; Lopes and Crawford-Cabral, 1992; Monadjem *et al.*, 2010d: 542; Monadjem *et al.*, 2010c: 382); Namibia (Monadjem *et al.*, 2010d: 542); Niger; Nigeria; Rwanda; São Tomé and Príncipe [São Tomé] (Juste and Ibáñez, 1993c: 906; Rainho *et al.*, 2010a: 37); Saudi Arabia; Senegal; Sierra Leone; Somalia; South Africa (De Graaf, 1960; Monadjem *et al.*, 2010d: 542); Sudan; Tanzania; Togo; Uganda (Kityo and Kerbis, 1996: 62); Yemen (Benda *et al.*, 2011b: 47); Zambia (Ansell, 1969; Ansell, 1973; Ansell, 1978; Monadjem *et al.*, 2010d: 543); Zimbabwe (Cotterill, 2004a: 261; Monadjem *et al.*, 2010d: 543).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
From western Uganda, Monadjem *et al.* (2011: 30) reported the following data: Fa: 38.95 mm, mass: 10.5 g, wing loading: 12.4 N/m^2, aspect ratio: 7.3.

DETAILED MORPHOLOGY:
Brain
Tambusso and Fariña (2015: Suppl.) mention a brain mass of 0.29 g for an average body mass of 13.3 g.

Amrein *et al.* (2007) from specimens collected from Bénin reported moderate proliferating cell activity, detected with Ki-67 and MCM2, in the subgranular layer of the dentate gyrus, with doublecortin (DCX) they detected young migrating neuron in the subgrannular layer of the hippocampus. Amrein *et al.* (2007) also reported moderate to ample proliferating cells (Ki-67 positive cells) and migrating young neurons (DCX positive cells) in the rostral migratory stream. No NeuroD was detected in the hippocampal granule cells (Amrein *et al.*, 2007). Kruger *et al.* (2010a) describe, based on three brains from Kenya, using immunohistochemical methods, the nuclear organization of the cholinergic, catecholaminergic and serotonergic systems. Kruger *et al.* (2010b) describes, based on three brains from Kenya, the distribution of Orexin-A immunoreactive cell bodies and terminal networks.

Gastro-intestinal tract (GIT)
Aylward *et al.* (2019: 1108) reported for six specimens an average weight of 9.17 ± 0.85 g, and a GIT of 0.44 ± 0.05 g (4.85 ± 0.40 %).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 11.8 Pa, aspect ratio 8.6 and tip shape index of 1.66 for a wingspan of 27 cm and a wing area of 87 cm^2 and a body mass of 11 g.

In their study on rewarming along an altitudinal gradient in the RSA, Marsden *et al.* (2022: 5) found that the body mass of these bats decreases with increasing altitude. Their mass-specific rewarming rate was positively correlated with altitude.

SEXUAL DIMORPHISM:
Chaverri *et al.* (2018: 1944) [referring to Bouchard, 2001b] indicates that the sexes can be distinguished by scent produced from the interaural and muzzle glandular areas.

ECHOLOCATION:
Frequency modulated call. In Kenya, Taylor *et al.* (2005) reported a peak frequency of 25.6 ± 1.7 kHz from Kivoko. In Tanzania, Aspetsberger *et al.* (2003) reported a F_{max}: 22.7 ± 3.3 kHz from Amani Nature Reserve. In Swaziland, Taylor (1999b) reported a F_{max}: 32.9 ± 4.5 kHz from Mlawula, and maximum frequencies at three different localities around Durban in South Africa of 43.0 ± 1.0 kHz, 28.7 ± 1.8 kHz and 28.7 ± 2.5 kHz. Fenton *et al.* (2004) reported a F_{max}: 29 ± 4.6 kHz for a locality in Durban, South Africa. Rainho *et al.* (2010a: 21) reports the calls [as *Tadarida pumila*] of 32 individuals from Sao Tomé. Bohmann *et al.* (2011: 1) [referring to Monadjem *et al.* (2010d)] mention F_{peak}: 25 - 40 kHz. Schoeman and Waddington (2011: 291) mention a F_{peak} 28.2 ± 1.5 kHz and a duration: 10.8 ± 0.2 ms for specimens from Durban, South Africa. From the Durban area, Naidoo *et al.* (2011: 23) report F_{peak} = 24.7 ± 1.0 kHz and a duration: 12.4 ± 0.9 ms.

Taylor *et al.* (2013b: 18) recorded the following parameters for 8 calls from specimens from Swaziland: F_{max}: 27.7 ± 4.40 (23.0 - 32.8) kHz, F_{min}: 23.3 ± 2.38 (20.9 - 27.4) kHz, F_{knee}: 26.2 ± 3.34 (22.6 - 30.8) kHz, F_{char}: 24.3 ± 2.91 (21.5 - 28.1) kHz, duration: 8.3 ± 2.10 (5.3 - 11.9) ms, and for 6 calls from KwaZulu-Natal, South Africa: F_{max}: 31.6 ± 4.05 (24.6 - 36.7) kHz, F_{min}: 24.5 ± 1.55 (21.7 - 26.5) kHz, F_{knee}: 28.9 ± 2.51 (24.4 - 31.3) kHz, F_{char}: 25.6 ± 1.57 (22.7 - 27.3) kHz, duration: 8.4 ± 1.71 (6.6 - 11.0) ms. From

Swaziland also, Monadjem *et al.* (2017c: 179) reported the following values: F_{min}: 23.3 ± 1.41 (20.8 - 26.5) kHz, F_{knee}: 26.1 ± 2.09 (22.5 - 29.6) kHz, F_c: 24.0 ± 1.53 (21.3 - 27.2) kHz and duration: 9.0 ± 2.10 (3.9 - 12.6) ms. They were able to detect these calls up to a distance of 15 m.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 29 (24 - 31) kHz.

Linden *et al.* (2014: 40) mentioned the following parameters for the Soutpansberg area (RSA): F_{min}: 21 - 27 kHz, F_{char}: 22 - 28 kHz, F_{knee}: 23 - 31 kHz, slope: 13 - 124 OPS, duration: 5 - 12 ms.

20 calls from Mapungubwe National Park (RSA) were recorded by Parker and Bernard (2018: 57) with the following characteristics: F_{char}: 26.65 ± 2.53 kHz, F_{max}: 34.87 ± 5.75 kHz, F_{min}: 24.67 ± 2.68 kHz, F_{knee}: 29.72 ± 3.05 kHz, duration: 8.80 ± 2.65 ms, with 4.24 ± 1.89 calls/sec.

Monadjem *et al.* (2011: 32) reported values for two calls from a "*Chaerephon* cf. *pumilus*" from western Uganda: F_{min}: 24.95 kHz, F_{max}: 27.78 kHz, F_{char}: 25.22 kHz, F_{knee}: 75.61 kHz, and duration: 8.4 ms.

Two calls from specimens from the Aberdares Range in Kenya were reported by Eisenring *et al.* (2016: SI 2) with F_{peak}: 26.3 ± 2.8 (24.4 - 28.3) kHz, F_{max}: 32.6 ± 1.2 (31.8 - 33.5) kHz, F_{min}: 20.9 ± 0.4 (20.6 - 21.1) kHz, duration: 11.8 ± 1.5 (10.7 - 12.9) ms.

From Maroua, Cameroon, Manga Mongombe (2012: 79) reported for 3 calls a call type of FM and the following parameters: F_{max}: 44.2 ± 3.4 (40.4 - 47.0) kHz, F_{min}: 38.2 ± 2.6 (35.3 - 40.4) kHz, F_{mean}: 41.2 ± 3.0 (37.9 - 43.7) kHz, F_{knee}: 44.1 ± 3.4 (40.4 - 47.0) kHz, F_{char}: 39.1 ± 2.4 (36.5 - 41.2) kHz, and duration: 1.32 ± 0.11 (1.26 - 1.45) ms.

Two calls by bats from the Kalahari Desert had the following characteristics: F_{char}: 22.9 ± 0.3 kHz, F_{max}: 25.0 ± 0.1 kHz, Fmin: 22.4 ± 0.4 kHz and duration: 5.6 ± 1.5 ms (Adams and Kwiecinski, 2018: 4).

Weier *et al.* (2020: Suppl.) reported on 11 calls from the Okavango River Basin with the following characteristics: F_{max}: 29.69 ± 4.89 kHz, F_{min}: 22.96 ± 1.91 kHz, F_{knee}: 25.46 ± 1.84 kHz, F_{char}: 23.65 ± 1.71 kHz, slope: 35.10 ± 33.29 OPS, duration: 8.54 ± 4.71 ms.

Luo *et al.* (2019a: Supp.) reported the following data (bats leaving their roost): F_{peak}: 23.9 kHz, F_{start}: NA kHz, F_{end}: NA kHz, Band width: NA kHz, and duration: 13.6 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 6 bats: F_{max}: 39.45 ± 8.59 kHz, F_{min}: 26 ± 5.24 kHz, F_{knee}: 30.63 ± 2.69 kHz, F_{char}: 27.92 ± 2.46 kHz, slope: -357.75 ± 2923 OPS, duration: 7.42 ± 4.04 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 14 *Chaerephon pumilus* calls from the Kruger Park (RSA): F_{min}: 22 ± 1.4 (20.1 25.4) kHz, duration: 7.6 ± 2.0 (3.2 10.9) ms, F_{max}: 26.2 ± 4.8 (21.9 36.9) kHz, F_{knee}: 23.7 ± 3.2 (21.3 33.8) kHz, F_{char}: 22.9 ± 2.2 (20.9 29.4) kHz.

Rainho *et al.* (2022: 605) reported on 32 calls froù Sáo Tomé: F_{min}: 24.9 ± 2.7 (19.8 - 29.4) kHz, F_{max}: 36.0 ± 8.7 (24.7 - 51.5) kHz, F_{maxE}: 28.4 ± 2.3 (23.4 - 31.5) kHz, duration: 13.6 ± 3.0 (8.1 - 18.6) ms and interpulse interval: 258.4 ± 156.5 (62.8 - 472.0) ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 26.65 ± 2.53 kHz, F_{max}: 34.87 ± 5.75 kHz and F_{min}: 24.67 ± 2.68 kHz.

For Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 6 calls: Interpulse interval: 118.9 ± 27.4 (87.9 - 160.0) ms; F_{max}: 25.7 ± 4.0 (23.0 - 33.6) kHz; Start slope: -3.1 ± 1.3 (-2.1 - -5.5) kHz/ms; End slope: -3.8 ± 1.3 (-2.1 - -5.3) kHz/ms; Ledge duration: 0.4 ± 0.1 (0.3 - 0.5) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

Molecular Biology:

Karyotype

Đulić and Mutere (1973a), Smith *et al.* (1986), Rautenbach *et al.* (1993) and Sreepada *et al.* (2008) all reported 2*n* = 48, and an acrocentric Y chromosome. However, while Đulić and Mutere (1973a) and Smith *et al.* (1986) reported FN = 58, BA = 12, Rautenbach *et al.* (1993) reported FN = 66, BA = 20. And, while Đulić and Mutere (1973a) and Rautenbach *et al.* (1993) reported a metacentric X chromosome, Smith *et al.* (1986) reported a submetacentric X chromosome. The work of Rautenbach *et al.* (1993) included specimens from the Western Cape that have subsequently been reidentified as *Sauromys petrophilus* (Jacobs and Fenton, 2001: 134), hence these karyotypic variations should be viewed with caution.

For an Ethiopian female, Tolera *et al.* (2021: 125) reported *2n* = 48 and FN = 54. Five pairs were metacentric, 11 pairs acrocentric-subacrocentric and eight pairs acrocentric. The X chromosomes are most likely medium sized metacentrics.

Genetics
See Hoofer and Van Den Bussche (2003).

Reddy (2008: ii) used the cytochrome *b* (845 nucleotides) and D-loop (314 nucleotides) regions of the mitochondrial DNA to assess the phylogenetic relationships within *M. pumilus* (southern Africa) and in relation to "*Chaerephon*" species from Madagascar (*Mops pumilus, M. leucogaster*). The result indicates the possibility of cryptic species in southern African *M. pumilus*, which are closer related to the Malagasy *M. leucogaster* than to the Malagasy *M. pumilus*.

In South Africa, Naidoo *et al.* (2015b) were able to retrieve a strong mitochondrial structure, but only little nuclear genetic structure, which suggests a single interbreeding population. They found these data to be consistent with female philopatry, secondary contact between diverged genetic lineages and introgression.

HABITAT:
Noer *et al.* (2012: 1) found that *M. pumilus* preferred to forage over sugarcane fields rather than over savanna, riparian forest and urban areas. To reach their foraging grounds, they travelled up to 4.2 km from their roost, and their mean activity area encompasses 976 to 1319 ha.

On São Tomé, Castro-Fernandes *et al.* (2024: 2) reported this species to be an open-space forager.

Uusitalo *et al.* (2024: 1, 5) found that the strongest drivers for current environmental suitability fo this species were close proximilty to rivers, higher precipitation during the driest months, sparse vegetation (which is generally linked to urban areas) and a restricted yearly temperature variation. These conditions are currently present in the area south of the central and southern Taita Hills (Kenya). Areas below 750 m or above 1 500 m appeared less suitable for *Mops pumilus*, although this species was found at altitudes higher than 1 500 m.

HABITS:
Bouchard (2001b: 109) found that, in scent-choice-experiments, only males were able to distinguish the gender of conspecifics as well as the difference between roost mates and strangers. Females did not show any preference during these experiments.

Happold and Happold (2023: 127) indicate that these bats can not hover, nor take off from the ground. They must dive at least 1.5 m to have sufficient speed to be able to fly, and they must swoop upward to reduce their speed before landing.

ROOST:
Taylor *et al.* (1999: 67) found these bats to be roosting in a variety of roofs in the Durban area: from corrugated iron to tiles, between the tiles and the plastic lining underneath, or in any convenient crevices between rafters and brickwork. These roofs were located at a height of 3 to 12 m.

In the Mount Nimba area, Monadjem *et al.* (2016y: 367) found a roost in the roof of a school at 540 m.

In Taita-Taveta county (Kenya), Jackson *et al.* (2023: 5) reported 65 roosts in buildings, of which 21 were shared with six other species.

DIET:
Based on DNA analysis of 59 faecal pellets collected between April and May (austral summer) in the Simunye region of Swaziland, Bohmann *et al.* (2011) reported insects from 24 families (belonging to seven orders) being taken as prey. The highest frequency of occurrence was for Lepidoptera (52.5 %), Diptera (40.7 %), and Hemiptera (18.6 %). Within the Lepidoptera, Noctuidae (Owlet moths - 25.4 %), Nymphalidae (Brush-footed butterflies 30.5 %) and Crambidae (Grass moths - 10.2 %) were found the most. Within the Diptera, it were representatives of the Culicidae (Mosquitoes - 27.1 %), which occurred most frequently, followed by the Tephritidae (Fruit flies and kin - 10.2 %). In the Hemiptera, both Lygaeidae (Chinch bugs and seed bugs) and Pentatomidae (Stink bugs) were found in 10.2 % of the faecal pellets.

Naidoo *et al.* (2011: 26) reported the following volume percentages in the bat's diet at Umbilo River (KwaZulu Natal, RSA): in summer: Lepidoptera (9.9 ± 9.5), Coleoptera (47.7 ± 30.5), Hemiptera (32.8 ± 6.9), Diptera (5.4 ± 8.3), and Trichoptera (4.2 ± 7.2); in winter: Lepidoptera (30.3 ± 16.0), Coleoptera (19.5 ± 16.5), Hemiptera (8.0 ± 7.4), Diptera (24 ± 7.7), Trichoptera (6.5 ± 10.4), and Hymenoptera (11.8 ± 11.1).

In the Limpopo province (RSA), Taylor *et al.* (2017b: 246, 252 - 254) found the diet to contain

21 prey items, covering five insect orders: Coleoptera (unmatched), Hemiptera (*Macrorhaphis acuta* + *Nezara viridula* + unmatched), Lepidoptera (*Toxocampinae tathorhynchus* + *Isturgia roraria* + *Sena* sp. + *Sena prompta* + *Cortyta canescens* + *Enmonodia capensis* + *Leucania imperfecta* + *Pericyma atrifusa* + *Rhesala moestalis* + *Spodoptera exigua* + *Maurilia arcuata* + *Stenoptilia* sp. + unmatched), Orthoptera (Tettigoniinae + unmatched) and Blattodea (unmatched). They also remarked that the diet of *C. pumilus* varies geographically.

From Maroua (Cameroon), and based on faecal analyses, Bol A Anong (2013: 31) reported the diet to include Hemiptera (35.60%), Coleoptera (34.81%), Lepidoptera (17.00%), Diptera (10.22%), Hymenoptera (1.55%) and Orthoptera (0.02%).

PREDATORS:
At the Kruger Park, Rautenbach *et al.* (1990: 17) reported that "*Tadarida pumila*" was regularly taken as prey by a pair of African goshawks (*Accipiter tachiro* (Daudin, 1800)). On some occasions, 1 to 5 bats were taken per evening (see Kemp and Rautenbach, 1987).

Mikula *et al.* (2016: Supplemental data) mention the following avian predators for "*Tadarida pumila*": African goshawk (*Accipiter tachiro* (Daudin, 1800)), Fox kestrel (*Falco alopex* (Heuglin, 1861)), Lanner falcon (*Falco biarmicus* Temminck, 1825), Eurasian hobby (*Falco subbuteo* Linnaeus, 1758), Common kestrel (*Falco tinnunculus* Linnaeus, 1758), Wahlberg's eagle (*Hieraaetus wahlbergi* (Sundevall, 1850)), Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850), Black kite (*Milvus migrans* (Boddaert, 1783)).

POPULATION:
Structure and Density
The colonies of this species range from a few animals (between 5 and 20) to hundreds of individuals (Mickleburgh *et al.*, 2008dr; IUCN, 2009; Mickleburgh *et al.*, 2014b; Mickleburgh *et al.*, 2019m). There are no estimates of its population in Madagascar, but it is thought to be locally common in the eastern zone. On Aldabra, the population might be fewer than 250 animals.

In Kenya, Lunn *et al.* (2024a: 9) found a relatively balanced male-to-female population composition of 1:1.84.

Trend
2018: Unknown (Mickleburgh *et al.*, 2019m).
2014: Unknown (Mickleburgh *et al.*, 2014b).
2008: Unknown (Mickleburgh *et al.*, 2008dr; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
van der Merwe *et al.* (1986: 355) indicate that in Transvaal *M. pumilus* has an extended breeding of 8 months. They found females to be polyoestrous and could have up to three pregnancies (one young) per breeding season. Implantation only occurs in the right uttering horn and the gestation period was about 60 days. The young are weaned before 21 days of age and females become sexually mature at the age of 5 to 12 months.

Happold and Happold (1989b: 133) found that in Malawi, *Mops pumila* can have up to 5 births per year, all followed by a post-partum oestrus. Happold and Happold (1990b: 568) mention two to four consecutive litters, with births at the end of November, January, March, and May. Females giving birth in November, all had a second litter in January, and 44 % had a third litter in March.

Krutzsch (2000: 95) refers to Marshall and Corbet (1959), who pointed out that in Uganda spermatogenesis was not continuous in all males (as "*Tadarida (Chaerephon) hindei*"). They also indicated that it is one of the best known virtually continuous breeding molossids.

le Grange *et al.* (2011: 173 - 174) indicate that *M. pumilus* is a seasonal polyoestrous bat, which reduces the number of reproductive cycles per season with increasing latitude.

In Ethiopia, Kruskop *et al.* (2016: 61) found a maternity colony with both pregnant and lactating females (one even in both stages) on 9 November 2012.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births in early November, late January and April.

Lunn *et al.* (2024a: 2) report that gestation takes place after 67 to 72 days and the lactation period spans 21 to 28 days.

MATING:
Webber *et al.* (2017: Suppl.) indicate that this species' mating system is polygyny.

McWilliam (1988a) and McCracken and Wilkinson (2000: 331) showed that there is a correlation between the male body size and the harem size, where larger males have larger harems, consisting of up to 21 females). McWilliam (1988a) also suggests that the harem might be kin groups.

PARASITES:

BACTERIUM

Gram-negative bacterium

Cassel-Béraud and Richard (1988), Cassel-Beraud *et al.* (1989: 234), and Sara (2002: 41) reported *Alkalescens dispar*, *Aeromonas hydrophila*, *Citrobacter freundii*, *Enterbacter aerogens*, *Enterobacter agglomerans*, *Enterobacter cloacae*, *Enterobacter intermedius*, *Enterobacter* sp., *Escherichia coli*, *Hafnia alvei*, *Klebsiella oxytoca*, *Klebsiella pneumoniae*, *Kluyvera* sp., *Koserella trabulsii*, *Proteus mirabilis*, *Proteus morganii*, *Proteus rettgeri*, *Proteus vulgaris*, *Providencia* sp., *Pseudomonas* spp., *Salmonella enterica* subsp. *enterica*, *Salmonella enteritidis*, and *Serratia marcescens*.

Kamani *et al.* (2021: 5) reported *Leptospira borgpetersenii* from eight out pf nine Nigerian *Chaerephon pumilus* specimens examined.

APICOMPLEXA

Lainson and Naiff (2000: 128) and Duszynski (2002: 20) indicate that "*Nyctinomus limbatus / C. pumila*" is the type host of *Eimeria dukei* Lavier, 1927.

PROTOZOA

In northern Nigeria, Kamani *et al.* (2022a: Suppl.) found three out of eight examined *Mops* cf. *pumilus* to be infected by *Trypanosoma* cf. *erneyi*.

ARACHNIDA

Laelapidae

Taufflieb (1962: 112) reported *Chelanyssus aethiopious* Hirst, 1921 from "*Tadarida limbata*" from Brazzaville, Congo.

Macronyssidae

Orlova *et al.* (2024: 154) mentioned this species as host for *Chelanyssus aethiopicus* (Hirst, 1921).

Sarcoptidae

Fain (1959e: 149) described *Notoedres (Notoedres) tadaridae* from "*Tadarida (Chaerephon) faini*" from Mount Wago, near Blukwa, Haut-Ituri, DRC.

Trombiculidae

Stekolnikov (2018a: 163) reported *Microtrombicula nyctinomi* (Taufflieb, 1960) from a bat from Brazzaville, Congo.

HEMIPTERA

Cimicidae

Haeselbarth *et al.* (1966: 9) found a great number of *Loxaspis barbara* (Roubaud, 1913) in a roost, near Mopti, Former French Sudan (Haute Senegal-Niger). *Loxaspis miranda* Rothschild, 1912 recorded in Uganda (Haeselbarth *et al.*, 1966: 10, host referred to as "*Tadarida limbata*").

Polyctenidae

Hypoctenes clarus Jordan, 1922, from Congo (Haeselbarth *et al.*, 1966: 18, host referred to as "*Tadarida limbata*"; Szentiványi *et al.*, 2022: 6).

Hypoctenes faini Benoit, 1958 from Kenya (Szentiványi *et al.*, 2022: 6).

DIPTERA

Streblidae

Raymondia seminuda Jobling, 1954 in Nairobi, Kenya (Haeselbarth *et al.*, 1966: 103, host referred to as "*Tadarida faini*").

Nycteribiidae

Basilia ansifera Theodor, 1956 mainly a West African species, reaching Lake Victoria in the east and Lake Nyasa in the south, nearly all localities lie between 15° latitude north and south (Haeselbarth *et al.*, 1966: 110). *Dipseliopoda biannulate* (Oldroyd, 1953) distributed over the tropical parts of Africa and recorded from localities in Nigeria, Cameroon, the Congo and the Sudan and Kenya (Haeselbarth *et al.*, 1966: 116, host referred to as "*Tadarida faini*"). However, Dick *et al.* (2023: 72) indicate that host-parasite association between "*T. faini*" and *Dipseliopoda biannulata* (Oldroyd, 1953) is most probably erroneous.

SIPHONAPTERA

Ischnopsyllidae

Lagaropsylla consularis Smit, 1957 from Ethiopia, Kenya, Uganda, Congo and Congo (Democratic Republic of), Angola, Zimbabwe and Mozambique (Haeselbarth *et al.*, 1966: 1990, host referred to as "*Tadarida limbata*"), Malawi (Beaucournu and Kock, 1996), Madagascar (Hastriter, 2016: 16). *Lagaropsylla idae* Smit ,1957 widespread in tropical Africa (Haeselbarth *et al.*, 1966: 190, host referred to both "*Chaerephon pumilus*" as well as "*Tadarida limbata*"). *Lagaropsylla oblique* Smit, 1957 from Sierra Leone, Cameroon and the Congo (Haeselbarth *et al.*, 1966: 191, host referred to as "*Tadarida limbata*").

NEMATODA

Durette-Desset and Chabaud (1975: 315) described *Molinostrongylus benexae* from a "*Chaerophon limbatus*" from Périnet, Madagascar.

TREMATODA

Prosthodendrium (Prosthodendrium) chilostomum madagascariense was described by Richard (1966: 423) from a "*Chaerophon limbatus*" from Périnet, Madagascar.

VIRUSES:
Conrardy *et al.* (2014) tested 6 bats sampled in Kenya for the presence of adenoviruses, rhabdoviruses and paramyxoviruses, all samples tested negative.

In their country-wide survey of Kenyan bats, Waruhiu *et al.* (2017) found the following viruses in *Mops pumilus*: Astroviruses and Coronaviruses.

In Uganda, Kading *et al.* (2018: 3) found neutralizing antibodies against dengue 2 virus (DENV-2) and non-specific Flaviviruses.

Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested between 1986 to 1999, for antibody to SARS-CoV in sera in 35 individuals from Limpopo Province, South Africa, none were tested positive (0/35) and 18 individuals from Mpumalanga Province, South Africa, none tested positive (0/18) and one individual from Bandundu Province, DRC, not tested positive (0/1). Tong *et al.* (2009) report the detection of coronavirus RNA from faecal material of this species in Kenya and was found to be distantly related to the human coronavirus 229E.

Anthony *et al.* (2017b: Suppl.) mention the alpha-coronavirus: Charephon_CoV_KY22. Nziza *et al.* (2019: 156) reported this virus in a rectal swap from a bat from Rwanda. Shapiro *et al.* (2021a: 423) recovered very similar viruses from three bats in Eswatini.

For the two Congos, Kumakamba *et al.* (2021: 7) reported four out of 65 bats to test positive for coronaviruses.

Lane *et al.* (2022: 221) found the following viruses in bats from Ethiopia: Chaerephon bat coronavirus/Kenya/KY22/2006, Chaerephon bat coronavirus/Kenya/KY41/2006, Eidolon bat coronavirus and PREDICT_PMV-24.

Filoviridae
Ebolavirus
EFSA AHAW Panel (EFSA Panel on Animal Health and W (2017: 5) refer to Swanepoel *et al.* (1996), who experimentally inoculated the virus in this bat.

Goldstein *et al.* (2018: 1084) described a new *Ebolavirus* from three Sierra Leonan *Mops pumilus* and one *M. condylurus*: Bomali virus (BOMV). They were sampled in human dwellings in small villages in the Bomali district. This virus might infect humans, but it is not known (yet) whether it is virulent in humans too.

Flaviviridae
Flavivirus
Bukalasa bat virus
Williams *et al.* (1964) report the isolation of the virus in Uganda, 1964, from the salivary glands of *Mops pumilus*. Reported by de Jong *et al.* (2011: 10) and Luis *et al.* (2013: suppl).

Dakar bat virus
Kemp *et al.* (1974) report the isolation of the virus from Nigeria, 1974, from the salivary glands and organ pools of *Mops pumilus*. Reported by de Jong *et al.* (2011: 10) and Luis *et al.* (2013: suppl).

Denque virus
Bonilla-Aldana *et al.* (2020: 3) reported *Chaerephon pumilus* as one of the species which carried this virus.

Entebbe bat virus
Peat and Bell (1970) report the isolation of the virus in Uganda, 1957, from the salivary glands of *M. pumilus*. Reported by de Jong *et al.* (2011: 10).

Zika virus (ZIKV)
Malmlov *et al.* (2019: 2) refer to Shepherd and Williams (1964) who examined 44 *pumilus* specimens in Uganda, of which 16 had antibodies against ZIKV.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Horton *et al.* (2014: Table S1) tested 25 Tanzanian *Mops pumilus* specimens but failed to find neutralising antibodies to IKOV (Ikoma lyssavirus). This study was also referred to by Bunuma *et al.* (2025: 6), who indicated that no other studies covering the period 1993 - 2023 wa able to find rabies viruses in Tanzanian bats. Kia *et al.* (2014: 1) tested 33 specimens from Kanke (Nigeria), and found one of them to test positive for Lagos bat virus and one for Shimoni bat virus.

Togaviridae
Alphavirus
de Jong *et al.* (2011: 10) reported Chikungunya virus occurring on *M. pumilus*. Luis *et al.* (2013: suppl.) also reported this virus but used "*Tadarida pumila*" as name for the bat.

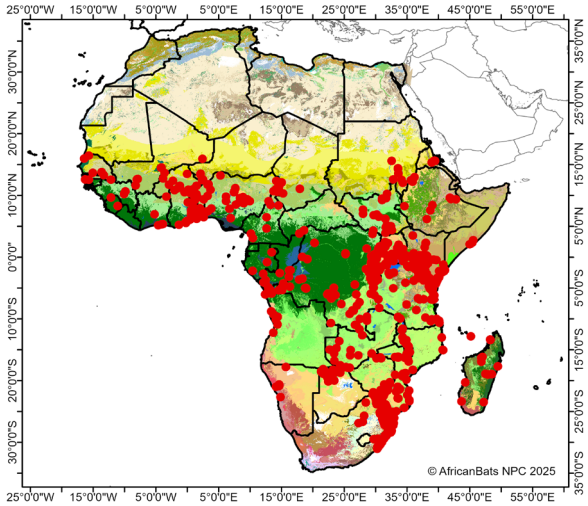

Figure 180. Distribution of *Mops (Chaerephon) pumilus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Central African Republic, Chad, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Egypt, Equatorial Guinea, Eritrea, Eswatini, Ethiopia, Gabon, Ghana, Guinea, Kenya, Madagascar, Malawi, Mali, Mayotte, Mozambique, Namibia, Niger, Nigeria, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

Mops (Chaerephon) pusillus (Miller, 1902)

1838.	*Nyctinomus pusilus:* Lesson, Compléments de Buffon, ed 2, Paris, 1: 328. Publication date: 1838. (Lapsus).
1879.	*Nyctinomus pumilus:* Gunther. Publication date: 1879.
*1902.	*Nyctinomus pusillus* Miller, Proc. Biol. Soc. Wash., 15: 245. Publication date: 16 December 1902. Type locality: Seychelles: Aldabra Island. [Goto Description]. Holotype: USNM 20991: ♀, skull and alcoholic. Collected by: Dr. William Louis Abbott. Holotype: USNM 37852: ad ♀, skull and alcoholic. Collected by: Dr. William Louis Abbott. Alcoholic catalogued: 30 June 1893, skull catalogued: 12 February 1900. Poole and Schantz (1942: 120) also mention the number as 20991/37852, and furthermore indicate "Type designated by No. 37852/20997, an error for 20991/37852".
1971.	*Tadarida pumila:* Hayman and Hill. Publication date: 1971.

2004.	*Tadarida pumilus:* Louette. Publication date: 2004.
2007.	*Chaerephon pusillus:* Goodman and Ratrimomanarivo. (Name Combination).
2020.	*Mops pusillus:* Simmons and Cirranello, BatNames.org. (Current Combination).
?	*Chaerephon pumila:*
?	*Chaerephon pumilus:*
?	*Mops (Chaerephon) pusillus:* (Current Combination).

TAXONOMY:
Included in *pumilus* by a large number of authors, but its status has been revised by Goodman and Ratrimomanarivo (2007: 391) and Goodman *et al.* (2010a: 21). Naidoo *et al.* (2016: 639) suggested that *pusillus* evolved from the continental *pumilus* ancestor when dispersing over the Mozambique Channel to the Comoro archipelago.

COMMON NAMES:
Czech: morous seychelský. English: Seychelles Free-tailed bat. French: Tadaride des Seychelles. German: Seychellen Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Assessed as Vulnerable (VU D2 ver 3.1 (2001)) as there are only two (2) severely fragmented subpopulations occurring on five island areas (Comoros and Aldabra Atoll). Increasing risk of extreme weather events caused by climate change as well as sea level rise could very quickly affect the species' population, decreasing their numbers substantially and drive the species to a Critically Endangered Status (Bielsa *et al.*, 2020).

Assessment History
Global
2020: VU D2 ver 3.1 (2001) (Bielsa *et al.*, 2020).
2014: LC ver. 3.1 (2001) as a synonym of *Chaerephon pumilus* (Mickleburgh *et al.*, 2014b).

MAJOR THREATS:
Comoros is amongst the countries with the highest rate of deforestation per year, with 3.9% of forests being lost annually (Sewall *et al.*, 2011b; UNDP 2007), and there is very little natural forest remaining (Hawlitscheck *et al.*, 2011). Furthermore, there has been little conservation attention and protection of these forests, which hold a lot of endemic biodiversity (Sewall *et al.*, 2011b). Therefore, it is presumed that a lot of the natural roosting sites of *M. pusillus* have been lost through deforestation.

As a result, this species seems to prefer roosting in non–natural locations, such as under the roofs of buildings. Infrastructure maintenance and renovation is therefore a threat to the majority of their known roosting sites (Goodman *et al.*, 2010a; van Dinther, 2014).

This species is restricted to Aldabra Atoll and the Comoros Archipelago, and it is therefore under threat of climate change related events such as destructive storms. Furthermore, with Aldabra Atoll lying lowly 8m above sea level, they are at risk of losing habitat due to sea level rise (Bielsa *et al.*, 2020).

CONSERVATION ACTIONS:
The Aldabra Atoll is a UNESCO World Heritage Site as well as a Special Reserve (Mickleburgh *et al.*, 1992; Hutson, 2004a) and has been a legally protected special reserve since 1981. Aldabra Atoll is managed by the Seychelles Islands Foundation.

Bielsa *et al.* (2020) report that some local and international organizations such as Dahari, Action Comores and Action Comores International are attempting to mitigate some of the threats of the biodiversity of Comoros, through - for example - reforestation. Nonetheless, unsustainable use of resources continues, mostly due to the population's reliance on their exploitation for fuel wood and farmland.

Currently, there is no monitoring or research of the species underway. Rigorous monitoring is needed to get a population estimate and trend data. Protection and monitoring of known roost sites of both subpopulations is also recommended. Furthermore, as the species has only just been split from *Chaerephon pumilus* in Madagascar and the African continent, and its genus has recently been changed again, more genetic research is likewise recommended (Bielsa *et al.*, 2020).

GENERAL DISTRIBUTION:
M. pusillus was restricted to the Seychelles, but recent molecular work (Goodman *et al.*, 2010a) indicates that the populations on the Comore Islands should assigned to *M. pusillus* and not *M. pumilus*.

Louette (2004) recorded as "*Tadarida pumilus*" occurs on at least three of the Comore Islands (Grande Comore, Anjouan, and Mayotte. Goodman *et al.* (2010c: 126) also recorded "*Charephon pusillus*" from Moheli. Its known elevational range is 15 to 250 m on Grande Comore, 5 to 410 m on Anjouan, 5 to 10 m on Moheli, and 10 to 90 m on Mayotte (Goodman *et al.*, 2010c: 126).

Native: Comoros (Louette, 2004; Goodman *et al.*, 2010c: 126); Seychelles (Goodman *et al.*, 2010c: 126).

GEOGRAPHIC VARIATION:
Based on Cyt *b* analyses, Tidière *et al.* (2022: 1, 7) found a weak, geographically based genetic structure in *Chaerephon pusillus*. The animals from Grande Comore, Mohéli and Anjouan were slightly different from those captured on Mayotte.

ROOST:
On the Comoros, Goodman *et al.* (2010c: 127) did not find a single roost in a natural location, but rather all were synanthropic (see also Wilkinson *et al.*, 2012: 160). The roosts sites were often in the attics of public buildings (schools, civic centres, and hospitals).

MIGRATION:
Goodman *et al.* (2010c: 128) interviewing a director of a primary school on Mitsamiouli mentioned that the presence of bats in the school attic is very seasonal, and as the cold season approaches the site is abandoned.

POPULATION:
Structure and Density
There are only two known subpopulations of this species, on Aldabra Atoll, and on the Comoros Archipelago. Although data are limited, the species is inferred to have a declining population (Bielsa *et al.*, 2020). There is very limited data about the population of *M. pusillus* on Aldabra Atoll. The first specimens identified as *M. pusillus* were collected in 1893 by Abbot (1894). The specimens that were collected and/or examined in later years match the descriptions made of those first collected (Hutson, 2004a). This species of bat has been recorded in three islands from Aldabra Atoll. On Picard, the species has been recorded along and near the settlement (Hill, 1971a; van Dinther, 2014). On Malabar, there is records of them being caught in Middle Camp hut by Passe Horaeau, the eastern channel of the Atoll (SIF photographs). On Grande Terre, the southern island they have been recorded in the Takamaka Grove area (Hill, 1971a), south east of the island and away from the coast, as well as at Anse Mais, in the south west of the island, by the coast (Hill, 1971a; van Dinther, 2014). This is not to say that this species does not occur on Polymnie, the fourth largest island of the Atoll, but merely that it has not yet been recorded there. Polymnie is the island that is least visited on the atoll, with no regular monthly monitoring. *Mops pusillus* is known to fly

as much as 80km between islands in the Comoros (Goodman *et al.*, 2010a), and it is therefore presumed that they occur across the entirety of the Aldabra Atoll.

A roost was found in a tree hollow in 1986 (van Dinther, 2014) by the settlement on Picard, and between 10-20 individuals were seen around Anse Mais, (Grande Terre) between 2013 and 2014 (date not specified) (van Dinther, 2014), suggesting a roost might be nearby. In October 2013, 12 individuals were spotted roosting in the roof of one of the houses at the Settlement, Picard Island (van Dinther, 2014). Counts of individuals leaving and coming back to the roost were done regularly, and by February 2014, the numbers had increased to 38 as a result of breeding. In March 2014, a storm hit the island, and the numbers of individuals roosting under the roof increased to 60 - presumably another roost location had been damaged during the storm and the individuals joined the house roost. By October 2014, when the counts ceased, there were over 100 individuals roosting under the roof (van Dinther, 2014). In June 2018, a roost was again heard in the same house, and monthly monitoring of five (5) houses across the settlement began, where it was believed they might be roosting. The principal roost began with about 100 individuals in June 2018, and had about 150 in November 2018, potentially indicating an increase due to breeding, although no other signs of pupping were recorded. After May 2019, no bats were recorded entering or leaving the roosting site of this house (Sanchez and A'Bear, 2020).

Another roost was identified under the laundry building roof in January 2019, and monthly monitoring began then. At most, this roost was recorded having about 50 individuals, and it was still active in January 2020 when the monitoring ceased (Sanchez and A'Bear, 2020). Bielsa *et al.* (2020) recommends more extensive surveys would need to be carried out on Aldabra Atoll to get a population estimate.

There is also not enough data about the population in the Comoros to have an estimate, but this species is confirmed to occur on all four main islands of the Comoros (Grande Comore, Anjouan, Moheli and Mayotte) (Goodman *et al.*, 2010a). All roosts found during 2006/2007 were in synanthropic locations, with none being found in natural hollows or crevices (Goodman *et al.*, 2010a). It is believed that with wide-scale renovation of infrastructure in Mayotte, a lot of roosts that resided in the old buildings were lost (Goodman *et al.*, 2010c). It is reported that *M. pusillus* and *M. leucogaster* in Mayotte share roosting sites, but molecular and morphological genetic analyses show that they act as good biological species (Goodman *et al.*, 2010a, O'Brian, 2011).

On Aldabra, the population might be fewer than 250 animals (Mickleburgh *et al.*, 2008dr; IUCN, 2009, as "*Chaerephon pumilus*").

Trend
2020: Decreasing (Bielsa *et al.*, 2020)..

REPRODUCTION AND ONTOGENY:
Goodman *et al.* (2010c: 126) provide data that indicates possible inter island seasonal variation in breeding in the Comoros. On 14 November 2006, all of the 10 individuals caught in a colony in central Moroni were female and all reaching term in their pregnancy with single embryos measuring 17 - 20 mm. The same colony was visited on the 28 March 2007, an additional 10 individuals were captured, all of which were females of which five had placental scars, four assumed to be sub-adults without placental scars, and one had a tiny embryo. Juste (unpublished data in Goodman *et al.* (2010c: 127)) report that the site was visited in December 2005, and all of the 20 individuals caught were female. As no males were caught on the two visits with a 5 month difference, Goodman *et al.* (2010c: 127) presumes that this site is a maternity colony.

Between 20 November and 26 November 2006, Goodman *et al.* (2010c: 127) visited five different *M. pusillus* colonies on Anjouan and in contrast to the Moroni site, these colonies contained both males and females. At three of the sites on Anjouan, females outnumbered males with a consistent sex ratio in each case of 0.5, and at one site the sex ratio was 1.0, and the fifth site it was 1.6. Goodman *et al.* (2010c: 127) found at all the colonies, the breeding females were reaching term, with embryos ranging in crown-rump length from 17 - 23 mm, and at one site neonates were present. Of the 25 males captured at the Anjoun sites, all were adult, only seven (28 %) had scrotal testes and convoluted epididymides. The only evidence of non-synchronized breeding in *M. pusillus* on Anjouan was a free-flying animal captured at Patsi on 20 November with a single embryo measuring 1 mm in crown rump length.

Goodman *et al.* (2010c: 127) report on a visit between 28 November and 2 December 2006 that two separate colonies on Moheli were visited and both male and females were captured and the sex ratios were 0.57 and 0.66. At the first colony visited 28 November, of the seven females captured, four had recently given birth and were

lactating and three had single embryos measuring 24 mm in crown-rump length. At the second site visited on the 2 December, all the females were still pregnant with single embryos and with crown-rump length of 19 - 22 mm. Of the males handled from these two colonies, three of 12 (25 %) were in breeding condition with largely scrotal testes with enlarged epididymides.

On Mayotte, between 27 February and 1 March 2007, two colonies were visited and both had males and females, not one of the females showed signs of active reproduction, in several cases the females had remaining lactation tissue and placental scars or large mammae and placental scars, indicating that they had recently terminated a breeding period, also none of the males caught were in reproductive condition (Goodman *et al.*, 2010c). Four different colonies were visited on Grande Comore between 29 March and 1 April 2007, and in all cases, both sexes were found in each and the sex ratio varied from 0.15 to 2.3, with one exception none of the individuals showed active signs of reproduction, although many of the females had large mammae and placental scars. The exception was a female captured on the 29 March in oestrous (Goodman *et al.*, 2010c: 127).

PARASITES:
Lagadec *et al.* (2012: 1696) found this species to be infected by *Leptospira* bacteria.

Hutson (2004a: 130) mentions an endemic ectoparasitic polyctenid bug, *Hypoctenes hutsoni* Maa, 1970.

Dick *et al.* (2023: 73) mentioned the following nycteribiid fly has been found on *Chaerephon pusillus*: *Basilia (Basilia) ansifera* Theodor, 1956.

VIRUSES:
Astroviridae
Hoarau *et al.* (2018: 1) tested 58 bats from the Comoros, found none of them to test positive for this group of viruses.

Coronaviridae
Joffrin *et al.* (2020: 5) reported an Alphacoronavirus from a bat from Mayotte.

Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 20 individuals from the Comoros using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids.

Rhabdoviridae
Of the 19 bats from Anjouan that were tested by Mélade *et al.* (2016a: 6), two showed seroreactivity to *Lagos bat lyssavirus*, and two of seven other bats showed the same reaction to *Duvenhage lyssavirus*. On Mayotte, one out of three were positive for these two viruses.

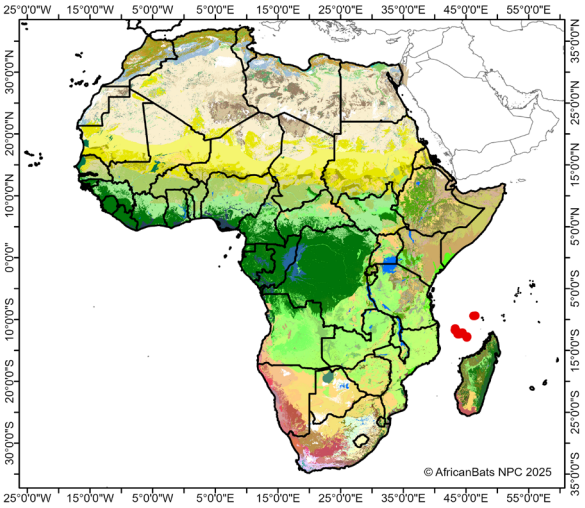

Figure 181. Distribution of *Mops (Chaerephon) pusillus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Comoros, Mayotte, Seychelles.

Mops (Chaerephon) russatus (J.A. Allen, 1917)

*1917. *Chærephon russatus* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 458, text fig 25. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Medje [02 25 N 27 18 E, 800 m]. [Goto Description]. Holotype: AMNH 48925: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 8 September 1910; original number: 993. Topotype: MCZ 17386: ♀, skin and skull. Collection date: 8 September 1910. Topotype: MCZ 17387: ♀, skin and skull. Collection date: 8 September 1910.
1989. *Chaerophon russata:* Fenton, Can. J. Zool., 67 (8): 2035. Publication date: 1 August 1989. (Lapsus).
2015. *Chaerophon russatus:* Plumptre, Ayebare, Mugabe, Kirunda, Kityo, Waswa, Matovu, Sebuliba, Behangana, Sekisambu, Mulondo, Mudumba, Nsubuga, Isoke, Prinsloo and Nangendo, Biodiversity surveys of Murchison Falls protected area, 10. Publication date: August 2015. (Lapsus).
2020. *Mops russatus* Simmons and Cirranello, BatNames.org. (Current Combination).
? *Chaerephon russata:* (Alternate Spelling).
? *Chaerephon russatus:* (Name Combination).
? *Mops (Chaerephon) russatus:* (Current Combination).
? *Tadarida russata:* (Name Combination).

TAXONOMY:
See Simmons (2005).

Gregorin and Cirranello (2015: 10) suggest that "*Chaerephon russatus*" is the basalmost branch of the *Chaerephon* + *Mops* clade within the Molossidae.

COMMON NAMES:
Chinese: 赤犬吻蝠. Czech: morous guinejský. English: Russet Wrinkle-lipped bat, Russet Free-tailed Bat. French: Tadaride rousse. German: Rostfarbene Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Mickleburgh *et al.*, 2008bu; IUCN, 2009; Mickleburgh *et al.*, 2019k).

Assessment History
Global
2018: DD ver 3.1 (2001) assessed as *Chaerephon russatus* (Mickleburgh *et al.*, 2019k). 2008: DD ver 3.1 (2001) assessed as "*Tadarida russata*" (Mickleburgh *et al.*, 2008bu; IUCN, 2009). 2004: NT ver 3.1 (2001) assessed as "*Chaerephon russata*" (Mickleburgh *et al.*, 2004aj; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It is presumably threatened by habitat loss in parts of its West African range, although further studies are needed to confirm this (Mickleburgh *et al.*, 2008bu; IUCN, 2009; Mickleburgh *et al.*, 2019k).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bu) [in IUCN (2009)] and Mickleburgh *et al.* (2019k) report that there appear to be no direct conservation measures in place. The species has been recorded from the Hell's Gate National Park in Kenya and Tai National Park in Côte d'Ivoire. Further studies are needed into the distribution, natural history and threats to this species.

GENERAL DISTRIBUTION:
Mops russatus has only been recorded from a dozen or so, widely dispersed, localities. It has been recorded from the Tai National Park in Côte d'Ivoire in the west to the Hell's Gate Canyon National Park in Kenya.

Native: Cameroon; Congo (The Democratic Republic of the); Côte d'Ivoire (Beaucournu and Fahr, 2003: 157); Ghana; Guinea (1st record: Decher *et al.*, 2016: 275); Kenya; Uganda (Plumptre *et al.*, 2015: 10).

POPULATION:
Structure and Density
It is believed to be a quite rare species that occurs in small colonies (Mickleburgh *et al.*, 2008bu; IUCN, 2009; Mickleburgh *et al.*, 2019k).

Trend
2018: Unknown (Mickleburgh *et al.*, 2019k). 2008: Unknown (Mickleburgh *et al.*, 2008bu; IUCN, 2009).

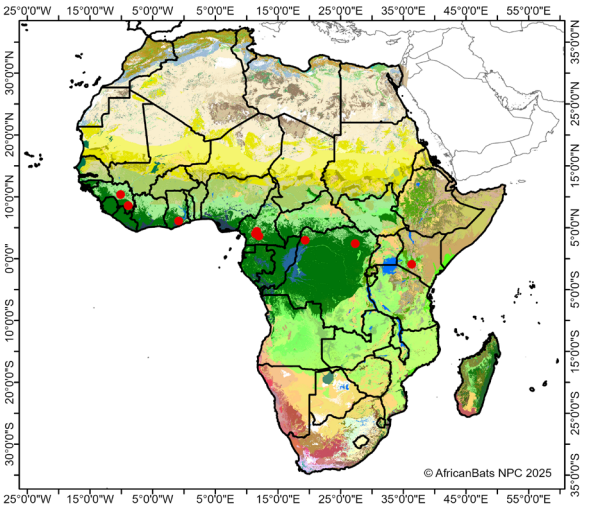

Figure 182. Distribution of *Mops (Chaerephon) russatus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Guinea, Kenya.

Mops (Chaerephon) shortridgei (Thomas, 1926)

*1926. *Chaerephon (Lophomops) shortridgei* Thomas, Proc. zool. Soc. Lond., 1926, I: 289. Publication date: 29 April 1926. Type locality: Namibia: NW Ovamboland: 32 mi NW of Rehoboth Mission Station: Ukualukasi [17 32 S 14 37 E, 3 400 ft]. [Goto Description]. Holotype: NHMUK 1925.12.4.24: skin and skull. Collected by: Captain Guy Chester Shortridge; original number: 1389. - Etymology: I have named this striking species in honour of Capt. Shortridge, to whose energy and enthusiasm the great success of the South West African collecting expeditions has been almost wholly due, and who was greatly struck by its remarkable appearance (see Thomas, 1926).

1941. *Chaerephon shortridgei:* J. Eric Hill and Carter, Bull. Am. Mus. Nat. Hist., 78 (1): 57. Publication date: 25 July 1941. (Name Combination).
2023. *Mops shortridgei:* Simmons and Ciranello, Zenodo, 19. Publication date: 8 March 2023. (Name Combination).
? *Mops (Chaerephon) shortridgei:* (Current Combination).

TAXONOMY:
Considered a valid species by Hill and Carter (1941: 57), Peterson *et al.* (1995: 159), Goodman and Cardiff (2004: 236) and Simmons and Cirranello (2023a: 19; 2023b: 19)

COMMON NAMES:
Czech: morous namibijský

CONSERVATION STATUS:
Assessment History
NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004ak; IUCN, 2004).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Botswana, Namibia.

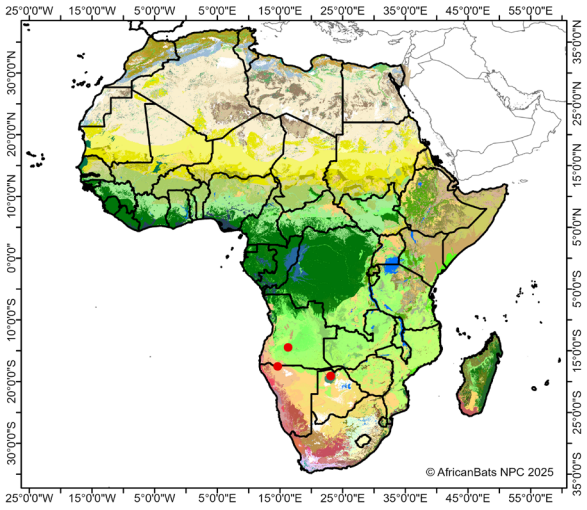

Figure 183. Distribution of *Mops (Chaerephon) shortridgei*.

†*Mops kerio* Gunnell and Manthi, 2018

*2018. *Mops kerio* Gunnell and Manthi, J. Hum. Evol., p "6", fig 6Bj. Publication date: 6 April 2018. Type locality: Kenya: Kanapoi Bat Site [02 18 00 N 36 04 00 E]. Holotype: NMK KP-69821. The holotype consists of a M^2. - Etymology: Referring to the Kerio river that flows through the Kanapoi area (Gunnell and Manthi, 2018: "6").

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Pliocene (Brown *et al.*, 2019: Suppl.)

Subgenus *Mops (Mops)* Lesson, 1842

*1842. *Mops* Lesson, Nouv. Tabl. Regn. Anim. Mammifères, 18. Publication date: 1842. - Comments: Type species: *Mops indicus* Lesson, 1842 (=*Molossus mops* de Blainville, 1840; Genotype *Mops indicus* Lesson = *Dysopes mops* F. Cuvier; listed in synonymy of *Nyctinomus* by Miller, 1907, Bull. U.S. Nat. Mus., 57, p. 251; but listed as a genus with distinct characters by Thomas, 1913, J. Bombay Nat. Hist. Soc., 22, p. 91). - Etymology: From the masculine German substantive *Mops*, meaning "pug", a small companion dog resembling a bulldog, corresponding to the French "carlin" and the Italian "carlino"; the name refers to the wrinkled lips characteristic of the genus *Mops* and the family Molossidae. According to one seemingly erroneous interpretation, from the Malaysian substantive *mòps*, meaning "bat" (see Lanza *et al.*, 2015: 293). (Current Combination).
1917. *Allomops* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 470, text-fig 12 - 15. Publication date: 29 September 1917 [Goto Description]. - Comments: Type species: *Chærephon (Allomops) osborni* Allen, 1917 (=*Nyctinomus condylurus* A. Smith, 1833).
1951. *Tadarida (Mops):* Ellerman and Morrison-Scott. (Name Combination).
? *Mops (Mops):* (Name Combination).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Benin, Chad, Kenya, South Sudan, Tanzania, Uganda.

Mops (Mops) condylurus (A. Smith, 1833)

*1833. *Nyctinomus Condylurus* A. Smith, S. Afr. Quart. J., ser 2, 1 (2): 54. Publication date: November 1833. Type locality: South Africa: KwaZulu-Natal: Port Natal [=Durban], near [29 52 S 31 00 E]. [Goto Description]. - Etymology: From the masculine scientific Latin adjective made up of the masculine Greek substantive "*κονδύλς*" (kóndylos), meaning "knob, knuckle" and the feminine Green substantive "*oúrá*" (ūrá), meaning "tail" as, according to Smith (1833: 54) the tail is "[…] enlarged and wrinkled at the point" (see Lanza *et al.* (2015: 298).

1864. *Dysopes hepaticus* Heuglin, Nov. Act. Acad. Cæs. Leop.-Carol., 31 (7): 14. Type locality: South Sudan: Bahr-el-Ghazal province: Country of the Req natives: Djur River [08 35 19 N 28 26 46 E]. [Goto Description]. - Comments: Meester *et al.* (1986: 74): "Allen (1939a), who regards it as a synony of *bivittata*. Hayman and Hill (1971) regard it as unidentifiable, but point out that Kock (in litt) believes that it probably represents *condylurus*. The latter view is expressed also by Kock (1969a) and Koopman (1975)".

1870. *Nyctinomus angolensis* Peters, J. Sci. mat. phys. nat., ser 1, 3 (10): 124. Publication date: December 1870. Type locality: Angola: Quenza river [= Quanza River] [09 20 S 13 00 E]. [Goto Description]. Holotype: ZMB 4904: ad ♂, skull and alcoholic. Collected by: Toulson (Museum Bocage). Formerly Mus. Bocage; see Turni and Kock (2008: 70). - Comments: Considered a synonym of *leucostigma* by Peterson *et al.* (1995: 168). Roberts (1951: 97), and Ansell and Dowsett (1988: 47) assigned it to Gunther, 1870, 1871. According to Meester *et al.* (1986: 74) "Günther 1871, Zoological Record (1870): 8. Quenza River [="?Cuanza River], Angola. Usually wrongly attributed to Peters, 1870, but see Cabrera and Ruxton, Ann. Mag. Nat. Hist., (9) 17: 595, 1926." According to Peterson *et al.* (1995)? "Kaudern, 1915: Ark. Zool., 9 (18): 77", but Peters, 1870 according to Simmons (2005).

1911. *Chærephon emini* Wroughton, Ann. Mag. nat. Hist., ser 8, 8 (46): 458. Publication date: 1 October 1911. Type locality: Sudan: Rosieres [11 52 N 34 23 E]. - Comments: Not of de Winton, 1901: see Meester *et al.* (1986: 74).

1917. *Chærephon (Allomops) osborni:* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 470. Publication date: 29 September 1917. (Name Combination, Lapsus).

1917. *Mops (Allomops) osborni* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 470, 473, text-fig 12 - 14, 26. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Kinshasa (near Leopoldville) [04 18 S 15 18 E, 350 m]. [Goto Description]. Holotype: AMNH 49230: ad ♂, skull and alcoholic. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 22 December 1914; original number: 2570. Paratype: AMNH 49244: ad ♀. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition.

1936. *Mops angolensis wonderi* Sanborn, Field Mus. Nat. Hist., Zool. Ser., (362) 20 (14): 114. Publication date: 15 August 1936. Type locality: Mali: 7 km E Bamako: Sotuba [12 36 N 07 55 W]. [Goto Description]. Holotype: FMNH 42138: ad ♀, skin and skull. Collected by: Frank C. Wonder; collection date: 13 April 1934; original number: 814. - Comments: Considered a valid subspecies by Grubb *et al.* (1998: 93).

1939. *Mops osborni occidentalis* Monard, Arq. Mus. Bocage, 10: 78. Publication date: March 1939. Type locality: Guinea-Bissau: Mansoa [12 04 N 15 19 W]. [Goto Description]. Syntype: MHNG 1326.010: ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 234. Syntype: MHNG 861.045: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 215. Syntype: MHNG 861.046: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 217. Syntype: MHNG 861.047: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 218. Syntype: MHNG 861.048: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 225. Syntype: MHNG 861.049: ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 228. Syntype: MHNG 923.019: ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11 December 1937; original number: 231. Syntype: NMBA 5268: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11-12 December 1937; original number: 226. See Oakeley (1998: 2). From Mansoa (see Monard, 1939: 78). Syntype: NMBA 5269: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11-12 December 1937; original number: 275. See Oakeley (1998: 2). From Mansoa (see Monard, 1939: 78). Syntype: RMCA 15307: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 1937; original number: 223. From Mansoa (see Monard, 1939: 78). Syntype: RMCA 15308: ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; original number: 498. From Contubo-el (see Monard, 1939: 78). - Comments: The type locality is either Mansoa [12 04 N 15 19 W], Contubo-el [12 22 N 14 34 W] or Pitche [12 20 N 13 57 W]. Monard (1939: 78) does not mention a holotype, but a series of specimens from Mansoa (14), Cotubo-el (5) and Pitche (9).

1939. *Mops osborni occidentalis f. fulva* Monard, Arq. Mus. Bocage, 10: 80. Publication date: March 1939. Type locality: Guinea-Bissau: Mansoa [12 04 N 15 19 W]. [Goto Description]. Syntype: NMBA 5270: ♀, alcoholic (skull not removed). Collected by: Dr. Albert Monard; collection date: 11-12 December 1937; original number: 232. Monard (1939: 80) mentions a series of 10 specimens (nrs 228 to 237, 5 MM + 5 FF) from Mansoa and 1 M (nr 781) from Pitche. Syntype: RMCA 15309: ♂, alcoholic (skull not removed). Collected by: Dr. Albert Monard; original number: 229. Monard (1939: 78) mentions a larger series: nrs 215 to 227, 275 (13 MM + 1 F from Mansoa); 494 to 498 (1 M + 4 FF) from Contubo-el; 77. - Comments: The type locality is either Mansoa [12 04 N 15 19 W] or Pitche [12 20 N 13 57 W]. Grubb *et al.* (1998: 93) indicate that Monard's quadrinominal name was validated, in accordance with International Code of Zoological Nomenclature Articke 45 (g)(ii)(1), by its use as a trinomial (Freeman (1981b: 159). Monard (1939: 80) mentions a series of 10 specimens (nrs 228 to 237, 5 ♂♂ + 5 ♀♀) from Mansoa and 1 ♂ (nr 781) from Pitche.

1942. *Mops angolensis orientis* G.M. Allen and Loveridge, Bull. Mus. comp. Zool., 89 (4): 151, 166. Publication date: February 1942. Type locality: Tanzania: SE Tanzania, Mtwara, Rovuma river: Kitaya. [Goto Description]. Holotype: MCZ 38829: ad ♂, skin and skull. Collected by: Professor Arthur Loveridge; collection date: 3 April 1939. See Allen and Loveridge (1942: 166). Helgen and McFadden (2001: 146) also mention 9 paratypes (MCZ 38826 - 38828, 38830 - 38835 (4 FF+ 5 MM, skin and skull): see Helgen and McFadden (2001: 145). Paratype: MCZ 38826: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38827: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38828: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38830: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38831: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38832: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38833: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38834: Collected by: Professor Arthur Loveridge. Paratype: MCZ 38835: Collected by: Professor Arthur Loveridge. - Comments: Possibly valid as a subspecies.

TAXONOMY:

Figure 184. An adult female *Mops (Mops) condylurus* caught at Mlawula-NR, Swaziland.

Includes *angolensis* and *leucostigma* but see Peterson *et al.* (1995: 168).

In their analyses, Ammerman *et al.* (2012: 20) found that *Mops condylurus* from clusters with *M. leucostigma* from Madagascar when present, and these two form a close relationship with African *Chaerephon* and not other *Mops*. They also indicate that the two species separated from one another less than 2 million years ago (Ammerman *et al.*, 2012: 23).

COMMON NAMES:

Afrikaans: Angola-losstertvlermuis, Angolase Losstervlermuis. Chinese: 安哥拉犬吻蝠. Czech: morous angolský. English: Angolan Mops Bat, Knob-tailed Mops Bat, Angolan Free-tailed Bat, Knob-tailed Nyctinome. French: Tadaride d'Angola, Molosse d'Angola. German: Angola-Bulldoggfledermaus, Centralafrikanische Doggengrämler. Italian: Carlìno condilùro. Malawian: Liputiputi, Ndemiya, Namzeze. Portuguese: Morcego de cauda livre.

ETYMOLOGY OF COMMON NAME:

Originally described from the former Natal province, it might more appropriately have been called the Natal free-tailed bat, but this name is taken by *Mormopterus acetabulosus*.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

Gunnell *et al.* (2015a: 20) report on a right distal humerus from a Pleistocene deposit at Olduvai Gorge (Tanzania), which they assigned to *Mops* cf. *M. condylurus*.

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008af; IUCN, 2009; Monadjem *et al.*, 2017ab).

Assessment History

Global

2016: LC ver 3.1 (2001) [assessed as *Mops condylurus*] (Monadjem *et al.*, 2017ab). 2008: LC ver 3.1 (2001) [assessed as *Tadarida condylura*] (Mickleburgh *et al.*, 2008af; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004aq; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016b). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:

There are no major threats to this species. Some colonies roosting within buildings are possibly threatened by general persecution (Mickleburgh *et al.*, 2008af; IUCN, 2009; Monadjem *et al.*, 2017ab).

CONSERVATION ACTIONS:

Mickleburgh *et al.* (2008af) [in IUCN (2009)] and Monadjem *et al.* (2017ab) report that this species is present in a number of protected areas. No direct conservation actions are currently needed for the species as a whole.

GENERAL DISTRIBUTION:

Mops condylurus is widely distributed over much of sub-Saharan Africa. It ranges from Senegal,

the Gambia and Mali in the west, to the Sudan, Ethiopia and Somalia in the east; from here it ranges southwards through much of eastern and southern Africa, as far south as eastern South Africa and Swaziland. The species appears to be largely absent from the Congo Basin.

Monadjem *et al.* (2010d) does not record any specimens occurring in Namibia.

Besides *Mops condylurus*, Taylor *et al.* (2018b: 63) also mention *Mops* cf. *condylurus* from Angola, whose echolocation calls do not match any known species.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,057,626 km^2. In the RSA, Babiker Salata (2012: 49) found that its distribution is stongly associated with the mean temperature of the coldest quarter.

Native: Angola (Lopes and Crawford-Cabral, 1992; Monadjem *et al.*, 2010d: 543; Taylor *et al.*, 2018b: 62); Benin (Capo-Chichi *et al.*, 2004: 163); Botswana (Monadjem *et al.*, 2010d: 543); Burkina Faso (Kangoyé *et al.* (2012: 6025; 2015a: 618); Burundi; Cameroon (Bakwo Fils *et al.*, 2014: 4); Congo (Bates *et al.*, 2013: 336); Congo (The Democratic Republic of the) (Allen, 1917; Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 543); Côte d'Ivoire; Eswatini (Monadjem *et al.*, 2010d: 544, Monadjem *et al.*, 2021: 5); Ethiopia (Lavrenchenko *et al.*, 2004b: 141); Gambia (Emms and Barnett, 2005: 50); Ghana; Guinea (Fahr *et al.*, 2006b: 245; Decher *et al.*, 2016: 275); Guinea-Bissau (Seabra, 1900a; Monard, 1939; Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 75); Kenya; Liberia (Fahr, 2007a: 104); Malawi (Happold *et al.*, 1988; Happold and Happold, 1997b: 823; Monadjem *et al.*, 2010d: 543); Mali; Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 543; Monadjem *et al.*, 2010c: 382); Namibia; Niger; Nigeria; Rwanda; Senegal; Sierra Leone; Somalia; South Africa (De Graaf, 1960; Monadjem *et al.*, 2010d: 544); Sudan;Tanzania; Togo; Uganda (Kityo and Kerbis, 1996: 62); Zambia (Monadjem *et al.*, 2010d: 544); Zimbabwe (Cotterill, 2004a: 260; Monadjem *et al.*, 2010d: 3422).

Presence uncertain: Madagascar.

Dental Formula:

Dorst (1949: 47-48, fig 2) discussed the milk dentition of this species (as *Mops angolensis*) and indicated that the incisors are quite different from both the canines and premolars, as the prior are tricuspid and the latter are peg-like.

Detailed morphology:

Brain

Amrein *et al.* (2007) from specimens collected from Bénin reported sparse proliferating cell activity, detected with Ki-67 and MCM2, in the subgranular layer of the dentate gyrus, with doublecortin (DCX) they detected young migrating neuron in the subgrannular layer of the hippocampus. Amrein *et al.* (2007) also reported moderate to ample proliferating cells (Ki-67 positive cells) and migrating young neurons (DCX positive cells) in the rostral migratory stream. No NeuroD was detected in the hippocampal granule cells (Amrein *et al.*, 2007).

Functional morphology:

Maloney *et al.* (1999: 385) indicate that *M. condylurus* is well adapted to tolerated high ambivalent temperatures, which may enable them to exploit thermally challenging roost sites and allow them to survive in habitats where less stressful roosts are limited. In some of these roosts, the temperature can reach over 40° C, and the bat's body temperature may exceed 43* C (Bronner *et al.*, 1999: 7; Czenze *et al.*, 2021: 2).

Buffenstein *et al.* (1999: 15) found that urine voided prior to feeding in summer was 22% more concentrated than that in autumn, suggesting that periods of exposure to high temperatures were more stressful. The urine produced was up to eight times more concentrated than plasma.

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 18.0 Pa, aspect ratio 9.1 for a wingspan of 36 cm and a wing area of 142 cm^2 and a body mass of 26 g.

Sexual dimorphism:

Chaverri *et al.* (2018: 1944) [referring to Bouchard, 2001b] indicates that the sexes can be distinguished by scent produced from the interaural and muzzle glandular areas.

Echolocation:

Bohmann *et al.* (2011: 1) [referring to Monadjem *et al.* (2010d)] mention peak frequencies between 26 - 35 kHz. Schoeman and Waddington (2011: 291) mention a peak frequency of 24.8 ± 1.5 kHz and a duration of 15.7 ± 2.1 ms for specimens from Durban, South Africa. From the same area, Naidoo *et al.* (2011: 23) mention a F_{peak} of 25.8 ± 0.5 kHz and a duration of 6.8 ± 1.8 ms.

In Swaziland, Taylor *et al.* (2013b: 18) recorded the following parameters for 6 calls: F_{max}: 34.8 ± 2.78 (31.5 - 38.6) kHz, F_{min}: 25.8 ± 1.79 (23.9 - 28.2) kHz, F_{knee}: 30.2 ± 2.16 (27.4 - 32.4) kHz, F_{char}: 27.3 ± 1.98 (24.9 - 29.3) kHz, duration: 5.5 ± 1.40 (3.4 - 7.2) ms. Additional values reported by Monadjem *et al.* (2017c: 179) are: F_{min}: 25.1 ± 1.68 (23.5 - 26.1) kHz, F_{knee}: 30.1 ± 2.03 (28.1 - 32.1) kHz, F_c: 27.3 ± 1.56 (25.9 - 28.8) kHz and duration: 4.3 ± 2.08 (2.2 - 6.4) ms. These calls could be detected up to 30 m away.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 30 (27 - 32) kHz.

Linden *et al.* (2014: 40) reported the following parameters from the Soutpansberg range (RSA): F_{min}: 24 - 28 kHz, F_{char}: 25 - 29 kHz, F_{knee}: 27 - 32 kHz, slope: 40 - 160 OPS, duration: 3 - 7 ms. From the Mapungubwe National Park (RSA), Parker and Bernard (2018: 57) recorded 6 calls with: F_{char}: 29.12 ± 0.70 kHz, F_{max}: 30.72 ± 1.52 kHz, F_{min}: 28.45 ± 0.50 kHz, F_{knee}: 29.82 ± 0.97, duration: 15.44 ± 3.78 ms, at 5.57 ± 1.11 calls/sec.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 29.12 ± 0.70 kHz, F_{max}: 30.72 ± 1.52 kHz, F_{min}: 28.45 ± 0.50 kHz.

Five calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 30.74 ± 2.64 kHz, F_{min}: 27.88 ± 4.69 kHz, F_{knee}: 30.12 ± 1.92 kHz, F_{char}: 29.00 ± 1.49 kHz, slope: 11.60 ± 12.27 OPS, duration: 7.09 ± 3.46 ms.

From Maroua, Cameroon, Manga Mongombe (2012: 79) and Bakwo Fils *et al.* (2018: 4) reported for 12 calls a call type of FM and the following parameters: F_{max}: 37.8 ± 3.8 (33.9 - 41.6) kHz, F_{min}: 34.2 ± 4.9 (30.1 - 40.0) kHz, F_{mean}: 36.4 ± 4.5 (31.0 - 41.0) kHz, F_{knee}: 38.2 ± 4.7 (33.9 - 41.5) kHZ, F_{char}: 33.67 ± 5.1 (30.1 - 40.0) kHz, and duration: 0.78 ± 0.89 (0.57 - 0.88) ms.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 26.7 kHz, F_{start}: NA kHz, F_{end}: NA kHz, Band width: NA kHz, and duration: 10 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 12 bats: F_{max}: 34.5 ± 4.44 kHz, F_{min}: 27.89 ± 3.95 kHz, F_{knee}: 31.59 ± 3.22 kHz, F_{char}: 29.03 ± 2.8 kHz, slope: -480.97 ± 2206.86 OPS, duration: 3.88 ± 1.71 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 26 *Mops condylurus* calls from the Kruger Park (RSA): F_{min}: 25.4 ± 1.4 (22.5 27.2) kHz, Duration: 4.6 ± 1.2 (2.9 8.6) ms, F_{max}: 38.4 ± 4.9 (28.6 45.4) kHz, F_{knee}: 32.3 ± 4.2 (25.5 42.1) kHz, F_{char}: 29.5 ± 3.2 (25.4 37.9) kHz,

101 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 24 - 28 kHz, F_{max}: 32 - 38 kHz, F_{char}: 25 - 29 kHz, F_{knee}: 27 - 32 kHz and duration 4 - 7 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 29.12 ± 0.70 kHz, F_{max}: 30.72 ± 1.52 kHz and F_{min}: 28.45 ± 0.50 kHz.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

MOLECULAR BIOLOGY:

Karyotype

Đulić and Mutere (1973a) described the karyotype as having a diploid number of 2*n* = 48, aFN = 56, BA = 10, X = SM, Y = A. While Smith *et al.* (1986) found that the fundamental number was aFN = 66, BA = 20, this is supported by Rautenbach *et al.* (1993). Koubínová (2013: 7) mentioned: 2*n* = 48 and FN = 54.

The karyotype of an Ethiopian female consists of *2n* = 48, FN = 54, including one pair of large metacentrics, four pairs of medium sized metacentrics and 19 pairs of acrocentrics; the X chromosome could be one of the metacentrics (Tolera *et al.*, 2021: 126).

Genetics

See Hoofer and Van Den Bussche (2003).

HABITAT:

Noer *et al.* (2012: 1) indicate that *M. condylurus* prefers to forage over sugarcane fields rather than over savanna, riparian forest and urban areas. They also indicated that the bats travel up to 4.8 km from their roosts during their foraging trips. Their activity area ranges from 1,190 to 1,437 ha.

HABITS:

Bouchard (2001b: 109) found that, in scent-choice-experiments, both males and females were able to distinguish the gender of conspecifics as well as the difference between roost mates and strangers. Chaverri *et al.* (2018: 1944) [referring to Ravel *et al.*, 2010] further indicate that there is an inverse relation between

the number of individuals that can be recognized based on olfactory cues and the size of the colony. This would suggest that recognition is based on individual signatures rather than on group signatures.

ROOST:
In the Mount Nimba area, Monadjem *et al.* (2016y: 368) found a roost in the roof of a school at 540 m.

Bronner *et al.* (1999: 1) investigated the roost microclimates in three man-made structures in South Africa. The ambient temperature in these varied from below 10°C to over 40°C, but the bats preferred zones where the temperature was between 35 and 40°C, where they could maintain their basal metabolic rate.

DIET:
Based on DNA analysis of 30 faecal pellets collected between April and May (austral summer) in the Simunye region of Swaziland, Bohmann *et al.* (2011) reported insects from 24 families (belonging to seven orders) being taken as prey. The highest frequency of occurrence was for Lepidoptera (47.6 %), Diptera (26.7 %), and Hemiptera (20 %). Within the Lepidoptera, Noctuidae (Owlet moths - 23.3 %), Nymphalidae (Brush-footed butterflies - 17.6 %) and Geometridae (Geometer moths - 10 %) were found the most. Within the Diptera, it were primarily representatives of Drosophilidae (Pomace flies - 6.5 %) and Muscidae (House flies and alike - 6.5 %). Within the Hemiptera, Lygaeidae (Chinch bugs and seed bugs) and Pentatomidae (Stink bugs) were found in 6.7 % of the pellets.

From Maroua (Cameroon), and based on faecal analyses, Bol A Anong (2013: 32) reported the diet to include Coleoptera (63.49%), Hemiptera (27.64%), Diptera (7.42%), Lepidoptera (0.05%) and Hymenoptera (0.40%).

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention "*Tadarida condylura*" to be preyed upon by: African goshawk (*Accipiter tachiro* (Daudin, 1800)), Eurasian hobby (*Falco subbuteo* Linnaeus, 1758), Wahlberg's eagle (*Hieraaetus wahlbergi* (Sundevall, 1851)), Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850).

Bronner *et al.* (1999: 8) reported on the presence of an Eastern Tiger Snake (*Telescopus semiannulatus semiannulatus* Smith, 1849) in a colony of *M. condylurus*.

POPULATION:
Structure and Density
This is a common species (Mickleburgh *et al.*, 2008af; IUCN, 2009; Monadjem *et al.*, 2017ab).

In Kenya, Lunn *et al.* (2024a: 9) found a relatively balanced male-to-female population composition of 1:1.08, whereas Happold and Happold (1989b: 136) found a ratio of 2.6:1 in Malawi.

Trend
2016: Unknown (Monadjem *et al.*, 2017ab).
2008: Unknown (Mickleburgh *et al.*, 2008af; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Mutere (1968, 1973b: 271) reported that "*T. condylura*" has a bimodal breeding rhythm in Uganda (pregnancies during December-March and June-September and births in March and September), which is correlated with the rainfall pattern (April-May and October-November), and that the gestation period for this species is about two months. He also indicated [in Krutzsch (2000: 95)] that the testicular position (intra-abdominal or scrotal) showed no significant seasonal variation in sperm production.

Happold and Happold (1990b: 568) reported that in southern Malawi, births occurred early in the wet season and at the end of the wet season and that gestation takes about 1.5 months. Births in mid-Malawi occur earlier and in northern Malawi later.

Happold and Happold (1989b: 133) indicate that "*Tadarida condylura*" is monotocous in Malawi, where it has two births per year. They also found that the interval between births decreases with increasing latitude.

Mutere (1973b) mentioned that the pattern of reproduction is not followed by a postpartum oestrous, whereas Happold and Happold (1989b) mention the opposite.

Wyant and Adams (2007) present data on prenatal growth, development, and skeletal ossification, by integrating data from changes in body size, wing area, and skeletogenesis, from specimens collected from east African countries.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births between early September and early May.

Vierhaus (2011: 295) - referring to Kulzer (2005) - mentioned that females can already reproduce in the second half of their first year. Their

pregnancy takes about 85 days and the young leave their mothers after 50 to 60 days.

PARASITES:

BACTERIA

Höhne *et al.* (1975: 505) found *Listeria monocytogenes* bacteria in two out of 234 "*Tadarida condylura*" specimens from Lomé, Togo.

Studying faecal samples from freshly captured bats, Edenborough *et al.* (2020: 5) found bacteria belonging to Proteobacteria, Bacilli, Firmicutes, Gammaproteobacteria, and Actinobacteria.

One out of 70 Nigerian *Mops condylurus* specimens examined by Kamani *et al.* (2021: 4) was infected by *Leptospira interogans*.

PROTOZOA

Lima *et al.* (2012: 858) described a new species of *Trypanosoma* from Mozambican *Mops condylurus*: *T. (Schizotrypanum) erneyi*. This parasite was also found in two unidentified *Tadarida* specimens. This *Trypanosoma* species, as well as *T. livingstonei*, was reported by Babyesiza *et al.* (2025: 4) in bats from Uganda. They also indicate (p. 5) that *T. erneyi* has a high host specificity for bats of the genera *Tadarida* and *Mops*.

ARACHNIDA

Laelapidae

Taufflieb (1962: 112) reported *Chelanyssus aethiopious* Hirst, 1921 from a "*Tadarida angolensis* [=*Mops osborni*]".

Macronyssidae

Orlova *et al.* (2024: 154) mention this species as host for *Chelanyssus aethiopicus* (Hirst, 1921).

Sarcoptidae

Notoedres tadaridae Fain, 1959 was found by Fain and Aellen (1994: 64) on a "*Tadarida condylura*" specimen from Tandara, DRC.

Trombiculidae

Stekolnikov (2018a: 69, 172) reported *Holubicula toroensis* Daniel and Vercammen-Grandjean, 1985 on a bat from Uganda, and *Microtrombicula tadarida* Vercammen-Grandjean, 1965 on a bat from Rwanda.

HEMIPTERA

Cimicidae

Loxaspis miranda Rothschild, 1912 were found in the hollow trunk of a *Borassus* palm containing many dead *T. condylura*, at the Fambani river, near mouth of Zambesi, in Mozambique (Haeselbarth *et al.*, 1966: 10).

SIPHONAPTERA

Ischnopsyllidae

Lagaropsylla idea Smit, 1957 widespread in tropical Africa (Haeselbarth *et al.*, 1966: 1990; Beaucournu and Kock, 1996). *Lagaropsylla leleupi* Smit, 1957 from Bugesera, Burindi (Haeselbarth *et al.*, 1966: 191). *Lagaropsylla obliqua* Smit, 1957 from Sierra Leone, Cameroon and the Congo (Haeselbarth *et al.*, 1966: 191).

Lagaropsylla incerta (Rothschild, 1900) was reported from Madagascar by Beaucournu and Kock (1996).

VIRUSES:

Astroviridae

Viruses belonging to this family were recorded by Waruhiu *et al.* (2017) from these bats in Kenya, in one (out of 52) tested by Hoarau *et al.* (2018: 2) in Mozambique, and in bats from Guinea (Hermida Lorenzo *et al.*, 2021: 6).

Bornaviridae

Hermida Lorenzo *et al.* (2021: 6) reported Carbovirus from Guinean bats.

Bunyaviridae

Sudi *et al.* (2018: 3) refer to Krüger *et al.* (2015), who reported the presence of Lompole virus (LMPV) in *Mops condylurus* from the DRC (although the latter authors didn't identify the bats involved).

Caliciviridae

Viruses belonging to this family were recorded by Waruhiu *et al.* (2017) from these bats in Kenya.

Coronaviridae - Coronaviruses

SARS-CoV

Müller *et al.* (2007b) tested between 1986 and 1999, for antibody to SARS-CoV in sera in 19 individuals from Limpopo Province, South Africa, three were tested positive (3/19, 15.8 %) and 96 individuals from Mpumalanga Province, South Africa, 11 tested positive (11/96, 11.9 %) (14/115, 12.2 %).

Anthony *et al.* (2017b: Suppl.) mention the alpha-coronavirus Charephon_CoV_KY22. RNA of the same virus (Chaerephon bat coronavirus/Kenya/KY22/2006) was detected by Suu-Ire *et al.* (2022: 6) in one of 25 tested bats from Ghana. They also found RNA of Kenya bat coronavirus/BtKY56/BtKY55 in four bats and PREDICT_PMV-15 in one bat.

Maganga *et al.* (2020: 5) reported Alphacoronaviruses found in bats from Cameroon, Mozambique and South Africa.

For the two Congos, Kumakamba *et al.* (2021: 7) reported eight out of 105 bats testing positive for coronaviruses.

George *et al.* (2022: 4) found 22.3 % of the *Mops condylurus* specimens they sampled in Nigeria containing RNA of Alphacoronaviruses. George *et al.* (2023: 1) found that these viruses represent a unique subgenus only found in molossid bats.

Filoviridae - Filo viruses
Ebolavirus
Muyembe-Tamfum *et al.* (2012: 9) refer to Pourrut *et al.* (2005) who found ZEBOV-specific antibodies in this species.

Saéz *et al.* (2014) indicate that the two-year old boy, who was patient zero for the 2014 Ebola outbreak in West Africa may have been infected while playing in a hollow tree housing a colony of *M. condylurus*. However, Wood *et al.* (2015: 9-10) find "the suggestion that *Mops condylurus* was the source of infection in the index human case in Guinea noteworthy if somewhat speculative." Additionally, Ouattara and Århem (2021: 19 - 20) convincingly argue that the boy wasn't patient zero and hasn't played near the hollow tree. According to their information, the first patient was a sick woman (from either Sierra Leone or Liberia) seeking treatment in the village and who stayed at the boy's family home. Therefore any link to bats becomes at least unlikely.

Goldstein *et al.* (2018: 1084) described a new *Ebolavirus* from three Sierra Leonan *C. pumilus* and one *Mops condylurus*: Bomali virus (BOMV). They were sampled in human dwellings in small villages in the Bomali district. This virus might infect humans, but it is not known (yet) whether it is virulent in humans too.

Forbes *et al.* (2019: 955) reported this virus from one *M. condylurus* from Kenya (out of 16 *M. condylurus* + 92 other bats collected). Kareinen *et al.* (2021: 3008) found three out of 332 tested Kenyan *condylurus* to be infected by BOMV (two from Busia in the west and one from Taita in the east). Karan *et al.* (2019: 1774) reported this virus from three out of 109 *M. condylurus* bats from Guinea. BOMV RNA was furthermore reported from three female Mozambican bats (Lebarbenchon *et al.*, 2022: 2583).

Bokelmann *et al.* (2021: 1) investigated the replication, tolerance, and persistence of Ebola virus in 10 different primary bat cell isolates from *Mops condylurus* and found that the virus could persist for at least 100 days in lung primary cells, which seems to support the hypothesis that this bat is a likely reservoir for the ebolavirus.

Kareinen *et al.* (2023: 1031) examined a limited number of BOMV-positive bats from Kenya and found no substantial pathologies, suggesting that these bats might act as a reservoir species. Düx *et al.* (2024: 1) found BOMV RNA in Tanzanian *Mops condylurus*, supporting this species' role as a reservoir species.

Riesle-Sbarbaro *et al.* (2024: 2) inoculated 22 wild caught *Mops condylurus* specimens with either EBOV, MARV, REST or TAFV viruses and found some potential for horizontal transmission of EBOV as well as evidence of vertical transmission of this virus. This suggests that *Mops condylurus* might be relevant for the maintenance of entzootic cycles if EBOV.

Flaviviridae
Flavivirus
de Jong *et al.* (2011: 10) reported Bukalasa bat virus, Dakar bat virus, Entebbe bat virus. The latter two are also reported by Luis *et al.* (2013: suppl.), Blitvich and Firth (2017: 3). In Uganda, Kading *et al.* (2018: 3) found neutralizing antibodies against Dengue 2 virus (DENV-2) and non-specific Flaviviruses.

Banzi virus
Gonzalez and Banerjee (2022: 10) mentioned this virus.

Dakar virus
Kemp (1975: 616) mentions that this virus was isolated in Nigeria on *M. condylurus* for the first time on 25 January 1966.

Dengue virus
Bonilla-Aldana *et al.* (2020: 3) reported this bat as one of the bats carrying this virus.

Zika virus (ZIKV)
Malmlov *et al.* (2019: 2) refer to Shepherd and Williams (1964) who examined 36 Ugandan *condylurus* specimens of which 26 had antibodies against ZIKV.

Pegivirus (BPgV)
1 of 10 specimens from the Democratic Republic of Congo examined by Quan *et al.* (2013: Table S5) (10.0 %) was infected by clade G type *Pegivirus*. Of the same 10 specimens, 2 were infected by clade K type

Hantaviridae
Weiss *et al.* (2022: 1) reported a new virus from Angolan (and Tanzanian) bats: Kiwira virus,

which also represents the first hantavirus discovered in this bat species.

Paramxoviridae
Viruses belonging to this family were recorded by Waruhiu *et al.* (2017) from these bats in Kenya.

Hermida Lorenzo *et al.* (2021: 6) identified Lophuromys jeilongvirus, Bat paramyxovirus and Avian avulavirus from Guinean bats.

Hoarau *et al.* (2021: Suppl.) reported them also in bats from Mozambique.

Peribunyaviridae
Orthobunyavirus
Fagre and Kading (2019: 4) report that Bunyamwera virus (BUNV) was found either by virus isolation or molecular/serologic evidence.

Retroviridae
Hermida Lorenzo *et al.* (2021: 6) reported Bat gammaretrovirus, Melomys burtoni retrovirus and Squirrel monkey retrovirus from Guinean bats.

In their overview tables, Maganga *et al.* (2014a: 8) and Willoughby *et al.* (2017: Suppl.) reported that the following viruses were already found on *M. condylurus*: Bukalasa bat virus, Dakar bat virus, Entebbe bat virus, Coronavirus (SARS-CoV), Bunyamwera orthobunyavirus, West Nile virus, Yellow fever virus, Zaïre Ebola, Zika virus.

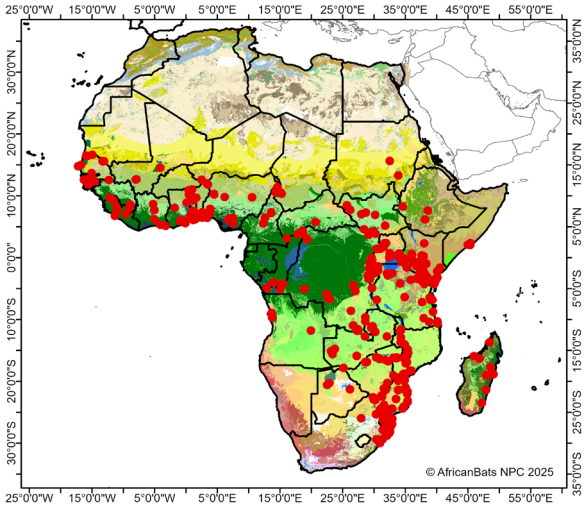

Figure 185. Distribution of *Mops (Mops) condylurus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burundi, Cameroon, Central African Republic, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Eswatini, Ethiopia, Gabon, Ghana, Guinea, Guinea-Bissau, Kenya, Liberia, Madagascar, Malawi, Mali, Mauritania, Mozambique, Namibia, Niger, Nigeria, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

Mops (Mops) congicus J.A. Allen, 1917

*1917. *Mops congicus* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 467, pl 55. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Medje [02 25 N 27 18 E, 800 m]. [Goto Description]. Holotype: AMNH 48893: ad ♀, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 8 September 1910; original number: 966.
? *Mops (Mops) congicus:* (Name Combination, Current Combination).
? *Mops congica:* (Alternate Spelling).
? *Tadarida congica:* (Name Combination).

TAXONOMY:
Does not include *trevori*; see Peterson (1972).

COMMON NAMES:
Czech: morous konžský. English: Medje Mops Bat, Medje Free-tailed Bat, Medje Greater Free-tailed Bat. French: Tadaride de Medje. German: Kongo-Bulldoggfledermaus, Medje-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bp; IUCN, 2009; Monadjem *et al.*, 2017ay).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Mops congicus*] (Monadjem *et al.*, 2017ay). 2008: LC ver 3.1 (2001) [assessed as *Tadarida congica*] (Mickleburgh *et al.*, 2008bp; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004bx; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It is threatened in parts of its range by habitat loss, largely resulting from logging activities and conversion of land to agricultural use

(Mickleburgh *et al.*, 2008bp; IUCN, 2009; Monadjem *et al.*, 2017ay).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bp) [in IUCN (2009)] and Monadjem *et al.* (2017ay) report that it is not known if the species is present in any protected areas. Further studies are needed into the distribution, abundance, natural history, and threats to this poorly known species.

GENERAL DISTRIBUTION:
Mops congicus has been patchily recorded in Central Africa. It is found from southern Cameroon, east into the northern part of the Democratic Republic of the Congo and western Uganda.

Earlier records of this species from Ghana (Koopman, 1993a: 236) and Nigeria (Bergmans, 1977b: 285) are now allocated to *Mops trevori* (Simmons, 2005: 442; Fahr *et al.*, 2006a: 74); Tanshi *et al.*, 2022a: 314).

Native: Cameroon; Congo (The Democratic Republic of the); Uganda.

POPULATION:
Structure and Density
The species has been rarely collected. While a single large colony of approximately several dozen bats has been reported, it is suspected to generally occur in much smaller roosts (Mickleburgh *et al.*, 2008bp; IUCN, 2009; Monadjem *et al.*, 2017ay).

Trend
2016: Unknown (Monadjem *et al.*, 2017ay).
2008: Unknown (Mickleburgh *et al.*, 2008bp; IUCN, 2009).

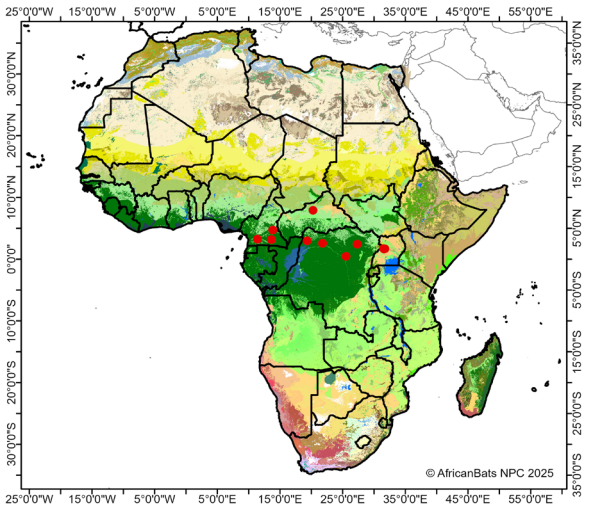

Figure 186. Distribution of *Mops (Mops) congicus*.

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: morous mongallanský. English: Mongalla Mops Bat, Mongallan Mops Bat, Mongalla Free-tailed Bat. French: Tadaride de Mongalla. German: Mongalla-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bs; IUCN, 2009; Monadjem *et al.*, 2017u).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Mops demonstrator*] (Monadjem *et al.*, 2017u). 2008: LC ver 3.1 (2001) [assessed as *Tadarida demonstrator*] (Mickleburgh *et al.*, 2008bs; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004az; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
In part of its range this species is threatened by habitat loss, mostly the cutting of larger roosting trees from savanna. It may also be threatened by encroaching desertification in the northern limits of its range (Mickleburgh *et al.*, 2008bs; IUCN, 2009; Monadjem *et al.*, 2017u).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bs) [in IUCN (2009)] and Monadjem *et al.* (2017u) report that this species has been recorded from the Garamba National Park in the Democratic Republic of the Congo (Freeman, 1981b), and may be present in additional protected areas. There is a need to protect suitable large roosting trees in savanna. Further research is needed to better understand the distribution, natural history and major threats to this species.

GENERAL DISTRIBUTION:
Mops demonstrator has been patchily recorded from West Africa (Côte d'Ivoire, Ghana and Burkina Faso) and Central to East Africa (Cameroon, eastern Democratic Republic of the Congo, western Uganda and Sudan).

A record from the Gambia appears to be in error (Koopman, 1989b; Grubb *et al.*, 1998).

Native: Burkina Faso (Kangoyé *et al.*, 2015a: 618); Cameroon; Congo (The Democratic Republic of the); Côte d'Ivoire; Ghana; Sudan; Uganda.

MOLECULAR BIOLOGY:
Karyotype
Smith *et al.* (1986) reported 2*n* = 48, FN = 54, BA = 8, a submetacentric X chromosome and an acrocentric Y chromosome.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure and Density
This species is rarely recorded. Animals are usually found singly or as small groups of up to 12 bats (Mickleburgh *et al.*, 2008bs; IUCN, 2009; Monadjem *et al.*, 2017u).

Trend
2016: Decreasing (Monadjem *et al.*, 2017u). 2008: Decreasing (Mickleburgh *et al.*, 2008bs; IUCN, 2009).

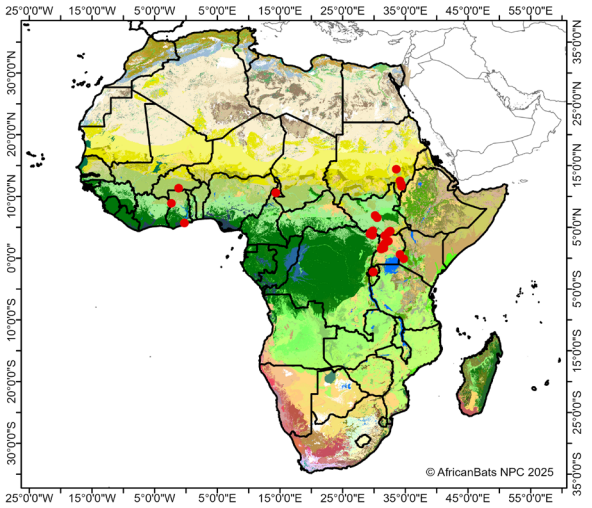

Figure 187. Distribution of *Mops (Mops) demonstrator*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Burkina Faso, Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Kenya, Rwanda, South Sudan, Sudan, Uganda.

Mops (Mops) leucostigma (G.M. Allen, 1918)

*1918. *Chaerephon leucostigma* G.M. Allen, Bull. Mus. comp. Zool., 61 (14): 513. Publication date: 27 February 1918. Type locality: Madagascar: Tananarive [=Antananarivo] [18 55 S 47 31 E, 1 300 m]. Holotype: MCZ 16344: ad ♀, skin and skull. Collected by: Dr. Frederik Roelker Wulsin; collection date: December 1915. See Peterson *et al.* (1995: 168); Helgen and McFadden (2001: 145). Paratype: MCZ 16345: ♂, skin and skull. See Helgen and McFadden (2001: 145). - Comments: Ratrimomanarivo *et al.* (2008: 66 - 67) mentions the following: "In his description of *Mops leucostigma*, Allen (1918) cited two specimens - the holotype (MCZ 16344), which was sexed as a 'female' and the paratype (MCZ 16345), which was sexed as a 'male' (also see Helgen & McFadden, 2001). We examined these two specimens. In Allen's description he specifically states, 'The skull is provided with a prominent sagittal crest, which in the type, though partly broken, must have been at least a millimetre high.' This is an accurate description of the MCZ 16344. In members of the genus *Mops* in general (Freeman, 1981) and in *M. leucostigma* specifically (this study), adult males are distinctly larger than adult females and have a prominent and more developed occipital and sagittal crests. Based on size, skull shape, and the development of the occipital and sagittal crests, the holotype is a male and the paratype a female.

Given that all of the collection data for the holotype (MCZ 16344) and paratype (MCZ 16345) are identical, we strongly suspect that the museum labels for these two specimens have been accidentally exchanged before the publication of Allen (1918).".

2018. *Mops leucogaster:* Kemp, López-Baucells, Rocha, Wangensteen, Andriatafika, Nair and Cabeza, Agric. Ecosyst. Environ., 269: 88 (for 2019). Publication date: 1 October 2018. (Lapsus).

? *Mops (Mops) leucostigma:* (Name Combination, Current Combination).

? *Mops condylura leucostigma:* (Name Combination, Alternate Spelling).

? *Mops leucostigma:* (Name Combination).

? *Tadarida (Mops) leucostigma:* (Name Combination).

? *Tadarida leucostigma:* (Name Combination).

TAXONOMY:

Included in *condylurus* by Koopman (1993a: 236), but considered a valid species in *Tadarida (M.)* by Peterson *et al.* (1995: 152) and Russ *et al.* (2001). Considered a valid species in the genus *Mops* by Hutson *et al.* (2001: 34), Goodman and Cardiff (2004: 227), Simmons (2005).

COMMON NAMES:

Czech: morous běloskvrnný. English: Malagasy large white-bellied Free-tailed Bat, Madagascar White-bellied Free-tailed Bat, Malagasy White-bellied Free-tailed Bat, White-shouldered bat. French: Tadaride à queue libre de Madagascar, Grand molosse malgache. German: Gefleckte Bulldoggfledermaus.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

Gunnell *et al.* (2014: 3) refer to fossils material from the Andrahomana cave on Madagascar.

CONSERVATION STATUS:

Global Justification

This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its large distribution range, and its ability both to tolerate persecution and to persist in a variety of habitats in many parts of its range (Andriafidison *et al.*, 2008m; IUCN, 2009; Monadjem *et al.*, 2017ca).

Assessment History

Global

2016: LC ver 3.1 (2001) [assessed as *Mops leucostigma*] (Monadjem *et al.*, 2017ca). 2008: LC ver 3.1 (2001) [assessed as *Tadarida leucostigma*] (Andriafidison *et al.*, 2008m; IUCN, 2009). 2000: DD ver 2.3 (1994).

Regional

None known.

MAJOR THREATS:

In some areas it is hunted for food (Goodman *et al.*, 2008d) or persecuted, but these are not thought to be serious threats (Andriafidison *et al.*, 2008m; IUCN, 2009; Monadjem *et al.*, 2017ca).

CONSERVATION ACTIONS:

Andriafidison *et al.* (2008m) [in IUCN (2009)] report that this species is known from Kirindy CFPF and Parc National de Zombitse-Vohibasia (Goodman *et al.*, 2005a). It is also common in villages adjacent to several protected areas (Goodman *et al.*, 2005a; Russ *et al.*, 2003; Monadjem *et al.*, 2017ca).

GENERAL DISTRIBUTION:

Mops leucostigma is known from Madagascar and the Comoros archipelago (Mohéli and Anjouan islands). On Madagascar it is found from the north to the southwest of the island (Eger and Mitchell, 2003; Peterson *et al.*, 1995) including the islands of Nosy Be and Nosy Komba (Rakotonandrasana and Goodman, 2007: 6). Recorded at an elevation span of 5 to 1,300 m above sea level (Allen, 1918b; Eger and Mitchell, 2003).

Native: Madagascar (Eger and Mitchell, 2003; Peterson *et al.*, 1995; Rakotonandrasana and Goodman, 2007: 6); Comoros (Ratrimomanarivo *et al.*, 2008: 57).

DETAILED MORPHOLOGY:

Baculum

Rakotondramanana and Goodman (2017: 62) describe the baculum as displaying a distinct "m"-shape; length: 0.75 ± 0.097 (0.56 - 0.86) mm, width: 1.09 ± 0.137 (0.83 - 1.35) mm.

FUNCTIONAL MORPHOLOGY:

Amador *et al.* (2019: Suppl.) [referring to Garbutt (2007) and Taylor *et al.* (2012a)] mention a wing loading value of 14.2 Pa, aspect ratio 8.3 for a wingspan of 32 cm and a wing area of 121 cm^2 and a body mass of 18 g.

HABITAT:

Dammhahn and Goodman (2013: 108) indicate that this species' foraging habitat consists of open areas and the area above the forest canopy.

Crowley and Goodman (2025: 4) report it to be widespread in intact and degraded forests, ecotones, agricultural, and urban areas (near forests).

ROOST:
This bat roosts in caves and hollow trees (7 to 25 animals group together) or buildings (group size to 250 bats) (Garbutt, 2022: 96)..

MIGRATION:
Reher *et al.* (2019: 121) found that *M. leucostigma* was only present in the Vintany Cave (southwestern Madagascar) during the rainy season, whereas other species such as *Triaenops menamena* and *Miniopterus mahafaliensis* were present in both the dry and wet season.

DIET:
Rakotondramanana *et al.* (2015: 78) report the following insect orders (by volume percent, by frequency percent): Coleoptera (64.0, 100.0); Lepidoptera (30.0, 100.0); Trichoptera (6.0, 60.0).

Kemp *et al.* (2018: Suppl.) used DNA metacarcoding to detect insect pest species in the diet of these bats and found the following prey orders (in descending order): Coleoptera, Diptera (*Simulium lineatum* (Meigen, 1804)), Lepidoptera (*Anthozela* sp., *Celsumaria elongata* Brown, 2017, *Spodoptera mauritia* (Boisduval, 1833)), Blattodea, Hemiptera (*Yanga guttulata* (Signoret, 1860)), Ephemeroptera, Sarcoptiformes, Orthoptera, Hymenoptera, Mesostigmata, Trombidiformes, Trichoptera.

Todilahy *et al.* (2022: 127, 130) investigated the diet based on fecal pellets and found representatives of Coleoptera, Hymenoptera, Lepidoptera, Hemiptera, and Diptera. In adult males and juveniles of both sexes, Coleoptera were the most abundant, whereas Hymenoptera formed the main part of the diet in adult females (see also Crowley and Goodman, 2025: 28).

PREDATORS:
Goodman *et al.* (2015c: 78) found the remains of two individuals in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar.

POPULATION:
Structure and Density
The population and local abundance of this species are not known (Andriafidison *et al.*, 2008m; IUCN, 2009; Monadjem *et al.*, 2017ca).

Trend
2016: Unknown (Monadjem *et al.*, 2017ca).
2008: Unknown (Andriafidison *et al.*, 2008m; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Six bats collected at Sarahandrano on 6 May 2021, five were females of which three had large mammae, one had small mammae and the last one was lactating. The male specimen had enlarged testicles and convoluted epididymes.

PARASITES:
ARACHNIDA
Macronyssidae
Orlova *et al.* (2024: 154) mention this species as host for *Chelanyssus aethiopicus* (Hirst, 1921).

SIPHONAPTERA
Ischnopsyllidae
Duchemin *et al.* (2022: 1077) reported the presence of *Lagaropsylla hoogstraali* Smit, 1957 and *Lagaropsylla idae* Smit, 1957.

VIRUSES:
Astroviridae
Three bats from Madagascar were found to harour viruses of this family (Hoarau *et al.*, 2021: Suppl.).

Paramyxoviridae
Specimens from this species tested by Wilkinson *et al.* (2014: 8270) were found to be positive for paramyxoviruses.
11 out of 68 Madagascan specimens tested by Mélade *et al.* (2016b: 4) were positive for paramyxoviruses.

Rhabdoviridae
Mélade *et al.* (2016a: 6) tested 20 bats for *Lagos bat lyssavirus* and found positive reactions in two of them.

UTILISATION:
See Goodman *et al.* (2008d).

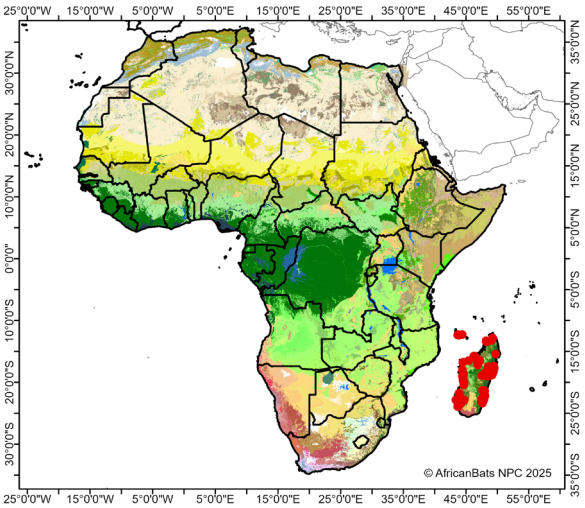

Figure 188. Distribution of *Mops (Mops) leucostigma*.

Comoros, Madagascar.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

Mops (Mops) midas (Sundevall, 1843)

*1843. *Dysopes Midas* Sundevall, Kongl. Svenska Vet.-Akad. Hand., ser 3, 30: 207, pl 2, fig 7 [for 1842]. Publication date: 1843. Type locality: Sudan: Blue Nile Province: E-bank White Nile: Valid Sohey [= Wad Shala]: restricted by Turni and Kock (2008: 68). [14 34 N 13 48 E]. [Goto Description]. Syntype: NHMUK 1846.6.2.20: ad ♂, skin and skull. Formerly Stockholm Museum (ZSM no. 523), locality: Bahr el Abiad. See Turni and Kock (2008: 68). Syntype: NRM 590521:; collection date: 1 June 1937. Syntype: NRM 630520:; collection date: 1837. Syntype: ZMB 535: skin only. Collected by: Hedenborg; collection date: 1831 - 1835. From [Dar] Sennar, Sudan; see Turni and Kock (2008: 68). Syntype: ZSM |TS237|: Collected by: Hedenborg; collection date: 1846. See Turni and Kock (2008: 68). Syntype: ZSM |TS612|: skin only. Collected by: Hedenborg; collection date: 1836. See Turni and Kock (2008: 68). - Comments: Horáček *et al.* (2000: 137) mention "Bahr-el-Abiad, White Nile" as type locality. Meester *et al.* (1986: 73): "Bahr-el-Abiad (White Nile), Sudan. Kock (1969a: 154) suggests that the type locality is at Jebel el Funj, between the White and Blue Nile, and Koopman (1975, and in litt.) restricts it to the east (not west, as shown in 1975: 429) bank of the White Nile at 11 45 N 33 30 E, Blue Nile Province, Sudan."). El-Rayah (1980: 264) believes the restriction to Jebel el Funj is incorrect as Sundevall described the type locality as Bahr el-Abiad which is the area south of Omdurman (15 19 N 32 29 E) and commonly known as Bahar Abiad and restricts the type locality to the vicinity of Jebel Aulia (15 19 N 32 31 'E). For a deeper discussion on the type locality, see Turni and Kock (2008: 68). - Etymology: According to a legend the mythological King Midas of Phrygia offended Apollo, so the god turned Midas' ears into those of a donkey, i.e. in very long ears; which in this species are relatively large (see Lanza *et al.*, 2015: 304).

? *Mops midas:* (Name Combination).
? *Tadarida (Mops) midas:* (Name Combination).
? *Tadarida midas:* (Name Combination).

TAXONOMY:

Figure 189. A female *Mops (Mops) midas* (TM 48104) caught at Makalali Game Reserve, Limpopo Province, South Africa.

Dunlop (1999), following Koopman (1994), recognizes two subspecies: *M. m. midas* (Sundevall 18437) occurring over most of the range and *M. m. miarensis* (Grandidier, 1869) occurring in Madagascar (Peterson *et al.* (1995). Although *miarensi* has previously been considered a subspecies endemic to the island of Madagascar (Simmons (2005), Ratrimomanarivo *et al.* (2007) found no distinctive or taxonomically definitive differences between populations of *Mops midas* occurring on the African continent and Madagascar.

COMMON NAMES:

Afrikaans: Midas se losstertvlermuis, Midas-losstertvlermuis. Chinese: 米达犬吻蝠. Czech: morous oslí. English: Midas Mops Bat, Midas Bat, Midas Free-tailed Bat, Sundevall's Free-tailed Bat, Midas Groove-cheeked Bat. French: Tadaride Midas, Molosse Midas, Tadarida de Midas, Molosse de Midas. German: Midas-Bulldoggfledermaus, Sennaarische Doggengrämler. Italian: Carlìno Mìda. Malawian: Liputiputi, Ndemiya, Namzeze.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

No known fossils (Dunlop, 1999).

CONSERVATION STATUS:

Global Justification

This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread but patchy distribution. The species is locally hunted and persecuted, but it is not thought to be declining fast enough to place it in a higher category of threat (Jenkins *et al.*, 2008a; IUCN, 2009; Monadjem *et al.*, 2017ag).

Assessment History

Global

2016: LC ver 3.1 (2001) [assessed as *Mops midas*] (Monadjem *et al.*, 2017ag). 2008: LC ver 3.1 (2001) [assessed as *Tadarida midas*] (Jenkins *et al.*, 2008a; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004ax; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: LC ver 3.1 (2001) (Taylor *et al.*, 2016a). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
This species is thought to be locally threatened by general persecution, collection for food and habitat loss (Jenkins *et al.*, 2008a; IUCN, 2009; Monadjem *et al.*, 2017ag).

CONSERVATION ACTIONS:
Jenkins *et al.* (2008a) [in IUCN (2009)] and Monadjem *et al.* (2017ag) report that there is a need to protect large trees and other known roosting sites for this species (this does not apply to populations on Madagascar). In Madagascar, it is known from Beza Mahafaly and Zombitse-Vohibasia National Parks.

GENERAL DISTRIBUTION:
Mops midas is a widespread lowland, savanna species ranging from West Africa eastwards to East Africa and southwards into southern Africa. It has been recorded from the Arabian Peninsula. It is present on Madagascar (including the island of Nosy Be), where it is generally distributed in the drier western and southern habitats of the island below 150 m asl (Ratrimomanarivo *et al.*, 2007). In South Africa, the species' distribution is mostly affected by precipitation seasonality (Babiker Salata, 2012: 49). Taylor *et al.* (2018b: 63) predict that the species might also occur in Angola.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 441,324 km^2.

Native: Benin; Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 544); Burkina Faso (Kangoyé *et al.*, 2015a: 618); Burundi; Central African Republic; Chad; Congo (The Democratic Republic of the); Eritrea (Lavrenchenko *et al.*, 2004b: 133); Eswatini (Shapiro and Monadjem, 2015: "1", Monadjem *et al.*, 2021: 5)): Ethiopia; Gambia; Ghana; Kenya; Madagascar (Peterson *et al.*, 1995; Rakotonandrasana and Goodman, 2007: 6); Malawi (Ansell and Dowsett, 1988: 47; Monadjem *et al.*, 2010d: 544); Mali; Mozambique; Namibia (Cotterill, 2004a: 260; Monadjem *et al.*, 2010d: 544); Niger; Nigeria; Rwanda; Saudi Arabia; Senegal; South Africa (Monadjem *et al.*, 2010d: 544); Sudan; Tanzania; Togo; Uganda; Zambia (Ansell, 1973; Cotterill, 2004a: 260; Monadjem *et al.*, 2010d: 544); Zimbabwe (Monadjem *et al.*, 2010d: 544).

BIOGEOGRAPHY:
Samonds *et al.* (2012: 5356) indicate that *M. midas* seems to have migrated multiple times between the African continent and Madagascar.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Dunlop (1999).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Dunlop (1999).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 62) describe the baculum as an elongated rod, which has a notable twist to the mid-shaft in a lateral view. The distal tip is rounded, and the proximal tip terminates in a blunt point length: 1.90 ± 0.091 (1.80 - 2.05) mm, width: 0.39 ± 0.058 (0.32 - 0.46) mm.

Other
For a description of the crania, teeth, ears and tragus, and wingshape and aspect ratio see Dunlop (1999).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 11.4 Pa, aspect ratio 8.9 for a wingspan of 46 cm and a wing area of 235 cm^2 and a body mass of 44 g.

SEXUAL DIMORPHISM:
Sexual dimorphism in *M. midas* occurs primarily in the stronger development of the sagittal and lambdoidal crests (Kingdon, 1974; Smithers, 1983; Dunlop, 1999), as well as the greater length and width of the skull (Peterson *et al.*, 1995) in males.

ECHOLOCATION:
See Dunlop (1999) and Taylor (1999b).

In Waterberg, South Africa, Taylor *et al.* (2013b: 18) recorded the following parameters for 6 calls: F_{max}: 14.5 ± 1.45 (12.7 - 16.2) kHz, F_{min}: 12.8 ± 0.82 (11.7 - 13.7) kHz, F_{knee}: 13.8 ± 1.02 (12.5 - 15.0) kHz, F_{char}: 13.1 ± 0.88 (12.0 - 14.0) kHz, duration: 10.3 ± 2.89 (7.8 - 15.8) ms.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 14 (12 - 15) kHz.

Linden *et al.* (2014: 40) reported the following parameters from the Southpansberg range (RSA): F_{min}: 12 - 14 kHz, F_{char}: 12 - 14 kHz, F_{knee}: 12 - 15 kHz, slope: 32 - 66 OPS, duration: 8 - 16 ms.

At the Mapungubwe National Park (RSA), Parker and Bernard (2018: 57) recorded 13 calls: F_{char}: 13.11 ± 1.04 kHz, F_{max}: 14.66 ± 1.46 kHz, F_{min}: 12.33 ± 1.42 kHz, F_{knee}: 13.71 ± 0.98 kHz,

duration: 14.79 ± 3.78 ms, with 4.29 ± 2.73 calls/sec.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 14.23 ± 1.91 kHz, F_{max}: 15.81 ± 2.51 kHz, F_{min}: 13.67 ± 1.83 kHz.

From Swaziland, the following values were reported by Monadjem *et al.* (2017c: 179): F_{min}: 11.8 ± 0.50 (11.3 - 12.5) kHz, F_{knee}: 13.1 ± 1.08 (11.9 - 14.5) kHz, F_c: 12.3 ± 0.72 (11.6 - 13.4) kHz and duration: 14.2 ± 3.89 (9.0 - 20.7) ms.

Weier *et al.* (2020: Suppl.) reported on four calls from the Okavango River Basin with the following characteristics: F_{max}: 18.51 ± 5.52 kHz, F_{min}: 14.78 ± 4.17 kHz, F_{knee}: 16.79 ± 4.44 kHz, F_{char}: 15.27 ± 3.89 kHz, slope: 25.69 ± 20.05 OPS, duration: 10.63 ± 5.28 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 20 bats: F_{max}: 18.69 ± 0.81 kHz, F_{min}: 17.09 ± 2.01 kHz, F_{knee}: 18.39 ± 0.66 kHz, F_{char}: 17.49 ± 0.67 kHz, slope: -120.48 ± 998.33 OPS, duration: 5.67 ± 3.18 ms. 15 calls recorded at the Venatia mine by Cory-Toussaint and Taylor (2022: Tabls S1) had a duration of 7.43 ± 1.98 ms, F_{min}: 14.67 ± 1.19 kHz, F_{max}: 16.52 ± 0.80 kHz, F_{knee}: 16.06 ± 0.64 kHz and F_{char}: 15.03 ± 0.62 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 7 *Mops midas* calls from the Kruger Park (RSA): F_{min}: 13.7 ± 1.8 (11.7 17.3) kHz, Duration: 9.6 ± 2.2 (6.0 13.2) ms, F_{max}: 15.8 ± 2.5 (12.8 18.9) kHz, F_{knee}: 14.4 ± 2.0 (12.1 17.9) kHz, F_{char}: 14.2 ± 1.9 (12.1 17.6) kHz, 45 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 12 - 14 kHz, F_{max}: 13 - 16 kHz, F_{char}: 12 - 14 kHz, F_{knee}: 12 - 15 kHz and duration 8 - 16 ms.

MOLECULAR BIOLOGY:
Karyotype
Smith *et al.* (1986) described the karyotype as having a diploid number of 2*n* = 48, aFN = 66, BA = 20, X = SM, Y = A, this is supported by Rautenbach *et al.* (1993).

HABITAT:
See Dunlop (1999).

HABITS:
See Dunlop, 1999).

ROOST:
See Dunlop (1999).

Happold and Happold (2023: 124) indicate that, in the DRC, these bats roost in groups of about a dozen, whereas in Botswana and Zimbabwe the colony size can reach several hundreds. In Madagascar, colonies in old buildings can contain up to 600 bats (Garbutt, 2022: 96).

MIGRATION:
May make local migrations, as they only appear in parts of their range (northeastern Congo) at the end of the dry season (Allen *et al.*, 1917; Dunlop, 1999).

DIET:
In the Limpopo province (RSA), Taylor *et al.* (2017b: 246, 252 - 254) found 93 prey items spread over seven insect orders: Lepidoptera (100 % [found in all faecal pellets] and covering 17 families: *Synemon austera* + *Talanga sexpunctalis* + *Antaeotricha* sp. + *Elachista* sp. + *Araeopteron* sp. + *Dyops subdifferens* + *Eublemma* sp. + *Peridrome orbicularis* + *Spargaloma sexpunctata* + *Eutelia polychorda* + *Lophoptera* sp. + *Phlegetonia callichroma* + *Acanthovalva inconspicuaria* + *Achrosis pyrrhularia* + *Aethalura punctulata* + *Cabera AH02SA* + *Chiasmia interrupta* + *Ennominae* sp. + *Eupithecia* sp. + *Isturgia arizeloides* + *Isturgia roraria* + *Isturgia pulinda* + *Scopula atricapilla* + *Hyblaea puera* + *Gonometa postica* + *Sena* sp. + *Sena prompta* + *Xenopseustis* sp. + *Acronicta psi* + *Adisura marginalis* + *Athetis ignava* + *Bastilla torrida* + *Bryophila AH01Pe* + *Chasmina lispodes* + *Chasmina* sp. + *Condica parista* + *Copitarsia* + *Cortyta canescens* + *Enmonodia capensis* + *Grammodes stolida* + *Harrisimemna trisignata* + *Heterochroma BioLep767* + *Hypotacha* sp. + *Leucania BioLep10* + *Leucania BioLep162* + *Leucania multilinea* + *Leucania Poole05* + *Leucania porphyrodes* + *Mythimna consanguis* + *Mythimna convecta* + *Mythimna impura* + *Mythimna oxygala* + *Mythimna nigrisparsa* + *Mythimna obsoleta* + *Mythimna* sp. + *Niphonyx segregata* + *Hadenini* sp. + *Ophiusa tirhaca* + *Pandesma robusta* + *Paratrachea laches* + *Pericyma atrifusa* + *Polia piniae* + *Rhesala moestalis* + *Spodoptera exigua* + *Tycomarptes* sp. + *Xanthodes malvae* + *Garella nilotica* + *Maurilia arcuata* + *Meganola dentata* + *Meganola baracoana* + *Pseudosomera noctuiformis* + *Stenoptilia* sp. + *Phycitinae* + *Copaxa lavendera* + *Pseudautomeris irene* + *Agrius convolvuli* + *Cochylidia implicitana* + *Platphalonidia felix* + unmatched), Coleoptera (67 % - *Cybister tripunctatus* + unmatched), Hemiptera (29 % - *Macrorhaphis acuta* + *Nezar viridula* + unmatched), Diptera, Orthoptera (Tettigoniinae), Blattodea (25 % - *Pycnoscelus* sp. + unmatched) and Neuroptera (29 % - unmatched).

PREDATORS:
Malan *et al.* (2022: 167) reported two individuals found in pellets from a South African bat hawk (*Macheiramphus alcinus* Bonaparte, 1850.
The barn owl (*Tyto alba* (Scopoli, 1769)) is another predator (Garbutt, 2022: 96).

POPULATION:
Structure
Verschuren (1957) found females outnumbered males in the roost at a ratio of four to one.

Density
Smithers, 1983) reported *M. midas* roosting in groups of up to several hundred; however, Verschuren, 1957) only recorded groups of 10-20 individuals leaving roosts. In Madagascar, no large colonies have been found and it is thought to be a locally common species with a patchy distribution. The maximum recorded colony was near Amboasary of 600 individuals (Jenkins *et al.*, 2008a; IUCN, 2009; Monadjem *et al.*, 2017ag).

Trend
2016: Decreasing (Monadjem *et al.*, 2017ag).
2008: Decreasing (Jenkins *et al.*, 2008a; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
See Dunlop (1999).

REPRODUCTION AND ONTOGENY:
See Dunlop (1999).

Krutzsch (2000: 127) indicates that this species is polyoestrous.

Happold and Happold (1990b: 568) reported that in Malawi, births occur at the end of the wet season.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] suggest that the birth season runs from December to March.

MATING:
See Dunlop (1999).

PARASITES:
ARARCHNIDA
Several mites have been recorded for this species, including *Chelanyssus aethiopicus* (Family Macronyssidae) and *Nycteriglyhus tadaridae* (Family Rosensteiniidae) (Anciaux de Faveaux, 1971; 1976a). Bat fleas (Siphonaptera) have also been recorded (Dunlop, 1999). *Lagaropsylla hoogstraali* (Ischnopsyllidae: Ischnopsyllinae) was found amongst a batch of fleas taken from *M. midas* in the Kruger National Park, South Africa in the Pafuri area (Segerman and Braack, 1988).

Argasidae
Orlova *et al.* (2024: 155) reported this species as host for *Argas vespertilionis* (Latreille, 1802).

SIPHONAPTERA
Ischnopsyllidae
Lagaropsylla hoogstraali Smit, 1957 from Rwanda (Haeselbarth *et al.*, 1966: 190), and Madagascar (Hastriter, 2016: 17).

VIRUSES:
Astroviridae
Hoarau *et al.* (2021: Suppl.) reported one Madagascan bat testing positive for viruses of this family.

Circoviridae
Vidovszky *et al.* (2023: Suppl.) found Bat associated cyclovirus 3 in a DRC bat identified as *Mops* cf. *midas*.

Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested between 1986 and 1999, for antibody to SARS-CoV in sera in 15 individuals from Limpopo Province, South Africa, none were tested positive (0/15). One out of two specimens tested by Geldenhuys *et al.* (2013: 517) in Makhado, Limpopo, RSA was found to be positive for CoV.

Positive testing bats were also reported from Madagascar by Hoarau *et al.* (2021: Suppl.).

Lane *et al.* (2022: 221) found PREDICT_CoV-114 and PREDICT_PMV-175 viruses in Ethiopian bats.

Paramyxoviridae
Mélade *et al.* (2016b: 4) tested 19 Madagascan specimens of which one was positive for paramyxoviruses.

UTILISATION:
In Madagascar, Goodman *et al.* (2008d) found that these bats were caught, cooked and then fed to domestic pigs.

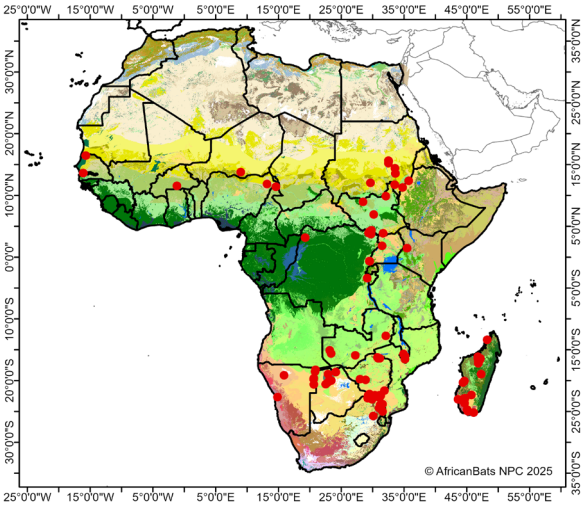

Figure 190. Distribution of *Mops (Mops) midas*.

? *Mops midas miarensis:* (Name Combination).

GENERAL DISTRIBUTION:
E, SW, S Madagascar.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Mops (Mops) midas midas (Sundevall, 1843)

*1843. *Dysopes Midas* Sundevall, Kongl. Svenska Vet.-Akad. Hand., ser 3, 30: 207, pl 2, fig 7 [for 1842]. Publication date: 1843. Type locality: Sudan: Blue Nile Province: E-bank White Nile: Valid Sohey [= Wad Shala]: restricted by Turni and Kock (2008: 68). [14 34 N 13 48 E]. [Goto Description]. Syntype: NHMUK 1846.6.2.20: ad ♂, skin and skull. Formerly Stockholm Museum (ZSM no. 523), locality: Bahr el Abiad. See Turni and Kock (2008: 68). Syntype: NRM 590521:; collection date: 1 June 1937. Syntype: NRM 630520:; collection date: 1837. Syntype: ZMB 535: skin only. Collected by: Hedenborg; collection date: 1831 - 1835. From [Dar] Sennar, Sudan; see Turni and Kock (2008: 68). Syntype: ZSM |TS237|: Collected by: Hedenborg; collection date: 1846. See Turni and Kock (2008: 68). Syntype: ZSM |TS612|: skin only. Collected by: Hedenborg; collection date: 1836. See Turni and Kock (2008: 68). - Comments: Horáček *et al.* (2000: 137) mention "Bahr-el-Abiad, White Nile" as type locality. Meester *et al.* (1986: 73): "Bahr-el-Abiad (White Nile), Sudan. Kock (1969a: 154) suggests that the type locality is at Jebel el Funj, between the White and Blue Nile, and Koopman (1975, and in litt.) restricts it to the east (not west, as shown in 1975: 429) bank of the White Nile at 11 45 N 33 30 E, Blue Nile Province, Sudan."). El-Rayah (1980: 264) believes the restriction to Jebel el Funj is incorrect as Sundevall described the type locality as Bahr el-Abiad which is the area south of Omdurman (15 19 N 32 29 E) and commonly known as Bahar Abiad and restricts the type locality to the vicinity of Jebel Aulia (15 19 N 32 31 'E). For a deeper discussion on the type locality, see Turni and Kock (2008: 68). - Etymology: According to a legend the mythological King Midas of Phrygia offended Apollo, so the god turned Midas' ears into those of a donkey, i.e. in very long ears; which in this species are relatively large (see Lanza *et al.*, 2015: 304).

? *Mops (Mops) midas midas:* (Name Combination, Current Combination).

? *Mops midas midas:* (Name Combination).

? *Tadarida midas midas:* (Name Combination).

GENERAL DISTRIBUTION:
Continental Africa; Arabia.

South Africa, South Sudan, Sudan, Uganda, Zambia, Zimbabwe.

Mops (Mops) niangarae J.A. Allen, 1917

*1917. *Mops niangaræ* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 468. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Niangara [03 24 N 27 52 E]. [Goto Description]. Holotype: AMNH 48901: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 12 December 1910; original number: 1313. - Etymology: Referring to the locality where the type specimen was found.
? *Mops (Mops) niangarae:* (Name Combination, Current Combination).
? *Mops niangarae:* (Current Spelling).
? *Tadarida congica niangarae:* (Name Combination).

TAXONOMY:
Peterson (1972) and Thorn *et al.* (2009: 68) included this species in *trevori*. Hayman and Hill (1971) listed it as a subspecies of *Tadarida congica* (= *Mops congicus*). Freeman (1981b: 111, 159) considered it a distinct species pending collection of additional specimens.

Additional studies are needed into the systematic status of *Mops niangarae*, especially with regards to its relationship to *M. trevori* (see Hayman and Hill, 1971; Peterson, 1972; Freeman, 1981b; Simmons, 2005).

COMMON NAMES:
Czech: morous niangaranský. English: Niangara Mops Bat, Niangaran Mops Bat, Niangara Free-tailed Bat. French: Tadaride du Niangara. German: Niangara-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of continuing problems with its taxonomy, and lack of recent information on its extent of occurrence, ecological requirements and threats (Mickleburgh *et al.*, 2008bq; IUCN, 2009; Mickleburgh *et al.*, 2014; Mickleburgh *et al.*, 2019l).

Martin *et al.* (2022: Suppl.) point out that this taxon is known from the holotype only, which was collected in 1917, and should possibly be considered as Critically Endangered (Possibly Extinct) or Extinct.

Assessment History
Global
2018: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2019l). 2014: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2014). 2008: DD ver 3.1 (2001) [assessed as *Tadarida niangarae*] (Mickleburgh *et al.*, 2008bq; IUCN, 2009). 2004: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2004bj; IUCN, 2004). 2002: CR B1+2c (Mickleburgh *et al.*, 2002a: 22). 1996: DD (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are currently unknown (Mickleburgh *et al.*, 2008bq; IUCN, 2009; Mickleburgh *et al.*, 2014; Mickleburgh *et al.*, 2019l).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bq) [in IUCN (2009)], Mickleburgh *et al.* (2014) and Mickleburgh *et al.* (2019l) report that it is not known if the species is present in any protected areas. Additional studies are needed into the distribution, natural history and threats to this little-known bat.

GENERAL DISTRIBUTION:
Mops niangarae is known only from the holotype collected from "Niangara, northeastern Belgian Congo" (Democratic Republic of the Congo near the border with Sudan) (Allen *et al.*, 1917; Lang and Chapin, 1917a).

Native: Congo (The Democratic Republic of the) (Allen *et al.*, 1917; Lang and Chapin, 1917a).

POPULATION:
Structure and Density
It is known only from the holotype (Mickleburgh *et al.*, 2008bq; IUCN, 2009; Mickleburgh *et al.*, 2014; Mickleburgh *et al.*, 2019l).

Trend
2018: Unknown (Mickleburgh *et al.*, 2019l). 2014: Unknown (Mickleburgh *et al.*, 2014). 2008: Unknown (Mickleburgh *et al.*, 2008bq; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Congo (Democratic Republic of the).

Mops (Mops) niveiventer Cabrera and Ruxton, 1926

*1926. *Mops angolensis niveiventer* Cabrera and Ruxton, Ann. Mag. nat. Hist., ser 9, 17 (103): 594. Publication date: 1 May 1926. Type locality: Congo (Democratic Republic of the): Kasai Occidental province: St. Joseph de Luluabourg [=Kananga] [ca. 05 53 S 22 26 E, 610 m]. [Goto Description]. Holotype: NHMUK 1926.7.6.109: ♀, skin and skull. Collection date: 16 April 1924; original number: 409.

1937. *Mops chitauensis* J.Eric Hill, Am. Mus. Novit., 916: 2, 3, text-fig 1. Publication date: 17 April 1937. Type locality: Angola: Malange district: Chitau [11 15 S 17 01 E, 4 930 ft]. [Goto Description]. Holotype: AMNH 88116: ad ♂, skin and skull. Collected by: Lee S. Bradley and the Phipps-Bradley Expedition; collection date: 10 February 1933; original number: 676.

1975. *Tadarida nivieventer:* Fenton, Life Sci. Occ. Pap., R. Ont. Mus., 104: 23. (Lapsus).

? *Mops (Mops) niveiventer:* (Name Combination, Current Combination).

? *Mops niveiventer:* (Name Combination).

? *Tadarida (Mops) niveiventer:* (Name Combination).

? *Tadarida niveiventer:* (Name Combination).

TAXONOMY:
Koopman (1993a) suggested that *niveiventer* is possibly a subspecies of *demonstrator*. Here considered a distinct species following Simmons (2005).

COMMON NAMES:
Czech: morous sněhobílý. English: White-bellied Mops Bat, White-bellied Free-tailed Bat. French: Tadaride à ventre blanc. German: Weißbauch-Bulldoggfledermaus. Portuguese: Morcego de cauda livre de ventre branco.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, tolerance of a degree of habitat modification, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Cotterill, 2008f; IUCN, 2009; Monadjem and Cotterill, 2017c).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Mops niveiventer*] (Monadjem and Cotterill, 2017c). 2008: LC ver 3.1 (2001) [assessed as *Tadarida niveiventer*] (Cotterill, 2008f; IUCN, 2009). 2004: LC ver 3.1 (2001) (Cotterill, 2004f; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is locally threatened in parts of its range, often through general deforestation and the conversion of suitable habitat by shifting agricultural practices (Cotterill, 2008f; IUCN, 2009; Monadjem and Cotterill, 2017c).

CONSERVATION ACTIONS:
Cotterill (2008f) [in IUCN (2009)] and Monadjem and Cotterill (2017c) report that there appear to be no direct conservation measures in place for this species. It is not known if the species is present within any protected areas. Further studies are needed into the distribution and systematics of this species.

GENERAL DISTRIBUTION:
Mops niveiventer is present in Central Africa and parts of Southern Africa. It has been recorded

from eastern Angola, southern Democratic Republic of the Congo, northern Zambia, Rwanda, northern Mozambique and possibly from Malawi.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 722,774 km^2.

Records from Botswana and Madagascar are definitely *condylurus* (see Hayman and Hill, 1971: 61; Meester *et al.*, 1986: 74; Simmons, 2005).

Native: Angola (Monadjem *et al.*, 2010d: 544); Burundi; Cameroon (Bol A Anong *et al.*, 2011: 48; Bakwo Fils *et al.*, 2014: 4); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 544); Mozambique (Monadjem *et al.*, 2010d: 544); Rwanda; Tanzania; Zambia (Ansell, 1973; Monadjem *et al.*, 2010d: 544).
Presence uncertain: Malawi.

The record from Cameroon is probably doubtful (Jakob Fahr, pers. comm.).

DENTAL FORMULA:
Dorst (1957b: 134) indicated the milk dentition of *Mops angolensis niveiventer* shows some differences with the dentition of *Mops angolensis* he described previously (Dorst, 1949), a fact he attributed to it being a different geographic race. However, the latter form is currently considered to belong to a separate species: *Mops (Mops) condylurus*. The upper milk toothrow of *niveiventer* consists of three functional teeth which are reduced to pegs, and two additional, vestigial teeth. In the lower toothrow there are three incisors of different shape and a remarkably developed canine. There is also one premolar, which is clearly developed, but not functional as it doesn't erupt through the gum. This tooth is resorbed in the young.

ECHOLOCATION:
From Maroua, Cameroon, Manga Mongombe (2012: 79) and Bakwo Fils *et al.* (2018: 4) reported a FM call type for 10 calls and the following parameters: F_{max}: 37.7 ± 2.9 (32.2 - 40.8) kHz, F_{min}: 34.1 ± 2.6 (29.9 - 37.6) kHz, F_{mean}: 35.9 ± 2.8 (31.1 - 39.3) kHz, F_{knee}: 37.6 ± 2.7 (32.1 - 40.8) kHZ, F_{char}: 34.1 ± 2.6 (30.1 - 37.6) kHz, and duration: 0.74 ± 0.10 (0.65 - 0.95) ms.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 20.3 kHz, F_{start}: NA kHz, F_{end}: NA kHz, Band width: NA kHz, and duration: 8.1 ms.

DIET:
In fecal pellets from Maroua (Cameroon), Bol A Anong (2013: 32) found Coleoptera (64.75%), Hemiptera (25.00%), Diptera (9.53%) and Lepidoptera (0.23%).

POPULATION:
Structure and Density
This is a locally common species that can be found in large colonies of up to hundreds of individuals within buildings, but is more often present in smaller numbers (Cotterill, 2008f; IUCN, 2009; Monadjem and Cotterill, 2017c).

Trend
2016: Unknown (Monadjem and Cotterill, 2017c).
2008: Unknown (Cotterill, 2008f; IUCN, 2009).

PARASITES:
DIPTERA
Nycteribiidae
Dick *et al.* (2023: 75) mentioned that *Nycteribia schmidlii scotti* Falcoz, 1923 has been found on *Mops niveiventer* from the DRC.

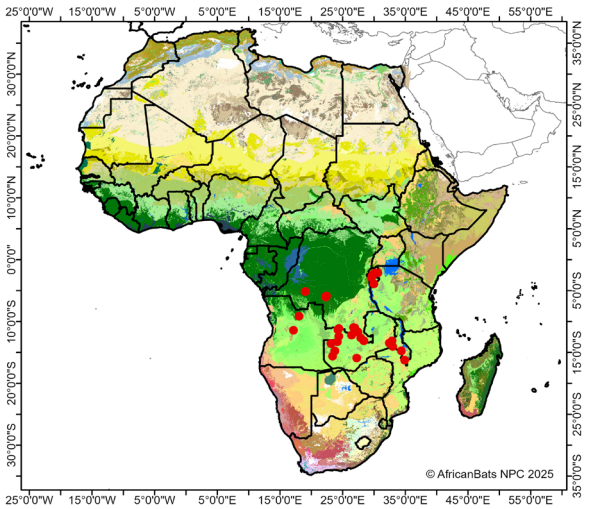

Figure 192. Distribution of *Mops (Mops) niveiventer*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Burundi, Congo (Democratic Republic of the), Malawi, Mozambique, Rwanda, Zambia, Zimbabwe.

Mops (Mops) trevori J.A. Allen, 1917

*1917. *Mops trevori* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 469, pl 48, fig 2. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Faradje [03 44 N 29 43 E]. [Goto Description]. Holotype: AMNH 49250: ad ♀, skull and alcoholic. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 29 September 1912;

original number: 1954. - Etymology: In honour of John B. Trevor, a Trustee of the American Museum of Natural History and Chairman of the Committee on African Exploration, whose enthousiasm and generosity in support of the Congo Expedition contributed to its success (see Allen, 1917: 469).
1996. *Mops trevoli:* Kityo and Kerbis, J. East Afr. Nat. Hist., 85: 63. (Lapsus).
? *Mops (Mops) trevori:* (Name Combination, Current Combination).
? *Tadarida trevori:* (Name Combination).

TAXONOMY:
Formerly included in *niangarae*; see Freeman (1981b: 111, 159).

COMMON NAMES:
Czech: morous Trevorův. English: Trevor's Mops Bat, Trevor's Free-tailed Bat, Trevor´s Bat. French: Tadaride d'Allen, Tadaride de Trevor. German: Trevors Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) since, although it has been recorded over a very wide area, there are only very few records, and very little is known about its status, threats and habitat requirements (Mickleburgh *et al.*, 2008bv; IUCN, 2009; Mickleburgh *et al.*, 2014a; Mickleburgh *et al.*, 2019e).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2018: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2019e). 2014: DD ver 3.1 (2001) [assessed as *Mops trevori*] (Mickleburgh *et al.*, 2014a). 2008: DD ver 3.1 (2001) [assessed as *Tadarida trevori*] (Mickleburgh *et al.*, 2008bv; IUCN, 2009). 2004: VU A4c ver 3.1 (2001) (Mickleburgh *et al.*, 2004aw; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is generally threatened by habitat loss, resulting from the conversion of land to agricultural use, and the extraction of firewood and timber (Mickleburgh *et al.*, 2008bv; IUCN, 2009; Mickleburgh *et al.*, 2014a; Mickleburgh *et al.*, 2019e).

Siddig (2014: 548) also mentions that the conflicts between Sudan and South Sudan, in combination with droughts play an important role.

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bv) [in IUCN (2009)], Mickleburgh *et al.* (2014a) and Mickleburgh *et al.* (2019e) who report that there appear to be no direct conservation measures in place, however, it has been recorded from some protected areas. Further studies are needed into the distribution, natural history and threats to this little-known bat.

GENERAL DISTRIBUTION:
Mops trevori has been patchily recorded in parts of West and Central Africa. In West Africa It has been recorded from Guinea, Côte d'Ivoire, Comoe in Ghana, and Agege in Nigeria. In Central Africa it has been recorded from the Central African Republic, parts of eastern Democratic Republic of the Congo and western Uganda.

Native: Central African Republic; Congo (The Democratic Republic of the); Côte d'Ivoire; Ghana; Guinea; Nigeria; Sierra Leone (Weber *et al.*, 2019: 28 - first record); Sudan; Uganda (Kityo and Kerbis, 1996: 63).

POPULATION:
Structure and Density
Little is known about the abundance of this apparently rare species, but it is presumed that colony size is likely to be small (Mickleburgh *et al.*, 2008bv; IUCN, 2009; Mickleburgh *et al.*, 2014a; Mickleburgh *et al.*, 2019e).

Trend
2018: Decreasing (Mickleburgh *et al.*, 2019e). 2014: Decreasing (Mickleburgh *et al.*, 2014a). 2008: Decreasing (Mickleburgh *et al.*, 2008bv; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
One of two females reported from Sierra Leone by Weber *et al.* (2019: 28) was pregnant on 25 March.

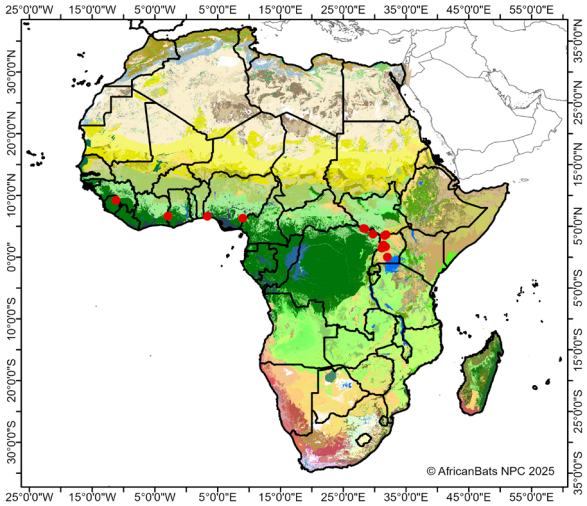

Figure 193. Distribution of *Mops (Mops) trevori*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Nigeria, Sierra Leone, South Sudan, Uganda.

Subgenus *Mops (Ornatomops)* Torrent, Garin, Aihartza, Méndez-Rodríguez, Alene and Juste, 2025

*2025. *Ornatomops* Torrent, Garin, Aihartza, Méndez-Rodríguez, Alene and Juste, Ecol. Evol., 15 (5): 6. Publication date: 14 May 2025. - Etymology: From the Latin word 'ornatus' meaning 'ornament' and and *mops* is from a Malayan word that means 'bat' (Torrent *et al.*, 2025a: 7)...

TAXONOMY:
Torrent *et al.* (2025a: 1) collected a male bat in continental Equatorial Guinea which closely resembled three female specimens of *Mops tomensis* collected on São Tomé. This species was believed to be endemic to that Gulf of Guinea island. These bats showed a major genetic and morphological likeness with *Mops gallagheri* described from the DRC (and which is known from one male specilmen). These features separated them from the other African *Mops* species and resulted in the description of this new subgenus.

Torrent *et al.* (2025a: 9) indicate that this subgenus forms a clade in between *Chaerephon* and *Mops*.

Currently recognized species of the subgenus *Ornatomops* ***gallagheri*** (Harrison,1975); ***tomensis*** (Juste and Ibañez, 1993).

GENERAL DISTRIBUTION:
This subgenus is only known from three localities in Central Africa: São Tomé Island, mainland Equatorial Guinea and the DRC (Torrent *et al.*, 2025a: 9)..

Mops (Ornatomops) gallagheri (Harrison, 1975)

*1975. *Tadarida (Chaerephon) gallagheri* Harrison, Mammalia, 39 (2): 313. Type locality: Congo (Democratic Republic of the): Kivu province: 30 km SW Kindu: Scierie Forest [03 10 S 25 46 E]. [Goto Description]. Holotype: HZM 1.7797: ♂. Collected by: Major Michael Desmond Gallagher; collection date: 14 November 1974; original number: MDB-3256. Holotype: NHMUK 1976.207: ad ♂. Collected by: Major Michael Desmond Gallagher; collection date: 14 November 1974; original number: MDG-3256. Formerly HZM 1.7797. - Etymology: In honour of Major M.D. Gallagher, the collector of the type specimen.
2020. *Mops gallagheri:* Simmons and Cirranello, BatNames.org. (Current Combination).
2025. *Mops (Ornatomops) gallagheri:* Torrent, Garin, Aihartza, Méndez-Rodríguez, Alene and Juste, Ecol. Evol., 15 (4): 6. Publication date: 14 May 2025. (Current Combination).
2025. *Mops Ornatomops gallagheri:* Torrent, Garin, Aihartza, Méndez-Rodríguez, Alene and Juste, Ecol. Evol., 15 (5): 6. Publication date: 14 May 2025. (Lapsus).
? *Chaerephon gallagheri:* (Name Combination).
? *Mops (Chaerephon) gallagheri:* (Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: morous kivuský. English: Gallagher's Wrinkle-lipped Bat, Gallagher's Free-tailed Bat, Zaïre Gland-tailed Bat. French: Tadaride de

Gallagher, Molosse du Zaïre. German: Gallaghers Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status (Mickleburgh *et al.*, 2008ag; IUCN, 2009; Mickleburgh *et al.*, 2019c).

Assessment History
Global
2018: DD ver 3.1 (2001) assessed as "*Chaerephon gallagheri*" (Mickleburgh *et al.*, 2019c). 2008: DD ver 3.1 (2001) assessed as "*Tadarida gallagheri*" (Mickleburgh *et al.*, 2008ag; IUCN, 2009). 2004: CR D ver 3.1 (2001) (Mickleburgh *et al.*, 2004ai; IUCN, 2004). 2002: CR: B1+2c (Mickleburgh *et al.*, 2002a: 22). 1996: CE (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are unclear. It may be threatened by habitat loss, through the conversion of forest to agricultural use and timber extraction, however, this needs to be confirmed (Mickleburgh *et al.*, 2008ag; IUCN, 2009; Mickleburgh *et al.*, 2019c).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ag) [in IUCN (2009)] and Mickleburgh *et al.* (2019c) report that there are no direct conservation measures in place for this species. It is not known if the species is present within any protected areas. Additional studies are needed into the distribution, abundance, natural history and threats to this poorly known species.

GENERAL DISTRIBUTION:
Mops gallagheri has only been recorded from the type locality of 'Scierie Forest, 30 km of southwest Kindu, Kivu' in the Democratic Republic of the Congo. It may range more widely distributed, however, other surveys in the general area have not recorded this species.

Native: Congo (The Democratic Republic of the) (Gallagher and Harrison, 1977; Harrison, 1975a).

POPULATION:
Structure and Density
There is little information on the abundance of this species (Mickleburgh *et al.*, 2008ag; IUCN, 2009; Mickleburgh *et al.*, 2019c).

Trend
2018: Unknown (Mickleburgh *et al.*, 2019c). 2008: Unknown (Mickleburgh *et al.*, 2008ag; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Congo (Democratic Republic of the).

Mops (Ornatomops) tomensis (Juste and Ibáñez, 1993)

*1993. *Tadarida (Chaerephon) tomensis* Juste and Ibáñez, J. Mamm., 74 (4): 901, figs 1 - 2. Publication date: November 1993. Type locality: São Tomé and Príncipe: São Tomé Island: 3 km NW Guadalupe: Praia das Conchas [00 24 N 06 37 E]. [Goto Description]. Holotype: EBD 18256M: ♀, complete skeleton. Collected by: Javier Juste and Antonio Ayong; collection date: 22 April 1988; original number: B7085. Paratype: EBD 17371M: ♀. Collected by: Javier Juste and Carlos J. Ibáñez Uargui; collection date: 11 April 1988. From Agua Izé. Paratype: EBD 17734M: ♀. Collected by: Javier Juste and Antonio Ayong; collection date: 22 April 1988. - Etymology: Referring to the island of São Tomé, where the species occurs.
2020. *Mops tomensis:* Simmons and Cirranello, BatNames.org. (Current Combination).
2025. *Mops (Ornatomops) tomensis:* Torrent, Garin, Aihartza, Méndez-Rodríguez, Alene and Juste, Ecol. Evol., 15 (5): 7. Publication date: 14 May 2025. (Current Combination).
2025. *Mops Ornatomops tomensis:* Torrent, Garin, Aihartza, Méndez-Rodríguez, Alene and Juste, Ecol. Evol., 15 (5): 7. Publication date: 14 May 2025. (Lapsus).
? *Chaerephon tomensis:* (Name Combination).
? *Mops (Chaerephon) tomensis:* (Current Combination).
? *Tadarida tomensis:* (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: morous tomášský. English: São Tomé Free-tailed Bat. French: Tadaride de São Tomé. German: São Tomé-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Endangered (EN B1ab(iii) ver 3.1 (2001)) because its extent of occurrence is less than 1000 km^2 (933 km^2), all individuals are in a single location (the island of São Tomé). There is continuing decline in the extent and quality of its lowland habitat (Mickleburgh *et al.*, 2008dl; IUCN, 2009), mainly due to coastal development, including tourism activities, conversion of land to agricultural use and possible port construction (Monadjem *et al.*, 2019d).

Assessment History
Global
2016: EN B1ab(iii) ver 3.1 (2001) assessed as "*Chaerephon tomensis*" (Monadjem *et al.*, 2019d). 2008: EN B1ab(iii) ver 3.1 (2001) assessed as "*Tadarida tomensis*" (Mickleburgh *et al.*, 2008dl; IUCN, 2009). 2004: CR B1ab(I,iii) ver 3.1 (2001) (Mickleburgh *et al.*, 2004cy; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The species is believed to be threatened by general habitat loss resulting from coastal development, including tourism activities, conversion of land to agricultural use and possible port construction. The possible impact of recent oil extraction activities near the cost is of concern (Monadjem *et al.*, 2019d). The species may be competing with the much more abundant species *Mops pumilus* (J. Juste *pers. comm.,* 2008 in Mickleburgh *et al.*, 2008dl in IUCN, 2009), with further studies into this relationship needed (Mickleburgh *et al.*, 2008dl; IUCN, 2009; Monadjem *et al.*, 2019d)..

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008dl) [in IUCN (2009)] and Monadjem *et al.* (2019d) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed into the distribution, natural history and threats to this species.

GENERAL DISTRIBUTION:
Mops tomensis has been recorded from two lowland localities, Praia das Conchas (3 km NW of Guadalupe) and Agua Izé, in the northern part of São Tomé Island, of São Tomé and Príncipe. Extensive surveys have not located the species elsewhere on the island.

Native: São Tomé and Príncipe [São Tomé] (Rainho *et al.*, 2010a: 40).

ECHOLOCATION:
Rainho *et al.* (2022: 605) reported the following parameters for 26 calls from Sáo Tomé tentatively assigned to this species: F_{min}: 21.0 ± 1.1 (19.0 - 22.4) kHz, F_{max}: 23.0 ± 1.1 (20.4 - 25.5) kHz, F_{maxE}: 22.1 ± 1.0 (19.9 - 24.1) kHz, duration: 16.3 ± 1.7 (12.7 - 19.9) ms and interpulse interval: 350.7 ± 97.2 (137.0 - 558.5) ms.

HABITAT:
On São Tomé, Castro-Fernandes *et al.* (2024: 2) reported this species to be an open-space forager.

POPULATION:
Structure and Density
It seems to be a very rare species that, despite considerable trapping effort, is currently only known from the type series of three specimens (Mickleburgh *et al.*, 2008dl [in IUCN, 2009]; Monadjem *et al.*, 2019d; Rainho *et al.*, 2022: 607).

Trend
2016: Decreasing (Monadjem *et al.*, 2019d). 2008: Decreasing (Mickleburgh *et al.*, 2008dl; IUCN, 2009).

Stanley; collection date: 5 - 6 August 2006; original number: WTS 7334. - Etymology: In honour of Dr. Bakari Asseid, director of the Department of Commercial Crops, Fruits and Forestry, Zanzibar, to recognize his significant contributions to the conservation of natural habitats and biota of Zanzibar (including both Pemba and Unguja Islands) (see Stanley, 2008: 185).

? *Mops (Xiphonycteris) bakarii:* (Name Combination, Current Combination).

COMMON NAMES:
Czech: morous Stanleyův. German: Bakaris Bulldoggfledermaus, Pemba-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Shapiro (2017) report this species is listed as Data Deficient due to only one known locality and lack of further data, while population size is not known.

Assessment History
Global
2016: DD ver. 3.1 (2001) [assessed as *Mops bakarii*] (Shapiro, 2017).

Regional
None known.

MAJOR THREATS:
Specific threats to this species are known at present (Shapiro, 2017).

CONSERVATION ACTIONS:
Shapiro (2017) report there are no specific conservation measures are in place for this species.

GENERAL DISTRIBUTION:
O'Brien (2011: 288) reports it from Pemba.

POPULATION:
Structure and Density
There is no information about the species population size and population trend (Shapiro, 2017).

Trend
2016: Unknown (Shapiro, 2017).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Tanzania.

Mops (Xiphonycteris) brachypterus (Peters, 1852)

*1852. *Dysopes brachypterus* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 59, pl 15, fig 1. Publication date: 1852. Type locality: Mozambique: Mozambique Island [15 03 S 40 46 E]. [Goto Description]. Holotype: ZMB 536/85537: ad ♂, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008) [skin: ZMB 536 + skull: ZMB 85537 (=An 16356)]. Neotype: ROM 46721: ad ♂, skin and skull. Collected by: Terence Michael Shortt and A.E. Williams; collection date: 24 June 1968; original number: SG301. - Etymology: From the Greek adjective "*βραχύς*" (brakhìs), meaning "short" and the Greek neuter substantive "*πτερόν*" (pteròn), meaning "wing"; but actually the species' wings are not particularly short (see Lanza *et al.*, 2015: 295).

1877. *Nyctinomus [(Nyctinomus)] brachypterus:* Dobson, Proc. zool. Soc. Lond., 1876, IV: 722. Publication date: April 1877. (Name Combination).

1908. *Nyctinomus leonis* Thomas, Ann. Mag. nat. Hist., ser 8, 2 (10): 373. Publication date: 1 October 1908. Type locality: Sierra Leone: "Sierra Leone". [Goto Description]. Holotype: NHMUK 1862.12.23.3: ad ♂, skin and skull. Presented/Donated by: J. Brown Esq. (Specimen "c" of Dobson's catalogue).

1917. *Nyctinomus ochraceus* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 455. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Medje [02 25 N 27 18 E, 800 m]. [Goto Description]. Holotype: AMNH 48821: ad ♀, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 16 March 1910; original number: 745.

1939. *Mops leonis:* G.M. Allen, Bull. Mus. comp. Zool., 83: 108. Publication date: February 1939. (Name Combination).

1980. *Tadarida (Mops) brachyptera:* El-Rayah, Systematics of African molossid bats of the subgenus *Xiphonycteris* of the genus *Tadarida* (Molossidae: Chiroptera) - PhD Thesis - University of Toronto:, 231.

? *Chaerephon leonis ochraeus:*

? *Mops (Xiphonycteris) brachypterus:* (Name Combination, Current Combination).
? *Mops brachypterus leonis:* (Name Combination).
? *Mops brachypterus ochraceus:* (Name Combination).
? *Mops brachypterus:* (Name Combination).
? *Tadarida brachyptera leonis:* (Name Combination).
? *Tadarida brachyptera:* (Name Combination).
? *Tadarida leonis leonis:*
? *Tadarida leonis ochraeus:*
? *Tadaride brachyptera:* (Name Combination).
? *Xiphonycteris leonis:*

TAXONOMY:
Includes *leonis*; see El-Rayah (1981: 6). Stanley (2008: 190) points out that *brachypterus* is in need of revision, since the dental features (e.g., size of upper canines and first upper premolar) differ between for the holotype and continental specimens attributed to it.

Monadjem *et al.* (2016y: 368) and Herkt *et al.* (2017: Appendix S9) found differences in the ecological niches and a clear geographic gap between the distribution areas of *brachypterus* and *leonis sensu stricto*, but as genetic tests evaluating the distinct species status are still lacking, they are still considered to represent the same species.

COMMON NAMES:
Castilian (Spain): Murciélago Guanero. Chinese: 短翼犬吻蝠. Czech: morous krátkokřídlý. English: Sierra Leone Mops Bat, Short-winged Mops Bat, Sierra Leone Free-tailed Bat, White-fingered Free-tailed Bat. French: Tadaride de Peters, Tadaride à doigts blancs. German: Kurzflügel-Bulldoggfledermaus, Kurzflügeligen Doggengrämler. Italian: Carlìno brachìttero.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bo; IUCN, 2009; Monadjem *et al.*, 2017az).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Mops brachypterus*] (Monadjem *et al.*, 2017az). 2008: LC ver 3.1 (2001) [assessed as *Tadarida brachyptera*] (Mickleburgh *et al.*, 2008bo; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessed as *Mops brachypterus*] (Mickleburgh *et al.*, 2004bo; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The species is threatened in parts of its range by deforestation, presumably mostly through logging and mining activities and the conversion of land to agricultural use (Mickleburgh *et al.*, 2008bo; IUCN, 2009; Monadjem *et al.*, 2017az).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bo) [in IUCN (2009)] and Monadjem *et al.* (2017az) report that it is not known if the species is present in any protected areas. Further studies are needed into the taxonomy, distribution, natural history, and threats to this species.

GENERAL DISTRIBUTION:
Mops brachypterus ranges widely from West Africa to the East African coast. In West Africa, it is distributed from the Gambia and Sierra Leone in the west, through to Nigeria and Cameroon in the east. From Cameroon, it occurs patchily eastwards through the Congo Basin to Uganda, and to coastal parts of Kenya, Tanzania (including the islands of Unguja [=Zanzibar] [where its presence is questioned according to O'Brien (2011: 289)] and Mafia) and Mozambique in the south.

Native: Cameroon; Central African Republic; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 543); Côte d'Ivoire; Equatorial Guinea; Gabon; Ghana; Guinea (Simons *et al.*, 2014: 284); Kenya; Liberia; Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 543); Nigeria; Sierra Leone; Tanzania; Togo.

Presence uncertain: Zanzibar (Stanley, 2008: 191).

Bates *et al.* (2013: 339) reject the presence of this species in the Republic of Congo.

MOLECULAR BIOLOGY:
Karyotype
Smith *et al.* (1986) described the karyotype as having a diploid number of 2*n* = 48, aFN = 54, BA = 8, and a presumably submetacentric X (one female studied).

HABITAT:
Monadjem *et al.* (2016y: 368) captured this bat flying over small forest streams in the Mount Nimba area, at altitudes between 450 and 550 m.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure and Density
This is a common species (Mickleburgh *et al.*, 2008bo; IUCN, 2009; Monadjem *et al.*, 2017az).

Trend
2016: Unknown (Monadjem *et al.*, 2017az).
2008: Unknown (Mickleburgh *et al.*, 2008bo; IUCN, 2009).

PARASITES:
Apanaskevich and Tomlinson (2020: 602) described a new tick (*Haemaphysalis latitudinis* (Ixodidae) from multiple hosts, including a *Mops brachypterus* from Adiopodoumé, Côte d(Ivoire.

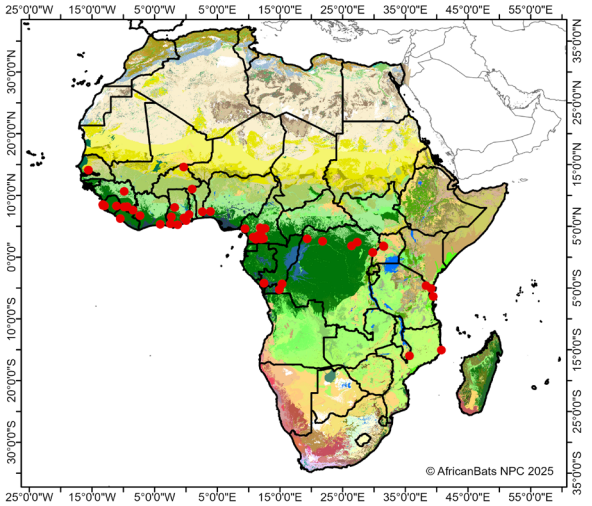

Figure 197. Distribution of *Mops (Xiphonycteris) brachypterus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Benin, Burkina Faso, Cameroon, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Guinea, Liberia, Malawi, Mozambique, Nigeria, Rwanda, Senegal, Sierra Leone, Tanzania, Uganda.

Mops (Xiphonycteris) nanulus J.A. Allen, 1917

*1917. *Mops (Allomops) nanulus* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 477. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Niangara [03 24 N 27 52 E]. [Goto Description]. Holotype: AMNH 48864: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 12 December 1910; original number: 1318. Topotype: AMNH 48860: ♀, skin and skull. ? *Mops nanulus:* (Name Combination).
? *Tadarida nanula calabarensis:* (Name Combination).
? *Tadarida nanula:* (Name Combination).

TAXONOMY:
Distinction from *spurrelli* not certain; see Koopman (1989a).

COMMON NAMES:
Chinese: 侏犬吻蝠. Czech: morous trpasličí. English: Dwarf Mops Bat, Dwarf Free-tailed Bat. French: Tadaride naine. German: Zwerg-Bulldoggfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008w; IUCN, 2009; Monadjem *et al.*, 2017l).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Mops nanulus*] (Monadjem *et al.*, 2017l). 2008: LC ver 3.1 (2001) [assessed as *Tadarida nanula*] (Mickleburgh *et al.*, 2008w; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004o; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
In general, there are no threats to this widespread and somewhat adaptable species. In parts of its range it is locally threatened by habitat loss, primarily deforestation resulting from logging operations and the conversion of land to agricultural use (Mickleburgh *et al.*, 2008w; IUCN, 2009; Monadjem *et al.*, 2017l).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008w) [in IUCN (2009)] and Monadjem *et al.* (2017l) report that it is not known if the species is present in any protected areas. Further studies are needed into the distribution, abundance, natural history, and threats to this species.

GENERAL DISTRIBUTION:
Mops nanulus is widely, but patchily, recorded in West, Central and East Africa. It ranges from Sierra Leone and Guinea in the west, through West Africa to Cameroon, and from here east to southern Sudan, Uganda, and western Kenya with an additional record from western Ethiopia and as far south as the southern portion of the Democratic Republic of the Congo. Start (1969: 222) suggests that the species' range might have been more continuous during the Pleistocene when there was a higher degree of rainfall, resulting in a continuous belt of lowland forest between Congo and Kenya.

Native: Benin (Capo-Chichi *et al.*, 2004: 163); Cameroon; Congo (The Democratic Republic of the) (Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 544); Côte d'Ivoire; Ethiopia; Gambia (Emms and Barnett, 2005: 50; Simmons, 2005); Ghana; Guinea (Fahr *et al.*, 2006a: 73; Decher *et al.*, 2016: 276); Kenya (Start, 1969: 220); Liberia (Fahr, 2007a: 104); Nigeria; Sierra Leone; Sudan; Uganda.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Start (1969: 221) indicates that there appears to be a general cline from pale-winged red forms in the west to dark-winged brown ones in the east, although this is not absolute.

MOLECULAR BIOLOGY:
Karyotype
Smith *et al.* (1986) reported 2*n* = 48, FN = 54, BA = 8, a submetacentric X chromosome and an acrocentric Y chromosome.

POPULATION:
Structure and Density
This is a common species (Mickleburgh *et al.*, 2008w; IUCN, 2009; Monadjem *et al.*, 2017l).

Trend
2016: Unknown (Monadjem *et al.*, 2017l). 2008: Unknown (Mickleburgh *et al.*, 2008w; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Start (1969: 221) reports on six female specimens collected in West Pokot (Kenya) between 25 and 29 August 1967, of which five were carrying well developed embryos, whereas the sixth was lactating.

Weber *et al.* (2019: 28) reported one pregnant female from Sierra Leone on 26 March.

Krutzsch (2000: 127) indicates that "*Tadarida (Mops) nanulus*" is polyoestrous.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Benin, Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Ethiopia, Gabon, Ghana, Guinea, Kenya, Nigeria, Sierra Leone, South Sudan, Togo, Uganda.

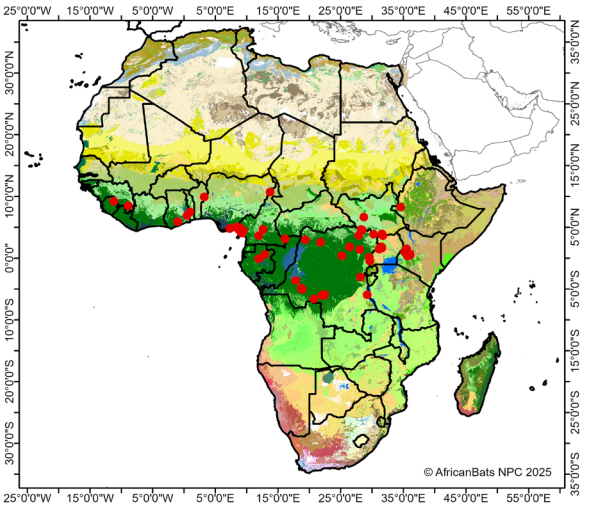

Figure 198. Distribution of *Mops (Xiphonycteris) nanulus*.

Mops (Xiphonycteris) petersoni (El Rayah, 1981)

*1981. *Tadarida [(Xiphonycteris)] petersoni* El Rayah, Life Sci. Occ. Pap., R. Ont. Mus., 36: 3, figs 1 - 2. Publication date: 11 December 1981. Type locality: Cameroon: Kumba, 15 km S [04 39 N 09 26 E]. [Goto Description]. Holotype: ROM 55813: ad ♂, skull and alcoholic. Collected by: Randolph Lee Peterson; collection date: 27 January 1970; original number: 0364. See El-Rayah (1981: 3). Paratype: AMNH 236332: ♂, skin and skull. 6 km SE Eseka(03°35'N 10°44'E) (See El-Rayah, 1981: 3). Paratype: AMNH 236333: ♂, skin and skull. 6 km SE Eseka(03°35'N 10°44'E) (see: El-Rayah, 1981: 3). Paratype: AMNH 241075: ♂, skin and skull. Near Okola (04°00'N 11°33'E) (see El-Rayah, 1981: 3). Paratype: AMNH 241076: ♂, skin and skull. 30 km E Nanga Emboko (04°38'N 12°21'E) (see El-Rayah, 1981: 3). Paratype: AMNH 241078: ♀, skin and skull. 30 km E Nanga Emboko (04°38'N 12°21'E) (see El-Rayah, 1981: 3). - Etymology: In honour of Randolph L. Peterson, collector of the type specimen.

? *Mops (Xiphonycteris) petersoni:* (Name Combination, Current Combination).

? *Mops petersoni:* (Name Combination).

? *Tadarida petersoni:* (Name Combination).

TAXONOMY:

Described in *Tadarida (Xiphonycteris)*, but see comments under *Tadarida* and *Mops*.

COMMON NAMES:

Czech: morous kamerunský. English: Peterson's Mops Bat, Peterson's Free-tailed Bat. French: Tadaride de Peterson. German: Petersons Bulldoggfledermaus.

CONSERVATION STATUS:

Global Justification

Listed as Near Threatened because this species is likely in significant decline (but probably at a rate of less than 30% over a 15 year period; i.e., three generations) because of ongoing loss of its primary forest habitat, which makes the species close to qualifying for Vulnerable (Mickleburgh *et al.*, 2010).

Assessment History

Global

2021: NT A2c ver 3.1 [assessed as *Mops petersoni*] (Bakwo Fils *et al.*, 2021a). 2010: NT ver 3.1 (2001) [assessed as *Mops petersoni*] (Mickleburgh *et al.*, 2010). 2008: VU A4c ver 3.1 (2001) [assessed as *Tadarida petersoni*] (Mickleburgh *et al.*, 2008bt; IUCN, 2009). 2004: VU A4c ver 3.1 (2001) (Mickleburgh *et al.*, 2004av; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional

None known.

MAJOR THREATS:

The species is considered to be threatened by loss and degradation of forest habitats within its known range, largely through the conversion of land to agricultural use and the extraction of firewood and timber (Mickleburgh *et al.*, 2008bt; IUCN, 2009; Mickleburgh *et al.*, 2010).

CONSERVATION ACTIONS:

Mickleburgh *et al.* (2010) and Bakwo Fils *et al.* (2021a: 5) repeat what was stated by Mickleburgh *et al.* (2008bt) [in IUCN (2009)] who report that there appear to be no direct conservation measures in place for this species. It is not known if the species is present within any protected areas. There is a need to maintain areas of suitable forest within the range of this species. Further studies are needed into the distribution, abundance, breeding biology and general ecology of this species.

GENERAL DISTRIBUTION:

Mops petersoni has only been recorded from Ghana and Cameroon (with type locality at '15 km S Kumba'), with no records from the intervening countries of Togo, Benin and Nigeria. Koopman (1993a) included "perhaps Sierra Leone" as part of the distribution, however, J. Fahr (*pers. comm.*, 2004 in Mickleburgh *et al.*, 2008bt; IUCN, 2009) indicates that there is no evidence of the species' presence. The specimen involved was re-identified as belonging to *Mops brachypterus*.

Native: Cameroon; Ghana.

Presence uncertain: Sierra Leone (Koopman, 1993a).

MOLECULAR BIOLOGY:

Karyotype

Smith *et al.* (1986) reported 2*n* = 48, FN = 54, BA = 8, a submetacentric X chromosome and an acrocentric Y chromosome.

HABITAT:

This species is only from rainforest (Bakwo Fils *et al.*, 2021a: 5), and possibly entering the Northern Rainforest–Savanna Mosaic (Happold, 2013cf: 526).

POPULATION:

Structure and Density

It is considered to be a very rare species (Mickleburgh *et al.*, 2008bt; IUCN, 2009; Mickleburgh *et al.*, 2010).

Trend
2021: Decreasing (Bakwo Fils *et al.*, 2021a). 2010: Unknown (Mickleburgh *et al.*, 2010). 2008: Unknown (Mickleburgh *et al.*, 2008bt; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Cameroon, Ghana.

Regional
None known.

MAJOR THREATS:
The species is locally threatened by deforestation, often through conversion of land to agricultural use or by extraction of timber and firewood (Mickleburgh *et al.*, 2008dm; IUCN, 2009; Monadjem *et al.*, 2017ak).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008dm) [in IUCN (2009)] and Monadjem *et al.* (2017ak) report that there appear to be no direct conservation measures in place for this species, and it is not known if the species is present within any protected areas. There is a need to maintain areas of suitable forest habitat for this species. Additional studies are needed into the distribution of this species.

GENERAL DISTRIBUTION:
Mops spurrelli ranges through parts of West and Central Africa. It occurs from Sierra Leone in the west, through Liberia, Guinea, Côte d'Ivoire and Togo, to Cameroon, Equatorial Guinea (Bioko and Rio Muni), the Central African Republic with

a record from the eastern part of The Democratic Republic of the Congo. It is possibly present in other countries, such as Benin, Nigeria and Congo, however, this needs to be confirmed.

Native: Cameroon; Central African Republic; Congo (The Democratic Republic of the); Côte d'Ivoire; Equatorial Guinea (Bioko); Ghana; Guinea (Fahr and Ebigbo, 2003: 128); Liberia; Sierra Leone; Togo.

Presence uncertain: Benin; Congo; Nigeria.

MOLECULAR BIOLOGY:
Karyotype
Smith *et al.* (1986) reported 2*n* = 48, FN = 64, BA = 18, a submetacentric X chromosome for a female.

HABITAT:
At Mount Nimba, Monadjem *et al.* (2016y: 368) recorded this species over small streams and swamps at altitudes between 450 and 600 m.

POPULATION:
Structure and Density
Within Central Africa this is a very common species and is believed to have quite large colonies (Mickleburgh *et al.*, 2008dm; IUCN, 2009; Monadjem *et al.*, 2017ak).

Trend
2016: Unknown (Monadjem *et al.*, 2017ak). 2008: Unknown (Mickleburgh *et al.*, 2008dm; IUCN, 2009).

COMMON NAMES:
Chinese: 无畏犬吻蝠. Czech: morous spílavý. English: Railer Mops Bat, Railer Bat. French: Tadaride de Railer. German: Thersites' Bulldoggfledermaus. Portuguese: Morcego de railer.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Gunnell *et al.* (2015a: 22) report on a number of humeri from a Pleistocene deposit at Olduvai Gorge (Tanzania), which they assigned to *Mops* cf. *M. thersites*.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, tolerance of a degree of habitat modification, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008dn; IUCN, 2009; Monadjem *et al.*, 2017al).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Mops thersites*] (Monadjem *et al.*, 2017al). 2008: LC ver 3.1 (2001) [assessed as *Tadarida thersites*] (Mickleburgh *et al.*, 2008dn; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004cl; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It is locally threatened by habitat destruction, often through conversion of land to agricultural use or timber extraction (Mickleburgh *et al.*, 2008dn; IUCN, 2009; Monadjem *et al.*, 2017al).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008dn) [in IUCN (2009)] and Monadjem *et al.* (2017al) report that there appear to be no direct conservation measures in place for this species. It is not known if the species is present within any protected areas. Additional studies are needed into the distribution of this species.

GENERAL DISTRIBUTION:
Mops thersites has been recorded from much of Western and Central Africa. It ranges from Sierra Leone in the west, through West Africa (where it has been recorded from most countries) to Cameroon, and from here south into southern parts of the Democratic Republic of the Congo, and east into Uganda, Rwanda and western Kenya. It is present on Bioko Island, Equatorial Guinea.

Native: Cameroon; Central African Republic; Congo (The Democratic Republic of the) (Schouteden, 1944; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 544); Côte d'Ivoire; Equatorial Guinea [Bioko]; Gabon; Ghana; Guinea (Fahr *et al.*, 2006b: 245; Denys *et al.*, 2013: 284); Kenya; Liberia (Fahr, 2007a: 104); Nigeria; Rwanda; Sierra Leone; Uganda.

Presence uncertain: Mozambique and Zanzibar.

Bates *et al.* (2013: 339) reject the presence of this species in the Republic of Congo as Malbrant and Maclatchy (1949) only suggested it might occur in that country and subsequent authors did not provide supporting records.

MOLECULAR BIOLOGY:
Karyotype
Denys *et al.* (2013: 284) report the karyotype for a single female specimen from the Guinean Mount Nimba area attributed to this species as: 2*n* = 48, NFa = 70, including four pairs of metacentric, eight pairs of subtelocentric, 11 pairs of acrocentric autosomes and a middle-sized submetacentric X chromosome.

HABITAT:
This species was captured by Monadjem *et al.* (2016y: 368) in the Mount Nimba area above water in forested and open habitats between 450 and 880 m.

In the Yapi Daniel private forest (Côte d'Ivoire), this bat was the most abundant species in the wetland area (Kadjo *et al.*, 2021: 26).

POPULATION:
Structure and Density
It appears to be quite abundant in parts of its range (Mickleburgh *et al.*, 2008dn; IUCN, 2009; Monadjem *et al.*, 2017al).

Trend
2016: Stable (Monadjem *et al.*, 2017al). 2008: Stable (Mickleburgh *et al.*, 2008dn; IUCN, 2009).

PARASITES:
HEMIPTERA
Polyctenidae
Hypoctenes clarus Jordan, 1922, from near Kribi, Cameroon and Ghana (Haeselbarth *et al.*, 1966: 18; Szentiványi *et al.*, 2022: 6).

SIPHONAPTERA
Ischnopsyllidae
Lagaropsylla oblique Smit, 1957 from Sierra Leone, Cameroon and the Congo (Haeselbarth *et al.*, 1966: 191).

VIRUSES:
Filoviridae - File viruses
Marburgvirus
Weiß (2013: 58, 66) found antibodies against MARV in one *M. thersites* from the Taï National Park (Côte d'Ivoire).

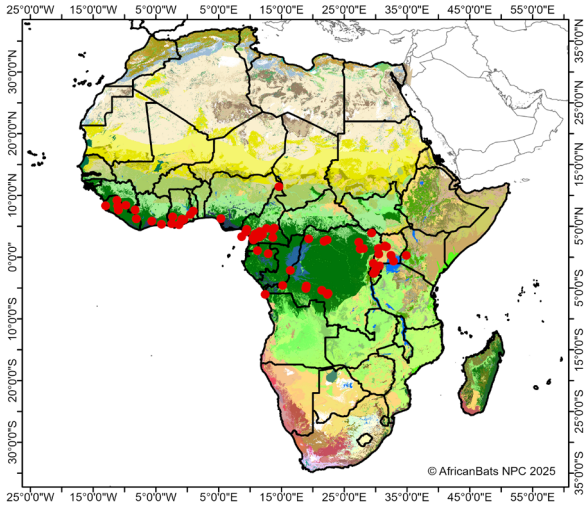

Figure 201. Distribution of *Mops (Xiphonycteris) thersites*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Gabon, Ghana, Guinea, Kenya, Liberia, Nigeria, Rwanda, Sierra Leone, Togo, Uganda.

Genus ***Mormopterus*** Peters, 1865

*1866. *Mormopterus* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 1865: 258. - Comments: Type species: *Nyctinomus (Mormopterus) jugularis* Peters, 1865. - Etymology: From the Greek "*mormopterus*" meaning phantom- or ghost-winged or winged goblin (Flannery, 1990: 367; 1995a: 408). - Phonetics: morm-op'-te-rus, morm-op-ter'-us. (Current Combination).
? *Tadarida (Mormopterus):* (Name Combination).

TAXONOMY:
Meester *et al.* (1986) state that this treatment of *Mormopterus* is provisional; it has been regarded as a subgenus of *Tadarida* (Hayman and Hill, 1971) or as a valid genus that includes *Platymops* and *Sauromys* as subgenera (Freeman, 1981b; Legendre, 1984), and the extralimital *Micronomus* as either a subgenus (Legendre loc. cit.) or a synonym (Freeman, 1981b; Peterson, 1985).

Bronner *et al.* (2003) mention that the status of *Sauromys*, described as a monotypic subgenus of the extralimital (to southern Africa) *Platymops* for the South African flat-headed free-tailed bat, remains unclear. Peterson (1965) raised it to generic rank, a treatment endorsed by many subsequent authors, and corroborated by a limited multivariate analysis of wing bone and cranial characteristics (Peterson, 1985). However, morphometric studies by Freeman (1981b) and Legendre (1984) concluded that it is a subgenus of *Mormopterus*, a position followed by Koopman (1993a, 1994). Simmons (2005) retains *Sauromys* as a valid genus in the 3rd Edition of Mammal Species of the World, a treatment we favour because of the unique ecology and morphology of *S. petrophilus*. The separation between *Mormopterus* and *Sauromys* is also supported by the analysis of the Rag2 data by Ammerman *et al.* (2013: 309).

Meester *et al.* (1986) furthermore state that it was originally described as a subgenus, but this genus was regarded as a synonym of *Platymops* by Shortridge (1942), Roberts (1951) and Ellerman *et al.* (1953). Harrison (1962) retains it as a subgenus, while Peterson (1965) raises it to generic rank, in which he is followed by Hayman and Hill (1971), Smithers (1971), Corbet and Hill (1980) and Rautenbach (1982). However, Freeman (1981b), followed by Koopman (1982) and Legendre (1984), conclude that both *Sauromys* and *Platymops* are subgenera of *Mormopterus*. We take the view that both *Platymops* and *Sauromys* are valid genera.

From their molecular study, Lamb *et al.* (2010: 203; 2011: 10) found that *M. jugularis* and *M. francoismoutoui* form a monophyletic clade (dated about 31.2 MYR), whereas a third member of the genus (the New World *M. kalinowskii*) seems more related to the South American *Nyctinomops laticaudatus* and *Nyctinomops aurispinosus*.

Goodman *et al.* (2022: 1904) indicate that as *jugularis* was the first species associated with the genus *Mormopterus* this genus name should be restricted to the species occurring in the western Indian Ocean area (= Malagasy region).

The analysis of the recombination activating gene 2 (Rag2) sequence data led Ammerman *et al.* (2013: 307) to conclude that the genus *Cheiromeles* is the most basal lineage within the

Molossinae, and that *Mormopterus* is a sistergroup of the rest of the Molossinae.

Key in Jacobs and Fenton (2002, Mammalian Species, 703).

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Mormopterus*: ***acetabulous*** (Hermann, 1804); *doriae* K. Andersen, 1907 – Sumatra (Indonesia) (Simmons, 2005: 445); ***francoismoutoui*** Goodman, Jansen Van Vuuren, Ratrimomanarivo, Probst and Bowie, 2008; ***jugularis*** (Peters, 1865); *kalinowskii* (Thomas, 1893) – Peru, northern Chile (Simmons, 2005: 445); *minutus* (Miller, 1899) – Cuba (Simmons, 2005: 445); *phrudus* Handley, 1956 – Peru (Simmons, 2005: 4435).

COMMON NAMES:
Czech: Petersovi morousi. English: Phantom-winged Bats, Little Bulldog Bats, Little Mastiff Bats, Little Goblin Bats, Flat-headed Bats, Flat-headed Bulldog Bats, Goblin bats. French: Tadarides. German: Mastino-Fledermäuse.

PARASITES:

Mormopterus acetabulosus (Hermann, 1804)

*1804. *V[espertilio] acetabulosus* Hermann, Obs. Zool. , 19. Publication date: 31 August 1804. Type locality: Mauritius: Port Louis. [Goto Description]. Holotype: MNHN ZM-MO-1984-368: ad? ♀. Collected by: Julien François Desjardins; collection date: 1829; original number: A488. Goodman *et al.* (2008c: 1324) incidcate that the specimen is labeled as type, but was collected 25 years after Hermann (1804) described it. Neotype: FMNH 187489: Collected by: Steven M. Goodman and V. Florens; collection date: 29 October 2006. Mauritius, Black River District, Palma, Palma Cave, 20 16'40.5"S 57 27'14.7"E. Goodman *et al.* (2008c: 1327) designated this as the neotype. Cheke (2009b) rejects the assignment of the neotype by Goodman *et al.* (2008c), based on article 73.1.4 and 75.8 (rules of Nomenclature - ICZN 1999). - Comments: Cheke (2009b: 1) rejects the assignment of the neotype, based on article 73.1.4 (rules of Nomenclature - ICZN 1999), which indicates that Paul Jossigny's drawings made of the specimen that Commerson once had before him in Mauritius should be considered the holotype of Hermann's *Vespertilio acetabulosus*, and that the designation of a neotype by Goodman *et al.* (2008c: 1324) is invalidated by article 75.8. The drawings on which Commerson based himself (and which were referred to by Hermann, 1804: 19) are to be found amongst the Commerson papers, in the folder of other similar drawings at MS 282(II), labelled No. 51 (Moutou, 1982, pers. obs. 2006) in the archives of the Bibiothèque du Muséum; the folder is described in paragraph 73 of Laissus's (1974) catalogue.
1820. *Nyctinomus acetabulosus:* Desmarest, Encyclopédie Méthodique, (Zoologie, Mammalogie), 1: 117. Publication date: 1820. (Name Combination).
1877. *Nyctinomus [(Mormopterus)] acetabulosus:* Dobson, Proc. zool. Soc. Lond., 1876, IV: 734. Publication date: April 1877. (Name Combination).
? *Molossus acetabulosus:* Commerson. - Comments: Dobson (1877: 734) refers for this combination to Peters (1869a: 402), and suggests it is only a manuscript name. (Name Combination).
? *Mormopterus acetabulosus:* (Name Combination, Current Combination).
? *Tadarida acetabulosus natalensis:* (Name Combination).

TAXONOMY:
See Simmons (2005: 444) and Goodman *et al.* (2008c).

Cheke (2009a: 115) indicates that Jossigny's drawing used by Hermann to describe the species in 1804 is to be considered as the lectotype of the species, which would overrule the need for a neotype as designated by Goodman *et al.* (2008c: 1324).

COMMON NAMES:
Afrikaans: Natalse losstertvlermuis. Czech: morous mauricijský. English: Natal Flat-headed Bat, Natal Wrinkle-lipped Bat, Natal Free-tailed Bat. French: Sauromys du Natal, Tadaride à lèvres ridées, Petit molosse de Port Louis. German: Mauritius Mastino-Fledermaus, Maurizische Doggengrämler.

CONSERVATION STATUS:
Global Justification
Listed as Endangered (EN A2bc; B1ab(iii,v)+2ab(iii,v)) because this species has a restricted range and decline in population size. It occurs in less than five sites on Mauritius. It is restricted to lava tube caves. The population of the species has declined by over 80% during the last 18 years, however the rate of decline over the last three generations is unknown; it is likely that it approached 67% over three generations (11-12 years based on a generation length of 3.9 years; see Pacifici *et al.*, 2013). The major roosting cave system for the species had been

developing into a tourism attraction for the past three years, resulting in loss of over 10,000 bats from a single location.

Assessment History
Global
2016: EN A2bc; B1ab(iii,v)+2ab(iii,v) ver. 3.1 (2001) (Bergmans *et al.*, 2017c). 2014: EN A2b; B1ab(iii)+2ab(iii) ver 3.1 (2001) (Bergmans *et al.*, 2017c). 2008: VU D2 ver 3.1 (2001) (Hutson and Bergmans, 2008; IUCN, 2009). 2004: VU D2 ver 3.1 (2001) (Hutson and Bergmans, 2004; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
South Africa: 2004: considered a vagrant not assessed, known from single locality (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
It is threatened by disturbance of roosting caves, and the removal of protective grills over the caves for landfill purposes Hutson and Bergmans, 2008; IUCN, 2009; Bergmans *et al.*, 2017c).

CONSERVATION ACTIONS:
Hutson and Bergmans (2008) [in IUCN (2009)] and Bergmans *et al.* (2017c) report that it is not known if the species is present in any protected areas. There is a need to protect cave roosts of this species in Mauritius by re-grilling important sites, cleaning the caves from household waste, education of local community (Bergmans *et al.*, 2017c).

GENERAL DISTRIBUTION:
Mormopterus acetabulosus is endemic to the Mascarene Islands (Mauritius) (see Goodman *et al.*, 2008c: 1316; O'Brien, 2011: 288). Records from Réunion should be assigned to *Mormopterus francoismoutoui*).

There is a single doubtful record for Madagascar (Peterson *et al.*, 1995: 150). Taylor (1998: 60) mentioned a specimen from South Africa (Durban) collected by Andrew Smith in 1833, but also states that no further specimens have been collected since. An old record from between the district of Shoa and Lake Rudolph in southern Ethiopia (Hayman and Hill, 1971: 59), most probably should be attributed to *M. francoismoutoui* (Goodman *et al.*, 2008c: 1325). Furthermore, it is now considered most likely that specimens taken outside of the Mascarene Islands were vagrants.

Monadjem *et al.* (2010d) did not retain this species for south Central Africa, but did mention the specimen from Durban, South Africa in the appendix (p. 545).

Native: Mauritius (Smith, 1833: 54; Meester *et al.*, 1986: 67; Simmons, 2005: 444; Goodman *et al.*, 2008c: 1316).

Presence uncertain: Madagascar (Dobson, 1878; Allen, 1939a; Hayman and Hill, 1971; Meester *et al.*, 1986: 67; Peterson *et al.*, 1995: 150; Simmons, 2005: 444); South Africa (Meester *et al.*, 1986: 67; Taylor, 1998: 60; Taylor, 2000: 75; Simmons, 2005: 444; Monadjem *et al.*, 2010d: 545); Sudan (Freeman, 1981b: 75).

Presence incorrectly assigned: Ethiopia (Hayman and Hill, 1971: 59; Simmons, 2005: 444; Kaipf *et al.*, 2015: 13); Réunion.

ROOST:
Middleton (1998a: 91) mention large colonies occurring in two caves in the Plaine des Roches area (Mauritius), and indicate that elsewhere the colonies seldom reach 2,000 animals.

Bunsy *et al.* (2024) indicated that caves with larger entrances were preferred probably because the bats could be more manoeuvrable and protected from predators.

DIET:
Bunsy *et al.* (2024: 2) mention that *M. acetabulosus* feeds on agricultural pests, including *Cryptophlebia peltastica* (Meyrick, 1921) (Lepidoptera, Tortricidae) and on human disease vectors such as the African Malaria mosquito, *Anopheles gambiae* Giles, 1902.

POPULATION:
Structure and Density
The largest known day roost colony on La Réunion (at Trois Bassins), with estimates from 25,000 to 10,000 individuals, is abandoned in austral winter, and it is not known where these bats spend the winter (Devaux, 2006; Issartel, 2004; Probst, 2003; Goodman *et al.*, 2008c: 1325). Goodman (2007) found bats allocated to this species to be common at several sites on Mauritius. However, Taylor (2016) [in [Bergmans *et al.* (2017c)] found the species to be narrowed to only four caves in Mauritius. Based on the survey it has been estimated that the population decreased by over 80% during the last 18 years and it keeps declining.

Trend
2016: Decreasing (Bergmans *et al.*, 2017c). 2008: Unknown (Hutson and Bergmans, 2008; IUCN, 2009).

Recent research by Bunsy *et al.* (2024) revealed that 17 of the 130 investigated lava cave tunnels contained roosts, whereas only nine were inhabited in the 2017 survey. However, they were unable to determine whether these extra roosts were overlooked previously or whether this was a recent colonisation (or a combination of the two).

PARASITES:
Dietrich *et al.* (2018a: 3) reported the presence of sequences closely related to the bacterium *Leptospira borgpetersenii*.

Laudisoit *et al.* (2012: 739) indicate that the type host for *Araeopsylla martialis* (Rothschild, 1903) (Siphonaptera; Ischnopsyllidae) was originally mentioned as "*Nyctinomus acetabulosus*", but this should actually be *Mormopterus francoismoutoui*.

VIRUSES:
Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 55 individuals from the Mauritius using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 1 positive results for viral nucleic acids.

Rhabdoviridae
Of 31 specimens tested against *Lagos bat lyssavirus* and *Duvenhage lyssavirus* by Mélade *et al.* (2016a: 6), respectively five and six showed a seroreaction. This was also the case for one out of eight bats tested for *European bat lyssavirus 1*.

Mormopterus acetabulosus acetabulosus (Hermann, 1804)

*1804. *V[espertilio] acetabulosus* Hermann, Obs. Zool. , 19. Publication date: 31 August 1804. Type locality: Mauritius: Port Louis. [Goto Description]. Holotype: MNHN ZM-MO-1984-368: ad? ♀. Collected by: Julien François Desjardins; collection date: 1829; original number: A488. Goodman *et al.* (2008c: 1324) incidcate that the specimen is labeled as type, but was collected 25 years after Hermann (1804) described it. Neotype: FMNH 187489: Collected by: Steven M. Goodman and V. Florens; collection date: 29 October 2006. Mauritius, Black River District, Palma, Palma Cave, 20 16'40.5"S 57 27'14.7"E. Goodman *et al.* (2008c: 1327) designated this as the neotype. Cheke (2009b) rejects the assignment of the neotype by Goodman *et al.* (2008c), based on article 73.1.4 and 75.8 (rules of Nomenclature - ICZN 1999). - Comments: Cheke (2009b: 1) rejects the assignment of the neotype, based on article 73.1.4 (rules of Nomenclature - ICZN 1999), which indicates that Paul Jossigny's drawings made of the specimen that Commerson once had before him in Mauritius should be considered the holotype of Hermann's *Vespertilio acetabulosus*, and that the designation of a neotype by Goodman *et al.* (2008c: 1324) is invalidated by article 75.8. The drawings on which Commerson based himself (and which were referred to by Hermann, 1804: 19) are to be found amongst the Commerson papers, in the folder of other similar drawings at MS 282(II), labelled No. 51 (Moutou, 1982, pers. obs. 2006) in the archives of the Bibiothèque du Muséum; the folder is described in paragraph 73 of Laissus's (1974) catalogue.

1823. *Nyctinomus mauritianus* Horsfield, Zoological Research in Java, Part 5, 9th page of text in account of *N. tenuis*. Publication date: January 1823. Type locality: Mauritius: Port Louis. [Goto Description].

? *Mormopterus acetabulosus acetabulosus:* (Name Combination, Current Combination).

ROOST:
On Mauritius, these bats use caves as typical roosting sites (see Wilkinson *et al.*, 2012: 160).

VIRUSES:
Wilkinson *et al.* (2012: 160) found one specimen out of 55 examined on Mauritius, that tested positive for Respirovirus / Morbillivirus / Henipahvirus (RMH) and Paramyxovirinae (PMV)

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Mauritius, Réunion.

Mormopterus acetabulosus natalensis (A. Smith, 1847)

1833. *Nyctinomus dubius* A. Smith, S. Afr. Quart. J., ser 2, 1 (2): 54. Publication date: November 1833. Type locality: South Africa: Cape Province and Natal, between. [Goto Description].

*1847. *Dysopes natalensis* A. Smith, Illustrated Zoology of South African Mammals, pl 49 and text. Publication date: December 1847. Type locality: South Africa: KwaZulu-Natal: Port Natal [=Durban], near [ca. 29 52 S 31 00 E]. - Comments: Dobson (1877: 734) mentions that the original name used by Smith (1847: pl. 49) was *Nyctinomus natalensis*, but this could not be checked yet. If this isn't the case, then this combination should probably be attributed to Dobson (1877). - Etymology: The name reflects the two specimens collected in KwaZulu-Natal.

? *Mormopterus acetabulosus natalensis:* (Name Combination, Current Combination).

TAXONOMY:
Allen (1939a) tentatively treats *dubius* as a species of *Nyctinomus* (= *Tadarida*), remarking that its status is uncertain; Roberts (1951), without giving reasons, regards it as a prior name for *natalensis*. Ellerman *et al.* (1953) are doubtful whether or not the two names are synonymous, and although they list *dubius* in the synonymy of *natalensis* they suggest that it may be necessary to discard the name as not being certainly identifiable. Hayman and Hill (1971: 65) list *dubius* as *incertae sedis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa".

Mormopterus francoismoutoui Goodman, Jansen Van Vuuren, Ratrimomanarivo, Probst, Bowie, 2008

*2008. *Mormopterus francoismoutoui* Goodman, Jansen Van Vuuren, Ratrimomanarivo, Probst and Bowie, J. Mamm., 89 (5): 1318, figs 2 - 6. Gill; collection date: 2 June 1967. - Etymology: The name *francoismoutoui* is a patronym in honour of Dr. François Moutou of the Unité d'Epidémiologie, Agence Française de Sécurité Sanitaire des Aliments, Maison Alfort, France. Dr. Moutou has made important contributions to the vertebrate fauna of the Mascarene Islands, particularly La Réunion (Goodman *et al.*, 2008c: 1319). (Current Combination).

2013. *Mormopterus francoimoutoui:* Barataud and Giosa, Le Rhinolophe, 19: 151. (Lapsus).

Taxonomy:

Formerly identified as *M. acetabulosus* see Goodman *et al.* (2008c: 1316).

Common Names:

Czech: morous réunionský. English: Reunion Free-tailed bat. French: Petit molosse, Tadaride de La Réunion. German: Reunion Mastino-Fledermaus.

Conservation status:

Global Justification

Goodman *et al.* (2008c: 1325) state it is under no serious threat of population decline in the near future. Augros *et al.* (2015: 372) refer to IUCN (2010) and mention "LC" as status. Goodman (2017f) report that this species is known from numerous sites on La Réunion, which include large maternity and day roosting colonies in caves and numerous synanthropique roost sites, such as under bridges and in houses, churches, and the principal airport (Dietrich *et al.*, 2015b). No clear threats are known.

Assessment History

Global

2016: LC ver. 3.1 (2001) (Goodman, 2017f).

Regional

None known.

Major threats:

No threats identified by Goodman (2017f). However, Aguillon *et al.* (2023: 10) [referring to Augros *et al.* (2015)] mention that displacement from its roosts might be an issue, due its excrement and musky smell leading to considerable nuisance for humans.

Conservation actions:

On the basis of territorial legislation, all bats on La Réunion are protected by law (Arrêté of 17 April 1981 and of 17 February 1989) (Goodman *et al.*, 2008c: 1325). More details are needed on the ecology, bioacoustics, and dispersal patterns of La Réunion bats (Goodman, 2017f).

General distribution:

Mormopterus francoismoutoui has been recorded from a variety of localities on La Réunion from sea level to about 2,000 m (Moutou, 1982; Goodman *et al.*, 2008c).

Native: Réunion (Goodman *et al.*, 2008c: 1316).

Biogeography:

Aguillon *et al.* (2024: 1) estimated that these bats arrived on Reunion during a single colonisation event about 175,000 years ago, after which an in-situ diversification and evolution of divergent ancestral lineages took place. The population appeared to have expanded about 55,000 years ago.

General description of external morphology:

Mormopterus francoismoutoui is a relatively large member of the genus *Mormopterus*. Its dorsal body fur is short and dense with a rich dark brown color and its ventrum is slightly paler. Wing membrane and uropatagium are brownish black and show no noticeable change in pigmentation across their surface area. In adult males, there is a large glandular sac on the ventral portion of the lower neck; this gland is absent in females (Goodman *et al.* (2008c).

An albino specimen was reported by Ramasindrazana *et al.* (2014: 103) and Lucati and López-Baucells (2016: Suppl.).

DENTAL FORMULA:
The permanent dental formula is as follows: $I^1/_3$, $C^1/_1$, $PM^1/_2$, $M^3/_3$ = 30

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Goodman *et al.* (2008c): The skull of *M. francoismoutoui*, as with most other members of this genus, is not noticeably flattened and has a long rostrum and well-developed lachrymal tubercles. The postorbital processes are well developed and distinctly shaped. The palatal emargination is well developed, similar to character state 4 for variable C65 of Freeman (1981b). Basisphenoid pits are present, but are not prominent, and there is a pronounced extension of the palatal spine descending onto the palatine bone.

SEXUAL DIMORPHISM:
The study by Aguillon *et al.* (2023: 9) showed that a subtle, but significant sexual dimorphism exitsted in the length of the forearm, with males being the larger. Adult females, on the other hand, had a higher BCI than males.

ECHOLOCATION:
Barataud and Giosa (2013: 150) analysed 253 sequences from *M. francoismoutoui* specimens on Réunion and found Fsub start: 64 ± 24.3 kHz, F_{end}: 41.5 ± 6.1 kHz, bandwidth: 24 ± 22.1 kHz, F_{max}: 45 ± 8.1 kHz and duration: 11.2 ± 2.9 ms.

MOLECULAR BIOLOGY:
Genetics
Dietrich *et al.* (2019: 6) developed 12 polymorphic molecular markers to facilitate further investigations into population genetics of this species.

Using mitochondrial DNA and microsatellite markers, Aguillon *et al.* (2024: 8) identified 410 haplotypes (in 603 sequences) for *mt*DNA and 1135 genotypes (in 1136 individuals) for the microsatellites.

HABITS:
The holotype and associated specimens roosting in the expansion joint of a bridge were observed to roost in a vertical position (head down) in very narrow crevices (Goodman *et al.*, 2008c: 1319).

ROOST:
Found in a variety of different roost sites, ranging from natural caves to synanthropic situations (Goodman *et al.*, 2008c). The holotype and associated specimens were extracted by hand from the expansion fissures in the lower portion of a concrete bridge (Goodman *et al.*, 2008c). Moutou (1982) found the species to roost in the crevices found in the rock faces around the island. It is also associated with a variety of human structures, including open roofs, roof slats, and window shutters (Goodman *et al.*, 2008c).

Augros *et al.* (2015: 374) provide an overview of 112 roosts, of which 74 (66 %) were artificial.

Aguillon *et al.* (2023: 2, 5) mention that the roosts are monospecific and can contain few hundred to tens of thousands of individuals. In one cave (of about 30 m^3), the authors estimated the number of bats possibly reaching 100,000 (based on a density of 900 bats/m^2). The roost size started to increase in October and reached its maximum around January-February (in one case by a factor of 400). Hoarau *et al.* (2023: 2) mention that the cave was only used from October to June, and that the females leave this cave about one month after parturition. From January onwards, the cave is primarily inhabited by newborns and juveniles.

MIGRATION:
The bats abandon Trois Bassins (with estimates of 10,000 to 25,000 individuals) during the austral winter, and it is not known where these bats spend the winter (Probst, 2003; Issartel, 2004; Devaux, 2006; Goodman *et al.*, 2008c).

POPULATION:
Structure and Density
The largest known day roost colony on La Réunion (at Trois Bassins), with estimates from 10,000 to 25,000 individuals, is abandoned in austral winter, and it is not known where these bats spend the winter (Devaux, 2006; Issartel, 2004; Probst, 2003; Goodman *et al.*, 2008c: 1325) [as *M. acetabulosus*]. While Goodman (2017f) report that this species is not correctly estimated but presumably substantial, with one maternity cave-dwelling colony estimated at 66,500 animals (Ramasindrazana *et al.*, 2014). In urban areas across the island, considerable numbers can be seen foraging at night around outside lighting (Goodman, 2017f).

Joffrin *et al.* (2022: 2) report on a 30 m^3 natural cave on the west coast of Réunion estimated to contain between 40,000 and 50,000 adult bats.

At the juvenile stage, both sexes were in equilibrium, but in adult bats, Aguillon *et al.* (2023: 6, 8) found a bias towards males (56%, based on captures at 19 roosts). A female biased sex ratio was found in the largest maternity roost. A sex ratio in favour of females was also observed during the summer (October to

December), whereas during the winter (June - July) more males were found.

Aguillon *et al.* (2024: 11) calculated that a major expansion of the population started about 55,000 years ago, and lasted for about 10,000 years. They also indicated that the population decline started about 500 years ago, well before humans colonised the island (about 350 years ago). Unfortunately, no data is available for the last few decades (p. 13).

Trend
2016: Increasing (Goodman, 2017f). 2008: Unknown (Hutson and Bergmans, 2008; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Aguillon *et al.* (2023: 2, 8, 10) mention that parturition takes place between December and February and this occurred in just a few roosts (one in a huge natural cave where bat density is very high, a second in an electric building (releasing heat), and a third under a sheet metal roof (accumulating heat during the day), all of these conditions probably offering warm conditions), but flying juveniles were observed in almost all roosts between January and September. Based on the structure of the epiphyses, juveniles were no longer identifiable after July (Aguillon *et al.*, 2023: 3).

MATING:
Aguillon *et al.* (2023: 11, 8) found that mating occurred in March and was followed by a seven month delay before the start of pregnancy. Most of the males were reproductively active from late January to early April, whereas 5 % were active in October.

PARASITES:
Laudisoit *et al.* (2012: 739) indicate that *M. francoismoutoui* is actually the type host for *Araeopsylla martialis* (Rothschild, 1903) (Syphonaptera; Ischnopsyllidae) and not "*Nyctinomus acetabulosus*".

Dietrich *et al.* (2015b: 4280) found similar infection dynamics for *Leptospira* bacteria and paramyxoviruses, which showed peak infections during late pregnancy and two months after the initial birth period. Both pathogens, however, did not seem to interact with one another.

Guernier *et al.* (2016: 1) found *M. francoismoutoui* on Réunion to be infected by *Leptospira borgpetersenii* bacteria, which also infect humans. However, these bacteria had different haplotypes, indicating that the bats do not have any role in human infections. Dietrich *et al.* (2018a: 2) mention the bacterium to be closely related to *L. borgpetersenii*.

VIRUSES:
Hoarau *et al.* (2023: 3) reported on co-infections. They found bats that were infected by both corona and paramyxoviruses (0.7 %), and to a lesser extent by corona and astroviruses (0.3 %) or by paramyxo and astrovirusesn (0.1 %) but never by the three.

Niu and McKee (2025: 232) mentioned that the shedding of viruses in this species has a clear seasonal pattern, with a peak in the weaning period, when neonates matured into juveniles. For Coronaviruses, the major peaks occurred in February and March, but there was also a minor peak in December, which aligned with the parturition season.

Astroviridae
Joffrin *et al.* (2021) reported on astroviruses collected from guano samples over a 28 month period.

Coronaviridae
Two bats tested by Hoarau *et al.* (2021: Suppl.) were posifive for viruses of this family. Joffrin *et al.* (2022: 1, 4) found virus shedding pulses during late pregnancy (December-January) and within two months of parturition (February-March).

Orthoherpesviridae/Herpesviridae
Aguillon *et al.* (2025: 1) reported a rapid herpesvirus (HSV) infection of juveniles (< 6 months). The prevalence of HSV was slightly lower in large colonies, but Aguillon *et al.* (2025: 6) indicated that this was linked to the presence of large numbers of juvenile bats, which showed low infection rates. The mean shedding prevalence in adults was 96.2 ± 0.65 %, whereas this in juveniles was 15.03 ± 5.66 % at the time they started to fly, but reached 60.67 ± 7.82 % after 6 months.

Paramyxoviridae
Nieto-Rabiela *et al.* (2019: Suppl.) reported Bat paramyxovirus to be present.
Data collected by Aguillon *et al.* (2025: 1) suggest that juveniles have a longer protection by maternal antibodies.

Rhabdoviridae
A large amount of bats from La Réunion were tested for lyssaviruses by Mélade *et al.* (2016a: 6), which resulted in the following numbers: *Lagos bat lyssavirus*: 3 seroreactions for 121 bats; *Duvenhage lyssavirus*: 14/117, and *European bat lyssavirus 1*: 9/82.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Réunion.

Mormopterus jugularis (Peters, 1865)

*1865. *Nyctinomus (Mormopterus) jugularis* Peters, in: Sclater, Proc. zool. Soc. Lond., 1865, II: 468. Publication date: October 1865. Type locality: Madagascar: Antananarivo (formerly Tananarive) [18 55 S 47 31 E]. Holotype: ZMB 2977: ad ♂, skull and alcoholic. Collected by: Harry R. Caldwell. Presented/Donated by: William Lutley Sclater. See Turni and Kock (2008: 70).

1877. *Nyctinomus [(Mormopterus)] albiventer* Dobson, Proc. zool. Soc. Lond., 1876, IV: 733. Publication date: April 1877. Type locality: Madagascar: "Madagascar". [Goto Description]. Holotype: NHMUK 1863.12.26.1: ♀. - Comments: Type: NHMUK ???, ad ♀, alcoholic, purchased.

? *Mormopterus albiventer:*

? *Mormopterus jugularis:* (Name Combination, Current Combination).

TAXONOMY:
See Simmons (2005: 445).

COMMON NAMES:
Czech: morous Petersův. English: Peters's Goblin bat, Peters's Wrinkle-lipped Bat, Peters' Wrinkle-lipped Bat. French: Sauromys à jugulaire, Sauromys de Peters, Tadaride de Madagascar. German: Madagaskar Mastino-Fledermaus. Japanese: Pita-ohiki-koumori.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Muldoon *et al.* (2009: 1114) report on subfossil remains from the Ankilitelo fauna (late Holocene, appr. 500 years ago).
Gunnell *et al.* (2014: 3) refer to fossil material from Tsimanampetsotsa (one tooth and a few pieces of a forelimb according to Sabatier and Legendre (1985: 23)), Ankilitelo, and Andrahomana on Madagascar.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread distribution across Madagascar and because it is not thought to be facing any major threats across its range (Andriafidison *et al.*, 2008g; IUCN, 2009; Monadjem *et al.*, 2017cb).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cb). 2008: LC ver 3.1 (2001) (Andriafidison *et al.*, 2008g; IUCN, 2009). 1996: VU A2c ver 2.3 (1994) (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is not threatened by loss of native forests because it forages in open areas associated with agriculture. It is locally persecuted when roosting in buildings although this is not yet a major threat. Some colonies are subject to hunting and although this is thought to have resulted in abandonment in at least two cases (Goodman *et al.*, 2008d), harvest levels do not appear a major threat (Andriafidison *et al.*, 2008g; IUCN, 2009; Monadjem *et al.*, 2017cb).

Fernández-Llamazares *et al.* (2018: 273) indicate that *M. jugularis* is often hunted in sacred caves in and around the Tsimanampetsotsa National Park, although in the park, it is generally restricted to periods of famine, e.g., in 2007, when the bats fed 200 people for two months.

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008g) [in IUCN (2009)] and Monadjem *et al.* (2017cb) report that as this species is more commonly found roosting in buildings than natural settings it is not found in many of the protected areas in Madagascar (Goodman *et al.*, 2005a). However, there is no need for any conservation measures at present as this species appears to be widely distributed and is locally abundant.

GENERAL DISTRIBUTION:
Mormopterus jugularis is endemic to Madagascar (Peterson *et al.*, 1995) and very widespread (but patchy) across the island with a known distribution extending from the coast up to the high plateau at 1,400 m in Anjozorobe (J. Ranivo *pers. comm.,* in Andriafidison *et al.*, 2008g; IUCN, 2009).

Native: Madagascar (Peterson *et al.*, 1995; Simmons, 2005: 445)

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 62) describe the baculum of this species as proportionately broad at the proximal, rounded base and tapering to a rounded distal tip. In lateral view, the structure has a slight curve to the main shaft; length: 0.69 ± 0.015 (0.68 - 0.71) mm, width: 0.24 ± 0.016 (0.22 - 0.26) mm.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Garbutt (2007) and Taylor *et al.* (2012a)] mention a wing loading value of 13.4 Pa, aspect ratio 7.9 for a wingspan of 25 cm and a wing area of 80 cm^2 and a body mass of 11 g.

ECHOLOCATION:
Hending *et al.* (2023: 372) reported F_{peak}: 32.6 ± 2.8 kHz, duration: 23 ± 16 ms, and interpulse interval: 195 ± 079 ms.

MOLECULAR BIOLOGY:
Karyotype
Richards *et al.* (2010) reported one male with a 2*n*=48 and a FNa=54. They found one large metacentric, three medium-sized metacentric and 19 acrocentric autosomal pairs. The X chromosome is submetacentric and the Y chromosome is metacentric. FISH using *Myotis* probes was also applied.

Volleth *et al.* (2023b: 6) reported one male with a 2*n*=48 and a FNa=60. The X chromosome was medium-sized submetacentric with the proximal third of the long arm darker stained after C-banding, whereas the Y chromosome was a small submetacentric and nearly completely heterochromatic and about half the size of the X. The difference in FNa number is attributed to the identification of three subtelocentric chromosomal pairs (p. 26).

HABITAT:
Dammhahn and Goodman (2013: 108) indicate that this species' foraging habitat consists of open areas and the area above the forest canopy.

ROOST:
Synantropic structures are the typical roosting sites for this species on Madagascar (Wilkinson *et al.*, 2012: 160). The roosts usually contain less than 100 animals, but a cave in Ankarana housed over 22,000 bats (Garbutt, 2022: 94).

MIGRATION:
Reher *et al.* (2019: 121) found that *M. jugularis* was only present in a southwestern Madagascan cave during the rainy season, whereas other species such as *Triaenops menamena* and *Miniopterus mahafaliensis* were present in both the dry and wet season.

DIET:
Kemp *et al.* (2018: Suppl.) used DNA metacarcoding to detect insect pest species in the diet of these bats and found the following prey orders (in descending order): Coleoptera (*Xyleborus ferrugineus* (Fabricius, 1801)), Ephemeroptera, Diptera (*Simulium lineatum* (Meigen, 1804), *Culex annulioris* Theobald, 1901, *Culex* MBI-27, *Anopheles squamosus* Theobald, 1901), Lepidoptera (*Meyrickiella homosema* (Meyrick, 1887), *Herpetogramma licarsisalis* (Walker, 1859)), Blattodea, Dermaptera, Hemiptera, Neuroptera, Orthoptera, Sarcoptiformes, Astigmata, Hymenoptera

PREDATORS:
Goodman *et al.* (2015c: 78) found the remains of three individuals in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar. Other predators include the barn owl (*Tyto alba* (Scopoli, 1769) and the Madagascar Long-eared Owl (*Asia madagascariensis* (A. Smith, 1834).

POPULATION:
Structure and Density
There are no quantitative data available on populations of this species; however, it is assumed to have a high population size because it is widespread and roosts in large colonies in buildings (Andriafidison *et al.*, 2008g; IUCN, 2009; Monadjem *et al.*, 2017cb).

Trend
2016: Unknown (Monadjem *et al.*, 2017cb).
2008: Unknown (Andriafidison *et al.*, 2008g; IUCN, 2009).

PARASITES:
Lagadec *et al.* (2012: 1696) and Gomard *et al.* (2016: 5) report the presence of *Leptospira* sp bacteria in this species, which, according to Dietrich *et al.* (2018a: 3), were having sequences closely related to *L. borgpetersernii*

Laudisoit *et al.* (2012: 739) refer to Lumaret (1962), who reported the present of *Araeopsylla martialis* (Rothschild, 1903) (Siphonaptera; Ischnopsyllidae) on "*Tadarida albiventer*" [= *M. jugularis*]. This flea was also reported by Hastriter (2016: 15) and Duchemin *et al.* (2022: 1077).

Durette-Desset and Chabaud (1975: 10) described the Nematode *Molinostrongylus richardae* from a "*Mormopterus albiventer*" from Anjiro, Madagascar.

VIRUSES:
Coronaviridae
Joffrin *et al.* (2020: 5) reported an Alphacoronavirus from a bat from Madagascar.

Flaviviridae
Flavivirus
Reynes *et al.* (2011: 3) reported the isolation of Dakar bat virus from *M. jugularis*.

Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 13 individuals from the Mauritius using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids. Wilkinson *et al.* (2014) tested 19 individuals in Madagascar with an RT-PCR specific for the Respiro-, Morbilli- and Henipavirus genera, two of the 19 individuals tested positive for paramyxovirus RNA.

12 out of 152 Madagascan specimens tested by Mélade *et al.* (2016b: 4) were positive for paramyxoviruses.

Rhabdoviridae
58 specimens were tested by Mélade *et al.* (2016a: 6), which laid to three seroreactive results for *Lagos bat lyssavirus* and 17 for *Duvenhage lyssavirus*.

UTILISATION:
See Goodman *et al.* (2008d).

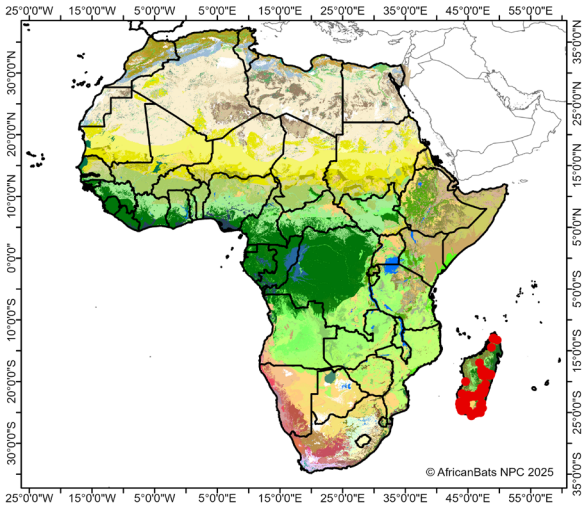

Figure 204. Distribution of *Mormopterus jugularis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Madagascar.

Genus ***Myopterus*** E. Geoffroy St.-Hilaire, 1818

*1818. *Myopterus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 113. Publication date: 1818 [Goto Description]. - Comments: Type species: *Myopterus senegalensis* Oken, 1816 (not available) (=*Myopteris daubentonii* Desmarest, 1820). - Etymology: From the Greek "*μύς*" or "*έμυός*", meaning mouse and "*πτέρυξ*", meaning wing (see Palmer, 1904: 440). (Current Combination).
1820. *Myopteris* Desmarest, Encyclopédie Méthodique, (Zoologie, Mammalogie), 1: 131. Publication date: 1820. - Comments: Type: *Myopteris daubentonii* Desmarest, 1820.
1837. *Myoptera* de Blainville, C. R. séances Acad. Sci., Paris, 5: 815. Publication date: 1837.
1905. *Eomops* Thomas, Ann. Mag. nat. Hist., ser 7, 16 (95): 572. Publication date: 1 November 1905 [Goto Description]. - Comments: Type species: *Mormopterus whitleyi* Scharff, 1900.

TAXONOMY:
Includes *Eomops*; see Hayman and Hill (1971: 56). Grubb *et al.* (1998: 97) indicate that *Myopterus* Oken, 1816, Lehrbuch Naturgesch. Pt 3, Zool. Sect. 2: 952, type species *Myopterus senegalensis* Oken (= *Myopteris daubentonii* Desmarest, 1820), is not available according to Opinion 417 of the ICZN.

Grubb *et al.* (1998: 97) indicate that Mahoney and Walton (1988a: 116) considered the date of Geoffroy's publication to be 1813. Gardner and Hayssen (2004: 12) mention that the correct date

should be 1818, not 1813 as mentioned on the publication itself.

Currently (Simmons and Cirranello, 2023b) recognized species of the genus *Myopterus*: ***daubentonii*** Desmarest, 1820; ***whitleyi*** (Scharff, 1900).

Myopterus daubentonii Desmarest, 1820

1816. *Myopterus senegalensis* Oken, Lehrbuch Naturgeschichte, Jena, 3 (2): 952. Type locality: Senegal. Lectotype: MNHN ZM-MO-1985-1718: ad ♀, skull and alcoholic. Collected by: René Vuattoux; collection date: 10 September 1966. Paralectotype: MNHN ZM-MO-1990-53: ad ♂, skull and alcoholic. Collected by: René Vuattoux; collection date: 10 September 1966. - Comments: Not available (Opinion 417 of the ICZN) see Grubb *et al.* (1998: 97).

*1820. *Myopterus daubentonii* Desmarest, Encyclopédie Méthodique, (Zoologie, Mammalogie), 1: 132. Publication date: 1820. Type locality: Senegal: "Senegal". Holotype: [Unknown] lost. See Koopman (1993a: 238). Neotype: MNHN ZM-MO-1982-1035: ad ♂, skull and alcoholic. Collected by: René Château; collection date: 16 March 1973. Paraneotype: MNHN ZM-MO-1982-1034: ♂, skull and alcoholic. Collected by: René Château; collection date: 16 March 1973. - Comments: Type specimen lost (see Koopman, 1993a: 238). - Etymology: In honour of the French naturalist Louis-Jean-Marie d'Aubenton [=Daubenton] (1716 - 1799/1800) (see Bogdanowicz, 1994: 5; Kozhurina, 2002: 15). (Current Combination).

1915. *Myopterus albatus* Thomas, Ann. Mag. nat. Hist., ser 8, 16 (96): 469. Publication date: 1 December 1915. Type locality: Congo (Democratic Republic of the): Uele River [04 09 N 22 26 E]. [Goto Description]. Holotype: NHMUK 1919.5.9.1: Collected by: M. Hutereau; original number: 17. Congo Museum o. 2911.

? *Myopterus daubentonii albatus:* (Name Combination).

Taxonomy:
Koopman (1989a) and Simmons (2005) recognise *albatus* Thomas, 1915 as a subspecies. Allen (1939a: 110) used *Myopterus senegalensis* Oken, 1816 for this species.

Common Names:
Czech: morous krysový, spaka krysová. English: Daubenton's Winged-mouse Bat, Daubenton's Free-tailed Bat, Senegal Mastiff Bat. French: Myoptère de Daubenton, Myoptère du Sénégal. German: Daubentons Pergamentflügel-Fledermaus.

Conservation status:
Global Justification

Listed as Data Deficient (DD ver 3.1 (2001)) since, although it has been recorded over a very wide area, there are only very few records, and very little is known with certainty about its distribution, threats and habitat requirements (Mickleburgh *et al.*, 2008bc; IUCN, 2009; Mickleburgh *et al.*, 2019i).

Assessment History

Global

2018: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2019i). 2008: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2008bc; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004ca; IUCN, 2004). 1996: DD (Baillie and Groombridge, 1996).

Regional

None known.

Common Names:
Czech: krysoví morousi, spaky. English: Winged-mouse Bats, African Free-tailed Bats, Winged-rat Free-tailed Bats. French: Myoptères. German: Pergamentflügel-Fledermäuse.

Major threats:
The species is generally threatened by habitat loss, especially the removal of potential roost trees (Mickleburgh *et al.*, 2008bc; IUCN, 2009; Mickleburgh *et al.*, 2019i).

Conservation actions:
Mickleburgh *et al.* (2008bc) [in IUCN (2009)] and Mickleburgh *et al.* (2019i) report that there appear to be no direct conservation measures in place, and it is not known if the species is present within any protected areas. Further studies are needed into the distribution, natural history and threats to this bat.

General distribution:
Myopterus daubentonii is patchily recorded from eight localities in West and Central Africa. It has been reported from Côte d'Ivoire, Central African Republic and northern Democratic Republic of the Congo. It is generally a lowland species but has been found up to 1,250 m asl.

Native: Central African Republic; Congo (The Democratic Republic of the); Côte d'Ivoire; Senegal.

Echolocation:
Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

Roost:
Brosset and Vuattoux (1968: 85) reported five specimens from Côte d'Ivoire (as *M. senegalensis*), that were captured in a hollow

trunk of a Borassus palm (*Borassus aethiopum*). The tree was standing in a savanna area, but only a few hundred meters from a gallery forest. The bats were roosting at an altitude of about 12 meters.

POPULATION:
Structure and Density
This appears to be a rare species, known from very few specimens (Mickleburgh *et al.*, 2008bc; IUCN, 2009; Mickleburgh *et al.*, 2019i).

Trend
2018: Unknown (Mickleburgh *et al.*, 2019i). 2008: Unknown (Mickleburgh *et al.*, 2008bc; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Senegal.

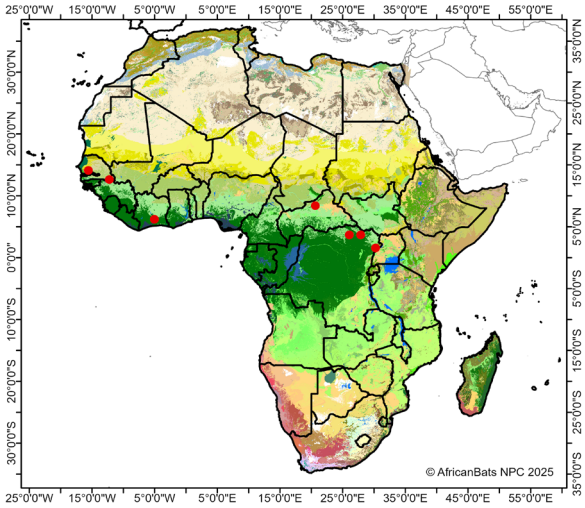

Figure 205. Distribution of *Myopterus daubentonii*.

Myopterus whitleyi (Scharff, 1900)

*1900. *Mormopterus Whitleyi* Scharff, Ann. Mag. nat. Hist., ser 7, 6 (36): 569. Publication date: 1 December 1900. Type locality: Nigeria: Mid-Western Region, Nikrowa Forest Reserve, Sapoba: Benin City [06 19 N 05 41 E]. [Goto Description]. Holotype: NHMUK 1900.10.26.1: ad ♂, skull and alcoholic.
? *Myopterus whitleyi:* (Name Combination, Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: morous západoafrický. English: Bini Winged-mouse Bat, Whitley's Winged-mouse Bat, Bini Free-tailed Bat. French: Myoptère de Whitley, Myoptère de Bini. German: Whitleys Pergamentflügel-Fledermaus, Bini Pergamentflügel-Fledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008bd; IUCN, 2009; Monadjem *et al.*, 2017ba).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017ba). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008bd; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004cf; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is presumably threatened by general conversion of forest to agricultural land and logging activities (Mickleburgh *et al.*, 2008bd; IUCN, 2009; Monadjem *et al.*, 2017ba).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008bd) [in IUCN (2009)] and Monadjem *et al.* (2017ba) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed into the species distribution, natural history, and adaptability to habitat degradation.

GENERAL DISTRIBUTION:
Myopterus whitleyi is distributed in West and Central Africa. It has been recorded from Ghana in the west, through parts of Nigeria, Cameroon, Gabon, and the Democratic Republic of the Congo to western Uganda in the east.

Native: Cameroon; Central African Republic (Barrière *et al.*, 2002: 234); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 545); Gabon; Ghana; Nigeria; Uganda.

POPULATION:
Structure and Density
It is generally considered to be a rare species. It is found roosting singly or in small numbers (Mickleburgh *et al.*, 2008bd; IUCN, 2009; Monadjem *et al.*, 2017ba).

Trend
2016: Decreasing (Monadjem *et al.*, 2017ba).
2008: Decreasing (Mickleburgh *et al.*, 2008bd; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Central African Republic, Congo (Democratic Republic of the), Gabon, Ghana, Nigeria, Uganda.

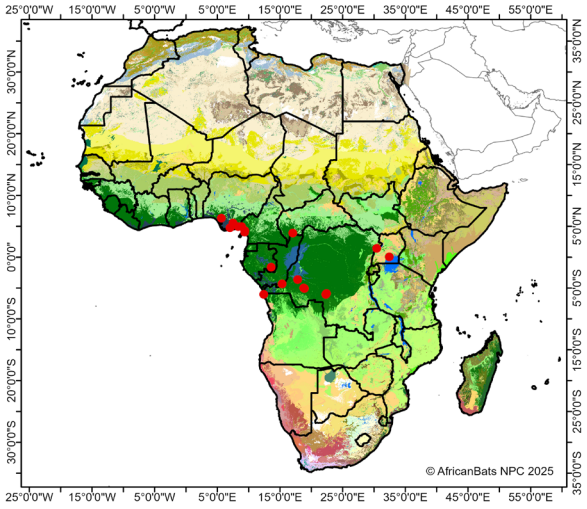

Figure 206. Distribution of *Myopterus whitleyi*.

Genus ***Otomops*** Thomas, 1913

*1913. *Otomops* Thomas, J. Bomb. nat. Hist. Soc., 22: 91. Publication date: April 1913. - Comments: Type species: *Nyctinomus wroughtoni* Thomas, 1913. - Etymology: From the Greek substantive "*οὖς*" (genitive "*ὠτός*", "*ûs*", "*ōtós*"), meaning "ear" and the masculine German substantive *Mops*, as the genus has outstandingly large ears (see Lanza *et al.*, 2015: 309). - Phonetics: oh'-toh-mops. (Current Combination).

TAXONOMY:
Richards *et al.* (2012: 910) suggest that three distinct taxa might be recognized in Africa: *Otomops madagascariensis* from Madagascar; *O. martiensseni* s.s. from southern, eastern, central, and western Africa; and an "undescribed taxon" (now identified as *O. harrisoni*) from north-east Africa and the Arabian Peninsula.

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Otomops*: *formosus* Chasen, 1939 – Java (Simmons, 2005: 447); ***harrisoni*** Ralph, Richards, Taylor, Napier, and Lamb, 2015; *johnstonei* Kitchener, How and Maryanto, 1992 – Alor Isl (Indonesia) (Simmons, 2005: 447); ***madagascariensis*** Dorst, 1953; ***martiensseni*** (Matschie, 1897); *papuensis* Lawrence, 1948 – southeastern New Guinea (Simmons, 2005: 448); *secundus* Hayman, 1952 – northeastern New Guinea (Simmons, 2005: 448); *wroughtoni* (Thomas, 1913) – southern and northeastern India, Cambodia (Simmons, 2005: 448).

COMMON NAMES:
Czech: velkouší morousi. English: Big-eared Bulldog Bats, Big-eared Free-tailed Bats, Mastiff Bats. French: Molosses à grandes oreilles. German: Riesen-Bulldoggfledermäuse. Italian: Otocarlìno.

ETYMOLOGY OF COMMON NAME:
So named because they have outstanding large round-pointed ears that are attached along the nose and lie in the plane of the face (see Taylor, 2005).

BIOGEOGRAPHY:
Lamb *et al.* (2008) suggests that African and Oriental *Otomops* lineages diverged around 4.2 Myr, while Malagasy and African lineages split around 1.5 Mya.

MOLECULAR BIOLOGY:
Genetics
Patterson *et al.* (2018: 7) found the average interspecific genetic distance (uncorrected cyt-*b* p-distance) between *O. harrisoni* and *O. martiensseni* to be 2.5 %.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Burundi, Kenya, Madagascar, Rwanda.

Otomops harrisoni Ralph, Richards, Taylor, Napier and Lamb, 2015

*2015. *Otomops harrisoni* Ralph, Richards, Taylor, Napier and Lamb, Zootaxa, 4057 (1): 1, 18, figs 8 - 10. Publication date: 9 December 2015. Type locality: Ethiopia: Bale district: Sof Omar Cave [06 54 N 40 48E, 1340 m]. Holotype: HZM 60.36217: ad ♂, skull and alcoholic. Collected by: Paul Jeremy James Bates, Malcolm J. Pearch and O. Nurhussein; collection date: 19 July 1998; original number: A51. Paratype: HZM 40.31315: ad ♂. Collection date: 19 July 1998. Paratype: HZM 41.31316: ad ♀. Collection date: 19 July 1998. Paratype:

HZM 42.31317: ad ♀. Collection date: 19 July 1998. Paratype: HZM 43.31318: ad ♀. Collection date: 19 July 1998. Paratype: HZM 44.31328: ad ♂. Collection date: 19 July 1998. Paratype: HZM 56.36213: ad ♀. Collection date: 19 July 1998. Paratype: HZM 57.36214: ad ♀. Collection date: 19 July 1998. Paratype: HZM 58.36215: ad ♀. Collection date: 19 July 1998. Paratype: HZM 59.36216: ad ♀. Collection date: 19 July 1998. Paratype: HZM 61.36218: ad ♀. Collection date: 19 July 1998. Paratype: HZM 62.36219: ad ♀. Collection date: 19 July 1998. Ralph *et al.* (2015: 19) mention "(also DM 14750)". Paratype: HZM 63.36220: ad ♀. Collection date: 19 July 1998. Paratype: HZM 64.36221: ad ♂. Collection date: 19 July 1998. - Etymology: In honour of Dr. David L. Harrison (1926 - 2015), who's numerous publications on Afro-Arabian Chiroptera, in particular the Molossidae, have significantly improved our knowledge of this poorly known family (Ralph *et al.* (2015: 20).

? *Otomops martiensseni:*

Common Names:

Chinese: 哈氏巨犬吻蝠. English: Harrison's large-eared giant mastiff bat. German: Harrison-Riesen-Bulldoggfledermaus

Similar Species:

Ralph *et al.* (2015: 25) report that *O. harrisoni* is in general larger than other *Otomops* species.

Conservation status:

Patterson *et al.* (2018: 11) report the status of *O. harrisoni* as Vulnerable.

General distribution:

Native: Djibouti; Eritrea (Kock and Zinner, 2004: 3 as *O. martiensseni*); Ethiopia (in a disused railway tunnel 8 km east of Asmara) for the first time (Kock and Zinner, 2004: 3 as *O. martiensseni*); Kenya (Patterson *et al.*, 2018: 1), Rwanda (Patterson *et al.*, 2018: 1) and Yemen (Hud Sawa cave, Ar-Rayadi Al-Gharbi Mountains) on the Arabian Peninsula (Al-Jumaily, 1999; Hutson *et al.*, 2001 as *O. martiensseni*).

Ralph *et al.* (2015: 27) suggest that the range might include additional localities in Uganda, northern areas of Tanzania and southern areas of Somalia.

Patterson *et al.* (2018: 1) found both O. martiensseni and *O. harrisoni* in a cave in the Musanze district, Rwanda. As they found both species in Kenya, they also caution the identifications of *Otomops* specimens from that country, especially those from Kwale, Lake Baringo, Nairobi, Naivasha, and
Wei-Wei River (p. 11).

Dental Formula:

The permanent dental formula of *O. harrisoni* is $I^1/_2$, $C^1/_1$, $PM^2/_2$, $M^3/_3$ = 30, characteristic of molossid bats (see Ralph *et al.*, 2015: 26).

Echolocation:

Ralph *et al.* (2015: 26) indicate that Taylor *et al.* (2005) reported the following values for *O. martiensseni* specimens from Bungule, Kenya: F_{peak}: 12.00 kHz, F_{min}: 10.50 kHz, F_{max}: 50 kHz, and duration of 9.00 ms. However, since this locality is equidistant from localities were either *O. martiensseni* or *O. harrisoni* was found, the taxonomic assignment of the specimens involved remains uncertain.

Patterson *et al.* (2018: Suppl.) recorded the following parameters for 10 Kenyan specimens identified as "*O.* cf. *harrisoni*: F_{max}: 13.99 ± 2.93 (9.52 - 17.95) kHz, F_{start}: 19.35 ± 3.50 (10.72 - 21.90) kHz, F_{end}: 11.58 ± 1.17 (9.63 - 13.13) kHz, duration: 10.13 ± 2.46 (7.04 - 15.16) ms. However, they also found (p. 7) differences between *O. harrisoni* populations from two localities in Kenya: Chyulu Hills: F_{peak}: 17.18 ± 0.42 (16.40 - 17.95) kHz, F_{max}: 21.67 ± 0.10 (21.48 - 21.90) kHz, F_{min}: 12.53 ± 0.29 (11.80 - 13.13) kHz and call duration: 10.72 ± 1.10 (7.57 - 12.67) ms; and Mount Suswa: F_{peak}: 11.86 ± 0.72 (9.52 - 13.80) kHz, F_{max}: 17.81 ± 1.70 (10.72 - 21.62) kHz, F_{min}: 110.94 ± 0.47 (9.63 - 12.80) kHz and call duration: 9.74 ± 1.21 (7.04 - 15.16) ms.

Molecular Biology:

Karyotype
Warner *et al.* (1974) reported 2*n* = 48, FN = 58, BA = 12, a submetacentric X chromosome and a submetacentric Y chromosome for one male *O. martiensseni* specimen from Kenya, which differed from previously reported karyotypes. It is therefore possible that this male might have been a representative of *O. harrisoni*.

Habitat:

Ralph *et al.* (2015: 27) mention that these bats are found at high altitudes (above 1,000 m) characterised by relatively drier climates (< 500 mm annual precipitation), including warm semi-arid, tropical savanna, warm desert and temperate oceanic climates (e.g., the Ethiopian highlands).

Roost:

Ralph *et al.* (2015: 27) indicate that individuals roost predominantly in mountain-associated cave systems and lava caves.

Diet:

Faecal data from Ethiopia indicate that medium (size range: 1 - 5 cm) to large (wing span size range: 2.5 - 30 cm) Lepidoptera (Noctuidae,

Geometridae and Saturniidae) form 97 % by volume of this bat's diet (see Ralph *et al.*, 2015: 26).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

PARASITES:
At Mount Suswa (Kenya), Patterson *et al.* (2018: 10, Suppl.) found the following ectoparasites: *Brachytarsina alluaudi* (Falcoz, 1923) [Diptera, Hippoboscidae], *Hypoctenes clarus* (Jordan, 1922) [Hemiptera, Polyctenidae], *Lagaropsylla* sp. [Siphonaptera, Ischnopsyllidae], and some unidentified Argasidae and Macronyssidae.

VIRUSES:
Kamau *et al.* (2022: 5) reported coronaviruses and retroviruses from bats from a cave at Mount Suswa, Kenya.

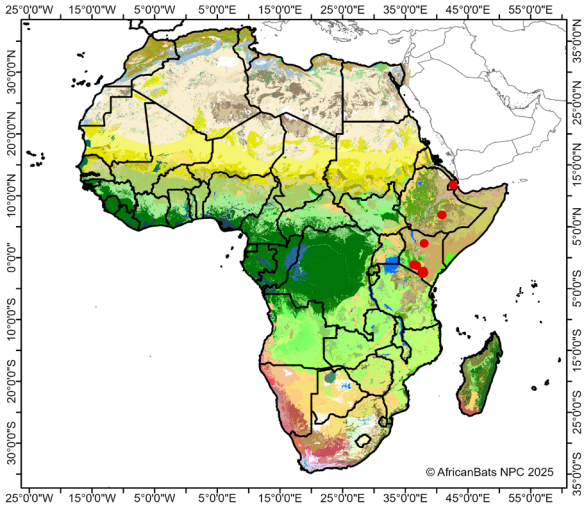

Figure 207. Distribution of *Otomops harrisoni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Djibouti, Ethiopia, Kenya.

Otomops madagascariensis Dorst, 1953

*1953. *Otomops madagascariensis* Dorst, Mém. Inst. Scient. Madagascar, (A) 8: 236. Type locality: Madagascar: S of Soalala: Namoroka, Réserve Naturelle: Cave P. Saboureau, No. 8 [16 23 S 45 28 E]. Holotype: MNHN ZM-MO-1953-1: ad ♀, skull and alcoholic. Collected by: Renaud ("René") Paulian; collection date: September 1952. See Peterson *et al.* (1995: 181), Richards *et al.* (2012: 912). Paratype: MNHN ZM-MO-1985-442: ad ♀, alcoholic (skull not removed). Collected by: Renaud ("René") Paulian; collection date: September 1952. - Etymology: Referring to the island where this taxon occurs. (Current Combination).
2000. *Otomops martiensseni madagascarensis:* Horáček, Hanák and Gaisler, Bats of the Palearctic region. (Lapsus).
? *Otomops madagascariensis madagascariensis:* (Name Combination).
? *Otomops martiensseni madagascariensis:* (Name Combination).

TAXONOMY:
Previously recognised as a subspecies or synonym of *Otomops martiensseni* (Koopman, 1993a: 239). Valdivieso *et al.* (1979) listed it as a distinct species, as did Peterson *et al.* (1995: 183) and Russ *et al.* (2001). We are (yet) unable to confirm whether the original spelling is *madagascariensis* (see Koopman, 1993a: 239, Peterson *et al.*, 1995, Russ *et al.*, 2001, Simmons, 2005: 447) or *madagascarensis* (see Horáček *et al.*, 2000: 137; Fenton *et al.*, 2002: 1584).

COMMON NAMES:
Czech: morous madagaskarský. English: Madagascar Large-eared Free-tailed Bat, Madagascar Free-tailed Bat, Madagascar Giant Free-tailed bat, Madagascar Mastiff Bat. French: Molosse à grandes oreilles de Madagascar. German: Madagassische Riesen-Bulldoggfledermaus.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Muldoon *et al.* (2009: 1114) report on subfossil remains from the Ankilitelo fauna (late Holocene, appr. 500 years ago).

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread but patchy distribution in Madagascar. It is not well known in Madagascar, but it is likely distributed more widely than current records suggest and it is unlikely that it is declining at a rate that would warrant listing in a higher category of threat (Andriafidison *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017cd).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cd). 2008: LC ver 3.1 (2001) (Andriafidison *et al.*, 2008l; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
The threats to this species are unclear, but more research is needed into possible disturbance at its roost sites (Andriafidison *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017cd).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008l) [in IUCN (2009)] and Monadjem *et al.* (2017cd) report that this species roosts in one cave that is locally protected by 'fady' or taboo (Andriafidison *et al.*, 2007). It has been recorded from five protected areas: Parc National du Tsingy de Bemaraha, Parc National de Namoroka, Parc National d'Isalo, Réserve Spéciale d'Ankarana and Réserve Spéciale d'Analamerana (Goodman *et al.*, 2005a). A total of nine roosting colonies are currently known: six in Réserve Spéciale d'Ankarana (Cardiff, 2006), two in Parc National du Tsingy de Bemaraha (Andriafidison *et al.*, 2007) and one in Sarodrano (Goodman *et al.*, 2005a; Andriafidison *et al.*, 2007), and all receive some form of protection. More research is needed on its roosting ecology and surveys are required in areas where this species is expected to occur.

GENERAL DISTRIBUTION:
Otomops madagascariensis is endemic to the island of Madagascar where it has a disjunct distribution from the north to the south-west of the island. It has an elevation range of 5 m to 800 m above sea level (Goodman *et al.*, 2005a), where it occurs in dry deciduous and spiny bush areas (Garbutt, 2022: 97).

O'Brien (2011: 289) reports it from the Tanzanian island of Mafia.

Native: Madagascar (Valdivieso *et al.*, 1979; Peterson *et al.*, 1995: 183; Russ *et al.*, 2001; Simmons, 2005: 447).

DETAILED MORPHOLOGY:
Baculum
The baculum of *O. madagascariensis* is an elongated rod with a notable twist to the mid-shaft. In lateral view, its proximal portion is distinctly wider than the proximal end (Rakotondramanana and Goodman, 2017: 62); length: 0.74 ± 0.057 (0.65 - 0.80) mm, width: 0.13 ± 0.028 (0.09 - 0.18) mm.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Taylor *et al.* (2012a) and Dammhahn and Goodman (2013)] mention a wing loading value of 12.9 Pa, aspect ratio 8.3 for a wingspan of 39 cm and a wing area of 183 cm^2 and a body mass of 24 g.

ECHOLOCATION:
Hending *et al.* (2023: 372) mention a F_{peak} of 17.3 ± 1.9 kHz, duration:31 ± 36 0.ms and Interpulse interval of 423 ± 148 ms.

MOLECULAR BIOLOGY:
Genetics
See Lamb *et al.* (2008).

HABITAT:
Dammhahn and Goodman (2013: 108) report that this species' foraging habitat includes open areas and the area above the forest canopy.

ROOST:
Otomops madagascariensis is an obligate cave-dweller (Betke *et al.*, 2024: 1), which roosts in limestone or sandstone (Goodman *et al.*, 2005a; Andriafidison *et al.*, 2007), where the colonies can count to 100 animals.

DIET:
This bat's diet primarily consists of moths (Lepidoptera - 43.5 %) and beetles (Coleoptera - 38.9 %), with smaller quantities of flies (Diptera), bugs (Hemiptera) and mayflies (Ephemeroptera) (Garbutt, 2022: 97; Goodman *et al.*, 2022: 1905).

PREDATORS:
O. madagascariensis is predated by Barn Owl (*Tyto alba* (Scopoli, 1769)) and Bat Hawk (*Macheiramphus alcinus* Bonaparte, 1850) (Garbutt, 2022: 97).

POPULATION:
Structure and Density
The colony of *O. madagascariensis* in a cave in the south of Parc National du Tsingy de Bemaraha consisted of between 90 and 100 individuals in 2003 (Andriafidison *et al.*, 2007). The Sarodrano roost in the south of Madagascar contained at least 67 animals in November 2003 (Andriafidison *et al.*, 2007). The maximum colony size at Réserve Spéciale d'Ankarana was 97 individuals (S. G. Cardiff *pers. comm.* [in Andriafidison *et al.* (2008l) in IUCN (2009); Monadjem *et al.*, 2017cd]).

Trend
2016: Unknown (Monadjem *et al.*, 2017cd).
2008: Unknown (Andriafidison *et al.*, 2008l; IUCN, 2009).

PARASITES:
Lagadec *et al.* (2012: 1696), Lei and Olival (2014: Suppl.) and Gomard *et al.* (2016: 5) report the presence of *Leptospira* sp. bacteria in this

species, which were identified as having sequences closely related to *L. borgpetersenii* by Dietrich *et al.* (2018a: 3).

Laudisoit *et al.* (2012) describe a new species *Lagaropsylla makay* (Siphonaptera; Ischnopsyllidae), and they also mention a new parasite-host association between *Araeopsylla martialis* (Rothschild, 1903) (Siphonaptera; Ischnopsyllidae) and *O. madagascariensis* (see also Duchemin *et al.*, 2022: 1077).

Ramasindrazana *et al.* (2016: 6) report the presence of an unnamed filariod in this bat species.

VIRUSES:

Paramyxoviridae

Wilkinson *et al.* (2012: 160) tested 8 individuals from the Madagascar using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids. Wilkinson *et al.* (2014) tested 18 individuals from Anjohikinakina in Madagascar with an RT-PCR specific for the *Respiro-*, *Morbilli-* and *Henipavirus* genera, five of the 18 individuals tested positive for paramyxovirus RNA.

Seven out of 39 Madagascan specimens tested by Mélade *et al.* (2016b: 4) were positive for paramyxoviruses.

Rhabdoviridae

Mélade *et al.* (2016a: 6) examined 20 specimens for *Lagos bat lyssavirus* and got three positive results. Four out of 18 animals had a positive outcome for *Duvenhage lyssavirus*.

Otomops martiensseni (Matschie, 1897)

*1897. *Nyctinomus martiensseni* Matschie, Arch. Naturgesch. Berlin, 63 (1): 84. Publication date: October 1897. Type locality: Tanzania: 25 mi W of Tanga, SE portion of W Usambara Mts: Magrotto Plantation [05 07 S 38 45 E]. [Goto Description]. Holotype: ZMB 97523: ♂, skin and skeleton and skull. Collected by: G. Martienssen; collection date: August 1897. See Turni and Kock (2008: 71). - Comments: Horáček *et al.* (2000: 137) mention the type locality as "Usanbara Mts., W of Tanga, NE Tanzania". Grubb *et al.* (1998: 98) indicate that the locality has been defined by Swynnerton, 1945, Proc. Zool. Soc. Lond., 115: 63). - Etymology: In honour of "Herr Martienssen of the Königlich Museum für Naturkunde" who found the type specimen (see Long, 1995: 4).

1966. *Otomops maertiensseni:* Hayman, Misonne and Verheyen, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., (8) 154: pl XX. Publication date: December 1966. (Lapsus).

2017. *O[tomops] martiensenni:* Waruhiu, Ommeh, Obanda, Agwanda, Gakuya, Ge, Yang, Wu, Zohaib, Hu and Shi, Virol. Sin., 32 (2): 10. Publication date: 6 April 2017. (Lapsus).

2017. *Otomops martiensenii:* Waruhiu, Ommeh, Obanda, Agwanda, Gakuya, Ge, Yang, Wu, Zohaib, Hu and Shi, Virol. Sin., 32 (2): 7. Publication date: 6 April 2017. (Lapsus).

2017. *Otomops martienssi:* Tao, Shi, Chommanard, Queen, Zhang, Markotter, Kuzmin, Holmes and Tong, J. Virol., 91 (5) e01953-16: Suppl. Publication date: 11 January 2017. (Lapsus).

? *Otomops martiensseni:* (Name Combination, Current Combination).

TAXONOMY:

Koopman (1993a: 239) included *madagascariensis*, but see Peterson *et al.* (1995: 183), Long (1995) and Simmons (2005: 447). Lamb *et al.* (2008: 30) indicate that there are two clades in *martiensseni*, of which "clade 1" (north-east Africa + Yemen) would constitute an undescribed taxon. Additionally, Lamb *et al.* (2008: 31) indicate that the population from Côte d'Ivoire may represent a distinct lineage.

Ralph *et al.* (2015) proved that the specimens from Ethiopia, Eritrea, Somalia, Djibouti and Yemen represent a different species: *O. harrisoni*, which is larger and more robust than any other *Otomops*.

Ammerman *et al.* (2012: 23) indicate that the separation between *martiensseni* and *madagascariensis* took place less than 2 million years ago.

Simmons (2005: 447) recognises one subspecies *icarus* Chubb, 1917.

COMMON NAMES:
Afrikaans: Bakoor-losstertvlermuis. Chinese: 大?犬吻?. Czech: morous Martienssenův. CONSERVATION STATUS:
Global Justification
Listed as Near Threatened (NT ver 3.1 (2001)) because this species is probably still in significant decline globally (but probably at a rate of less than 30 % over ten years), owing to the probable continued loss of the known major East African populations. Smaller populations from southern Africa may be increasing. The status of populations in Central and West Africa, where the species is still known from very few specimens, remains unclear. Almost qualifies as threatened under criterion A2c (Mickleburgh *et al.*, 2008dd; IUCN, 2009; Richards *et al.*, 2017).

Assessment History
Global
2016: NT ver 3.1 (2001) (Richards *et al.*, 2017). 2008: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2008dd; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004cq; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Richards *et al.*, 2016e). 2004: VU D2 ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

Legal Status
Richards (2017) report that it is a listed Threatened or Protected Species (ToPS) under the South African National Environmental Management (NEMBA): Biodiversity Act (No. 10 of 2004) and is protected by provincial ordinance in the KwaZulu-Natal province.

MAJOR THREATS:
The leading threat to this species appears to be roost disturbance (Ralph *et al.*, 2015). Populations in Durban (South Africa) have been found to use old buildings with attics as roosts, and it appears that the main threat to these populations is indirect poisoning through the application of toxic timber treatments (Fenton *et al.*, 2002).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008dd) [in IUCN (2009)] and report that there is a need to reassess the status of all known roosts (and to locate additional localities) to ascertain numbers and status of colonies, so that key sites can be identified. While Richards *et al.* (2017) report that species has been recorded from Comoe National Park, Côte d'Ivoire (Fahr and Kalko 2011 in Richards *et al.* (2017), Garamba National Park, Democratic Republic of Congo (Verschuren, 1957), and a national park in Rwanda (Hutson *et al.*, 2001). The species occurs in several protected areas in South Africa (Adams *et al.*, 2015). An IUCN Species Action Plan has been developed for this species (Hutson *et al.*, 2001); this action plan requires revision given the reviewed species limits of *O. martiensseni* (Lamb *et al.*, 2008; Richards *et al.*, 2012) and the description of new northeast African species, *O. harrisoni* (Ralph *et al.*, 2015).

GENERAL DISTRIBUTION:
Otomops martiensseni has been widely, but patchily, recorded from much of sub-Saharan Africa. In Africa, it has been reported from Côte d'Ivoire and Ghana in West Africa, through Central Africa (recorded from Central African Republic, the Democratic Republic of the Congo, Rwanda and western Uganda) to East Africa (Kenya and Tanzania) to southern Africa (Malawi, central Angola [Chitau], Zimbabwe, Zambia and eastern South Africa). It is found at elevations from sea level to 2,900 m asl, although the highest elevations might need to be referred to *O. harrisoni*.

Records from Madagascar are now referred to *O. madagascariensis* (see Taxonomy section above).

Lamb *et al.* (2008: 30, 39) mention it from Côte d'Ivoire, Ghana, and Burundi, but also see Taxonomy paragraph. Records from Djobuti, Eritrea, Ethiopia, Somalia, Yemen are now referred to *O. harrisoni*, as might be the case for some of the records from Kenya, Tanzania and Uganda (see Taxonomy section above).

Patterson *et al.* (2018: 1) found both *O. martiensseni* and *O. harrisoni* in a cave in the Musanze district of Rwanda.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 545; Taylor *et al.*, 2018b: 63); Botswana (Adams *et al.*, 2015: 711); Central African Republic; Congo (The Democratic

Republic of the) (Ansell, 1974; Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 545); Côte d'Ivoire; Ghana; Kenya (Patterson *et al.*, 2018: 5); Malawi (Monadjem *et al.*, 2010d:454); Rwanda (Patterson *et al.*, 2018: 1); South Africa (Monadjem *et al.*, 2010d:545;Adams *et al.*, 2015: 710-711); Tanzania; Uganda; Zambia Monadjem *et al.*, 2010d: 545); Zimbabwe (Lamb *et al.*, 2008; Monadjem *et al.*, 2010d: 545).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Large species, with narrowest wings of any bat for fast flying in open areas (Anonymus, 2004f: 57).

FUNCTIONAL MORPHOLOGY:
Based on the analysis of wing dimensions, Thollesson and Norberg (1991: 34) suggest that the longer hand wings and more pointed wing tips of *O. martiensseni* indicate that this is a species primarily flying in open areas at a high altitude. Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 12.9 Pa, aspect ratio 8.3 for a wingspan of 39 cm and a wing area of 183 cm^2 and a body mass of 24 g.

ECHOLOCATION:
From Bungule in Kenya Taylor *et al.* (2005) reported a F_{max}: 16.5 kHz. However, due to the split off of *O. harrisoni*, the taxonomic status of the specimens involved is uncertain (see Ralph *et al.*, 2015: 26).

At Sengwa in Zimbabwe, Jacobs (1996) and Fenton and Bell (1981) recorded a highest frequency of 17 kHz. Taylor (1999b) recorded F_{max}: 29.5 ± 2.4 kHz (open flight) and 14.7 ± 1.5 (emergence) from two localities in the Durban area in South Africa. Whereas, Fenton *et al.* (2004) reported a F_{max}: 14.7 ± 1.68 kHz from the Durban area in South Africa. From the same area, Schoeman and Waddington (2011: 291) mention a F_{peak}: 10.7 ± 0.4 kHz and a duration: 27 ± 1.5 ms.

Fenton (2004b: 4) states that there is evidence that, in this species, calls originally associated with echolocation may actually serve more for communication.

Adams *et al.* (2015: 709) report the following values from South Africa: F_{char}: 11.70 ± 3.61 (10.51 - 13.54) kHz; F_{high}: 13.19 ± 1.08 (11.01 - 15.67) kHz; F_{low}: 10.82 ± 0.65 (9.11 - 12.23) kHz; Band width: 2.40 ± 0.90 (0.65 - 5.64) kHz; F_{max}: 12.41 ± 0.90 (10.76 - 14.55) kHz; duration: 21.18 ± 3.61 (11.79 - 27.81) ms. Also from the RSA (Mapungubwe National Park), Parker and Bernard (2018: 57) reported on 20 calls: F_{char}: 10.74 ± 0.63 kHz, F_{max}: 11.52 ± 0.60 kHz, F_{min}: 10.28 ± 0.50 kHz, F_{knee}: 10.81 ± 0.64 kHz, duration: 22.68 ± 13.89 ms, with 3.98 ± 2.40 calls/sec.

Nine calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 13.16 ± 1.93 kHz, F_{min}: 9.75 ± 2.64 kHz, F_{knee}: 12.61 ± 1.63 kHz, F_{char}: 11.77 ± 1.02 kHz, slope: 16.52 ± 6.04 OPS, duration: 12.99 ± 5.28 ms.

For seven calls from the Aberdares Range in Kenya, Eisenring *et al.* (2016: SI 2) reported: F_{peak}: 14.8 ± 2.8 (9.9 - 17.4), Fsub max: 22.0 ± 4.2 (14.5 - 26.4), F_{min}: 9.9 ± 2.5 (5.2 - 13.2), DT: 0.1 ± 0.0 (0.1 - 0.2), DF: 12.1 ± 2.4 (9.3 - 16.0), IPI: 3.3 ± 2.0 (1.5 - 5.5).

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 9 bats: F_{max}: 12.88 ± 1.09 kHz, F_{min}: 11.83 ± 1.4 kHz, F_{knee}: 12.67 ± 0.98 kHz, F_{char}: 12.01 ± 0.83 kHz, slope: -31.73 ± 563.48 OPS, duration: 9.13 ± 5.96 ms. 17 calls recorded by Cory-Toussaint and Taylor (2022: Table S1) had a duration: 7.57 ± 2.16 ms, F_{min}: 11.54 ± 0.65 kHz, F_{max}: 12.03 ± 0.80 kHz, F_{knee}: 11.92 ± 0.82 kHz and F_{char}: 11.63 ± 0.62 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 3 *Otomops martiensseni* calls from the Kruger Park (RSA): F_{min}: 10.5 ± 1.1 (9.7 - 11.8) kHz, duration: 10.6 ± 2.0 (8.4 - 12.4) ms, F_{max}: 10.9 ± 1.2 (10.0 - 12.3) kHz, F_{knee}: 10.6 ± 1.1 (9.8 - 11.8) kHz, F_{char}: 10.6 ± 1.1 (9.8 - 11.8) kHz,

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 11.8 kHz and duration: 27 ms.

MOLECULAR BIOLOGY:
Karyotype
Đulić and Mutere (1973a) reported 2*n* = 48, FN = 56, BA = 10, a submetacentric X chromosome, and an acrocentric Y chromosome. However, Warner *et al.* (1974) reported 2*n* = 48, FN = 58, BA = 12, a submetacentric X chromosome and a submetacentric Y chromosome for one male specimen from Kenya. In view of the split off of *O. harrisoni* the Kenyan karyotype might represent the latter species rather than *O. martiensseni*.

Genetics
See Hoofer and Van Den Bussche (2003), Lamb *et al.* (2006) and Lamb *et al.* (2008).

HABITS:
O. martiensseni is probably a long-range forager, which hunts over a wide diversity of habitats, e.g., semi-arid areas and montane forests up to 2,000 m (Anonymus, 2004f: 57). Adams *et al.* (2015), referring to Fenton and Griffin (1997), indicate that foraging occurs at altitudes exceeding 600 m above ground. Actually, Fenton and Griffin (1997: 248) reported one call in the 10 - 13 kHz range (used by *O. martiensseni*) at an altitude between 500 and 550 m.

Foord *et al.* (2018: 5) indicate that open-air feeders (e.g., *O. martiensseni*) may commute over 10 km between roosts and feeding areas, but do prefer smaller feeding areas.

ROOST:
In the Durban area, Taylor *et al.* (1999: 67) found roosts on the brick surface of the inner gable apex wall within the roof space, with entrances height between 3 and 12 m. The colony size varied between one and 30. Richardson and Taylor (1995: 73) already remarked that the exit holes did not have obstructing trees in the way.

Anonymus (2004f: 57) indicates that *O. martiensseni* is generally colonial with larger colonies in underground sites (e.g., caves and lava tubes), whereas in South Africa small colonies occur in houses. Happold and Happold (2023: 115) indicate that the most common group size is up to 50 individuals, but sometimes there can be hundreds, and occasionally only singles or pairs.

POPULATION:
Structure and Density
Although *O. martiensseni* was once considered to be rare, with gaps in distribution, additional collecting has demonstrated local abundance in several areas (Long, 1995; Taylor, 1998; Fenton *et al.*, 2002; Skinner and Chimimba, 2005). For example, it is common around Durban in KwaZulu Natal Province of South Africa (Fenton *et al.*, 2002), and is fairly common in Comoe National Park, Côte d'Ivoire (Richards *et al.*, 2017).

Trend
2016: Decreasing (Richards *et al.*, 2017). 2008: Decreasing (Mickleburgh *et al.*, 2008dd; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Richardson and Taylor (1995: 73) found that males might be chased from their birth colony once they become mature.

REPRODUCTION AND ONTOGENY:
Martin and Bernard (2000: 32) indicate that the corpus luteum undergoes luteolysis in late pregnancy. Krutzsch (2000: 126) further mentions that the species exhibits classical mammalian male-female synchrony of reproductive cycles.

Richardson and Taylor (1995: 72) reported births in Durban (RSA) in early to mid-December, and that juveniles were of almost adult size by mid-January. The young could then still be distinguished by their greyer colour.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] indicated that juveniles have been recorded from October through May.

MATING:
Ober *et al.* (2016: 375) mention that *O. martiensseni* forms single male/multiple female groups.

PARASITES:
SIPHONAPTERA
Ischnopsyllidae
Beaucournu and Kock (1996) reported *Araeopsylla scitula* Rothschild, 1909 from a bat from Kenya. However, in view of the split off of *O. harrisoni*, this latter species might have been the host for this ectoparasite.

ACARI
Trombiculidae
Stekolnikov (2018a: 189) mentioned *Willmannium suswaensis* (Vercammen-Grandjean & Langston, 1976) from a bat collected at Mount Suswa (Kenya).

HEMIPTERA
Polyctenidae
Eoctenes faini Benoit, 1958 was reported from Rwanda by Szentiványi *et al.* (2022: 6).

VIRUSES:
In their country-wide survey of Kenyan bats, Waruhiu *et al.* (2017) found the following viruses in *Otomops martiensseni*: Adenoviruses and Polyomaviruses.

Adenoviridae
Adenovirus
Two of the 19 specimens from the Suswa Cave (Kenya) by Conrardy *et al.* (2014: 259) tested positive for this virus.

Coronaviridae - Coronaviruses
SARS-CoV

Tong *et al.* (2009) tested two bats collected in Kenya during 2006 positive for the presence of coronavirus RNA in faecal samples.

28.6 % (10 out of 35) of the Kenyan *O. martiensseni* specimens were positive for CoV (Tao *et al.*, 2017: 3).

Flaviviridae
Hepacivirus (BHV)
Quan *et al.* (2013: Table S5) report that 3 of 15 Kenyan specimens were infected with clade C *Hepacivirus* (20.0 %). Shchelkanov *et al.* (2020a: 18) assigned this virus to Hepacivirus M.

Pegivirus (BPgV)
2 of the 15 specimens examined by Quan *et al.* (2013: Table S5) were also infected with clade K *Pegivirus* (13.3 %).

Paramyxoviridae
Paramyxovirus
Five of the 19 specimens from the Suswa Cave by Conrardy *et al.* (2014: 259) tested positive for this virus, and this was also the case for nine out of 40 specimens from Kenya, which were tested by Mortlock *et al.* (2015: 1481).

Polyomaviridae
Orthopolyomavirus
Initially, three novel orthopolyomaviruses were detected in 2006 from Kenya by Tao *et al.* (2012). Additional surveillance detected 6 of the 19 specimens from the Suswa Cave to be positive tested by Conrardy *et al.* (2014: 259).

Rhabdoviridae
Lyssavirus - Rabies related viruses
Horton *et al.* (2014: Table S1) tested 16 Kenyan *O. martiensseni* specimens but failed to find neutralising antibodies to IKOV (Ikoma lyssavirus).

Remark: as most of these viruses were found on "*O. martiensseni*" specimens from Kenya, the actual host species might be *O. harrisoni*.

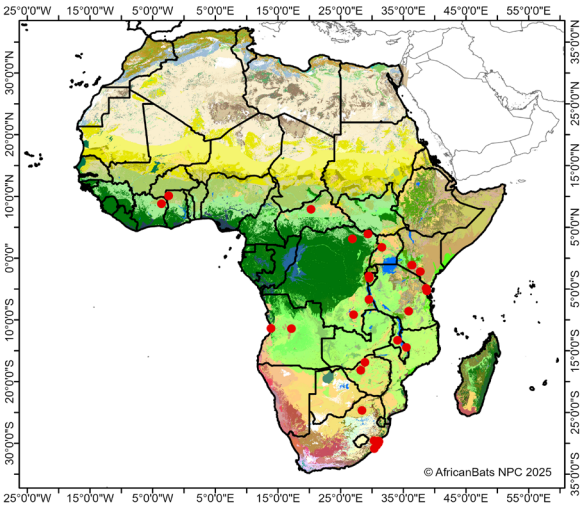

Figure 209. Distribution of *Otomops martiensseni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Kenya.

Otomops martiensseni icarus Chubb, 1917

*1917. *Otomops icarus* Chubb, Ann. Durban Mus., 1: 433, pl 21. Publication date: 21 May 1917. Type locality: South Africa: KwaZulu-Natal: Durban [29 52 S 31 00 E]. [Goto Description]. Holotype: NHMUK 1916.10.9.1: ♂. - Etymology: Named after Icarus, son of Daidalos, who fled from their prison with wings made of wax and feathers.
? *Otomops martiensseni icarus:* (Name Combination, Current Combination).

GENERAL DISTRIBUTION:
From Angola to KwaZulu-Natal, Malawi (Horáček *et al.*, 2000: 137).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Côte d'Ivoire, Ghana, South Africa, Uganda.

Otomops martiensseni martiensseni (Matschie, 1897)

*1897. *Nyctinomus martiensseni* Matschie, Arch. Naturgesch. Berlin, 63 (1): 84. Publication date: October 1897. Type locality: Tanzania: 25 mi W of Tanga, SE portion of W Usambara Mts: Magrotto Plantation [05 07 S 38 45 E]. [Goto Description]. Holotype: ZMB 97523: ♂, skin and skeleton and skull. Collected by: G. Martienssen; collection date: August 1897. See Turni and Kock (2008: 71). - Comments: Horáček *et al.* (2000: 137) mention the type locality as "Usanbara Mts., W of Tanga, NE Tanzania". Grubb *et al.* (1998: 98) indicate that the locality has been defined by Swynnerton, 1945, Proc. Zool. Soc. Lond., 115: 63). - Etymology: In honour of "Herr Martienssen of the Königlich Museum für Naturkunde" who found the type specimen (see Long, 1995: 4).
? *Otomops martiensseni martiensseni:* (Name Combination, Current Combination).

GENERAL DISTRIBUTION:
Central African Republic to Yemen and south to Zimbabwe (Horáček *et al.*, 2000: 137).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Burundi, Central African Republic, Congo (Democratic Republic of the), Ethiopia, Kenya, Malawi, Rwanda, South Africa, Tanzania, Zimbabwe.

Genus ***Platymops*** Thomas, 1906

*1906. *Platymops* Thomas, Ann. Mag. nat. Hist., ser 7, 17 (101): 499. Publication date: 1 May 1906 [Goto Description]. - Comments: Type species: *Platymops Macmillani* Thomas, 1906 (=*Mormopterus setiger* Peters, 1878). - Etymology: From the Greek adjective "*πλατύς*" (platýs), meaning "flat" and the masculine German substantive *Mops*, referring to the extremely flattened skull of the genus (see Lanza *et al.*, 2015: 315). (Current Combination).
? *Mormopterus (Platymops):* (Name Combination).

TAXONOMY:
Considered a subgenus of *Mormopterus* by Koopman (1993a: 238), Czaplewski *et al.* (2003: 68), but a valid genus by Kock (1969a: 155), Simmons (2005).

Included in *Mormopterus* by Jacobs and Fenton (2002: 1).

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Platymops*: ***setiger*** (Peters, 1878).

COMMON NAMES:
Czech: ploší morousi. English: East African Flat-headed Bats, Peters's flat-headed Bats. French: Tadarides à tête plate. German: Flachkopf-Bulldoggfledermäuse. Italian: Platicarlìni.

Platymops setiger (Peters, 1878)

*1878. *Mormopterus setiger* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 196, pl 1, fig 2. Type locality: Kenya: Taita district: Ndi [03 14 S 38 30 E, 2 000 m]. [Goto Description]. Syntype: ZMB 5265a: ♀, skull and alcoholic. Collected by: Dr. Johann Maria Hildebrandt; collection date: July 1877. See Turni and Kock (2008). Syntype: ZMB 5265b: ♀, skull and alcoholic. Collected by: Dr. Johann Maria Hildebrandt; collection date: July 1877. See Turni and Kock (2008). - Comments: Allen (1939a: 109) mentioned 1881; Monatsb. K. Preuss. Akad. Wiss., Berlin, p. 483, pl., fig. 3. - Etymology: From the masculine Latin adjective *sètiger*, meaning "covered with coarse hair, bristly", referring to the coarse fur of the species Lanza *et al.*, 2015: 316).
1960. *Platymops setiger:* Harrison and Fleetwood, Durban Mus. Novit., 5 (20): 269. (Name Combination, Current Combination).

TAXONOMY:
See Freeman (1981b: 133, 161). Included in *Platymops* by Harrison and Fleetwood (1960: 277 - 278).

COMMON NAMES:
Chinese: 彼德犬吻蝠. Czech: morous plochý. English: East African Flat-headed Bat, Peters's Flat-headed Bat, Flat-headed free-tailed bat. French: Sauromys à tête plate, Tadaride à tête plate de Peters. German: Peters' Flachkopf-Bulldoggfledermaus. Italian: Carlìno setolóso.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008al; IUCN, 2009; Monadjem *et al.*, 2017aj).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017aj). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008al; IUCN, 2009). 2004: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2004ay; IUCN, 2004). 1996: LR/lc [assessed as *Mormopterus setiger*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There are presumably no major threats to this species (Mickleburgh *et al.*, 2008al; IUCN, 2009; Monadjem *et al.*, 2017aj).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008al) [in IUCN (2009)] and Monadjem *et al.* (2017aj) report that there appear to be no direct conservation measures in place. In view of the species' East African range, it seems likely that it is present within some

protected areas, although this needs to be confirmed. Further studies are needed into the distribution, natural history and potential threats to this species.

GENERAL DISTRIBUTION:
Platymops setiger is an East African species present in Kenya, southwestern Ethiopia (Glass, 1965: 179), southeastern Sudan and is possibly present in adjacent Uganda, although this needs to be confirmed. It has been recorded at elevations of up to 2,000 m asl.

Native: Ethiopia; Kenya; Sudan.

Presence uncertain: Uganda.

DETAILED MORPHOLOGY:
Vomeronasal complex (VNC)
Smith *et al.* (2024: 9) found two oval depressions just caudal to the incisive foramen on the (pre)maxillary bones.

MOLECULAR BIOLOGY:
Karyotype
Warner *et al.*, 1974) reported 2*n* = 48, FN = 54, BA = 8 and submetacentric X and acrocentric Y chromosomes.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Mickleburgh *et al.*, 2008al; IUCN, 2009; Monadjem *et al.*, 2017aj).

Trend
2016: Unknown (Monadjem *et al.*, 2017aj). 2008: Unknown (Mickleburgh *et al.*, 2008al; IUCN, 2009).

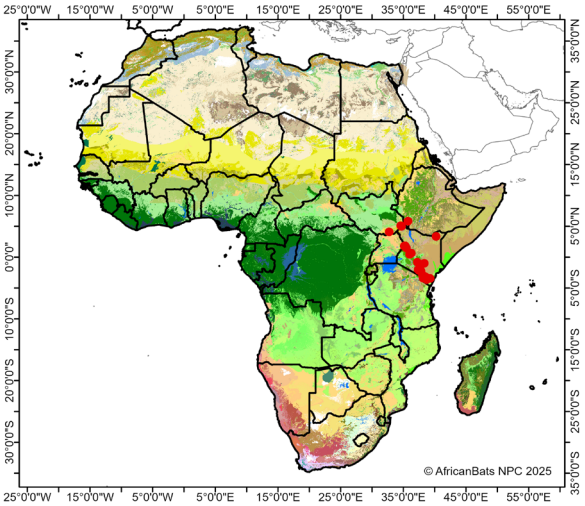

Figure 210. Distribution of *Platymops setiger*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Kenya.

Platymops setiger macmillani Thomas, 1906

*1906. *Platymops Macmillani* Thomas, Ann. Mag. nat. Hist., ser 7, 17 (101): 500. Publication date: 1 May 1906. Type locality: Ethiopia: Between Addis Ababa and Lake Rudolf. [Goto Description]. Holotype: NHMUK 1906.11.1.10: ad ♂, skull and alcoholic. Collected by: Ph.C. Zaphiro. Presented/Donated by: W.N. McMillan Esq. 7 specimens. - Etymology: In honour of Mr. W.N. McMillan, to whose liberality science is indebted for the exploration of which it is part of the outcome (see Thomas, 1906b: 501).

1956. *Platymops barbatogularis* Harrison, Ann. Mag. nat. Hist., ser 12, 9 (104): 549. Publication date: 18 December 1956. Type locality: South Sudan: SE Sudan, Ilemi triangle: Lokomarinyang Marsh [05 02 N 35 33 E]. [Goto Description]. Holotype: NHMUK 1967.1232: ad ♂, skin and skull. Collected by: John George Williams; collection date: 10 June 1953. Formerly HZM 2.1897 (see Harrison (1956e: 549). Paratype: NHMUK 1957.258. - Comments: Evenhuis (2003: 54) indicates that ser. 12, 9 (104) is the "August 1956" issue which was published on "18 December 1956".
Jelle Zijlstra (pers. comm., 26/02/2023) pointed out that the type locality is in the "Ilemi Triangle", an area disputed between South Sudan and Kenya, and is currently under the de facto control of Kenya.

1960. *Platymops barbatogularis parkeri* Harrison and Fleetwood, Durban Mus. Novit., 5 (20): 270, figs 1 - 6. Publication date: 30 April 1960. Type locality: Kenya: Lualeni borehole: Maktau [03 24 S 38 08 E]. [Goto Description]. Holotype: NHMUK 1959.524: ad ♀, skin and skull. Collected by: Ian Parker; collection date: 12 February 1958; original number: 2.

? *Mormopterus setiger macmillani:* (Name Combination).

? *Platymops setiger macmillani:* (Name Combination, Current Combination).

TAXONOMY:
Kock (1969a: 155) considers *barbatogularis* to be a synonym of *macmillani*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia, Kenya, South Sudan.

Platymops setiger setiger (Peters, 1878)

*1878. *Mormopterus setiger* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 196, pl 1, fig 2. Type locality: Kenya: Taita district: Ndi [03 14 S 38 30 E, 2 000 m]. [Goto Description]. Syntype: ZMB 5265a: ♀, skull and alcoholic.

Collected by: Dr. Johann Maria Hildebrandt; collection date: July 1877. See Turni and Kock (2008). Syntype: ZMB 5265b: ♀, skull and alcoholic. Collected by: Dr. Johann Maria Hildebrandt; collection date: July 1877. See Turni and Kock (2008). - Comments: Allen (1939a: 109) mentioned 1881; Monatsb. K. Preuss. Akad. Wiss., Berlin, p. 483, pl., fig. 3. - Etymology: From the masculine Latin adjective *sètiger*, meaning "covered with coarse hair, bristly", referring to the coarse fur of the species Lanza *et al.*, 2015: 316).

? *Mormopterus setiger setiger:* (Name Combination).

? *Platymops setiger setiger:* (Name Combination, Current Combination).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya, South Sudan.

Genus ***Sauromys*** Roberts, 1917

1917. *Platymops* Roberts, Ann. Transv. Mus., 6(1): 5. Publication date: 28 June 1917. - Comments: Type species: *Platymops (Sauromys) petrophylus* Roberts, 1917. Not of Thomas, 1906.

*1917. *Platymops (Sauromys)* Roberts, Ann. Transv. Mus., 6(1): 5. Publication date: 28 June 1917. - Comments: Type species: *Platymops (Sauromys) haagneri* Roberts, 1917 (=*Platymops petrophilus* Roberts, 1917). As a subgenus of *Platymops* Thomas, 1906. - Etymology: From Greek "*sauros*" meaning lizard and "mys" meaning mouse (see Jacobs and Fenton, 2002: 1).

? *Mormopterus (Sauromys):* (Name Combination).

? *Sauromys:* (Current Combination).

? *Tadarida (Sauromys):* (Name Combination).

TAXONOMY:
Bronner *et al.* (2003) state that the status of *Sauromys*, described as a monotypic subgenus of the extralimital *Platymops* for the South African flat-headed free-tailed bat, remains unclear. Peterson (1965) raised it to generic rank, a treatment endorsed by many subsequent authors, and corroborated by a limited multivariate analysis of wing bone and cranial characteristics (Peterson, 1985). However, morphometric studies by Freeman (1981b) and Legendre (1984) concluded that it is a subgenus of *Mormopterus*, a position followed by Koopman (1993a, 1994), and Jacobs and Fenton (2002: 1). Simmons (2005) retains *Sauromys* as a valid genus in the 3rd Edition of Mammal Species of the World, a treatment we favour because of the unique ecology and morphology of *S. petrophilus*. Analysis of the Rag2 data confirmed the split between *Mormopterus* and *Sauromys* (see Ammerman *et al.*, 2013: 309).

Meester *et al.* (1986) also state that originally described as a subgenus, this genus was regarded as a synonym of *Platymops* by Shortridge (1942), Roberts (1951) and Ellerman *et al.* (1953). Harrison (1962) retains it as a subgenus, while Peterson (1965) raises it to generic rank, in which he is followed by Hayman and Hill (1971), Smithers (1971), Corbet and Hill (1980) and Rautenbach (1982). However, Freeman (1981b), followed by Koopman (1982) and Legendre (1984), conclude that both *Sauromys* and *Platymops* are subgenera of *Mormopterus*. We take the view that both *Platymops* and *Sauromys* are valid genera.

Generic and species classification of African flat-headed molossids is unclear. Roberts (1917c) originally described *Sauromys* as a subgenus of *Platymops*. Later Roberts (1951, 1954) dropped *Sauromys* as a subgenus, as Shortridge (1942) reported that a minute upper premolar was found on the type *Platymops macmillani* Thomas, 1906. Peterson (1965) indicates that the minute premolar on the type *P. macmillani* is probably a milk premolar and that normal adult dental formula should be considered as having only one upper premolar. For this reason and others (e.g., glands not on wings) Peterson (1965) raises *Sauromys* to generic status. Koopman (1975) indicates that *Sauromys* is a subgenus within *Tadarida*, however Freeman (1981b) found that all the so-called flat-headed bats; *Sauromys*, *Platymops*, and *Neoplatymops*, are phenotypically related to *Mormopterus*. While the phenogram in Freeman (1981b) also indicates that *Tadarida aegyptiaca* (E. Geoffroy 1818) and *T. brasiliensis* (I. Geoffroy St.-Hilaire 1824) are phenetically similar to *Mormopterus*, this grouping is explained due to convergence of shape due to similar life styles (Freeman, 1981b). Meester *et al.* (1986) did not follow Freeman (1981b) and rather followed Peterson (1965) recognizing *Sauromys*, *Mormopterus* and *Platymops* as valid genera. While Koopman (1993a) followed Freeman (1981b) in classifying *Sauromys* and *Platymops* as subgenera in the genus *Mormopterus*, Simmons (2005) recognizes *Sauromys* as a distinct genus.

Peterson (1965) suggests that a detailed comparison between *Sauromys* and *Tadarida* needs to be performed, including an investigation into the specific status and geographic variation. Ammerman *et al.* (2012: 21) suggest that *Sauromys* is more appropriately recognized as a member of the genus *Tadarida*, which split off

from *T. aegyptiaca* some 6.5 million years ago. However, based on their morphological data, Gregorin and Cirranello (2015: 10) still find it premature to transfer *Sauromys* into *Tadarida*.

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Sauromys*: ***petrophilus*** (Roberts, 1917).

COMMON NAMES:
Czech: ještěří morousi. French: Sauromys. German: Flachkopf-Bulldoggfledermäuse.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Avery (2007: 619) reported on the presence of *Sauromys* sp. in Pleistocene deposits at Wonderwerk Cave, South Africa.

Sauromys petrophilus (Roberts, 1917)

*1917.	*Platymops (Sauromys) petrophilus:* Roberts, Ann. Transv. Mus., 6(1): 5. Publication date: 28 June 1917.
1917.	*Platymops petrophilus* Roberts, Ann. Transv. Mus., 6(1): 5. Publication date: 28 June 1917. Type locality: South Africa: Western Transvaal: near Rustenburg: Bleskop. [Goto Description]. Holotype: TM X835: ♂. Collected by: G.P. Van Dam; collection date: 2 February 1917; original number: 16. - Etymology: From the Greek "*petros*" meaning rock and "*philos*" meaning loving. (Name Combination).
?	*Mormopterus petrophilus petrophilus:* (Name Combination).
?	*Mormopterus petrophilus:* (Name Combination).
?	*Platymops haagneri haagneri:*
?	*Sauromys petrophilus:* (Name Combination, Current Combination).

TAXONOMY:

Figure 211. *Sauromys petrophilus umbratus* from Kliphuis, Cederberg, Western Cape South Africa.

Roberts (1951, 1954) recognised two species and five subspecies of flat-headed bats in southern Africa: *Platymops haagneri* Roberts, 1917 (*haagneri*, *umbratus* Shortridge and Carter, 1938) and *Platymops petrophilus* Roberts, 1917 (*petrophilus*, *erongensis* Roberts, 1946, *fitsimonsi* Roberts, 1946). Ellerman *et al.* (1953) suggested that the two species are conspecific, and rather recognized five subspecies of *Platymops petrophilus* (*petrophilus*, *haagneri*, *umbratus*, *erongensis* and *fitzsimonsi*). Meester *et al.* (1986) also recognized the five subspecies suggested by Ellerman *et al.* (1953) for *petrophilus* but within the genus *Sauromys*, following Peterson (1965: 12). Freeman (1981b) indicates that *erongensis* (Roberts, 1946) may be a synonym of *haagneri* (Roberts, 1917) and *fitzsimonsi* (Roberts, 1946) is possibly a synonym of *umbratus* (Shortridge and Carter, 1938). Included in *Mormopterus* by Jacobs and Fenton (2002: 1). Jacobs and Fenton (2002: 1) considered *M. petrophilus* to be monotypic.

COMMON NAMES:
Afrikaans: Platkop-losstertvlermuis. Czech: morous ještěří. English: Rock-loving Flat-headed Bat, Rock-dwelling Flat-headed Bat, Roberts' Flat-headed Bat, Roberts's Flat-headed Bat, Flat-headed Free-tailed Bat. French: Sauromys de Roberts. German: Roberts' Flachkopf-Bulldoggfledermaus. Portuguese: Morcego de cabeca curta.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
No fossils are known (Jacobs and Fenton, 2002: 1).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008an; IUCN, 2009; Monadjem *et al.*, 2017bh).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bh). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008an; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004bc; IUCN, 2004). 1996: LR/lc [assessed as *Mormopterus petrophilus*] (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Jacobs *et al.*, 2016f). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this species. In parts of its range it is believed to be threatened by considerable habitat change resulting from deforestation (Mickleburgh *et al.*, 2008an; IUCN, 2009; Monadjem *et al.*, 2017bh).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008an) [in IUCN (2009)] and Monadjem *et al.* (2017bh) report that this species is present in several protected areas in Namibia and Angola. In South Africa it has been reported from the protected Algeria forestry station. No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Sauromys petrophilus is found in southern Africa, ranging along the west coast from the Angola and Namibia border area, south into southern South Africa, and from here into northeastern South Africa, Zimbabwe, and western Mozambique. It is found between 100 m and 2,000 m asl. In the RSA, its distribution is best predicted by geology (Babiker Salata, 2012: 50).

Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 915,652 km^2.

The Ghanaian specimen which should be in the USNM (see Meester *et al.*, 1986), could not be located in the collection (see Jacobs and Fenton, 2002: 2).

Native: Angola; Botswana (Monadjem *et al.*, 2010d: 545); Mozambique (Monadjem *et al.*, 2010d: 545; Monadjem *et al.*, 2010c: 382); Namibia (Monadjem *et al.*, 2010d: 545); South Africa (Seamark and Kearney, 2007; Monadjem *et al.*, 2010d: 545)); Zimbabwe (Monadjem *et al.*, 2010d: 545).

Presence uncertain: Ghana.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Jacobs and Fenton (2002).

Schoeman and Jacobs (2002: 157) mention the following wing parameters for 51 specimens from the Algeria Forestry Station (RSA): Fa: 39.0 ± 1.0 mm, Wing area: 93.1 ± 11 cm^2, Wing span: 26.3 ± 1.9 cm, Wing loading: 11.2 ± 1.1 N/m^2, and aspect ratio: 7.4 ± 0.6.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
As indicated by Rautenbach and Nel (1980: 112), the extremely flattened skull is an adaptation to roosting in the narrowest of rock crevices.
For further details, see Jacobs and Fenton (2002).

DETAILED MORPHOLOGY:
Other
For a description of the crania, ears and tragus, and wingshape and aspect ratio, see Jacobs and Fenton (2002).

Curtis and Simmons (2018: 1390) found a relatively large, anteroposteriorly elongated, single, mineralized midline element positioned anterior to the dorsal margin of the nasal aperture in the cupular cartilages. Their CT-microscans showed a variation in the grayscale, suggesting porosity or trabeculae, which in turn might suggest a bony structure.

FUNCTIONAL MORPHOLOGY:
Toussaint and McKechnie (2012: 1138) found that the rapid increases in Evaporate Water Loss at high ambient temperatures in *S. petrophilus* may imply that, notwithstanding having a comparatively heat tolerance, this species may also be most vulnerable to lethal dehydration during future heat waves.

Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 10.8 Pa, aspect ratio 7.6 for a wingspan of 26 cm and a wing area of 89 cm^2 and a body mass of 10 g.

ECHOLOCATION:
See Jacobs and Fenton (2002).

From Algeria Forest Station (RSA), Schoeman and Jacobs (2002: 157) reported the type of calls to be low duty echolocation dominated by frequency modulated calls, with a F_{peak}: 29.2 ± 1.8 kHz.

Two calls by bats from the Kalahari Desert had the following characteristics: F_{char}: 24.0 ± 0.2 kHz, F_{max}: 30.3 ± 3.2 kHz, F_{min}: 23.7 ± 0.1 kHz, duration: 4.3 ± 0.7 ms (Adams and Kwiecinski, 2018: 4).

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 103 calls of 5 bats: F_{max}: 41.46 ± 6.35 kHz, F_{min}: 29.31 ± 2.95 kHz, F_{knee}: 31.89 ± 3.62 kHz, F_{char}: 29.85 ± 1.74 kHz, slope: 117.33 ± 1045.12 OPS, duration: 6.35 ± 2.42 ms. 15 calls recorded at the Venatia mine by Cory-Toussaint and Taylor

(2022: Table S1) had a duration: 7.06 ± 1.11 ms, F_{min}: 28.70 ± 0.44 kHz, F_{max}: 29.37 ± 0.52 kHz, F_{knee}: 29.19 ± 0.47 Khz and F_{char}: 28.85 ± 0.44 kHz.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported $2n$ = 48, FN = 62, BA = 16, a submetacentric X chromosome, and an acrocentric Y chromosome for specimens from Namibia and South Africa. However, this did not include specimens from the Western Cape that Rautenbach *et al.* (1993) included with *Chaerephon pumilus*, but have subsequently been reidentified as *S. petrophilus* (Jacobs and Fenton, 2001).

Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
Sirami *et al.* (2013: 34) recorded in the Western Cape Province, South Africa that *S. petrophilus* activity was significantly and positively influenced by size of wetland, while habitats 100 m surrounding wetlands were also significantly and positively influenced by the water body. *S. petrophilus* favoured open habitats surrounding wetlands (Sirami *et al.*, 2013: 35) .

HABITS:
See Jacobs and Fenton, 2002).

ROOST:
See Jacobs and Fenton (2002).

DIET:
See Jacobs and Fenton (2002).

From the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) reported the following prey groups based on 464 faecal pellets from 51 bats (in volume percent): Diptera (37.8 ± 31.2), Hemiptera (32.9 ± 23.7), Coleoptera (19.5 ± 23.1), Hymenoptera (7.9 ± 16.2), Neuroptera (0.6 ± 3.0), Trichoptera (0.4 ± 2.9), Lepidoptera (0.3 ± 2.2), and unknown (1.0 ± 3.3).

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention *S. petrophilus* as possible prey of Lanner falcon (*Falco biarmicus* Temminck, 1825) and Peregrine falcon (*Falco peregrinus* Tunstall, 1771),

POPULATION:
Structure and Density
This is a locally common species. It is generally found in small numbers, with colonies thought to be tens of animals rather than hundreds (Jacobs and Fenton, 2002).

Trend
2016: Stable (Monadjem *et al.*, 2017bh). 2008: Stable (Mickleburgh *et al.*, 2008an; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
See Jacobs and Fenton, 2002).

REPRODUCTION AND ONTOGENY:
See Jacobs and Fenton (2002).

VIRUSES:
Rhabdoviridae
Lyssavirus - Rabies related viruses
Rabies
Oelofsen and Smith (1993) tested 12 individuals from Riemvasmaak, Northern Cape, South Africa using "Trousse Platelia Rage" ELISA kit (Diagnostic Pasteur), none tested positive for antibodies to rabies virus glycoprotein G. Oelofsen and Smith (1993) tested 12 individuals from Riemvasmaak, Northern Cape, South Africa by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), none were tested positive.

Genus ***Tadarida*** Rafinesque, 1814

*1814. *Tadarida* Rafinesque, Précis des découvertes et travaux somiologiques, 55. Publication date: 3 June 1814. - Comments: Type species: *Cephalotes teniotis* Rafinesque, 1814. - Etymology: Meaning unknown (Flannery, 1990: 366). Possibly from the Greek "data" or Latin "taeda" and "nukterida" (see Kozhurina, 2002: 18). Braun and Mares (1995: 182) refer to Gotsch (1979), who states this is a word created by C.S. Rafinesque. Lanza *et al.* (2015: 317 - 318) gives the following explanation: "From the feminine Greek substantive "*νυκτερίς*" (nykterís) [genitive "*νυκτερίδος*" (nikterídos)], meaning "bat"; by aphaeresis] and dialectal deformation, the above genitive turned into "tadarida" in southern Italy. Some examples of similar dialect deformations are according to Forsyth Major (1893): tagddariti (Naples); taddarita, taddarida and taddarito (Calabria), tardaritòla and tardarira (Sicily)". See also Riccucci (2015a: 77; 2015b: 61) for some additional (although unlikely) suggestions. - Phonetics: tad-a-rid-a, tah-dah-reed′-ah. (Current Combination).

1818. *Nyctinomus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 114, pl 2. Publication date: 1818 [Goto Description]. - Comments: Type species: *Nyctinomus aegyptiacus* E. Geoffroy St. Hillaire, 1818.
In the original description, Geoffroy Saint-Hilaire (1818) mentions three species: *Nyctinomus Ægyptiacus* [=*Tadarida aegyptiaca*, *Vesp. acetabulosus* Hermann [=*Mormopterus acetabulosus*] and *Vesp. plicatus* Buchanan [=*Chaerephon plicatus*], which would make *Nyctinomus* a partial synonym of these three genera. - Etymology: From the Greek "*νύξ*" or "*νυκτός*", meaning night and "*νομός*", meaning habitation (see Palmer, 1904: 466). - Phonetics: nik-tee-noh′-mus.

1821. *Nyctimones* J. E. Gray, London Med. Repos., 15: 299. Publication date: 1 April 1821. - Comments: Generally, the name is reported as *Nyctinomes*, but Gray (1821: 299) actually mentioned *Nyctimones*, with one species *Vesp. acetabulosus*.

1821. *Nyctinoma* Bowdich, Analysis of the Natural Classification of Mammalia, p 28.

1822. *Nyctinomia* Fleming, The Philosophy of Zoology, 2: 178 [Goto Description].

1825. *Dinops* Savi, Nuov. Giorn. Letter. Pisa, Sci., 10: 229. - Comments: Type species: *Dinops cestoni* Savi, 1824 (=*Cephalotes teniotis* Rafinesque, 1814). - Etymology: From the Greek "*δεινός*", meaning terrible and "*ώψ*", meaning face or aspect, probably referring to the deeply grooved or wrinkled face (see Palmer, 1904: 234).

1830-1831. *Dysopes* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 69. Publication date: 1830-1831. - Comments: Not of Illiger, 1811. The publication date of Cretzschmar's work is sometimes indicated as "1826" (as mentioned on the title page), but also as "1827", "1828", "1830-1831".

1973. *Tatarida:* Eisentraut, Bonn. zool. Monogr., 3: 113. (Lapsus).

1984. *Rhizomops* Legendre, Rev. suisse Zool., 91 (2): 427. Publication date: June 1984. - Comments: Type species: *Rhizomops brasiliensis* (I. Geoffroy Saint-Hilaire, 1824). - Etymology: From the Greek "*riza*" meaning root (see Legendre, 1984: 427).

1995. *Dynops:* Pavlinov, Borissenko, Kruskop and Jahonton, Arch. Zool. Mus., Moscow State Univ., 133: ???. (Lapsus).

? *Tadarida sp.:*

TAXONOMY:
Formerly included *Chaerephon*, *Mops*, *Mormopterus*, and *Nyctinomops*; see Freeman (1981b: 133). Includes *Rhizomops*, but see Legendre (1984); see also Owen *et al.* (1990). Mahoney and Walton (1988c) regarded *Nyctinomus* as the prior name for this genus.

Based on their analysis of molecular data, Lamb *et al.* (2011: 9) suggest that the genus *Tadarida* - as currently recognized - is not a natural group. *Tadarida teniotis* - the type species of the genus - forms a separate clade from *T. aegyptiaca* - the type species of *Nyctinomus* - and "*C. jobimena*". They suggest that the two latter species - together with other species - might be placed in a separate genus: *Nyctinomus*, but they await further taxonomic sampling and resolution of the phylogeny of other African taxa before making this formal.

Currently (Simmons and Cirranello, 2024a) recognized species within the genus *Tadarida*: ***aegyptiaca*** (E. Geoffroy Saint-Hilaire, 1818); *brasiliensis* (I. Geoffroy Saint-Hilaire, 1824) – southern Brazil, Bolivia, Argentina and Chile to Oregon, south Nebraska and Ohio (USA), Greater and Lesser Antilles (Simmons, 2005: 450); ***fulminans*** (Thomas, 1903); *insignis* (Blyth, 1862) – Japan, Taiwan, Korea, southern China (Simmons, 2005: 450); *latouchei* Thomas, 1920 – northern China, Thailand, Laos, Japan (Simmons, 2005: 450); ***lobata*** (Thomas, 1891); ***teniotis*** (Rafinesque, 1814); ***ventralis*** (Heuglin, 1861).

COMMON NAMES:
Czech: širokouší morousi, hroznohledové, netopýři morousovití. English: Guano Bats, Free-tailed Bats, Tadarine Bats. French: Tadarides. German: Gewöhnliche Bulldoggfledermäuse. Italian: Tadarìde. Ukrainian: Тадарида [= Tadaryda].

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Avery (2007: 619) reported on the presence of *Tadarida* sp. in Pleistocene deposits at Wonderwerk Cave, South Africa.

PARASITES:
Barbosa *et al.* (2016: 215) reported *Trypanosoma erneyi* from a *Tadarida* sp. from Mozambique.

ACARI
Myobiidae
Fain (1994: 1280) reports one species of *Schizomyobia*, living on Old World *Tadarida*.

Trombiculidae
Zajkowska *et al.* (2018: 118) reported *Microtrombicula intranasalis* Vercammen-Grandjean, 1965 from a Rwandese bat originally identified as "*Nyctinomus* sp.".

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Cameroon, Congo (Democratic Republic of the), Egypt, Ghana, Kenya, Madagascar, Namibia, Niger, Somalia, South Africa, South Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia.

Tadarida aegyptiaca (E. Geoffroy St.-Hilaire, 1818)

*1818. *Nyctinomus ægyptiacus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 128, pl 2, No 2. Publication date: 1818. Type locality: Egypt: Giza province: Giza [30 01 N 31 13 E]. Holotype: MNHN ZM-MO-1986-1084: ad ♂, skull and alcoholic. Collected by: Etienne Geoffroy-Saint-Hilaire. Rode (1941: 251) mentions numbers "228" and "A.467". - Comments: Type locality restricted from "Egypt" to Giza by Koopman (1975: 422): see Qumsiyeh (1985: 73), Meester *et al.* (1986: 70). - Etymology: From the scientific Latin feminine adjective *aegyptiacus*, meaning "Egyptian", as the species was decribed from an Egyptian specimen (see Lanza *et al.*, 2015: 319).
1855. *D[ysopes] aegyptiacus:* Giebel, Die Säugethiere, 957. (Name Combination).
1923. *Nyctinomus tongaensis:* Thomas and Hinton, Proc. zool. Soc. Lond., 1923, II: 251. Publication date: 6 July 1923. (Name Combination, Current Spelling).
2012. *Nyctinomus aegyptiacus:* Benda, Faizolâhi, Andreas, Obuch, Reiter, Ševčík, Uhrin, Vallo and Ashraf, Acta Soc. Zool. Bohem., 76: 163, 516. Publication date: 27 December 2012. (Alternate Spelling).
2018. *Tadarida aegyptica:* Lazzeroni, Burbrink and Simmons, Ecol. Evol., 8 (24): 12584. Publication date: 28 November 2018. (Lapsus).
? *Tadarida (Tadarida) aegyptiaca:* (Name Combination).
? *Tadarida aegyptiaca:* (Name Combination, Current Combination).

TAXONOMY:
Benda *et al.* (2012a: 516) place this taxon in the genus *Nyctinomus*, a view followed by a.o. Bendjeddou *et al.* (2016b: 23).

Based on morphometrics, Reddy *et al.* (2019: 273) suggest that two distinct groupings occur across southern Africa: an eastern characterised by larger, angular crania, and a central-western one characterised by smaller, more rounded crania, which correspond to previously described taxa. Both also have different bacula. Whether the two taxa differ on (sub)specific level still needs to be determined.

COMMON NAMES:
Afrikaans: Egiptiese losstertvlermuis. Bengali: Lomba-leji Chamchika. Chinese: 北非犬吻. Czech: morous egyptský, přišerec egipecký, tadarida jižní, morous jižní. Dutch: Egyptischte bulvleermuis. English: Egyptian Free-tailed Bat, Egyptian Guano Bat, Egyptian Nyctinome. French: Tadaride d'Egypte, Molosse d'Egypte. German: Ägyptische Bulldoggfledermaus. Italian: Tadarìda egiziàna. Portuguese: Morcego de cauda livre do egipto. Tamil: எகிப்தி ய வாலற்ற வௌவால், Ekiptiya Vāarra Veḷavā.

ETYMOLOGY OF COMMON NAME:
The original specimens were collected in Egypt during the Napoleonic wars by E. Geoffroy Saint-Hilaire, who at that time served under Napoleon (see Taylor, 2005).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Avery and Avery (2011: 18) report on Holocene and Pleistocene remains from Wonderwerk (Northern Cape province, South Africa).

CONSERVATION STATUS:
Global Justification
Broadly distributed and locally common, hence is listed as Least Concern (LC ver 3.1 (2001)) (Mickleburgh *et al.*, 2008ar; IUCN, 2009; Monadjem *et al.*, 2017bi).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bi). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008ar; IUCN, 2009). 2004: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2004bb; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (MacEwan *et al.*, 2016a). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
No serious threats other than roost disturbance from human interference is noted for this species (Molur *et al.*, 2002). Pesticides used against locusts are a threat as for all bat species found in the Saharan belt (Mickleburgh *et al.*, 2008ar; IUCN, 2009; Monadjem *et al.*, 2017bi). Furthermore, Doty and Martin (2012: 75) report

on fatalities due to wind turbines in the Eastern Cape, South Africa. Aronson (2022: 225) found that this species accounts for the majority of carcasses (45 %) found near wind turbine facilities in the RSA, and that most of the fatalaties occurred between February and April.

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008ar) [in IUCN (2009)] and Monadjem *et al.* (2017bi) report that the species is protected by national legislation in some of the Mediterranean range states as well as in South Africa. It is likely to be found in protected areas. A survey using bat detectors should be undertaken to help clarify the distribution limits and population size of this species as it is probably more widespread than current records indicate. A study on the impacts of pesticides is required, especially ways in which the impact might be minimised.

GENERAL DISTRIBUTION:
Tadarida aegyptiaca is found throughout Africa, and in the Arabian Peninsula through to India, Sri Lanka and Bangladesh. In the Mediterranean region there are isolated records from southern Morocco and western Algeria, but it is more widely distributed in Egypt along the Nile River valley eastwards to the Red Sea coast and south to the Sudanese border. The species is thought to be more widely distributed than is currently known and may well occur elsewhere in the region. In South Asia, this widely distributed species is presently known from Afghanistan (Kabul Province) (Habibi, 2003), Bangladesh (no exact location) (Khan, 2001; Srinivasulu and Srinivasulu, 2005), India (Andhra Pradesh, Gujarat, Karnataka, Kerala, Madhya Pradesh, Maharashtra, Rajasthan, Tamil Nadu and West Bengal), Pakistan (Punjab and Sind) and Sri Lanka (Central and Uva Provinces) (Molur *et al.*, 2002). Elevation: sea level up to 2,100 m asl.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,214,127 km^2. In the RSA, the species' distribution is linked with land use/land cover (Babiker Salata, 2012: 50).

Native: Afghanistan; Algeria; Angola (Crawford-Cabral, 1989; Hayman, 1963; Monadjem *et al.*, 2010d: 545; Taylor *et al.*, 2018b: 63); Bangladesh; Botswana (Monadjem *et al.*, 2010d: 545); Congo (The Democratic Republic of the); Egypt; Eritrea (Lavrenchenko *et al.*, 2004b: 132); Eswatini (Monadjem *et al.*, 2010d: 546, Monadjem *et al.* (2021: 5); Ethiopia; India; Iran, Islamic Republic of; Kenya; Lesotho (Lynch, 1994: 197; Monadjem *et al.*, 2010d: 545); Mauritania; Morocco (Benda *et al.*, 2004d; El Ibrahimi and Rguibi Idrissi, 2015: 365; Dbiba *et al.*, 2025: 7); Mozambique (Monadjem *et al.*, 2010d: 545; Monadjem *et al.*, 2010c: 382); Namibia (Monadjem *et al.*, 2010d: 545); Nigeria; Oman; Pakistan; Saudi Arabia; South Africa (Seamark and Kearney, 2007; Monadjem *et al.*, 2010d: 546); Sri Lanka; Sudan; Tanzania; Tunisia (Bendjeddou *et al.*, 2016b: 23); Uganda; Yemen (Benda *et al.*, 2011b: 45); Zambia (Cotterill, 2004a: 260; Monadjem *et al.*, 2010d: 546); Zimbabwe (Monadjem *et al.*, 2010d: 546).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Schoeman and Jacobs (2002: 157) reported the following parameters for 43 specimens from the Algeria Forestry Station (RSA): Fa: 45.1 ± 1.2 mm, Wing area: 115.2 ± 8.4 cm^2, Wing span: 30.8 ± 1.0 cm, Wing loading: 13.1 ± 1.6 N/m^2, and aspect ratio: 8.3 ± 0.6.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 12.0 Pa, aspect ratio 9.7 for a wingspan of 35 cm and a wing area of 130 cm^2 and a body mass of 16 g.

In their study on rewarming along an altitudinal gradient in the RSA, Marsden *et al.* (2022: 5) found that the body mass of these bats increased with increasing altitude. Their mass-specific rewarming rate was negatively correlated with altitude.

ECHOLOCATION:
From Algeria Forest Station (RSA), Schoeman and Jacobs (2002: 157) reported the type of calls to be low duty echolocation dominated by frequency modulated calls, with a F_{peak}: 22.8 ± 1.9 kHz.

Schoeman and Waddington (2011: 291) mention a peak frequency of 21.8 ± 1.7 kHz and a duration of 12.8 ± 0.7 ms for specimens from Durban, South Africa.

From Waterberg, South Africa, Taylor *et al.* (2013b: 18) recorded the following parameters for 8 calls: F_{max}: 28.3 ± 3.36 (24.8 - 34.1) kHz, F_{min}: 21.6 ± 2.73 (17.2 - 24.0) kHz, F_{knee}: 24.2 ± 1.47 (21.9 - 26.1) kHz, F_{char}: 22.8 ± 1.39 (20.5 - 24.5) kHz, duration: 7.2 ± 3.10 (3.3 - 10.9) ms.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 24 (22 - 26) kHz.

Linden *et al.* (2014: 40) reported the following parameters from the Soutpansberg range (RSA): F_{min}:17 - 24 kHz, F_{char}: 20 - 24 kHz, F_{knee}: 22 - 26

kHz, slope: 65 - 221 OPS, duration: 3 - 11 ms. In the Mapungubwe National Park (RSA), Parker and Bernard (2018: 57) recorded 20 calls with the following characteristics: F_{char}: 23.68 ± 1.51 kHz, F_{max}: 29.23 ± 5.77 kHz, F_{min}: 22.47 ± 1.74 kHz, F_{knee}: 25.72 ± 2.92 kHz, duration: 9.87 ± 3.93 ms, with 4.10 ± 2.72 calls/sec.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 23.68 ± 1.51 kHz, F_{max}: 29.23 ± 5.77 kHz, F_{min}: 22.47 ± 1.74 kHz.

Moores and Brown (2017: 612) recorded the following parameters for 25 calls from southern Morocco: F_{start}: 26.0 ± 2.6 (22.2 - 30.4) kHz, F_{max}: 19.6 ± 1.6 (17.4 - 22.3) kHz, F_{end}: 18.4 ± 0.8 (17.2 - 19.5) kHz, duration: 9.4 ± 1.4 (8.1 - 12.2) ms, interpulse interval: 373 ± 153 (220 - 780) ms.

Adams and Kwiecinski (2018: 4) reported the following values for 5 calls from the Kalahari Desert: F_{char}: 21.6 ± 1.2 kHz, F_{max}: 25.2 ± 1.1 kHz, F_{min}: 21.2 ± 1.1 kHz, duration: 4.9 ± 0.6 ms.

Weier *et al.* (2020: Suppl.) reported on 16 calls from the Okavango River Basin with the following characteristics: F_{max}: 21.69 ± 1.48 kHz, F_{min}: 19.83 ± 3.23 kHz, F_{knee}: 21.25 ± 0.89 kHz, F_{char}: 20.65 ± 0.71 kHz, slope: 8.58 ± 9.28 OPS, duration: 6.07 ± 2.83 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 99 calls of 8 bats: F_{max}: 26.82 ± 2.55 kHz, F_{min}: 23.4 ± 0.89 kHz, F_{knee}: 25.19 ± 1.28 kHz, F_{char}: 23.52 ± 0.97 kHz, slope: 92.93 ± 90.54 OPS, duration: 6.49 ± 2.74 ms. 15 calls recorded by Cory-Toussaint and Taylor (2022: Table S1) had a duration: 6.70 ± 1.94 ms, F_{min}: 21.28 ± 0.77 kHz, F_{max}: 23.88 ± 1.81 kHz, F_{knee}: 22.84 ± 1.19 kHz and F_{char}: 21.34 ± 0.77 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 16 *Tadarida aegyptiaca* calls from the Kruger Park (RSA): F_{min}: 21.3 ± 2.2 (16.3 - 25.2) kHz, duration: 7.9 ± 3.0 (3.5 - 11.2) ms, F_{max}: 26.6 ± 3.9 (22.3 - 35.2) kHz, F_{knee}: 23.5 ± 1.9 (21.3 - 27.0) kHz, F_{char}: 22.6 ± 1.3 (21.0 - 25.3) kHz,

Luo *et al.* (2019a: Supp.) reported the following data (bats leaving their roost): F_{peak}: 19.44 kHz, F_{start}: 24.44 kHz, F_{end}: 16.67 kHz, Band width: 7.77 kHz, and duration: 15.5 ms.

54 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 17 - 24 kHz, F_{max}: 25 - 34 kHz, F_{char}: 21 - 25 kHz, F_{knee}: 22 - 26 kHz and duration 3 - 11 ms.

Based on 217 passes, Parker (2022: 20) reported the following data from the Mountain Zebra National Park (RSA): F_{min}: 22.26 ± 2.56 kHz, F_{char}: 23.70 ± 3.33 kHz and F_{max}: 26.33 ± 8.31.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 23.68 ± 1.51 kHz, F_{max}: 29.23 ± 5.77 kHz and F_{min}: 22.47 ± 1.74 kHz.

Molecular Biology:

Karyotype

Both Nagorsen *et al.* (1976: 10) and Rautenbach *et al.* (1993) reported $2n$ = 48 and an actrocentric Y chromosome. While Nagorsen *et al.* (1976: 10) reported FN = 54 [2 pairs of rnetacentrics, 2 pairs of submetacentrics and a graded series of 19 pairs·of acrocentrics], BA = 8, and a submetacentric X chromosome, Rautenbach *et al.* (1993) reported FN = 68, BA = 22, and a metacentric X chromosome, for specimens from Namibia and South Africa. Nagorsen *et al.* (1976: 10) do remark that (some of) the acrocentric chromosomes might actually be subtelocentric, which might explain the different FN.

Habitat:

Sirami *et al.* (2013: 34) recorded in the Western Cape Province, South Africa that *T. aegyptiaca* activity was significantly and positively influenced by wetland size, while habitats 100 m surrounding wetlands were also significantly and positively influenced by the water body. *T. aegyptiaca* favoured open habitats surrounding wetlands (Sirami *et al.*, 2013: 35).

Habits:

Rautenbach and Nel (1980: 112) indicate that this is fast flying bat which follows a relatively straight flight path.

Thomas and Jacobs (2013: 129) report that, at De Hoop Nature Reserve, South Africa, bats feeding on Diptera (such as *T. aegyptiaca*) emerged later than bats feeding on Lepidoptera (e.g., *Rhinolophus capensis* and *Nycteris thebaica*).

Roost:

In the Durban area (RSA), Taylor *et al.* (1999: 68) found these bats roosting in high-rise buildings of the Central Business District, and the colony sizes varied between 30 and an estimated 300.

Toussaint *et al.* (2010) examined roost temperature in Pretoria, South Africa, and in the same country, Czenze *et al.* (2021: 3) found

these bats inhabiting roosts where the temperature approached the bat's normothermic body temperature.

DIET:
In Zimbabwe, Fenton and Thomas (1980: 86) report that the diet of *T. aegyptiaca* consists of Lepidoptera and Coleoptera.

From the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) reported the following prey groups based on 314 faecal pellets from 43 bats (in volume percent): Diptera (34.6 ± 33.4), Coleoptera (25.5 ± 30.7), Hemiptera (19.2 ± 24.6), Hymenoptera (8.4 ± 22.2), Lepidoptera (5.4 ± 13.4), Ephemeroptera (2.7 ± 7.7), Neuroptera (1.5 ± 6.5), Orthoptera (0.6 ± 3.4), and unknown (1.4 ± 7.1).

For Saudi-Arabia, Benda *et al.* (2012a: 524) indicate that some diet samples were dominated by Lepidoptera, whereas others were dominated by Coleoptera and Hymenoptera or by Heteroptera and Brachycera. In Iran, three digestive tracts were analysed: One tract was empty, one contained Lepidoptera (30 % of volume), Coleoptera (Scarabaeidae) (30 %), Neuroptera (Myrmeleontidae) (10 %), and Orthoptera (Ensifera) (30 %), and the third tract contained Coleoptera (Elateridae, Carabidae) (60 %) and Orthoptera (Ensifera) (40 %).

PREDATORS:
Avery *et al.* (2005: 1054) found this species to be present in pellets from *Tyto alba* (Scopoli, 1769) in South Africa.

Mikula *et al.* (2016: Supplemental data) and Malan *et al.* (2022: 167) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure and Density
This species is widespread and common in its South Asian range, where its population seems to be stable (Molur *et al.*, 2002).

Trend
2016: Unknown (Monadjem *et al.*, 2017bi). 2008: Unknown (Mickleburgh *et al.*, 2008ar; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Toussaint *et al.* (2010) examined heterothermy in *T. aegyptiaca* in Pretoria, South Africa.

REPRODUCTION AND ONTOGENY:
In Pretoria (South Africa), Tsita (1993), Bernard and Tsita (1995: 18) and le Grange *et al.* (2011: 170 - 171) found spermatogenesis occurring in January, and spermatozoa were first found in the epididymis in May, where they were stored until the end of September. In females, follicular development was already taking place in January. Copulation, ovulation and fertilization took place in August to early September; and births took place in December. Their conclusion was that *T. aegyptiaca* is a monoestrous, monotocous seasonal breeder. le Grange *et al.* (2011: 173) also indicate that, at 33° S, spermatogenesis only started in February, and that follicular development only started in April, but copulation, ovulation, and fertilization also occurred at the end of August.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births in November or December.

PARASITES:
Copeland *et al.* (2011: 363) reported the rediscovery of the "terrible hairy fly" (*Mormotomyia hirsuta* (after 62 years) in guano produced by *C.* cf. *bivittatus* and *T. aegyptiaca* at Ukasi Hill, Kenya.

From Algeria, the following ectoparasites were reported by Bendjeddou *et al.* (2017: 15): Nycteribiidae: *Nycteribia (Nycteribia) pedicularia* Latreille, 1805 and *Phthiridium biarticulatum* Hermann, 1804; Streblidae: *Brachytarsina (Brachytarsina) flavipennis* Macquart, 1851: and Arachnida: *Spinturnix myoti* (Kolenati, 1856) and *Eyndhovenia euryalis* (G. Canestrini, 1885). Mechouk *et al.* (2022: 4) furthermore, mentioned *Argas vespertilionis* Latreille, 1796.

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species as having been found on "*Nyctinomus aegyptiacus*": Argasidae: *Carios vespertilionis* Latreille, 1802; Ischnopsyllidae: *Araeopsylla gestroi* (Rothschild, 1906); and Streblidae: *Raymondia huberi huberi* Frauenfeld, 1856;

Orlova *et al.* (2020b: 1) reported the first case of an infection by *Parasteatonyssus nyctinomi* in Namibia (Macronyssidae, Arachnida).

Sándor *et al.* (2021a: 4) mentioned the following Argasidae: *Chiropterargas boueti* (Roubaud and Colas-Belcour, 1933), *Chiropterargas confusus* (Hoogstraal, 1955), and *Carios vespertilionis* Latreille, 1802.

VIRUSES:
Bunyaviridae
Phlebovirus
Rift Valley Fever Virus (RVFV) - Oelofsen and Van der Ryst (1999) tested 24 individuals from two localities in the Free State Province, South Africa for RVFV antigen using an enzyme linked immunosorbet assay (ELISA), none tested positive.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Rabies
Oelofsen and Smith (1993) tested 55 individuals from four localities using "Trousse Platelia Rage" ELISA kit (Diagnostic Pasteur), none tested positive for antibodies to rabies virus glycoprotein G. Oelofsen and Smith (1993) tested 89 individual brains, from 9 localities by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), none were tested positive.

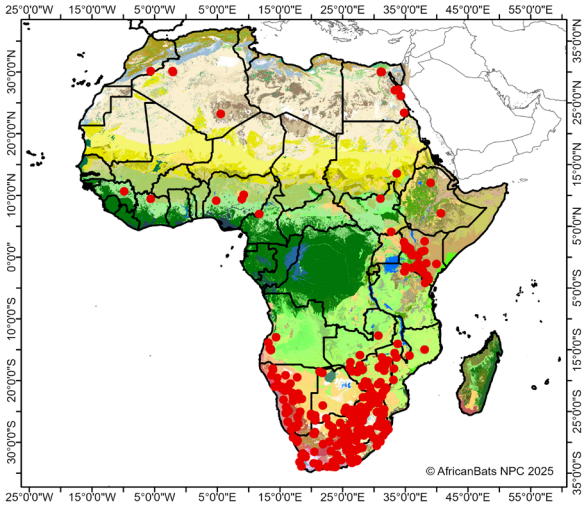

Figure 213. Distribution of *Tadarida aegyptiaca*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Botswana, Namibia, Niger, Nigeria, South Africa, Zambia.

Tadarida aegyptiaca aegyptiaca (E. Geoffroy St.-Hilaire, 1818)

*1818. *Nyctinomus ægyptiacus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 128, pl 2, No 2. Publication date: 1818. Type locality: Egypt: Giza province: Giza [30 01 N 31 13 E]. - Comments: Type locality restricted from "Egypt" to Giza by Koopman (1975: 422): see Qumsiyeh (1985: 73), Meester *et al.* (1986: 70). - Etymology: From the scientific Latin feminine adjective *aegyptiacus*, meaning "Egyptian", as the species was decribed from an Egyptian specimen (see Lanza *et al.*, 2015: 319).
1826. *Dysopes geoffroyi* Temminck, Monogr. Mamm, 1 (6): 226, pls 19, 23. Publication date: 1826. - Comments: Allen (1939a: 110), Qumsiyeh (1985: 73) mentioned 1827 as year of publication. Kock (1969a: 137), Meester *et al.* (1986: 70) mention 1826. Substitute for *aegyptiacus* E. Geoffroy St. Hilaire (see Ellerman and Morrison-Scott, 1951: 135; Harrison, 1964a: 109; Kock, 1969a: 137; Qumsiyeh, 1985: 73; Meester *et al.*, 1986: 70).
1877. *Dysopes talpinus* Heuglin, Reise in Nordost Afrika, 2: 28. Publication date: 1877. Type locality: South Sudan: Bahr-el-Ghazal province: Kidj district: Bahr el Jebel, West bank: "Kidj district" [ca. 07 06 N 30 46 E].

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Afrikaans: Madagaskarse grootlosstertvlermuis. Chinese: 岛犬吻蝠. Czech: morous východoafrický. English: Large Free-tailed Bat, Lightning Guano Bat, Large Guano Bat, Madagascan Large Guano Bat, Madagascan Large Free-tailed Bat, Madagascan Free-tailed Bat, Madagascar Large Free-tailed Bat, Malagasy Free-tailed Bat, Malagasy Large Free-tailed Bat.

French: Tadaride de Thomas, Grande Tadaride de Madagascar, Molosse de Madagascar. German: Madagassische Bulldoggfledermaus.

ETYMOLOGY OF COMMON NAME:
The colloquial name refers to the island where the species occurs.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide range across east and southern Africa. Although it is not a common species and can be patchily distributed, it is not thought to be facing any major threats (Cotterill *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bu).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bu). 2008: LC ver 3.1 (2001) (Cotterill *et al.*, 2008; IUCN, 2009). 2004: LC ver 3.1 (2001) (Cotterill, 2004b; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016z). 2004: Considered a vagrant. Not assessed, due to known form a single locality (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species (Cotterill *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bu).

CONSERVATION ACTIONS:
Cotterill *et al.* (2008) [in IUCN (2009)] and Monadjem *et al.* (2017bu) report that it has been recorded from one protected area in Madagascar and is presumed to exist in many protected areas within its range in eastern and southern Africa, however, there appear to be no active conservation measures in place. Further studies are needed into the distribution and taxonomic status of bats allocated to *Tadarida fulminans*.

GENERAL DISTRIBUTION:
Tadarida fulminans ranges through East Africa, southern Africa and a few localities on the island of Madagascar. Populations have been recorded through eastern and southeastern Africa, from around the border of Kenya and Uganda as far south as the border between Zimbabwe and South Africa. The most westerly record is from eastern Democratic Republic of the Congo. In Madagascar, it is only known from a few records, mostly from the central-south region near to Fianarantsoa and Isalo National Park, and from records at Tolagnaro near the southeast coast (Jenkins *et al.*, 2007a). Further surveys are needed within Madagascar (Goodman and Cardiff, 2004). It ranges from about sea level (at Fort Dauphin in Madagascar) to close to 2,000 m asl (Albertine Rift).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 541,523 km^2.

Native: Congo (The Democratic Republic of the); Kenya; Madagascar; Malawi (Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 546); Mozambique (Monadjem *et al.*, 2010d: 546; Monadjem *et al.*, 2010c: 382); Rwanda; South Africa (Monadjem *et al.*, 2010d: 546); Tanzania; Zambia (Ansell, 1957; Ansell, 1967; Monadjem *et al.*, 2010d: 547); Zimbabwe (Monadjem *et al.*, 2010d: 547).

ECHOLOCATION:
See Taylor (1999b).

MOLECULAR BIOLOGY:
Karyotype
Peterson and Nagorsen (1975) reported 2*n* = 48, FN = 54, BA = 8, a submetacentric X chromosome, and an acrocentric Y chromosome, for specimens from Zimbabwe. However, Rautenbach *et al.* (1993) reported 2*n* =48, FN =66, BA =20, a metacentric X chromosome and an acrocentric Y chromosome for specimens from South Africa.

HABITAT:
Thomas (1901d: 7) indicate that *T. fulminans* is the only molossid bat that is absent from urban areas, which is probably linked to its high wing loading coupled with high roost specificity.

ROOST:
Happold and Happold (2023: 122) indicate that *T. fulminans* roosts in groups of about 20 individuals (although not all of the animals were possibly captured at that time). Garbutt (2022: 97) mentions that colony sizes on Madagascar can contain 20-50 animals, but always less than 100.

POPULATION:
Structure and Density
Locally common, but patchily distributed in Africa. On Madagascar this bat is an uncommon, patchily distributed species. Colonies of this species may consist of dozens of individuals (although always fewer than 100 animals) (Cotterill *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bu).

Trend
2016: Stable (Monadjem *et al.*, 2017bu). 2008: Stable (Cotterill *et al.*, 2008; IUCN, 2009).

PARASITES:
Polyctenidae
Hypoctenes fani Benoit 1958, a single female collected from Rwanda (Haeselbarth *et al.*, 1966: 18; Szentiványi *et al.*, 2022: 6).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Congo (Democratic Republic of the), Kenya, Madagascar, Malawi, Mozambique, Namibia, Rwanda, South Africa, Tanzania, Zambia, Zimbabwe.

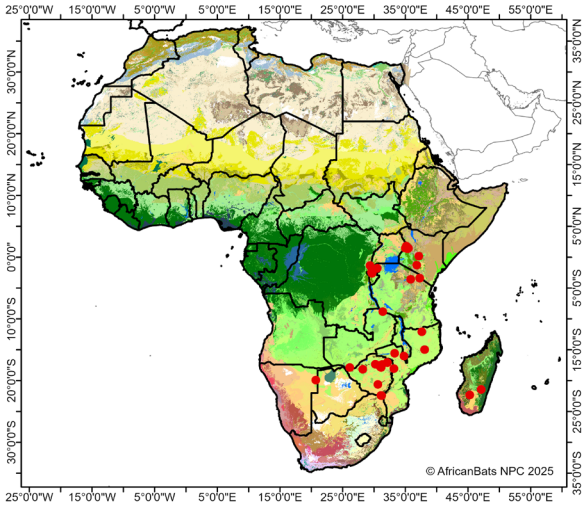

Figure 214. Distribution of *Tadarida fulminans*.

Tadarida lobata (Thomas, 1891)

*1891. *Nyctinomus lobatus* Thomas, Ann. Mag. nat. Hist., ser 6, 7 (39): 303. Publication date: 1 March 1891. Type locality: Kenya: West Pokot: upper reaches of Turkwell: Turkwell Gorge, at or near [ca. 01 52 N 35 22 E]. [Goto Description]. Holotype: NHMUK 1893.2.3.7: ♂, skull and alcoholic. Collected by: Sir Frederick John Jackson. Peterson and Harrison (1970: 1) indicate that this specimen is probably a male, although they could not find any trace of scrotal development. - Etymology: From "*lobata*" meaning lobed.
? *Tadarida (Chaerephon) pumila limbata:*
? *Tadarida lobata:* (Name Combination, Current Combination, Current Spelling).
? *Tadarida pumila limbata:*

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Afrikaans: Grootoor-losstervlermuis. Chinese: 大耳犬吻蝠. Czech: morous širokouchý. English: Big-eared Guano Bat, Big-eared Kenyan Guano Bat, Kenyan Big-eared Free-tailed Bat, Big-eared Free-tailed Bat, Big-eared Kenya Free-tailed Bat, Eastern Africa Free-tailed Bat. French: Tadaride du Kenya, Tadaride de l'Afrique orientale, Molosse à grandes oreilles. German: Großohr-Bulldoggfledermaus.

ETYMOLOGY OF COMMON NAME:
The colloquial name perhaps refers to the country from which the species was originally described (see Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) because it is associated with rocky areas in dry savanna habitat, and is unlikely to be declining fast enough to qualify for listing in a more threatened category (Cotterill, 2008e; IUCN, 2009; Monadjem and Cotterill, 2017).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Cotterill, 2017). 2008: LC ver 3.1 (2001) (Cotterill, 2008e; IUCN, 2009). 2004: DD ver 3.1 (2001) (Cotterill, 2004e; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no identifiable threats to this species (Cotterill, 2008e; IUCN, 2009; Monadjem and Cotterill, 2017).

CONSERVATION ACTIONS:
Cotterill (2008e) [in IUCN (2009)] and Monadjem and Cotterill (2017) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further surveys are needed to better determine the range of this species, and to understand whether it is restricted to rocky areas or can persist in modified habitats.

GENERAL DISTRIBUTION:
Tadarida lobata has only been recorded from four localities in Kenya and four localities in Zimbabwe

(Skinner and Chimimba, 2005). It is found between 600 and 2,000 m asl.

Native: Kenya; Zimbabwe (Monadjem *et al.*, 2010d: 547).

POPULATION:
Structure and Density
It appears to be a rare species found in small colonies (Cotterill, 2008e; IUCN, 2009; Monadjem and Cotterill, 2017). The apparent rarity might be attributed to their high-flying habits and inaccessible daylight roosts (Cotterill, 1996b).

Trend
2016: Unknown (Monadjem and Cotterill, 2017).
2008: Unknown (Cotterill, 2008e; IUCN, 2009).

PARASITES:
Duszynski (2002: 20) indicates that *T. lobata* might be a host for *Eimeria dukei* Lavier, 1927, but as Pellérdy (1974) mentioned the bat as "*Tadarida limbata*" this might not be correct.

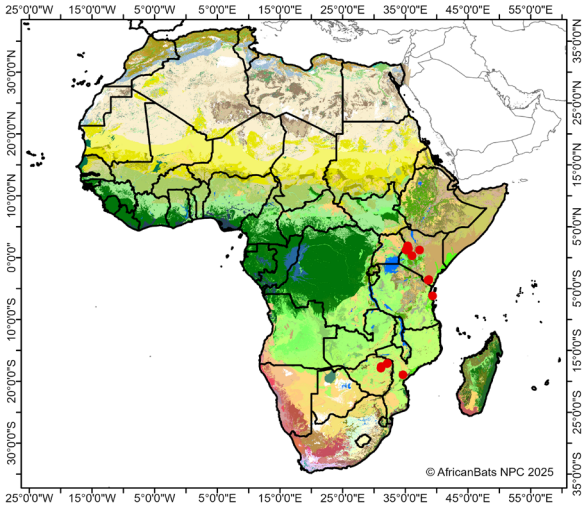

Figure 215. Distribution of *Tadarida lobata*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya, Mozambique, Tanzania, Zimbabwe.

Tadarida teniotis (Rafinesque, 1814)

*1814. *Cephalotes teniotis* Rafinesque, Précis des découvertes et travaux somiologiques, 12, 55. Publication date: 3 June 1814. Type locality: Italy: Sicily. [Goto Description]. - Etymology: From the Greek "*teniotis*" meaning striped, banded.

1825. *Dinops Cestonii* Savi, Nuov. Giorn. Letter. Pisa, Sci., 10: 230. Type locality: Italy: Tuscany: Pisa [43 43 N 10 24 E]. Syntype: ZFMK MAM-1983.0173: ♂, alcoholic (skull not removed). Ukrainian: Тадарида європейська [= Tadaryda yevropeys'ka]. Welsh: Ystlum cynffonog.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Amorim *et al.* (2013: 7) indicate that palaeodistribution models predict that during the Last Glacial Maximum (LGM: 23,000 - 18,000 YBP) the climatic conditions for *T. teniotis* were favorable in southern Europe and northern Africa.

CONSERVATION STATUS:
Global Justification
The species is widely distributed over a large extent of occurrence. It occurs in urban areas and forages in other modified habitats. Population trends are not known but are not believed to approach the threshold for the population decline criterion of the IUCN Red List. Consequently, it is assessed as Least Concern (LC ver 3.1 (2001)) (Aulagnier *et al.*, 2008e; IUCN, 2009; Benda and Piraccini, 2016).

Assessment History
Global
2016: LC ver 3.1 (2001) (Benda and Piraccini, 2016). 2008: LC ver 3.1 (2001) (Aulagnier *et al.*, 2008e; IUCN, 2009). 1996: LR: lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It is negatively affected by disturbance and loss of roosts in buildings, and by use of pesticides. It is also potentially threatened by wind farms (GMA Europe Workshop, 2006), and deforestation affects the species in some parts of its range (Z. Amr *pers. comm.,* 2005 [in Aulagnier *et al.* (2008e in IUCN, 2009]). However, none of these are considered to be major threats at present (Aulagnier *et al.*, 2008e; IUCN, 2009; Benda and Piraccini, 2016).

Sherwin *et al.* (2012: 174) report aerial hawking and long-distance dispersal to be risk factors related with climatic change.

CONSERVATION ACTIONS:
Aulagnier *et al.* (2008e) [in IUCN (2009)] and Benda and Piraccini (2016) report that it is protected by national legislation in a number of range states and receives international legal protection through the Bonn Convention (Appendix II and Eurobats Agreement) and Bern Convention in parts of its range where these

apply. It occurs in several protected areas across its range.

GENERAL DISTRIBUTION:
Tadarida teniotis is mainly a Palaearctic species, although the south-eastern edge of its range extends into the Indomalayan region. It is well known in the Mediterranean basin, occurring from Portugal, Spain eastwards through southern Europe to the Balkans, Turkey, Israel, Palestine and Jordan. In North Africa it has been recorded from Morocco, Algeria, Tunisia, Libya and Egypt. It is possibly present on Madeira (to Portugal) as there was a supposed old record, but it has not been recorded from there again. It occurs on all the Canary Islands (to Spain) except for Fuerteventura and Lanzarote. It is also recorded from a number of Mediterranean islands (Hutson, 1999; Simmons, 2005). It occurs from sea level to 3,100 m.

Populations in Japan, Taiwan and Korea are now considered to be a separate species, *T. insignis* (Simmons, 2005).

Native: Afghanistan; Albania; Algeria (Kock and Nader, 1984: 129: Horáček *et al.*, 2000: 136); Andorra; Armenia; Azerbaijan; Bangladesh; Bhutan; Bosnia and Herzegovina; Bulgaria; Croatia; Cyprus; Egypt; France [Corse]; Georgia; Gibraltar; Greece [Kriti]; Holy See (Vatican City State); India; Iran, Islamic Republic of; Iraq; Israel; Italy [Sardinia, Sicily]; Jordan; Kazakhstan; Kyrgyzstan; Lebanon; Libyan Arab Jamahiriya (Horáček *et al.*, 2000: 136); Macedonia, the former Yugoslav Republic of; Malta; Monaco; Montenegro; Morocco (Benda *et al.*, 2010a: 161; El Ibrahimi and Rguibi Idrissi, 2015: 364; Dbiba *et al.*, 2025: 7); Myanmar; Nepal; Portugal; Russian Federation; San Marino; Saudi Arabia; Serbia; Spain [Baleares, Canary Is.]; Switzerland; Syrian Arab Republic; Tajikistan; Tunisia (Kock and Nader, 1984: 131; Horáček *et al.*, 2000: 136; Dalhoumi *et al.*, 2014: 53; 2016b: 867; 2019b: 26; 2023: 4); Turkey; Turkmenistan; Uzbekistan.
Presence uncertain: China.

FUNCTIONAL MORPHOLOGY:
Maniakas and Youlatos (2012: 574) studied the external and muscular forelimb features that could be associated with high-speed flight in open air. They found (p. 576) that the mass of the muscles responsible for the downstroke represented 59.3 % of the total forelimb musculature, and that more than half of these muscles are formed by the M. pectoralis. The muscles responsible for the upstroke are comparatively small, which might indicate that the upstroke in this bat is less important than for other bat groups (p.580). All these features result in a fast, steady enduring flight with relatively limited manoeuvrability.

Amador *et al.* (2019: Suppl.) [referring to Marques *et al.* (2004)] mention a wing loading value of 19.2 Pa, aspect ratio 9.8 and tip shape index of 0.84 for a wingspan of 41 cm and a wing area of 200 cm^2 and a body mass of 30 g.

SEXUAL DIMORPHISM:
Bats from Libya Amorim *et al.* (2023: 709 [referring to Benda *et al.* (2014c)]) display some sexual dimorphism, with males weighting between 24.70 and 35.00 g and a forearm between 53.40 and 58.80 mm and females weighting between 27.50 and 34.20 g and a forearm between 56.70 and 60.70 mm.

ECHOLOCATION:
For 10 Greek specimens, Papadatou *et al.* (2008b: 133) report a start frequency of 15.4 ± 3.28 kHz, a terminating frequency of 11.1 ± 1.34 kHz, a peak frequency of 13.2 ± 1.18 kHz, and a bandwidth of 5.3 ± 1.49 kHz. The duration of the call is 18.4 ± 4.74 ms, and the interpulse interval is 764.6 ± 259.37 ms. Walters *et al.* (2012: suppl.) report the following figures for 35 calls from bats from France, Greece, Italy and Switzerland: duration: 15.03 ± 3.47 ms, F_{max}: 14.61 ± 4.95 kHz, F_{min}: 10.64 ± 1.51 kHz, bandwidth: 3.97 ± 3.76 kHz, F_{peak}: 11.76 ± 2.28 kHz.

In Jordan, Benda *et al.* (2010b: 204) recorded the following parameters for seven calls: F_{start}: 15.7 ± 3.8 (12.4 - 22.6) kHz, F_{end}: 9.8 ± 0.4 (9.4 - 10.5) kHz, F_{peak}: 11.7 ± 0.4 (11.1 - 12.6) kHz, duration: 16.3 ± 2.2 (13.1 - 19.3) ms, and interpulse duration: 571.8 ± 254.6 (163.0 - 800.0) ms.

14 calls from Iranian specimens were reported by Benda *et al.* (2012a: 183): F_{start}:19.0 ± 2.6 (14.1 - 22.2) kHz, F_{end}: 11.8 ± 2.2 (8.9 - 14.2) kHz, F_{peak}: 14.5 ± 1.3 (10.6 - 15.9) kHz, duration: 10.6 ± 0.8 (9.5 - 11.8) ms, and interpulse interval: 368.7 ± 89.8 (266.0 - 484.0) ms.

Hackett *et al.* (2016: 223) recorded 44 calls in Israel with the following values: Pulse duration: 12.17 ± 3.34 ms, F_{start}: 22.73 ± 5.02 (17.5 - 29.2) kHz, F_{end}: 15.90 ± 1.44 (13.1 - 17.5) kHz, F_{peak}: 18.49 ± 1.57 (15.1 - 21.4) kHz.

Disca *et al.* (2014: 226) indicate that in Morocco the type of call is FM-QFC, with the following parameters: F_{start}: 22.3 ± 4.2 kHz, F_{end}: 13.3 ± 0.7 kHz, F_{peak}: 14.4 ± 0.8 kHz, bandwidth: 9.0 ± 3.9 kHz, duration: 18.7 ± 2.7 ms.

In Tunisia, Dalhoumi *et al.* (2023: 5) reported F_{start}: 13.2 ± 1.76 (11.4 - 16.7) kHz, F_{end}: 11.71 ± 0.70 (11.1 - 12.8) kHz, F_{max}: 12.16 ± 0.81 (11.3 - 13.0) kHz, duration: 14.25 ± 2.06 (10.7 - 17.3) ms and Interpulse interval: 772.13 ± 179.48 (634.9 - 1095.0) ms.

Ait-Abdesselam *et al.* (2025: 40) reported an F_{max} of 12.83 ± 1.14 kHz for Algerian bats.

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats; 2 calls): F_{peak}: 13.2, 13 kHz, F_{start}: 15.4, 17 kHz, F_{end}: 11.1, 12.1 kHz, Band width: 4.3, 4.9 kHz, and duration: 18.4, 16.6 ms.

Molecular Biology:

Karyotype

Đulić and Mrakovcic (1980) reported 2*n* = 48, FN = 76, BA = 30, a submetacentric X chromosome and a subtelocentric Y chromosome for one male from Croatia. Arroyo Nombela *et al.* (1986), however, reported 2*n* = 48, FN = 78, BA = 32 , a submetacentric X and an acrocentric Y for specimens from Spain. Volleth and Eick (2012: 167) mention 2*n* = 48 and a segment number of 25. The autosomal complement consists of five meta- and submetacentrics, and 19 subtelocentric and acrocentric pairs, of which the smallest is dot-like (Arslan and Zima, 2014: 14). These authors also indicate that the X chromosome was found to be subtelocentric in some studies.

Volleth *et al.* (2023b: 7) reported 2*n* = 48 and Fna = 60 (provisionally) and a metacentric X chromosome.

Genetics

Combining mtDNA fragments, 14 microsatellites and ecological modelling tools, Amorim *et al.* (2017: 38) found three main haplogroups in Mediterranean *T. teniotis*: one restricted to the eastern Mediterranean and two that are widespread across the Iberian Peninsula and Morocco. The nuclear data indicated that the bats from the Canary Islands showed the lowest signs of gene flow with the continental populations. Furthermore, they found that gene flow between Morocco and the central Mediterranean area is higher than that between the Iberian Peninsula and the central Mediterranean. Amorim *et al.* (2019: 1) confirmed that the nuclear DNA of bats from the Canary Islands is highly differentiated and isolated from that the two other genetic populations they distinguished: one from Morocco, Iberia and France, and the other from Italy eastwards to Anatolia and the Middle East.

Mata *et al.* (2017: 152) reported the mitogenome to be 16,869 bp long, containing 13 protein-coding genes, 2 ribosomal RNA genes, 22 transfer RNA genes, and 1 control region (d-loop). All protein-coding genes start with the ATG start codon, except for ND2, ND3, and ND5 which begin with ATA or ATT. Eleven protein-coding genes terminated in a canonical stop codon, TAA or TAG, two contain incomplete stop codons, T or TA. Cytochrome b terminates in the mitochondria-specific stop codon AGA.

Habitat:

In her study on the summer foraging habitats of bats in the Mediterranean region of the Iberian Peninsula, Rainho (2007: 176) found that *T. teniotis* showed low activity over fresh-water habitats, and primarily seemed to use pine-tree woodlands and Mediterranean shrublands. For southern Portugal, Marques *et al.* (2004: 99) reported that *T. teniotis* foraged preferentially over forested areas, particularly pine and cork oak woodlands. They used both alluvial plains and the valleys of a mountainous area, but not its ridges. In northern Algeria, Ait-Abdesselam *et al.* (2025: 45) recorded this species mainly from urban and suburban areas.

Habits:

In southern Portugal, Marques *et al.* (2004: 99) found that *T. teniotis* is a late emerger, leaving its roost about one hour after sunset. They also found that these bats have only one foraging bout, which lasted on average 6 hours and 39 minutes. Its flight speed can reach over 50 km/h, and flying can be maintained for over 10 hours.

Ancillotto and Russo (2014: 221) found that that *T. teniotis* can discriminate between familiar and stranger individuals. They also found that the animals show higher rates of aggressive behaviours towards the strangers. Females show less aggressiveness than males, especially towards other females, and both sexes behave less aggressive towards juveniles.

Roost:

In Libya, Benda *et al.* (2014c: 119) found a roosting colony in a fissure in the ceiling in the portal of a large, but shallow cave.

Diet:

Rydell and Arlettaz (1994: 175) suggest that the intense narrowband echolocation calls with low frequency (11 - 12 kHz) without strong harmonics emitted by *T. teniotis* seems to be a specialization for long-range detection of large, tympanate insects such as Lepidoptera and Neuroptera, which are less well represented in the diet of

most other aerial-hawking bats. Based on faecal analyses, they found the following volume percents: southeastern France: Lepidoptera (68.3 %), Neuroptera (24.3 %), others (4.3 %), Acari (0.5 %), and unidentified (2.6 %); Kirghizstan: Lepidoptera (86.8 %), others (12.8 %), unidentified (0.4 %).

Benda *et al.* (2014c: 124) examined four sets of faecal pellets from Libya. Ten pellets from Wadi an Nazrat contained only large moths (Lepidoptera) as did one pellet from the quarry at Wadi al Kuf. Twenty pellets from another location at Wadi al Kuf contained 97 % by volume medium-sized moths and 3 % beetles (Coleoptera). Eight pellets from one animal from Wadi Darnah contained 56 % by volume medium-sized moths and 44 % lacewings (Neuroptera: Chrysopidae).

Benda *et al.* (2012a: 515) indicate that Orthoptera formed the largest contributing group in the diet of *T. teniotis* in Turkey and Jordan. On Rhodes, Coleoptera (especially Curculionidae) formed the most important group. In Iran, Lepidoptera were the most important diet item and Coleoptera, Orthoptera (Ensifera) and Heteroptera also contributed substantially to the diet. Neuroptera (Chrysopidae) and Auchenorrhyncha were almost negligible.

In northeastern Portugal, Mata *et al.* (2016: 1, 2) found significant dietary differences between males and females, where females ate more larger moths and more moths with migratory behaviour (* in below listing). In guano pellets of 69 females and 74 males, Lepidoptera were present in 98.6 % of the females pellets and in 100 % of the males pellets. Split over the various families and species (which all occur in northern African too), they found (wingspan; % in females, % in males): Crambidae: *Nomophila noctuella** (Denis and Schiffermüller, 1775) (rush veneer) (26 - 32 mm; 7.2, 14.9), other Crambidae 6 5.8 9.5; Gelechiidae: *Mirificarma mulinella* (Zeller, 1839) (5.5 - 7.5 mm; 7.2, 14.9), other Gelechiidae (0.0, 2.7); Geometridae: *Aspitates ochrearia* (Rossi, 1794) (yellow belle) (25 - 34 mm; 4.3, 10.8), *Rhodometra sacraria** (Linnaeus, 1767) (vestal) (22 - 28 mm; 14.5, 36.5), other Geometridae (20.3, 13.5); Noctuidae: *Agrotis ipsilon** (Hufnagel, 1766) (dark sword-grass) (40 - 45 mm; 21.7, 4.1), *Agrotis puta* (Hübner, 1803) (shuttle-shaped dart) (30 - 32 mm; 13.0, 18.9), *Agrotis segetum* (Denis & Schiffermüller, 1775) / *Agrotis trux* (Hübner, [1824]) (turnip/crescent dart) (32 - 42 mm; 37.7, 36.5), *Autographa gamma** (Linnaeus, 1758) (silver y) (30 - 45 mm; 43.5, 23.0), *Hoplodrina ambigua* (Denis & Schiffermüller, 1775) (vine's rustic) (32 - 34 mm; 18.8, 35.1), *Mythimna albipuncta* (Denis & Schiffermüller, 1775) (white-point) (30 - 35 mm; 5.8, 9.5), *Mythimna vitellina* (Hübner, 1808) (delicate) (36 - 43 mm; 24.6, 28.4), *Noctua pronuba* (Linnaeus, 1758) / *Noctua janthe* Borkhausen, 1792 (large/lesser broad-bordered yellow underwing) (50 - 60 mm / 30 - 40 mm; 14.5, 13.5), *Peridroma saucia** (Hübner, 1808) (pearly underwing) (43 - 50 mm; 24.6, 12.2), *Phlogophora meticulosa** (Linnaeus, 1758) (angle shades) (45 - 52 mm; 18.8, 8.1), other Noctuidae (31.9, 36.5); Tortricidae: *Tortrix viridana* Linnaeus, 1758 (European oak leafroller) (18 - 23 mm; 5.8, 13.5), other Tortricidae (2.9 5.4); other Lepidoptera (17.4, 21.6); unidentifiedLepidoptera (13.0, 23.0). Other orders present in the pellets were: Coleoptera (1.4, 1.4); Diptera (10.1, 12.2), Hemiptera (2.9, 8.1), Neuroptera (7.2, 12.2), unidentified Insecta (1.4, 1.4), and also some unidentified Arthropoda (7.2, 5.4).

PREDATORS:
In Israel, Reuven (1991: 79) observed *T. teniotis* being preyed upon by a Lanner Falcon (*Falco biarmicus* Temminck, 1825). Balmori (2012: 9) furthermore reports bats being taken by Peregrine Falcon (*Falco peregrinus* Tunstall, 1771) and Common Kestrel (*Falco tinnunculus* Linnaeus, 1758) as well as by Barn Owl (*Tyto alba* (Scopoli, 1769)) and Tawny Owl (*Strix aluco* Linnaeus, 1758), but also by a Garden Dormouse (*Eliomys quercinus* (Linnaeus, 1766)).
Mikula *et al.* (2016: Supplemental data) mention the following diurnal avian predators: Lanner falcon (*Falco biarmicus* Temminck, 1825), Peregrine falcon (*Falco peregrinus* Tunstall, 1771) and Eurasian hobby (*Falco subbuteo* Linnaeus, 1758),

POPULATION:
Structure and Density
It is a common species in suitable habitats. Summer and winter colonies typically number 5 - 100 individuals, although colonies of up to 300 - 400 animals have been recorded. It is probably sedentary, although seasonal in some areas (e.g., Malta). It is not abundant in the Caucasus, nor is it highly gregarious - large colonies are not known in this region (K. Tsytsulina *pers. comm.,* 2005 in Aulagnier *et al.*, 2008e [in IUCN, 2009) and Benda and Piraccini (2016)]). There are only six records for Iran, however, there have not been extensive survey efforts there (M. Sharifi *pers. comm.,* in Aulagnier *et al.*, 2008e [in IUCN, 2009] and Benda and Piraccini (2016)).

Trend
2016: Unknown (Aulagnier *et al.*, 2008e). 2008: Unknown (Aulagnier *et al.*, 2008e; IUCN, 2009).

LIFESPAN:
Szekely *et al.* (2015: Suppl.) and Lagunas-Rangel (2019: 2) report a maximum longevity of 13 years.

REPRODUCTION AND ONTOGENY:
In Spain, Balmori (2003: 37) reported births taking place from the end of June to the beginning of July.

In Portugal, Amorim *et al.* (2015: 228) found that drought had a severe negative influence on the reproduction of *T. teniotis*. This drought probably resulted in reduced food resources early in the pre-breeding season, which limited the ability to restore the bat's body condition after the winter and before the breeding season.

MATING:
In a colony in Valladolid, Spain, Balmori (2003: 37; 2017: 460) found that *T. teniotis* bats were organized in 'harems' made up by a dominant male together with a variable number of females, in which the male defends the refuge ("resource defence polygyny"). The males were emitting mating calls to attract passing-by females. These harems were formed between August and October. When competitors were present, the males reacted by noisy and fast chasing-flights and the releasing of a strong scent, probably used to mark their territory.

Balmori (2017: 465) found two peaks of sexual activity: one in spring (April - June) and another in summer/autumn (August - October), but also indicated that each female might only enter heat once a year.

PARASITES:
In Italy, Voyron *et al.* (2011: 193) reported the following fungal entities from live *T. teniois* specimens: *Aspergillus fumigatus var. fumigatus* and *Trichosporon chiropterorum*.

Benda *et al.* (2010b: 315) only found the mite *Parasteatonyssus hoogstraali* Keegan, 1956 parasiting on *Tadarida teniotis* in Jordan. They do report on other ectoparasites found previously: the bat fly *Nycteribia pedicularia* Latreille, 1805 found in Palestine, bat fleas *Araeopsylla wassifi* Traub, 1954 in Turkey and Egypt, *A. gestroi* (Rotschild, 1906) in Lebanon, and a tick *Argas vespertilionis* (Latreille, 1802) in Egypt. Geldenhuys *et al.* (2021: 21) reported the presence of *Argas (Chiropterargas) boueti* Roubaud and Colas-Belcour, 1933 on bats from northern Africa. Balmori (2012: 9) also mentioned *Steatonyssus periblepharus* Kolenati, 1858, *Ewingana baekelandae* Estrada-Peña, 1992, and unidentified Trombiculidae, as well as the bat bug *Cimex pipistrelli* Jenyns, 1839 and the flea *Araeopsylla gestroi* (Rothschild, 1906).

Parasteatonyssus hoogstraali Keegan, 1956 was already reported by Estrada-Peña and Sanchez (1988: 310) from *T. teniotis* on Frontera, Canary Islands.

The following enteroparasites were reported by Balmori (2012: 9): Trematodes *Plagiorchis vespertilionis* (Müller, 1784), *Prosthodendrium ascidia* (Van Beneden, 1873) and *Lecithodendrium linstowi* Dollfus, 1931; Nematodes: *Molinostrongylus alatus* (Ortlepp, 1932), *Pseudophysaloptera formosana* (Yokogawa, 1922), *Rictularia bovieri* Blanchard, 1886, *Litomosa aelleni* Tibayrenc, Bain & Ramachandran 1979, and further unidentified *Litomosa* sp. Amorim *et al.* (2020: 21) also reported on unidentified *Physaloptera* Rudolphi, 1819, *Rictularia* Froelich, 1802 and *Spirura* Blanchard, 1849.

Benda *et al.* (2014c: 124) reported the following ectoparasites from Libya: Ischnopsyllidae: *Araeopsylla gestroi* (Rothschild, 1906); Macronyssidae: *Parasteatonyssus hoogstraali* (Keegan, 1956) [1st record from Libya]; Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856).

From Algeria, Bendjeddou *et al.* (2017: 15) reported one ectoparasite: Arachnida: *Ixodes ricinus* (Linnaeus, 1758).

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Ischnopsyllidae: *Araeopsylla gestroi* (Rothschild, 1906); Ixodidae: *Ixodes ricinus* (Linnaeus, 1758); Macronyssidae: *Parasteatonyssus hoogstraali* (Keegan, 1956); Pulicidae: *Synosternus cleopatrae pyramidis* (Rothschild, 1903); and Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856).

Sándor *et al.* (2021a: 4) mentioned the argasid mites *Chiropterargas boueti* (Roubaud and Colas-Belcour, 1933) and *Carios vespertilionis* Latreille, 1802. Orlova *et al.* (2024: 155) reported the latter mite as *Argas vespertilionis*.

VIRUSES:
Herpesviridae
Cytomegalovirus
Nieto-Rabiela *et al.* (2019: Suppl.) mentioned this virus.

Reoviridae
Orthoreovirus
This virus was reported by Kohl and Kurth (2014: 3113) from Italian bats.

Rhabdoviridae
Lyssavirus - Rabies related viruses
European bat lyssavirus 1
Was reported by Luis *et al.* (2013: Suppl.), Willoughby *et al.* (2017: Suppl.).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Algeria, Egypt, Libya, Morocco, Sudan.

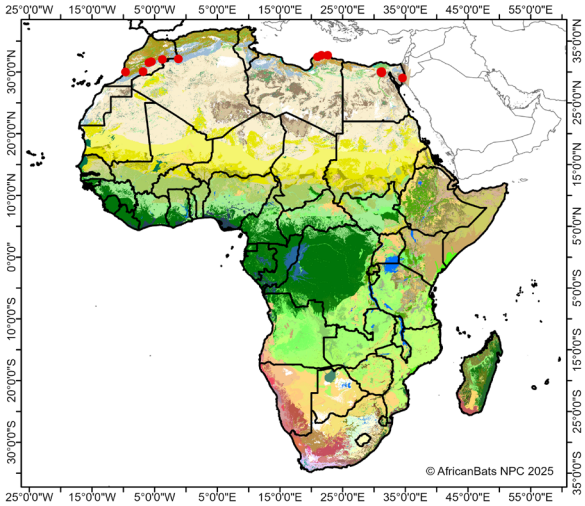

Figure 216. Distribution of *Tadarida teniotis*.

Tadarida ventralis (Heuglin, 1861)

*1861. *Nyctinomus (Dysopes) ventralis* Heuglin, Nov. Act. Acad. Cæs. Leop.-Carol., 29 (8): 4, 11. Publication date: 1861. Type locality: Eritrea: Kérén [ca. 15 45 N 38 20 E]. [Goto Description]. Lectotype: SMNS 982: ad ♀, skull and alcoholic. Collected by: Martin Theodor von Heuglin; collection date: 1861. See Dieterlen *et al.* (2013: 294), who confirm that the Lectotype status of this specimen was designated by Kock (1975: 6). - Etymology: From the scientific Latin feminine adjective *ventràlis*, meaning "ventral", referring to the presence of a wide, median, prominent orange ventral stripe (see Lanza *et al.*, 2015: 324).
1862. *Nyctinomus ventralis:* Heuglin, Peterm. Geographische Mittheilungen, 8: 26. (Name Combination).
1876. *Nyctinomus africanus* Dobson, Ann. Mag. nat. Hist., ser 4, 17 (101): 348. Publication date: 1 May 1876. Type locality: South Africa: Transvaal. [Goto Description]. Holotype: NHMUK 1875.11.19.1: ad ♂, skull and alcoholic. Presented/Donated by: Richard Browdler Sharp[e].
1877. *Dysopes ventralis:* Heuglin, Reise in Nordost Afrika, 2: 26. (Name Combination).
1877. *Nyctinomus [(Nyctinomus)] cestoni* Dobson, Proc. zool. Soc. Lond., 1876, IV: 719. Publication date: April 1877. - Comments: Not of Savi, 1825. In part (see Kock, 1975: 6).
1891. *N(yctinomus) taeniotis* Thomas, Proc. zool. Soc. Lond., 1891, II: 183. Publication date: August 1891. - Comments: Not of Rafinesque, 1814. See Kock (1975: 7).
1901. *N(yctinomus) midas* de Winton, Ann. Mag. nat. Hist., ser 7, 7 (37): 42. Publication date: 1 January 1901. - Comments: Not of Sundeval. In part. See Kock (1975: 7).
1928. *Mops ventralis:* Thomas, Ann. Mag. nat. Hist., ser 10, 1 (2): 302. Publication date: 2 February 1928. (Name Combination).
1939. *Mops rüppellii* Allen, Bull. Mus. comp. Zool., 83: 108. - Comments: Not of Temminck, 1827. In part. See Kock (1975: 7).
1951. *Tadarida africana:* Roberts, Mammals of Southern Africa, 101.
1953. *Tadarida (Tadarida) africana:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 66.
1974. *Tadarida (Tadarida) ventralis:* Largen, Kock and Yalden, Mon. Zool. ital., (NS) 16 (Suppl 5): 253. (Name Combination).
2015. *Nyctinomus taeniatus:* Lanza, Funaioli and Riccucci, The bats of Somalia and neighbouring areas, 323. (Lapsus).
? *Tadarida ventralis africana:* (Name Combination).
? *Tadarida ventralis:* (Name Combination, Current Combination).

TAXONOMY:
For use of this name in place of *africana*, see Kock (1975).

COMMON NAMES:
Afrikaans: Transvaalse losstertvlermuis, Reuse losstertvlermuis. Chinese: 非洲大犬吻蝠. Czech: morous africký, tadarida africká. English: Giant Guano Bat, Giant African Guano Bat, African Giant Free-tailed Bat, Giant African Free-tailed Bat, Transvaal Free-tailed Bat, Giant Free-tailed Bat. French: Tadaride géante d'Afrique, Grande tadaride africaine, Molosse géant. German: Große Bulldoggfledermaus, rothbraune Doggengrämler. Italian: Tadarìda ventràle. Portuguese: Morcego gigante de cauda livre.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Mickleburgh *et al.*, 2008aj; IUCN, 2009; Mickleburgh *et al.*, 2019d).

Assessment History

Global

2018: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2019d). 2008: DD ver 3.1 (2001) (Mickleburgh *et al.*, 2008aj; IUCN, 2009). 2004: NT ver 3.1 (2001) (Mickleburgh *et al.*, 2004ao; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: VU D2 ver 3.1 (2001) (Taylor *et al.*, 2016d). 2004: Considered a vagrant. Not assessed, known from a single locality (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:

The threats to this species are poorly known. It may be threatened through the conversion of suitable habitat to agricultural land and the use of pesticides in these modified areas (Mickleburgh *et al.*, 2008aj; IUCN, 2009; Mickleburgh *et al.*, 2019d).

CONSERVATION ACTIONS:

Mickleburgh *et al.* (2008aj) [in IUCN (2009)] and Mickleburgh *et al.* (2019d) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed into the distribution, natural history, and threats to this little-known species.

GENERAL DISTRIBUTION:

Tadarida ventralis is widely distributed in East and Southern Africa. It ranges from Eritrea in the north to Zimbabwe, and northern South Africa, in the south. The westernmost record is from the eastern Democratic Republic of the Congo, close to the border area with Uganda. Most records are from high altitude (1,500 m upwards to 2,500 m asl).

Native: Congo (The Democratic Republic of the); Eritrea; Ethiopia; Kenya; Malawi (Ansell and Dowsett, 1988: 46; Monadjem *et al.*, 2010d: 547); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 547); South Africa (Taylor *et al.*, 2015: 50); Sudan; Tanzania; Zambia (Ansell, 1986; Monadjem *et al.*, 2010d: 547); Zimbabwe (Cotterill, 2004a: 260; Monadjem *et al.*, 2010d: 547).

ECHOLOCATION:

See Taylor *et al.* (2005).

POPULATION:

Structure and Density

It has been rarely recorded and is largely known from single dead individuals (Mickleburgh *et al.*, 2008aj; IUCN, 2009; Mickleburgh *et al.*, 2019d).

Trend

2018: Unknown (Mickleburgh *et al.*, 2019d). 2008: Unknown (Mickleburgh *et al.*, 2008aj; IUCN, 2009).

REPRODUCTION AND ONTOGENY:

In Malawi, young were born at the beginning of the wet season (Happold and Happold, 1990b: 568). In E Zambia, a pregnant female was collected in November (Happold and Happold, 2023: 129).

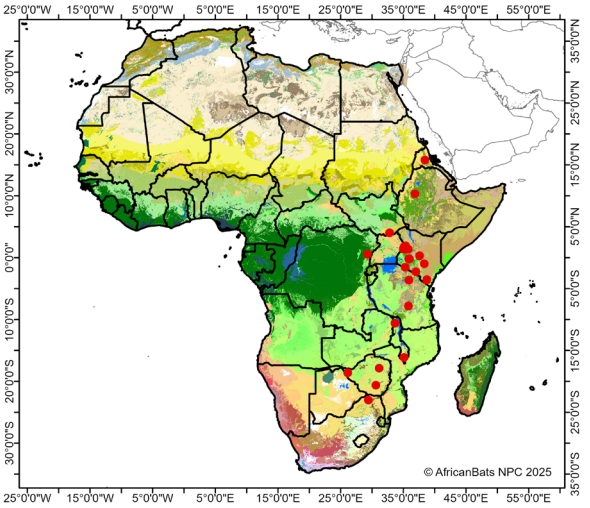

Figure 217. Distribution of *Tadarida ventralis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

Congo (Democratic Republic of the), Eritrea, Ethiopia, Kenya, Malawi, South Africa, South Sudan, Tanzania, Zambia, Zimbabwe.

Superfamily VESPERTILIONOIDEA J. E. Gray, 1821

*1821. *Vespertilionoidea* J. E. Gray, London Med. Repos., 15: 299. Publication date: 1 April 1821. (Current Combination).

1928. *Vespertilionoidea:* Weber, Die Säugetiere, 24. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Introduced as tribe (but actually similar to superfamily) and originally included the families Vespertilionidae J. Gray, 1821, Natalidae J. Gray, 1866, Myzopodidae Thomas, 1904 and Molossidae Gervais, 1855 (see Jackson and Groves, 2015: 265).

2025. *Vespertilionidea:* Guan, Huang, Huang, Zhou, Yang, Yu, Guo, Feng, Wu, Hu and Wei, Sci. China Life Sci., xxx: 1. Publication date: 18 July 2025. (Lapsus).

TAXONOMY:
Currently recognized families within the Superfamily VESPERTILIONOIDEA within Africa: **CISTUGONIDAE** Van Cakenberghe and Seamark, 2011; **MINIOPTERIDAE** Dobson, 1875; **VESPERTILIONIDAE** Gray, 1821.

COMMON NAMES:
Czech: netopýrov ci.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Ravel *et al.* (2011: 402) suggest that affinities such as the closure of the protofossa, the slender lophes, and a tiny metaconule on the upper molars (in the fossil genus *Dizzya* and an unnamed "Eochiropteran" from the El Kohol Formation in Algeria) could support an African endemic radiation of modern Vespertilionoidea.

Guan *et al.* (2025: 7) estimate that the split between the Vespertionidae and the Miniopteridae occurred some 48.18 mya, with the first Vespertilionidae appearing at 40.32 mya.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Congo (Democratic Republic of the), Morocco, South Sudan.

Family CISTUGONIDAE Lack, Roehrs, Stanley, Ruedi and Van den Bussche, 2010

2008. *Cistugoinae:* Van Cakenberghe and Seamark, African Chiroptera Report, 213. Publication date: 1 July 2008. - Comments: Spelling used for subfamily. (Name Combination).
*2010. *Cistugidae:* Lack, Roehrs, Stanley, Ruedi and Van den Bussche, J. Mamm., 91(4): 980. (Alternate Spelling).
2010. *Cistugonidae:* Benda, Vespertilio, 18-19: 271. - Comments: Type genus: Cistugo Thomas, 1912. (Current Combination, Current Spelling).

TAXONOMY:
Stadelmann *et al.* (2004b) showed that the genus *Cistugo* was not placed with the genus *Myotis*, but was basal to the vespertilioid radiation, which is also supported by Horáček *et al.* (2006). For this reason, the ACR (2008, 2009, 2010) recognized representatives of the genus *Cistugo* as a separate distinct subfamily within the Vespertilionidae.

Taylor *et al.* (2024: 9) reported this family's stem age at 42.7 (38.91 - 46.45) Mya, which is much earlier than the crown diversification, which dates from 1.42 (0.72 - 2.48) Mya,

Lack *et al.* (2010: 980) recognized that taxa within this group should be recognized at a family level and suggested the name “Cistugidae”. Benda (2010: 271) and ACR (2011) used a corrected form of the family (or subfamily) name: Cistugonidae (- goninae) - according to the code (genitive from *Cistugo* is *Cistugonis*, thus Cistugonidae).

Simmons and Cirranello (2020) refer to article 29.3.3 of the ICZN code to retain the usage of "Cistugidae" as family name, as this would indicate that "the stem for the formation of the family-group name is chosen by the author of the family level name". The article, however, explicitly mentions the "**entire** generic name", which would support the usage of "Cistugonidae". We therefore keep on using this name.

Currently (Simmons and Cirranello, 2024a) recognized genus within the family Cistugonidae: ***Cistugo*** Thomas, 1912.

COMMON NAMES:
Czech: žlázokřídlecovití.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
The study by Amador *et al.* (2016: 26) supports the long-time separation from the Vespertilionidae, which probably occurred in the early middle Eocene (crown age 43 MYA).

MOLECULAR BIOLOGY:
Karyotype
Sotero-Caio *et al.* (2017: 5) mention the karyotype as 2*n* = 50

Genus ***Cistugo*** Thomas, 1912

*1912. *Cistugo* Thomas, Ann. Mag. nat. Hist., ser 8, 10 (56): 205. Publication date: 1 August 1912 [Goto Description]. - Comments: Type species: *Cistugo seabræ* Thomas, 1912.

TAXONOMY:
Meester *et al.* (1986) included *Cistugo* as a subgenus of *Myotis*. Baker *et al.* (1974) recorded the karyotype of *Myotis* as 2*n* = 44, AA = 50, but Dippenaar *et al.* (1983) gave it as 2*n* = 50, AA = 48 in both *seabrai* and *lesueuri*.

Hayman and Hill (1971) doubt the validity of *lesueuri* and Corbet and Hill (1980) include it in *seabrai*, while Koopman (1982) retain it as a separate species. It is possible, particularly in view of their allopatric distribution, that *lesueuri* may best be treated as a subspecies of *seabrai*.

Included as subgenus in *Myotis* by Koopman (1993a: 207), but considered a valid genus by Thomas (1915), Roberts (1919), Rautenbach *et al.* (1993), Bickham *et al.* (2004: 333), Stadelmann *et al.* (2004b: 185) and Simmons (2005). Stadelmann *et al.* (2004b: 185) state that it might be possible that the two genera share closer phylogenetic relationships with other families of bats than with the Vespertilionidae.

Lack *et al.* (2010: 980) erected a new family: Cistugoidae (see family account above for information about corrected spelling of family name), containing only the genus *Cistugo* Thomas, 1912, which they separate from the Vespertilionidae by the presence of 2 to 4 glands in the wing membrane immediately behind the forearm (see also Seamark and Kearney, 2006), which are lacking in all other vespertilionoid bats.

Taylor *et al.* (2024: 7) mention a crown date of 1.42 (0.72 - 2.48) Mya for *Cistugo*.

Currently (Simmons and Cirranello, 2024b) recognized species of the genus *Cistugo*: ***lesueuri*** Thomas, 1912; ***seabrae*** Thomas 1912.

COMMON NAMES:
Czech: žlázokřídlecové. English: Wing-gland Bats. German: Mausohren.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Avery (2007: 619) reported on the presence of *Cistugo* sp. in Pleistocene deposits at Wonderwerk Cave, South Africa.

GENERAL DISTRIBUTION:
Seamark *et al.* (2012: 116-117) indicate that the ranges of the two species (*C. seabrae* and *C. lesueuri*) might not be allopatric as previously assumed but might be overlapping.

HABITAT:
Marsden *et al.* (2023: 7) indicate that bats of the genus *Cistugo* are generally urban avoiders. This can probably be attributed to their roost specificity and the rarity of these species.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Uganda.

Cistugo lesueuri Roberts, 1919

*1919. *Cistugo lesueuri* Roberts, Ann. Transv. Mus., 6(3): 112-113. Type locality: South Africa: SW Cape province: Paarl district: near Paarl, Franschhoek [=Frenchhoek] valley: L'Ormarins [=Lormarins] [33 44 S 18 58 E]. [Goto Description]. Holotype: TM 2286: ad ♂, skin and skull. Collected by: J.S. Le Sueur Esq. Collection date: 15 September 1917; original number: 154. - Comments: For details on the type locality, see Meester *et al.*, 1986: 49). - Etymology: Named after J.S. le Sueur of L'Ormarins in the Paarl district, Western Cape, who recovered the original specimen from his cat (see Smithers, 1983: 92; Taylor, 2005). (Current Combination).
? *Myotis (Cistugo) lesueuri:* (Name Combination).
? *Myotis lesueuri:* (Name Combination).

TAXONOMY:

Figure 218. A female *Cistugo lesueuri* (TM 48190) caught at the Farm Schaapplaats, Free State, South Africa.

Hayman and Hill (1971) doubt the validity of *lesueuri* and Corbet and Hill (1980) include it in *seabrae*, while Koopman (1982) retain it as a separate species. It is possible, particularly in view of their allopatric distribution, that *lesueuri* may best be treated as a subspecies of *seabrae*.

COMMON NAMES:
Afrikaans: Lesueur se langhaarvlermuis, Lesueur-langhaarvlermuis, Lesueurse Vlerkkliervlermuis. Czech: žlázokřídlec Lesueurův. English: Lesueur's Wing-gland Bat, Lesueur's Hairy Bat, Lesueur's Myotis, Wing-gland bat. French: Murin de Lesueur. German: Leseuers Mausohr.

CONSERVATION STATUS:
Global Justification
Monadjem *et al.* (2017cg) report that this species is restricted to South Africa and Lesotho in areas with suitable rock crevices and water sources. It has a large range, with an estimated extent of occurrence of over 400,000 km^2 and there are more than 20 known locations. This species is highly likely to be under collected and many more subpopulations are suspected to occur, especially within the Nama and Succulent Karoo regions of South Africa. Wind farms represent an emerging threat, as its preferred habitat coincides with suitable wind farm sites. Although declines have been recorded these are not suspected to be at levels high enough to qualify the species for listing under a threat category. However, systematic long-term monitoring should be used to estimate rates of decline across its range, as this species may require reassessing in a threatened category (Jacobs, 2008b; IUCN, 2009; Monadjem *et al.*, 2017cg).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cg). 2008: LC ver 3.1 (2001) (Jacobs, 2008b; IUCN, 2009). 2004: VU D2 ver 3.1 (2001) (Jacobs, 2004b; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Avenant *et al.*, 2016b). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate, assessed as *Myotis lesueuri* (Smithers, 1986).

MAJOR THREATS:
The species is locally threatened, in parts of its range, by conversion of land to agricultural use (Jacobs, 2008b; IUCN, 2009; Driver *et al.*, 2012). However, as this species occurs mostly in high-altitude areas, this is not a severe threat. The growing trend of developing wind farms in the eastern parts of South Africa and in Lesotho is starting to pose a threat to this species. The degree of impact and levels of decline to the population are currently unknown and should be monitored (Monadjem *et al.*, 2017cg).

CONSERVATION ACTIONS:
Monadjem *et al.* (2017cg) report that in the Western Cape, the species is recorded from the three protected areas, Cedarberg Wilderness Area, Gamkaberg Nature Reserve and Karoo National Park; in the Free State the species was recorded in the Golden Gate National Park; in Lesotho it is found in Sehlabathebe National Park, as well as in the Maloti-Drakensberg Transfrontier Conservation Area. No specific interventions are currently necessary, but conservation planning and engagement with the wind energy industry will be needed in future to mitigate subpopulation loss with wind farm construction (Monadjem *et al.*, 2017cg).

GENERAL DISTRIBUTION:
This species is restricted to South Africa and Lesotho, where its distribution is best predicted by geology (Babiker Salata, 2012: 50). Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 673,792 km^2.

Native: Lesotho (Lynch and Watson, 1990; Lynch, 1994: 192; Monadjem *et al.*, 2010d: 562); South Africa (Free State - Watson, 1998; Monadjem *et al.*, 2010d: 562; KwaZulu Natal - Monadjem *et al.*, 2010d: 562; Western Cape - Herselman and Norton, 1985; Rautenbach *et al.*, 1993; Seamark and Brand, 2005; Monadjem *et al.*, 2010d: 562).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
For 4 specimens from the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) mention the following parameters: Fa: 36.0 ± 0.4 mm, Wing area: 93.3 ± 1.6 cm^2, Wing span: 23.8

± 1.1 cm, Wing loading: 7.5 ± 1.4 N/m^2, and aspect ratio: 6.1 ± 0.7.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

Figure 219. Clockwise from top lateral, ventral and dorsal skull images of TM 2286, holotype of *Cistugo lesueuri* Roberts, 1919.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 7.1 Pa, aspect ratio 6.2 for a wingspan of 24 cm and a wing area of 93 cm^2 and a body mass of 7 g.

ECHOLOCATION:
From Algeria Forest Station (RSA), Schoeman and Jacobs (2002: 157) reported the type of calls to be low duty echolocation dominated by frequency modulated calls, with a F_{peak}: 36.8 ± 0.9 kHz.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 50, FN = 48, BA = 0, a submetacentric X chromosome, and an acrocentric Y chromosome, these results were the same as those obtained for *C. seabrae* from Namibia (Rautenbach *et al.*, 1993) .

HABITAT:
In the Free State Province of South Africa collected from broken country (e.g., koppies and cliffs), invariably away from human habitation and constructions, but close to open water (dams and streams). While in the Western Cape it inhabits fynbos and possibly the succulent karoo (Jacobs, 2008b; IUCN, 2009).

Cooper-Bohannon *et al.* (2016: Table S2) mention its occurrence in the following habitat types: Afromontane (43 %), High veld (29 %), SW Cape (13 %) and SW arid (11 %).

HABITS:
In the Free State Province of South Africa specimens were netted in the early evening, between 18:30 and 20:00, with only two specimens being caught after 21:15 (Watson, 1998: 128). When disturbed in their day roost they flew to another roost 50 meters away (Watson, 1998: 128).

ROOST:
Found in a crevice roughly four meters from the ground, on a west-facing dolorite rock face next to a river in the Free State Province of South Africa (Watson, 1998: 127).

Czenze *et al.* (2021: 3) classified this species as cool-roosting as they preferred roost sites with temperatures well below 30*C and where the maximum temperature was at least 10*C lower than outside.

DIET:
From the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) reported the following prey groups based on 39 faecal pellets from 4 bats (in volume percent): Diptera (47.3 ± 37.3), Hemiptera (32.5 ± 22.8), Hymenoptera (6.8 ± 13.5), Coleoptera (6.3 ± 4.9), Trichoptera (2.5 ± 5.0), Ephemenoptera (1.5 ± 3.0), and unknown (3.3 ± 6.5).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 75 minutes, and the digestibility rate about 80.3 %.

POPULATION:
Structure and Density
Although endemic, the species has a wide distribution within the assessment region, despite not being common and very rarely recorded (Monadjem *et al.*, 2017cg. In the Free State Province of South Africa, a group of approximately 40 individuals was located in a day roost (Watson, 1998: 127). Seamark and Brand (2005) showed that this species made up only 4.6% of the overall catch in the Cederberg, Western Cape. In inland Western Cape, near the border with the Northern Cape, a group of approximately 30 individuals was located in a day roost (T. Morgan *unpubl. data* in Monadjem *et al.* (2017cg)). Systematic long-term monitoring

should be used to estimate rates of decline across its range, as this species may be increasingly threatened by wind farm expansion (Monadjem *et al.*, 2017cg).

Trend
2016: Decreasing (Monadjem *et al.*, 2017cg).
2008: Decreasing (Jacobs, 2008b; IUCN, 2009).
2004: Decreasing (Jacobs, 2004b; IUCN, 2004).

VIRUSES:
Bunyaviridae
Phlebovirus
Rift Valley Fever Virus (RVFV)
Oelofsen and Van der Ryst (1999) tested a single individual from one locality in Lesotho for RVFV antigen using an enzyme linked immunosorbet assay (ELISA), none tested positive.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Rabies
Oelofsen and Smith (1993) tested 15 individual brains, from four localities by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), none were tested positive.

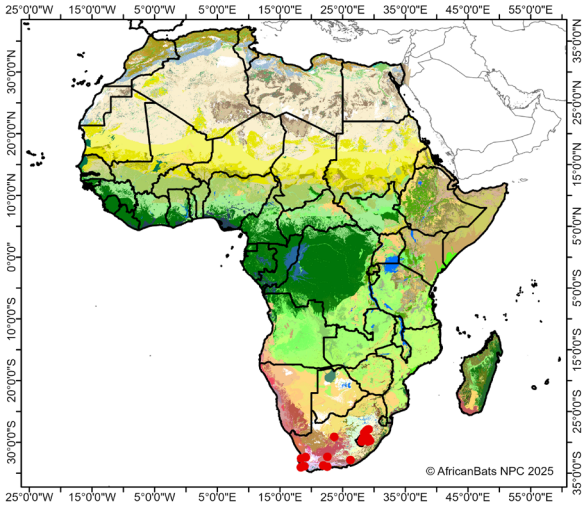

Figure 220. Distribution of *Cistugo lesueuri*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Lesotho, South Africa.

Cistugo seabrae Thomas, 1912

*1912. *Cistugo seabræ* Thomas, Ann. Mag. nat. Hist., ser 8, 10 (56): 205. Publication date: 1 August 1912. Type locality: Angola: Mossamedes [=Moçamedes] [ca. 15 56 S 12 10 E]. [Goto Description]. Holotype: NHMUK 1906.1.3.3: ad ♀, skull and alcoholic. Presented by the Lisbon Museum. (Current Combination).

? *Myotis seabrae:* (Name Combination).
? *Myotis seabrai:* (Name Combination).

TAXONOMY:

Figure 221. A male *Cistugo seabrae* (TM 47582) caught at Khamkirri, Northern Cape, South Africa. Note the gland on the wing.

See Simmons (2005).

COMMON NAMES:
Afrikaans: Angola-langhaarvlermuis, Angolase Vlerkkliervlermuis. Czech: žlázokřídlec Seabrův. English: Seabra's Wing-gland Bat, Angolan Wing-gland Bat, Angolan Hairy Bat. French: Murin d'Angola. German: Angola-Mausohr.

ETYMOLOGY OF COMMON NAME:
The colloquial name is derived from the fact that the original specimen originated from Moçâmedes on the south-western coast of Angola (Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because there are no threats, making it unlikely to be declining fast enough to qualify for listing in a more threatened category (Griffin and Jacobs, 2008; IUCN, 2009; Monadjem *et al.*, 2017bj).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bj). 2008: LC ver 3.1 (2001) (Griffin and Jacobs, 2008; IUCN, 2009). 2004: NT ver 3.1 (2001), assessed as *Cistugo seabrai* (Jacobs, 2004a; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: NT D1+D2 ver 3.1 (2001) (Jacobs *et al.*, 2016e). 2004: VU D2 ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate, assessed as *Myotis seabrai* (Smithers, 1986).

MAJOR THREATS:

There are no major threats to this species. It may be locally threatened by mining operations in a small part of its range (Griffin and Jacobs, 2008; IUCN, 2009; Monadjem *et al.*, 2017bj).

CONSERVATION ACTIONS:

Griffin and Jacobs (2008) [in IUCN (2009)] report that it is not known if there are any direct conservation measures in place for this species, and it is unclear if it occurs within any protected areas. Further studies are needed into the distribution and natural history of this little-known species.

GENERAL DISTRIBUTION:

This southern African species ranges from the type locality of Moçâmedes in southwestern Angola, southwards through western Namibia to the Northern Cape of South Africa.

Native: Angola (Crawford-Cabral, 1989; Thomas, 1912c; Monadjem *et al.*, 2010d: 562); Namibia (Thomas and Hinton, 1925; Shortridge, 1934; Rautenbach *et al.*, 1993; Kearney and Van Schalkwyk, 2009; Monadjem *et al.*, 2010d: 562); South Africa (Herselman and Norton, 1985; Stadelmann *et al.*, 2004b; Seamark and Kearney, 2006; Kearney and Van Schalkwyk, 2009; Monadjem *et al.*, 2010d: 562).

MOLECULAR BIOLOGY:

Karyotype

Rautenbach *et al.* (1993) reported 2*n* = 50, FN = 48, BA = 0, a submetacentric X chromosome, and an acrocentric Y chromosome, these results were the same as those obtained for *C. lesueuri* from South Africa (Rautenbach *et al.*, 1993).

Genetics

Stadelmann *et al.* (2004b).

HABITAT:

Little is known about the natural history of this species. All of the localities from which they have been collected are arid with a mean annual rainfall of less than 100 mm (Skinner and Chimimba, 2005).

HABITS:

Specimens have usually been caught close to open water and have been observed gleaning insects from orange trees (Roberts, 1951; Taylor, 2000; Skinner and Chimimba, 2005).

DIET:

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 80 minutes, and the digestibility rate about 79.5 %.

POPULATION:

Structure and Density

It appears to be a rarely recorded species (Griffin and Jacobs, 2008; IUCN, 2009; Monadjem *et al.*, 2017bj).

Trend

2016: Unknown (Monadjem *et al.*, 2017bj). 2008: Unknown (Griffin and Jacobs, 2008; IUCN, 2009). 2004: Decreasing (as *Cistugo seabrai*) (Jacobs, 2004a; IUCN, 2004).

PARASITES:

ACARI

Macronyssidae

Orlova *et al.* (2020c: 951) reported the presence of *Steatonyssus afer* Radovsky and Yunker, 1963 on two *Cistugo seabrae* bats from Namibia.

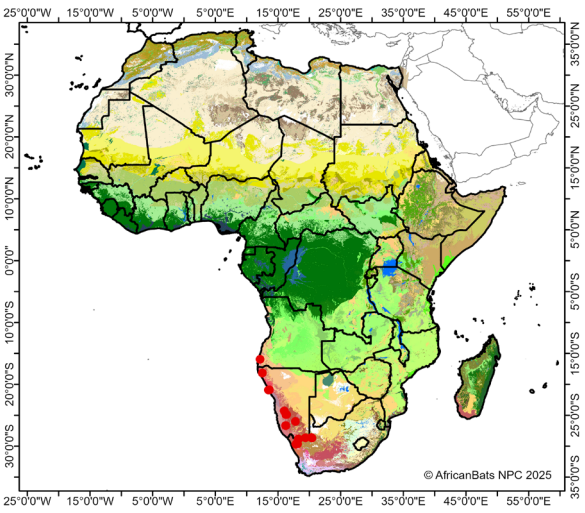

Figure 222. Distribution of *Cistugo seabrae*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

"Africa", Angola, Namibia, South Africa.

†Family INDETERMINATE

†Genus ***Chambinycteris*** Ravel, 2016

*2016. *Chambinycteris* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 356, 402. Publication date: 30 September 2016. - Etymology: Refers to Chambi, the locality where the specimens were collected (see Ravel *et al.*, 2016: 402).

TAXONOMY:
Ravel *et al.* (2016: 358) indicate that this genus has a basal position within the Emballonuridae.

Jones *et al.* (2024: 16) could not place *Chambinycteris* within a specific (super)family, but found it fell within the crown Chiroptera.

†***Chambinycteris pusilli*** Ravel, 2016

*2016. *Chambinycteris pusilli* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 403. Publication date: 30 September 2016. - Etymology: From the Latin "*pusilli*" meaning puny or sickly, referring to the small size and fragility of the species (see Ravel et al., 2016: 403). (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:

Late lower Eocene (Ypresian - Brown *et al.*, 2019: Suppl.) to early middle Eocene.

†Genus ***Drakonycteris*** Ravel, 2016

*2016. *Drakonycteris* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 356, 399. Publication date: 30 September 2016. - Etymology: From the Greek "*δράκων*" meaning dragon and "*νυκτερισ*" meaning bat (see Ravel *et al.*, 2016: 399).

†***Drakonycteris glibzegdouensis*** Ravel, 2016

*2016. *Drakonycteris glibzegdouensis* Ravel, in: Ravel et al., Geodiversitas, 38 (3): 356, 399, figs 23, 24. Publication date: 30 September 2016. Type locality: Algeria: Béchar province: Gour Lazib: Sahara, Hammada du Dra: Glib Zegdou [29 42 49 N 05 45 58 W]. - Etymology: Referring to the type locality of Glib Zegbou (see Ravel *et al.*, 2016: 399). (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:

Late lower Eocene (Ypresian - Brown *et al.*, 2019: Suppl.) to early middle Eocene.

Family MINIOPTERIDAE Dobson, 1875

1875. *Miniopteri* Dobson, Ann. Mag. nat. Hist., ser 4, 16 (95): 349. Publication date: 1 November 1875.
*1875. *Miniopteridae* Dobson, Ann. Mag. nat. Hist., ser 4, 16 (95): 348. Publication date: 1 November 1875. - Comments: Type genus: *Miniopterus* Bonaparte, 1837. Originally included the genera *Natalus* J. Gray, 1838; *Thyroptera* Spix, 1823 and *Miniopterus* Bonaparte, 1837. (Current Combination).
1878. *Miniopterææ* Trouessart, Rev. Mag. Zool., (3) 6: 253. - Comments: See Taylor (1934).
.
1897. *Minioptereae* Trouessart, Catalogus Mammalium tam viventium quam fossilium, p 134. (Alternate Spelling).
1907. *Miniopterinae:* Miller, Bull. U.S. natl. Mus., 57: xi, 227. Publication date: 29 June 1907. - Comments: Type genus: *Miniopterus* Bonapart, 1837.
1977. *Miniopteridae:* Mein and Tupinier, Mammalia, 41 (2): 207, 209. - Comments: Type genus: *Miniopterus* Bonaparte, 1837.

† indeterminate

TAXONOMY:
Bannikova *et al.* (2002: 722) indicate that the Miniopterinae do not deserve the rank of independent family (as did Koopman, 1984c, 1993a, 1994; Yoshiyuki, 1989; Corbet and Hill (1992; McKenna and Bell, 1997), but see Hoofer and Van Den Bussche (2003: 13) who make a strong case for attributing family rank. They follow Mein and Tupinier (1977), Groombridge (1994), Gopalakrishna and Chari (1983), Tiunov (1989), Pierson (1986). See also Hawkins *et al.* (2019: 11355).

In their study on rolling-circle transposons (*Helitrons*), Thomas *et al.* (2010: 55) found none of these in the Miniopteridae. They also indicated that these *Helitrons* colonized the Vespertilionidae some 30 - 36 mya, which is much later than the split between Vespertilionidae and Miniopteridae, which occurred some 43 million years ago. Patterson and Webala (2012: 32) indicate that the split between Vespertilionidae and *Miniopterus* occurred between 38 and 47 million years ago. Demos *et al.* (2019c: "6") indicate that the Miniopteridae diverged from the Vespertilionidae and Cistugidae some 48 mya.

Herkt *et al.* (2017: Appendix 4S), investigating the IUCN distribution maps and species distribution models, left out the Miniopteridae because of their exceptionally high cryptic diversity and level of phenetic similarity, which leads to unreliably identification of large amounts of published records.

Using UCE (ultraconserved elements) data, Demos *et al.* (2023: xxx) found that the continental African *Miniopterus* clade is monophyletic, with the exception of M. inflatus. This species is sister to the continental African + Malagasy clades

Currently (Simmons and Cirranello, 2024b) recognized genera of the family MINIOPTERIDAE: ***Miniopterus*** Bonaparte, 1837.

COMMON NAMES:
Czech: létavcovití, netopýři dlouhorucí. Dutch: Langvleugelvleermuizen. English: Long-fingered Bats. French: Minioptéridés. German: Langflügelfledermäuse. Italian: Miniottèridi, Minioptèridi. Russian: Длиннокрыловые. Ukrainian: Довгокрили [= Dovhokryly]. Vietnamese: Họ dơi cánh.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Amador *et al.* (2016: 26) estimated the split from the Vespertilionidae at c. 48 MYA, and a stem age at 13 MYA. Demos *et al.* (2023) situate the crown age of African Miniopteridae in the late Miocene (10.4 MYA), which also seems to be the timeframe in which the Afrotropic and Madagascar sister lineages diversified (at about 9.06 MYA). The crown age of the Malagay clade is estimated at 7.78 MYA and that of the Afrortropical clade at 8.4 MYA. They also indicate that the continental radiation originated in the Zambezian and Somalian/Ethiopian biogeographic regions, although it might be possible that a recolonisation from Madagascar might have happened.

MOLECULAR BIOLOGY:
Karyotype
Sotero-Caio *et al.* (2017: 5) indicate that the karyotype for all 25 species in the family has a 2*n* value of 46.

Based on the analysis of the karyotypes (more specifically the common derived condition of the MMY22 homolog), Volleth *et al.* (2023b: 1) state that the Miniopteridae are more closely related to the Vespertilionidae than to the Molossidae.

Genetics
Capanna *et al.* (1968: 240) already pointed out that there was a cytotaxonomic difference between the Vespertilioninae and the Miniopterinae, especially in the average length of the aploid female set.

Platt *et al.* (2016: 9) analysed the genome data for *M. natalensis* and compared it with that of several other vesper bats and they concluded that *Helitrons* and hATs were introduced into the genome of the Vespertilionidae after their divergence from *Miniopterus*.

VIRUSES:
Gutiérrez-Guerrero *et al.* (2020: Suppl. Fig 3A) report that worldwide 63 % of the species belonging to this family are confirmed viral carriers.

Three of the 15 bats collected in the dry season and examined by Kumakamba *et al.* (2021: 7) were positive for coronaviruses. One additional bat collected in the wet season was not.

Genus ***Miniopterus*** Bonaparte, 1837

*1837. *Miniopterus* Bonaparte, Iconografia Fauna italiana, 1, fasc 20 [Goto Description]. - Comments: Type species: *Vespertilio ursinii* Bonapate, 1837 (=*Vespertilio schreibersii* Kuhl, 1817). - Etymology: From the Greek "*μινύς*"

or "*μινός*", meaning small and "*πτέρυξ*", meaning wing, referring to the very short first phalanx of the third and longest finger (see Palmer, 1904: 426; Flannery, 1995a: 374; Kozhurina, 2002: 16). Lanza *et al.* (2015: 328) mention the following: "According to Bonaparte (1837) who described the genus and Lanza (2012), *Miniopterus* is a scientific masculine Latin substantive made up of the proper feminine Latin noun *Minyèias* 'Minyad', i. e. a daughter of Minyas, king of Orchomenus, turned into a bat, and of the Greek neuter substantive *πτερόν*" (pteròn) 'wing', meaning 'flying Minyad'. The etymology proposed by Kozhurina (2002), meaning 'with small (narrow) wings', is incorrect, even if formally logical. Also partially erroneous is the etymology given by some Italian dictionaries, such as Battaglia (1978) and Devoto & Oli (1997), who interpret 'minio' as 'minimum, red-lead', the red colouring agent, which obviously has nothing to do with the greyish brown colour of Miniopterus' wings". - Phonetics: min-ee-op′-ter-us. (Current Combination).

1846. *Minyopterus:* Agassiz, Nomenclator. Zool., Mamm, 235. - Comments: Variant spelling (Meester *et al.*, 1986: 45) or unjustified emendation (Jackson and Groves, 2015: 263). (Lapsus, Emendation).

1858. *Miniopteris:* Tomes, Proc. zool. Soc. Lond., 1858, XXVI (cccliv): 115. Publication date: 13 May 1858. - Comments: Variant spelling (Meester *et al.*, 1986: 45) or unjustified emendation (Jackson and Groves, 2015: 262). Not *Miniopteris* J. Gray, 1849 (Mammalia, Chiroptera, Vespertilionidae) (used as genus name for *Myotis macrotarsus* (Waterhouse, 1845) (see Jackson and Groves, 2015: 263). (Alternate Spelling).

1900. *Minneopterus:* Lampe, Jb. nass. Ver. Naturkde, 53: Cat Säugeth-Sammlung, p 12. Publication date: 1900. - Comments: Cat. Säugeth.-Sammlung, p. 12. Lapsus (see Allen, 1939a: 102; Meester *et al.*, 1986: 45). Jackson and Groves (2015: 263) indicate it appeart to be a *nomen nudum* or an unjustified emendation. (Lapsus, Emendation).

1920. *Mineopterus:* Haagner, South African Mammals, 22. (Lapsus).

1980. *Minioterus:* Bernard, Ann. Transv. Mus., 32 (3): 55. Publication date: January 1980. (Lapsus).

1986. *Mimopteris:* Castiblanco de V., Jaramillo and Muñoz A., Actual Biol., 15 (56): 27. Publication date: April-June 1986. (Lapsus).

2014. *Mineropterus:* Kohl and Kurth, Viruses, 6 (8): 3112. Publication date: 13 August 2014. (Lapsus).

2015. *Minioptera:* Golden and Comaroff, Ecol. Soc., 20 (2): 42: 5. (Lapsus).

2019. *Minioptreus:* Zeghbib, Herczeg, Kemenesi, Zana, Kurucz, Urbán, Madai, Földes, Papp, Somogyi and Jakab, Sci. Reps., 9 (15706): 1. Publication date: 31 October 2019. (Lapsus).

2024. *Minipteros:* Munjita, Mubemba, Changula, Tembo, Hamoonga, Bates, Chitanga, Munsaka and Simulundu, Front. Public Health, 12 (1471452): 3. Publication date: 20 November 2020. (Lapsus).

? *Miniopterus sp.*

? *Miniopterus sp. IVK-2011*

General Comments:

Given the rather recent taxonomic changes in *Miniopterus* from Madagascar, Goodman *et al.* (2022: 1908) indicate that it is not clear which literature data should be linked with which taxon.

Taxonomy:

Reviewed (in part) by Peterson (1981). See Goodwin (1979: 119), Maeda (1982), and Hill (1983). All have come to very different conclusions. Molecular systematics and biogeography is discussed by Appleton *et al.* (2004); their DNA data (p. 437) suggest that the number of species currently recognized (11 or 13) is a gross underestimate. Phylogenetic analyses performed by Christidis *et al.* (2014: 1) indicate that 18 clades are present within Malagasy *Miniopterus* of which only 11 have Latin binominals.

Šrámek *et al.* (2012: 165) investigated the taxonomic status of the bent-winged bats in the western Palaearctic and distinguished four species: *M. schreibersii* (s.str.) from Europe, coastal Anatolia, Levant, Cyprus, western Transcaucasia, and North Africa; *M. pallidus* from inland Anatolia, Jordan, eastern Transcaucasia, Turkmenistan, Iran and southern Afghanistan (Kandahar); a *Miniopterus* sp., recorded from Nangarhar province in eastern Afghanistan, which was tentatively assigned to *M.* cf. *fuliginosus*; and another *Miniopterus* sp. With Afro-tropic affinities confirmed from south-western Arabia and Ethiopia, which tentatively named *M.* cf. *arenarius*. They also indicate that a possible new taxon (subspecies) within *M. schreibersii* exists in the Atlas Mountains of Morocco. Bilgin *et al.* (2013: 21) indicate that this Maghrebian form possibly even represents a new species, which they tentatively call: *M. maghrebensis*.

See Taylor *et al.* (2019a: 318) for a discussion on the recent increase in Afro-Madagascan species. Demos *et al.* (2019c: "1") analysed cyt-*b* and nuclear data from sub-Saharan *Miniopterus* specimens and found evidence for five undescribed species. Their data (p. "9") confirmed the species status of *fraterculus, mossambicus, natalensis* and *newtoni* and tentatively for *africanus, arenarius, inflatus* and *minor*. *M. inflatus, minor* and *natalensis* are probably paraphyletic.

The 18 Malagasy clades recovered by Christidis *et al.* (2014) in their phylogenetic analysis were divided in into five primary lineages (representing sister species): (1) *M. griveaudi*; (2) *M. mahafaliensis, M. sororculus* and X3; (3) *M. majori, M. gleni* and *M. griffithsi*; (4) *M. brachytragos; M. aelleni* A, and *M. aelleni* B, and (5) *M. manavi* and *M. petersoni*. These are in turn linked to a group comprising *M. egeri* and five genetically distinct populations referred to as P3, P4, P5, P6 and P7.

Derouiche *et al.* (2024: 32) also distinguished five lineages in the Malagasy *Miniopterus* species, but they replaced *M. brachytragos* with *M. ambohitrensis*. On the African continent, they distinguished two groups: Group C (containing *M. inflatus* only) and group D, which is further subdivided in three subgroups: D2: *M. fraterculus* and *M. minor*; D3: *M. maghrebensis, M. natalensis* and extralimital *M. schreibersii*; D4: *M. africanus, M. mossambicus* and *M. newtoni.*

Currently (Simmons and Cirranello, 2024b) recognized species of the genus *Miniopterus*: ***aelleni*** Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, 2009; ***africanus*** Sanborn, 1936; ***ambohitrensis*** Goodman, Ramasindrazana, Naughton and Appleton, 2015; ***arenarius*** Heller, 1912; *australis* Tomes, 1858 – Philippines, Borneo, Java, Timor, Moluccas, southeast to Vanuatu and eastern Australia (Simmons, 2005: 519); ***brachytragos*** Goodman, Maminirina, Bradman, Christidis and Appleton, 2011; ***egeri*** Goodman, Ramasindrazana, Maminirina, Schoeman and Appleton, 2011; *eschscholtzii* G.R. Waterhouse, 1845 – Philippines; ***fraterculus*** Thomas and Schwann, 1906; *fuliginosus* (Hodgson, 1835) – Afghanistan to Myanmar; Japan; Vietnam; Korea; *fuscus* Bonhote, 1902 – Ryuku Isls (Japan) (Simmons, 2005: 519); ***gleni*** Peterson, Eger and Mitchell, 1995; ***griffithsii*** Goodman, Maminirina, Bradman, Christidis and Appleton, 2009; ***griveaudi*** Harrison, 1959; ***inflatus*** Thomas, 1903; *macrocneme* Revilliod, 1914 – New Guinea to Vanuatu and New Caledonia (Simmons, 2005: 520); ***maghrebensis*** Puechmaille, Allegrini, Benda, Bilgin, Ibáñez and Juste, 2014; *magnater* Sanborn, 1931 – northeastern India, southeastern China, Burma, Thailand, Laos and Vietnam to Malaysia, Sumatra, Java, Timor (Indonesia), Borneo, Moluccas and New Guinea including the Bismarck Arch. (Simmons, 2005: 520); ***mahafaliensis*** Goodman, Bradman, Christides and Appleton, 2009; ***majori*** Thomas, 1906; ***manavi*** Thomas, 1906; *medius* Thomas and Wroughton,1909 – southeastern China, Thailand, western Malaysia, Borneo, Java, Sulawesi, Philippines, New Guinea (Simmons, 2005: 520); ***minor*** Peters, 1867; ***mossambicus*** Monadjem, Goodman, Stanley and Appleton, 2013; ***natalensis*** (A. Smith, 1834); ***newtoni*** Bocage, 1889; ***nimbae*** Monadjem, Shapiro, Richards, Karabulut, Crawley, Nielsen, Hansen, Bohmann and Mourier, 2020; *orianae* Thomas, 1922 – Australia; *pallidus* Thomas, 1907 – N Arabia; Asian part of Turkey; Afghanistan; *paululus* Hollister, 1913 – Majuyod, Negros and Guimarás Island (Philippines), Borneo, Selaru (Simmons, 2005: 521); ***petersoni*** Goodman, Bradman, Maminirina, Ryan, Christidis and Appleton, 2008; *phillipsi* Kusuminda, Mannakkara, Ukuwela, Kruskop, Amarasinghe, Saikia, Venugopal, Karunarathna, Gamage, Ruedi, Csorba, Yapa and Patterson, 2020 – Sri Lanka; *pusillus* Dobson, 1876 – India, Nepal and Burma to Sumatra and Timor (Indonesia), Philippines and Moluccas (Simmons, 2005: 520); *robustior* Revilliod, 1914 – Loyalty Islands (east of New Caledonia) (Simmons, 2005: 521); ***schreibersii*** (Kuhl, 1817); *shortridgei* Laurie and Hill, 1957 – Java, Madura, Lombok, Sumbawa, Moyo, Alor, Wetar, Seralu, Timor, Semau, Roti and Savu Isls (Indonesia) (Simmons, 2005: 522); ***sororculus*** Goodman, Ryan, Maminirina, Fahr, Christidis and Appleton, 2007; *srinii* B. Srinivasulu and A. Srinivasulu, 2023 – India (Western Ghats); *tristis* (Waterhouse, 1845) – Philippines, Sulawesi, Sanan Isl, New Guinea, Bismarck Arch., Solomon Isls, New Hebrides (Simmons, 2005: 522); ***villiersii*** Aellen, 1956: ***wilsoni*** Monadjem, Guyton, Naskrecki, Richards, Kropff and Dalton, 2020.

Furthermore there is also the extinct African †***horaceki*** Gunnell, Eiting, and Geraads, 1837.

COMMON NAMES:
Czech: létavci, netopýři dlouhorucí. English: Long-fingered Bats, Bent-winged Bats. French: Minioptères. German: Langflügelfledermäuse, Sackfledermaus. Ukrainian: Довгокрил [= Dovhokryl].

ETYMOLOGY OF COMMON NAME:
The very long second phalanx of the third finger led to the name "long-fingered bats". The feature also allows these bats to fold or bent their wings back, hence "bent-winged bats" (see Demos *et al.*, 2019c: "2").

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
The oldest fossil remains for *Miniopterus* date from some 13.65 million years ago (see Shi and Rabosky, 2015: 1532).

Butler (1978) refers to African material of this genus, found from the early Pleistocene at Olduvai, and Avery (2007: 619) reported on the presence of *Miniopterus* sp. in Pleistocene deposits at Wonderwerk Cave, South Africa. Geraads *et al.* (2010: 279) reported *Miniopterus* in Late Cenozoic (ca. 2.5 MYA) deposits in Ahl al Oughlam, Morocco.

Weyeneth (2010) suggested that Malagasy *Miniopterus* colonized the Comoros during the Pleistocene, favored by prevailing winds.

GENERAL DISTRIBUTION:
Due to major changes in the taxonomy of this genus over the past few years, quite an amount of identifications of Madagascan bats became uncertain and require review.

BIOGEOGRAPHY:
Weyeneth *et al.* (2008) suggest that the Comoros were colonized independently at least two or three times by ancestors from Madagascar.

DETAILED MORPHOLOGY:
Brain
Maseko and Manger (2007) describe the nuclear parcellation and neuronal morphology of the cholinergic, catecholaminergic and serotonergic systems within the brain of six adult female *Miniopterus schreibersii* [possibly *M. natalensis* or *M. fraterculus*, not *Miniopterus schreibersii*], captured from caves in northwest region of Gauteng Province, South Africa.

SEXUAL DIMORPHISM:
Goodman and Maminirina (2007) found no notable evidence for sexual dimorphism in Malagasy *Miniopterus* spp.

ECHOLOCATION:
Bioacoustic data of 11 Malagasy (Madagascar and the Comoros) has been collected and investigated by Ramasindrazana *et al.* (2011).

Taylor-Boyd *et al.* (2025: 116) report the following values for 12 calls from Zambian *Miniopterus* sp.: Interpulse interval: 63.8 ± 14.1 (35.2 - 90.7) ms; F_{max}: 59.5 ± 2.3 (54.1 - 63.0) kHz; Start slope: -24.0 ± 5.8 (-13.1 - -38.2) kHz/ms; End slope: -8.8 ± 4.0 (-10.1 - -5.6) kHz/ms; Ledge duration: 0.5 ± 0.1 (0.3 - 0.7) ms.

HABITS:
Rainho *et al.* (2023: 7) assigned the *Miniopterus* bats in Meru county (Kenya) to a medium-to-high-flying guild flying at altitudes between 2 and 10 m.

PREDATORS:
Goodman *et al.* (2022: 1908) mention that a white-browed owl (*Athene superciliaris* (Vieillot, 1817) [= *Ninox superciliaris* (Vieillot, 1817)]) was seen feeding on small *Miniopterus* bats at Ankaranana (Madagascar).

PARASITES:
BACTERIA
Bartonellae
Bartonella
Kosoy *et al.* (2010: 1877) reported a prevalence of *Bartonella* spp. in *Miniopterus* sp. from Kenya of 22/105 (21.0 %) cultured from blood samples. Fifty-one *Bartonella* spp. *gltA* sequences were obtained from 3 identified species of *Miniopterus* (*africanus, minor, natalensis*), were 24 unique *gltA* genotypes representing at least 3 genogroups (Kosoy *et al.*, 2010: 1878). See also Kosoy (2010: 719) for further information.

HAEMOSPORIDA
Rasoanoro *et al.* (2021: 2) report that *Polychromophilus melanipherus* (Dionisi, 1899) is the only representative of this genus that infects Malagasy *Miniopterus* species.

ACARI
Myobiidae
Fain (1994: 1280) reported the genus *Calcarmyobia* to occur only on bats of the genus *Miniopterus* with 18 species and 8 subspecies.

Spinturnicidae
Szubert-Kruszyńska *et al.* (2018: 760) mentioned the presence of *Spinturnix psi* (Kolenati, 1856) on *Miniopterus* sp. grom Madagascar.

Trombiculidae
Trombigastia (Trombigastia) cadei (Vercammen-Grandjean and Brennan, 1957) was reported by Vercammen-Grandjean and Fain (1958: 26) and Stekolnikov (2018a: 118) on *Miniopterus* sp. specimens from N'Gong, S Kenya.

Uchikawa (1985c: 110) reported the presence of *Pteracarus miniopteri* Uchikawa, 1978 from *Miniopterus* sp. specimens from Madagascar, Central Africa, Cameroon, Kenya (Mombasa), South Africa (Transvaal).

DIPTERA
Streblidae
Raymondiodes leleupi Jobling, 1954 described form a poorly identified bat (*Hipposideros caffer* or *Miniopterus* sp.) from Thysville, Congo (Haeselbarth *et al.*, 1966: 104). *Nycteribosca kollari* Frauenfeld, 1855 was reported by Vermeil (1960) from Tunisia.

Nycteribiidae
Nycteribia tecta Theodor, 1957 (Haeselbarth *et al.*, 1966: 110). Duron *et al.* (2014: 2108) mention the presence of *Nycteribia stylidiopsis* (Speiser, 1908) on *Miniopterus* sp. from the Comoros, and of *Penicillidia leptothrinax* (Speiser, 1908) from Madagascar. The latter were carrying Enterobacteriales and *Bartonella* and *Wolbachia* bacteria (Szentiványi *et al.*, 2019a: Suppl.). Enterobacteriales were also found in *Penicillidia* cf. *fulvida* (Szentiványi *et al.*, 2019a: Suppl.).

Verrett *et al.* (2022: 6) collected *Penicillidia fulvida* (Bigot, 1885) from bats they assigned to *Miniopterus* clades 1, 2, 3, 4, 7, 8 and/or 10.

Dick *et al.* (2023) mentioned the following nycteribiid flies have been found on *Miniopterus* sp.: *Nycteribia schmidlii scotti* Falcoz, 1923, *Penicillidia (Penicillidia) fulvida* (Bigot, 1885) and *Phthiridium tectum* (Theodor, 1957). *N. s. scotti* has also been reported from *Miniopterus* clade 1/4/5/7 and *Miniopterus inflatus/africanus*, whereas i P. f. fulvida had been reported from *Miniopterus* clade 1/4/7.

SIPHONAPTERA
Ischnopsyllidae
Members of the genus *Rhinolophopsylla* Oudemans, 1909 are known to be parasites of *Miniopterus* and *Rhinolophus* (Haeselbarth *et al.*, 1966: 191).

VIRUSES:
Adenoviridae
These viruses were found by Waruhiu *et al.* (2017) in bats from Kenay.

Coronaviridae
18 out of 300 Kenyan *Miniopterus* bats tested by Tao *et al.* (2017: Suppl.) was positive for CoV (6 %).

Flaviviridae
Raulino *et al.* (2022: 256) found antibodies against Zika virus.

Paramyxoviridae
Mortlock *et al.* (2015: 1841) reported that 13 out of 77 examined Kenyan *Miniopterus* sp. specimens tested positive for *Paramyxovirus* sequences. This was also the case for two out of 41 specimens from the DRC.

Retroviridae
Farkašová *et al.* (2017: 3145) described an endogenous Deltaretrovirus, which only occurs in this family of bats and not in the closely related Vespertilionidae and Cistugonidae. This suggests that the endogenization occurred between 20 and 45 million years ago.

Rhabdoviridae
Lyssavirus - Rabies related viruses
West Caucasian Bat virus (WCBV)
Kuzmin *et al.* (2008b) detected WCBV in four of five localities sampled in Kenya with a seroprevalence of 17-26%.

Ikoma lyssavirus (IKOV)
Horton *et al.* (2014: Table S1) tested 229 Kenyan *Miniopterus* sp. specimens but failed to find neutralising antibodies.

Duvenhage lyssavirus (DUVV)
Banyard A. C. and Fooks A. R. (2017: 18) reported this virus from *Miniopterus* sp. specimens from South Africa and Kenya.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Algeria, Angola, Cameroon, Comoros, Congo (Democratic Republic of the), Ethiopia, Gabon, Kenya, Madagascar, Malawi, Mozambique, Namibia, South Africa, South Sudan, Tanzania, Tunisia, Uganda, Zambia, Zimbabwe.

Miniopterus 'incertae-sedis'

2014. *Miniopterus sp. P3:* Christidis, Goodman, Naughton and Appleton, PLoS ONE, 9 (3) e92440: 1. Publication date: 18 March 2014.

Madagascar.

Miniopterus aelleni Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, 2009

*2009. *Miniopterus aelleni* Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, Zool. Scr., 38 (4): 339, 353, figs 3d, 3e, 4, 7 - 10. Publication date: 22 June 2009. Type locality: Madagascar: Antsiranana province: Ankarana special reserve, Canyon d'Antsiroandoa Centre,: 6.2 km NW Mahamasina [12 55.1 S 49 07.6 E, 120 m]. Holotype: FMNH 173067: ad ♂, skull and alcoholic. Collected by: H. Vola Razakarivony and Scott G. Cardiff; collection date: 8 April 2002; original number: SMG 12809. See Goodman and Cardiff (2004: 230). Paratype: FMNH 173069: ad ♀, skull and alcoholic. Collected by: H. Vola Razakarivony and Scott G. Cardiff; collection date: 8 April 2002; original number: SMG. See Goodman and Cardiff (2004: 230). Paratype: FMNH 173070: ad ♀, skull and alcoholic. Collected by: H. Vola Razakarivony and Scott G. Cardiff; collection date: 8 April 2002; original number: SMG. See Goodman and Cardiff (2004: 230). Paratype: FMNH 173072: ad ♂, skull and alcoholic. Collected by: H. Vola Razakarivony and Scott G. Cardiff; collection date: 8 April 2002; original number: SMG. See Goodman and Cardiff (2004: 230). Paratype: FMNH 173075: ad ♂, skull and alcoholic. Collected by: H. Vola Razakarivony and Scott G. Cardiff; collection date: 8 April 2002; original number: SMG. See Goodman and Cardiff (2004: 230). Paratype: FMNH 173076: ad ♂, skull and alcoholic. Collected by: H. Vola Razakarivony and Scott G. Cardiff; collection date: 8 April 2002; original number: SMG. See Goodman and Cardiff (2004: 230). - Etymology: The name *aelleni* is a patronym for Villy Aellen (1926 - 2000) who was a mammalogist at the Muséum d'histoire naturelle de Genève from 1954 to his retirement in 1989, where he also served as curator, assistant director, and director (Mahnert, 2000; Goodman *et al.*, 2009a: 353). (Current Combination).

2014. *Miniopterus aelleni A:* Christidis, Goodman, Naughton and Appleton, PLoS ONE, 9 (3) e92440: 1. Publication date: 18 March 2014.

2022. *Miniopterus aellini:* Kettenburg, Kistler, Ranaivoson, Ahyong, Andrianiaina, Andry, DeRisi, Gentles, Raharinosy, Randriambolamanantsoa, Ravelomanantsoa, Tato, Dussart, Heraud and Brook, Front. Public Health, 10 (786060): 10. Publication date: 11 February 2022. (Lapsus).

Taxonomy:

See Goodman *et al.* (2009a).

Schoeman *et al.* (2014: 19) refer to Christidis *et al.* (2014) indicating that - from a phylogenetic species perspective - there is evidence that two sister species are present, which are tentatively named: *M. aelleni* A and *M. aelleni* B.

Common Names:

Czech: létavec Aellenův. English: Aellen's Long-fingered Bat, Aellen's Bent-winged Bat. French: Minioptère d'Aellen. German: Aellens Langflügelfledermaus.

Etymology of common name:

In honour of Villy Aellen (1926 - 2000), who was a mammalogist at the Muséum d'histoire naturelle de Genève from 1954 to his retirement in 1989, where he also served as curator, assistant director, and director. He devoted much of his professional interests to the study of bats, particularly those of Africa (see Goodman *et al.*, 2009a: 353).

Conservation status:

Global Justification

This species occurs at several sites in the western half of Madagascar (Goodman and Ramasindrazana, 2013); it is also known from a few specimens obtained on Anjouan Island in the Comoros Archipelago (Goodman *et al.*, 2010c). It is apparently not forest-dependant and may not be subjected to any important habitat degradation or other human pressures (Goodman *et al.*, 2010c).

Assessment History

Global

2016: LC ver. 3.1 (2001) (Goodman, 2017g).

Regional

None known.

Conservation actions:

Goodman (2017g) report that on Madagascar, this species is known from several protected areas, which include Ankarana, Namoroka and Bemaraha. While to their knowledge the sites this species occurs on Anjouan Island are not under any special protection.

General distribution:

Lowland portions of northern and western Madagascar up to 1,350 m (Goodman *et al.*, 2009a; Schoeman *et al.*, 2014: 28). Schoeman *et al.* (2014: 31) assigned *M. aelleni* A to the western or dry deciduous region bioclimatic zone, whereas *M. aelleni* B was classified to the humid forest region.

Goodman *et al.* (2010c: 131), O'Brien (2011: 289) and Garbutt (2022: 105) reported it also from the Comoros (Anjouan), where it occurs in more humid forests between 220 and 690 m..

General description of external morphology:

See Goodman *et al.* (2009a).

Dental Formula:

The permanent dental formula is as follows: $I^2/_3$, $C^1/_1$, $PM^2/_3$, $M^3/_3$ = 36.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Goodman *et al.* (2009a).

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls as *M. manavi sen lat.*, these calls were broadband FM/QCF sweeps produced at low duty cycle with most energy at about 58.1 kHz in the fundamental, with pulses having a short duration of about 4 ms.

Ramasindrazana *et al.* (2011: 294) recorded 19 calls from 7 *Miniopterus aelleni* specimens, and found the following echolocation call values: Frequency of maximum energy: 51.9 ± 1.57 (49.5 - 54.8) kHz, Maximum frequency: 99.8 ± 8.48 (75.0 - 119.0) kHz, Minimum frequency: 48.0 ± 1.43 (46.0 - 50.0) kHz, Call duration: 4.1 ± 0.65 (3.0 - 5.0) ms, Inter pulse interval: 87.3 ± 16.75 (61.0 - 118.5) ms.

MOLECULAR BIOLOGY:
Genetics
See Goodman *et al.* (2009a).

HABITAT:
Dammhahn and Goodman (2013: 108) mention the lower portion of forest structure and partially open areas as the foraging habitat for this species.

Also see Goodman *et al.*, 2009a).

ROOST:
This species seems to prefer roosting in caves (Garbutt, 2022: 105); see also Goodman *et al.* (2009a).

POPULATION:
Structure and Density
See Goodman *et al.*, 2009a). While Goodman (2017g) report that it is not known.

Trend
2016: (Goodman, 2017g).

REPRODUCTION AND ONTOGENY:
Somewhere between 17 November and 8 December, three bats reported by Goodman *et al.* (2025: 215) were one male with enlarged testes, another one with slightly enlarged testes and a non-reproductive female.

PARASITES:
Tortosa *et al.* (2013: 4) report the presence of the Nycteribiid bat fly *Nycteribia stylidiopsis* Speiser, 1908. Wilkinson *et al.* (2016) and Urushadze *et al.* (2017: 9) report *Penicillidia leptothrinax* Speiser, 1908, which in turn carried *Bartonella* bacteria and the blood parasite *Polychromophilus melanipherus* (Szentiványi *et al.*, 2019a: Suppl.). Ramasindrazana *et al.* (2017: Suppl.) report both flies.

Ramasindrazana *et al.* (2016: 6) reported the presence of *Litosoma* Clade 3 (Nematoda: Onchocercidae) on this bat species. They also mention *Litosoma goodmani* Martin, Bain, Jouvenet, Raharimanga, Robert & Rousset, 2006 from a *M. aelleni* specimen, that was previously identified as "*M. manavi*".

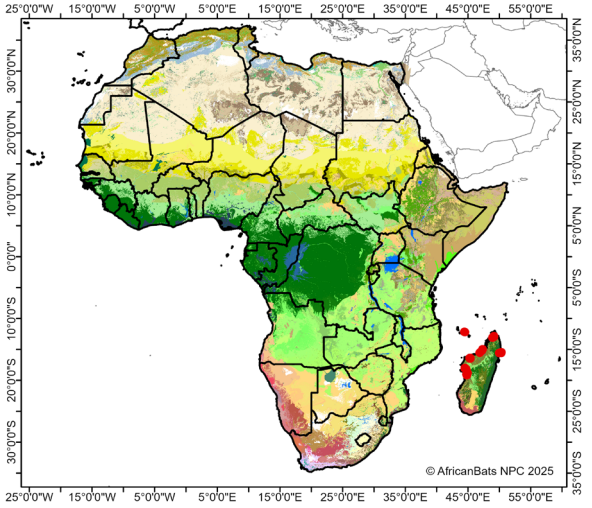

Figure 223. Distribution of *Miniopterus aelleni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Comoros, Madagascar.

Miniopterus africanus Sanborn, 1936

*1936. *Miniopterus africanus* Sanborn, Field Mus. Nat. Hist., Zool. Ser., (362) 20 (14): 111. Publication date: 15 August 1936. Type locality: Ethiopia: Shoa province: Mulo, Sanford's Ranch [ca. 09 00 N 39 00 E, 8000 ft]. [Goto Description]. Holotype: FMNH 28769: ad ♀, skin and skull. Collected by: Alfred Marshall Bailey; collection date: 25 October 1926; original number: 73. (Current Combination).

? *Miniopterus inflatus africanus:* (Name Combination).

TAXONOMY:
Included in *inflatus* by Koopman (1993a: 230), but considered a valid species by Peterson *et al.* (1995: 120), Lavrenchenko *et al.* (2004b: 144), Simmons (2005).

COMMON NAMES:
Chinese: 非洲长翼蝠. Czech: létavec východoafrický. English: African Long-fingered Bat. French: Minioptère d'Afrique orientale. German: Afrikanische Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Assessed as Data Deficient (DD ver 3.1 (2001)) as there are no data regarding its distribution, population, habitat, threats, or conservation measures following its recognition as a valid species by Juste [B.] *et al.* (2007). Additional clarification of this species complex is required to complete an assessment (Waldien and Webala, 2020).

Assessment History
Global
2019: DD ver 3.1 (2001) (Waldien and Webala, 2020). 2004: LC ver 3.1 (2001) (IUCN, 2004; Schlitter, 2004h).

MAJOR THREATS:
Waldien and Webala (2020) state that given the uncertainties surrounding the species, there is little data regarding the threats to the species. As it inhabits moist montane rainforest deforestation (logging and conversion to agricultural lands) are likely threats.

CONSERVATION ACTIONS:
Waldien and Webala (2020) suggest that given the uncertainties surrounding the species, there are few insights into current and needed conservation actions for the species. Protection of moist montane rainforest is a logical first step. Research is needed on the species taxonomy, population, distribution, and ecology.

GENERAL DISTRIBUTION:
Native: Botswana; Eritrea; Ethiopia; Kenya; Namibia; Tanzania.

MOLECULAR BIOLOGY:
Karyotype
Tolera *et al.* (2021: 127) reported *2n* = 46 and FN = 54 for an Ethiopian male. The chromosomes included two large, two medium and one small pair of metacentrics and 17 pairs of acrocentrics. The X chromosome is probably a small metacentric and the Y chromosome a small dot-like acrocentric.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 87 minutes, and the digestibility rate about 78.7 %.

POPULATION:
Structure and Density
Population size and trends are unknown (Waldien and Webala, 2020).

Trend
2019: Unknown (Waldien and Webala, 2020).
2004: Not assessed.

PARASITES:
Lutz *et al.* (2016: 9) examined 20 *M. africanus* specimens from East Africa and found four of them infected with the haemosporidan parasite *Polychromophilus melanipherus* Dionisi, 1899.

Polychromophilus sp. Parasites were also found in 11 of the 22 Kenyan bats examined by Lutz *et al.* (2021: Suppl.)

Uchikawa (1985a: 19) reported that the type specimen of *Miniopterus africanus* harboured the "atypical" form of *Calcarmyobia congoensis* Uchikawa, 1982 (Acari: Myobiidae). This species is also a host of *Calcarmyobia kenyaensis* Uchikawa, 1982 in Kenya (see Uchikawa (1985a: 22) as *M. inflatus africanus*). Possibly some other records mentioned by Uchikawa (1985a: 22) as collected from *M. inflatus* from Cameroon, Liberia, and The Democratic Republic of Congo should be included here.

Uchikawa (1985c: 110) also reported on the presence of the mite *Pteracarus miniopteri* Uchikawa, 1978 on some specimens from Kenya, that were identified as *M. inflatus africanus*.

Tortosa *et al.* (2013: 5) and Ramasindrazana *et al.* (2017: Suppl.) mention this species as host for the Nycteribiid bat flies *Nycteribia schmidlii* Schiner, 1853 and *Pencillidia fulvida* Bigot, 1885.

DIPTERA
Nycteribiidae
Lutz *et al.* (2021: Suppl.) found Kenyan *M. africanus* bats to be hosts for *Eucampsipoda africana* Theodor, 1955, *Nycteribia schmidlii* Schiner, 1853 and *Penicillidia fulvida* (Bigot, 1885). Dick *et al.* (2023) reported these flies as *Nycteribia schmidlii scotti* Falcoz, 1923 and *Penicillidia (Penicillidia) fulvida* (Bigot, 1885).

Streblidae
Raymondia intermedia Jobling, 1936 (Shapiro *et al.*, 2016: 255). *Raymondia seminuda* Jobling, 1954 (Shapiro *et al.*, 2016: 255).

VIRUSES:
In their study of bats from three Kenyan caves, Kamau *et al.* (2022:) found astrovirues,

herpesviruses and retroviruses, as well as one occurrence of Bole tick virus 4.

Coronaviridae - Coronaviruses
SARS-CoV
Tong *et al.* (2009) tested 1 bat collected in Kenya during 2006 positive for the presence of coronavirus RNA in a fecal sample. One Kenyan bat tested by Tao *et al.* (2017: Suppl.) was negative for CoV.

Polyomaviridae
Polyomavirus
Of the nine specimens tested from the Chyulu National Park (Kenya), one tested positive (Conrardy *et al.*, 2014: 259).

Rhabdoviridae
Rhabdovirus
One of the nine specimens tested from the Chyulu National Park (Kenya) tested positive (Conrardy *et al.*, 2014: 259).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Eritrea, Ethiopia, Kenya, Somalia.

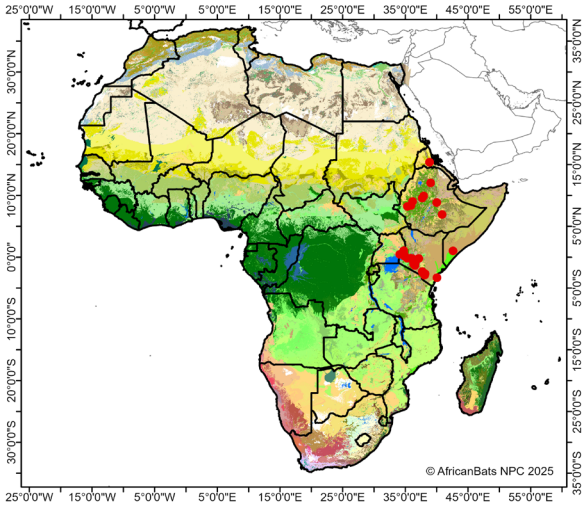

Figure 224. Distribution of *Miniopterus africanus*.

Miniopterus ambohitrensis Goodman, Ramasindrazana, Naughton and Appleton, 2015

2014. *Miniopterus aelleni B:* Christidis, Goodman, Naughton and Appleton, PLoS ONE, 9 (3) e92440: 1. Publication date: 18 March 2014.

*2015. *Miniopterus ambohitrensis* Goodman, Ramasindrazana, Naughton and Appleton, Zootaxa, 3936 (4): 538, 543, figs 2 - 5. Publication date: 23 March 2015. Type locality: Madagascar: Province d'Antsiranana: Parc National de la Montagne d'Ambre: Joffreville (Ambohitra), 5.5 km SW: Station Forestière des Roussettes [12 31 37.3 S 49 10 19.1 E, 1000 m]. Holotype: FMNH 202450: ad ♂, skull and alcoholic. Collected by: Steven M. Goodman; collection date: 9 May 2009; original number: SMG 16169. Paratype: FMNH 202452: ad ♀, skull and alcoholic. Collected by: Steven M. Goodman; collection date: 9 May 2008; original number: SMG-16171. See Demos *et al.* (2023: 4, fig. 1). - Etymology: The name *ambohitrensis* is derived from the geographical name of the type locality, which in Malagasy is Ambohitra and in French is Montagne d'Ambre. The nearby village of Joffreville is also referred to as Ambohitra. In the Malagasy language, the root word of Ambohitra is *vohitra* meaning mountain or highlands, giving an ecological context to the specific epithet of this bat, which occurs at higher elevations.

COMMON NAMES:
English: Montagne d'Ambre Long-fingered Bat, Ambohitra long-fingered bat, Malagasy Northern Long-fingered Bat, Montagne D'Ambre Bent-winged Bat. French: Minioptère de Montagne d'Ambre. German: Ambre-Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
This species is known from several sites in the northern portion of Madagascar (Goodman *et al.*, 2015b), most of which are montane and apparently not subjected to any important habitat degradation or other human pressures. It is notably common at several of these sites (Goodman, 2017h).

Assessment History
Global
LC 3.1 (2001) (Goodman, 2017h).

Regional
Endemic to Madagascar, therefore Global assessment should be consulted.

CONSERVATION ACTIONS:
Goodman (2017h) reports that this species is known from several protected areas, which include Marojejy, Montagne d'Ambre, Ambohitantely, and Bemanevika.

GENERAL DISTRIBUTION:
Only known from four localities, three in far north (including Mt D'Ambre and Marojejy National Parks) and one in Central Highlands (Ambohitantely) of Madagascar. These are in the wetter montane forest areas at altitudes between 810 and 1,570 m (Garbutt, 2022: 107).

Native: Madagascar.

HABITAT:
Chakravarty *et al.* (2024: 7) considers this species to be a "highland dwelling species".

ROOST:
This species roosts in caves and rock crevices (Garbutt, 2022:107).

DIET:
Fecal pellets of two individuals revealed Coleoptera (45.7 %), Hymenoptera (24.8 %), and Lepidoptera (24.4 %). (see Goodman *et al.*, 2023b: 241).

POPULATION:
Structure and Density
Not known (Goodman, 2017h).

Trends
2016: Unknown (Goodman, 2017h).

PARASITES:
Wilkinson *et al.* (2016) report the presence of *Penicillidia leptothrinax* on "*Miniopterus* cf. *ambohitrensis*", which was carrying Enterobacteriales bacteria (Szentiványi *et al.*, 2019a: Suppl.).

Referring to Rasoanoro *et al.* (2021), Minozzo *et al.* (2021: 8) report the presence of the haemosporidian *Polychromophilus* in *M. ambohitrensis*. Bajić *et al.* (2023: Suppl.) identified this parasite as *Polychromophilus melanipherus* (Dionisi, 1899).

VIRUSES:
Paramyxoviridae
Mélade *et al.* (2016b: 4) found one out of 19 *M.* cf. *ambohitrensis* specimens they tested to be infected with paramyxoviruses.

Rhabdoviridae
Four out of 15 *M.* cf. *ambohitrensis* specimens tested by Mélade *et al.* (2016a: 6) showed a reaction against *Duvenhage Lyssavirus*.

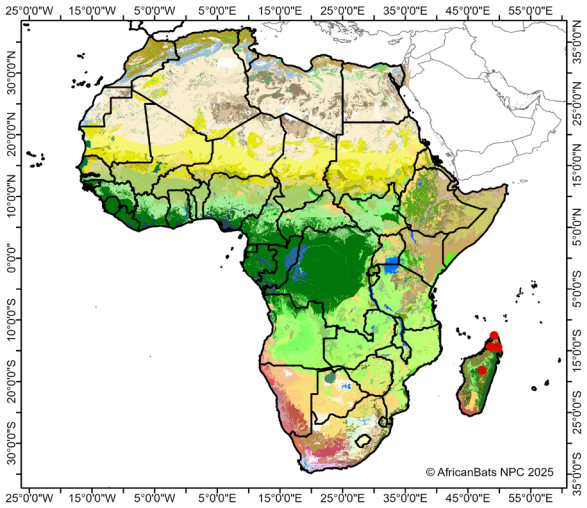

Figure 225. Distribution of *Miniopterus ambohitrensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus arenarius Heller, 1912

*1912. *Miniopterus natalensis arenarius* Heller, Smiths. Misc. Coll., 60 (12): 2. Publication date: 4 November 1912. Type locality: Kenya: Central province: Nanyuki district: Northern Guaso Nyiro: Nyuki (=Nanyuki) river [00 01 N 37 04 E]. [Goto Description]. Holotype: USNM 181811: ad ♀. Collected by: Edmund Heller; collection date: 4 October 1911; original number: 4413. - Comments: Coordinates mentioned as 00 21 N 36 55 E by Thorn *et al.* (2009: 49).
2010. *Miniopterus arenarius:* Benda, Vespertilio, 13-14: 307. (Name Combination).
? *Miniopterus cf. arenarius VG-2013*
? *Miniopterus schreibersi arenarius:* (Name Combination).

TAXONOMY:
Formerly included in either *Miniopterus schreibersii* or *Miniopterus natalensis*, but based on genetic and biometrical data considered a valid species by Farkašová *et al.* (2017: Suppl.), Kruskop *et al.* (2014: 102), Kassahun *et al.* (2015: 168), Farkašová *et al.* (2017: Suppl.), Wilson and Mittermeier (2019: 704) and Monadjem *et al.* (2020e: 242, 255), although the exact assignment still needs to be confirmed by material from the type locality.

Benda *et al.* (2025: 108) assigned their Kenyan material tentatively to Miniopterus aff. arenarius, indicating that this is a parataxon which contains several taxonomically undefined genetic lineages, at least two of which occur in Kenya (and one of them being *M. mossambicus*)..

COMMON NAMES:
Czech: létavec pískový. English: Sandy long-fingered bat, Aequatorial Broad Winged Bat.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
This species occurs in northeastern Africa, from the boundary between Tanzania and Kenya, through Uganda, South Sudan and Ethiopia to the Arabian Peninsula, where it has been reported from Saudi Arabia and Yemen (Harrison and Bates, 1991 [as *M. schreibersii*], Benda *et al.*, 2011b: 45 [as *M. natalensis*]).

HABITAT:
Primarily occurring in *Acacia - Commiphora* bushlands and thickets Ibáñez and Juste (2019: 704).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

PARASITES:
HAEMOSPORIDA
Lutz *et al.* (2016: 9) examined 42 *M. natalensis* specimens from East Africa and found 20 of them infected with *Polychromophilus melanipherus* Dionisi, 1899.

PROTOZOA
Kassahun *et al.* (2015: 168) examined two *M. arenarius* specimens from Masha (Ethiopia), and found one of them to be infected by *Leishmania* parasites (see also Azami-Conesa *et al.*, 2021: Suppl.; de Souza *et al.*, 2023: 4).

ARACHNIDA
Myobiidae
Uchikawa (1985a: 15) corrected the type host for *Calcarmyobia rhinolophi* from *Rhinolophus lobatus* to *Miniopterus natalensis arenarius*. Uchikawa (1985a: 22) mentioned *Calcarmyobia kenyaensis* Uchikawa, 1982 on "*Miniopterus schreibersi*" from Belgian Congo and on "*Miniopterus schreibersi arenarius*" (and *M. natalensis arenarius*) from Kenya. Uchikawa (1985c: 110) furthermore reported on the presence of *Pteracarus miniopteri* Uchikawa, 1978 on bats Kenya, Uganda (as either *M. natalensis arenarius* or *M. schreibersi arenarius*).

Spinturnicidae
Orlova *et al.* (2024: 152) reported a first host-parasite association for *Miniopterus* cf. *arenarius* and *Spinturnix faini* Benoit, 1959. They also reported (p. 153) a first host-parasite association between *Miniopterus arenarius* and *Spinturnix semilunaris* de Meillon and Lavoipierre, 1944.

SIPHONAPTERA
Ischnopsyllidae
Oxyparius isomalus (Waterston, 1915) from the foothills of Mt. Elgon, Kenya (Haeselbarth *et al.*, 1966: 188). *Rhinolophopsylla ectopa* (Jordan, 1937) found in a cave in the foothills of Mt. Elgon, Kenya (Haeselbarth *et al.*, 1966: 191). The hosts for these fleas might be *M. arenarius*.

DIPTERA)
Streblidae
Lutz *et al.* (2021: found one Ugandan "*Miniopterus natalensis*" to be parasitized by an *Ascodipteron* sp., another by *Penicillidia fulvida*, and 18 by *Nycteribia schmidlii* Schiner, 1853. Given the country of origin, the bats should probably be assigned to *M. arenarius*.

Nycteribiidae
Dick *et al.* (2023) mentioned the following nycteribiid flies have been found on *Miniopterus arenarius*: *Nycteribia latitergum* Theodor, 1957 and *Phthiridium tectum* (Theodor, 1957).

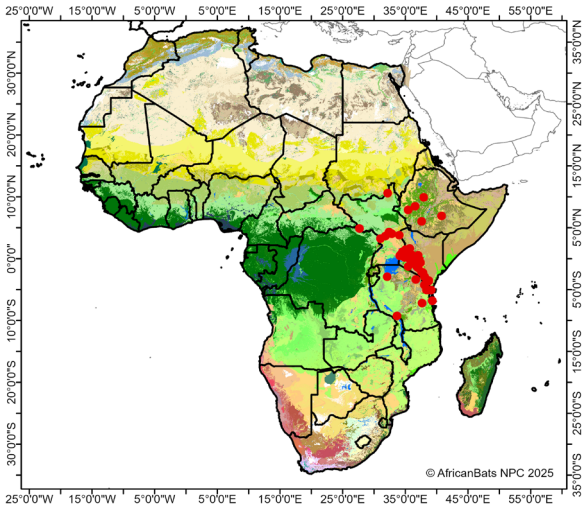

Figure 226. Distribution of *Miniopterus arenarius*.

Miniopterus brachytragos Goodman, Maminirina, Bradman, Christidis and Appleton, 2009

*2009. *Miniopterus brachytragos* Goodman, Maminirina, Bradman, Christidis and Appleton, Am. Mus. Novit., 3669: 1, 9, figs 3, 4A–C, 5. Publication date: 30 November 2009. Type locality: Madagascar: Province de Mahajanga: Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National]: Forêt d'Ambovonomby: 26 km NW Andranomavo [16 28.2 S 45 20.9 E, 200 m]. Holotype: FMNH 175840: ad ♀, skull and alcoholic. Collected by: Steven M. Goodman; collection date: 9 October 2002; original number: SMG 13040. Paratype: FMNH 172685:; collection date: 5 November 2001. Collected in Antsiranana Province, Forêt de Binara, near Analamazava River, 7.5 km SW Daraina (village), 13°15.3'S, 49°37.0'E, 325 - 600 m. Paratype: FMNH 172686:; collection date: 5 November 2001. Collected in Antsiranana Province, Forêt de Binara, near Analamazava River, 7.5 km SW Daraina (village), 13°15.3'S, 49°37.0'E, 325 - 600 m. Paratype: FMNH 172867:; collection date: 2 December 2001. Collected at the Parc National de Bemaraha, south bank Manambolo River, near Tombeau Vazimba, 3.5 km E Bekopaka, 19°08.4'S, 44°49.7'E, 100 m,. Paratype: FMNH 175846:; collection date: 9 - 10 October 2002. Same locality as holotype. Paratype: FMNH 175847:; collection date: 9 - 10 October 2002. Same locality as holotype. Paratype: FMNH 175850:; collection date: 9 - 10 October 2002. Same locality as holotype. Paratype: FMNH 175851:; collection date: 9 - 10 October 2002. Same locality as holotype. Paratype: FMNH 175852:; collection date: 9 - 10 October 2002. Same locality as holotype. Paratype: FMNH 175856:; collection date: 9 - 10 October 2002. Same locality as holotype. Paratype: FMNH 175864:; collection date: 11 October 2002. Collected just outside limit of Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], along Ampandra River, 22 km NW Andranomavo, 16°26.4429'S, 45°24.723'E, 120 m. Paratype: FMNH 175865:; collection date: 11 October 2002. Collected just outside limit of Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], along Ampandra River, 22 km NW Andranomavo, 16°26.4429'S, 45°24.723'E, 120 m. Paratype: FMNH 175867:; collection date: 11 October 2002. Collected just outside limit of Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], along Ampandra River, 22 km NW Andranomavo, 16°26.4429'S, 45°24.723'E, 120 m. Paratype: FMNH 175869:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175870:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175871:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175872:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175873:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175874:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175875:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175877:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175879:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175880:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175881:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175882:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175883:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175884:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 175885:; collection date: 14 - 15 October 2002. Collected at the Réserve Naturelle Intégrale de Namoroka [status subsequently changed to Parc National], near source of Mandevy River, 32 km NW Andranomavo, 16°22.8'S, 45°20.7'E, 100 m. Paratype: FMNH 188651:; collection date: 14 February 2006. Collected in Antsiranana Province, Nosy Komba, 0.9 km SW Ampangorinana, on trail to Station Forestière d'Antanampoera, 13°26.835'S, 48°20.466'E, 100 m. Paratype: FMNH 202523:; collection date: 26 November 2007. Collected in Toamasina Province, Masoala Peninsula, 1.8 km S Ambanizana (village), 15°38.291'S, 49°57.944'E, 5 m. - Etymology: From the Greek *brachys* ("short") and *tragos*, meaning "goat," a word ultimately borrowed into New Latin to mean "tragus," and has been chosen as this taxon is easily distinguished from its congeners by its diminutive tragus (see Goodman *et al.*, 2009c: 17).. (Current Combination).

COMMON NAMES:
English: Broad-tragused Long-fingered Bat, Short-tragus Long-fingered Bat. Frnech: Minioptère à tragus court. German: Namoroka-Langflügelfledermaus

CONSERVATION STATUS:
Global Justification
This species is known from seven sites in the northern and western portions of Madagascar (Goodman and Ramasindrazana, 2013; Goodman *unpublished data* in Goodman (2017i)), many of which are within existing protected areas. This species is apparently not forest-dependant and by extrapolation not subjected to any important habitat degradation or other human pressures.

Assessment History
Global
2016: LC ver. 3.1 (2001) (Goodman, 2017i).

Regional
Endemic to Madagascar, therefore Regional assessment is the same as Global.

MAJOR THREATS:
Not known (Goodman, 2017i).

Trend:- Unknown (Goodman, 2017i).

CONSERVATION ACTIONS:
Goodman (2017i) report that this species is known from several protected areas: Bemaraha, Loky-Manambato, Masoala and Namoroka.

GENERAL DISTRIBUTION:
Occur on Madagascar, from the Masoala Peninsula in the northeast, the Daraina region in the central northeast, and in the karstic zones of the Namoroka and Bemaraha massifs, as well as on the island of Nosy Komba (Goodman *et al.*, 2009c: 11).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the northwestern part of the island (western or dry deciduous region). It occurs at altitudes between sea level and 600 m in dry forest and humid forest locations, but also in adjacent disturbed and anthropogenic areas (Garbutt, 2022: 106).

ECHOLOCATION:
Ramasindrazana *et al.* (2011: 294) recorded 30 calls from 8 *Miniopterus brachytragos* specimens, and found the following echolocation call values: Frequency of maximum energy: 59.0 ± 1.06 (57.3 - 61.7) kHz, Maximum frequency: 105.8 ± 11.20 (85.0 - 128.0) kHz, Minimum frequency: 55.7 ± 0.84 (54.0 - 57.0) kHz, Call duration: 3.4 ± 0.49 (2.6 - 4.3) ms, Inter pulse interval: 84.6 ± 18.99 (56.1 - 122.5) ms.

ROOST:
M. brachytragos roosts in caves near native forests (Garbutt, 2022: 106).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

PARASITES:
Rasoanoro *et al.* (2019: 67) refer to Raharimanga *et al.* (2003), who reported *Trypanosoma* sp. from "*Miniopterus manavi*", but one of these bats belonged to the current species.

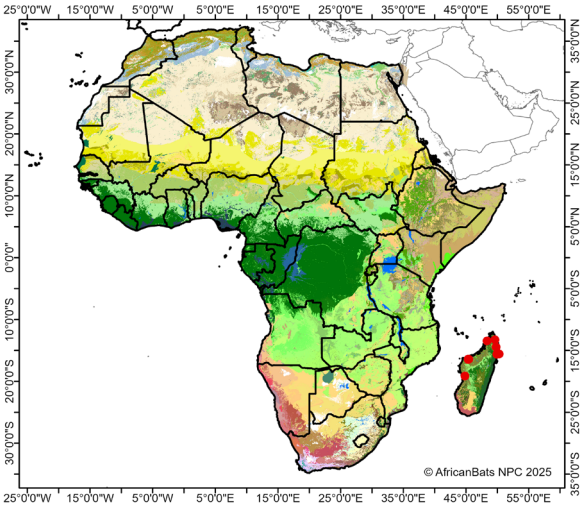

Figure 227. Distribution of *Miniopterus brachytragos*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus cf. fraterculus Tanshi, Chigozie Obitte, Monadjem and Kingston, 2022

2022. *Miniopterus cf. fraterculus* Tanshi, Chigozie Obitte, Monadjem and Kingston, Acta Chiropt., 23 (2): 318 (for 2021). Publication date: 14 February 2022.

TAXONOMY:
Tanshi *et al.* (2022a: 318) considered Nigerian specimens from the ROM that were identified as *Miniopterus fraterculus* actually to represent a separate species (*Miniopterus* cf. *fraterculus*), which is not likely to be related to *M. fraterculus*.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

PARASITES:
Ceballos-Pérez *et al.* (2024: 3) [referring to Lutz *et al.* (2016)] mention the presence of *Polychromophilus melanipherus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Nigeria.

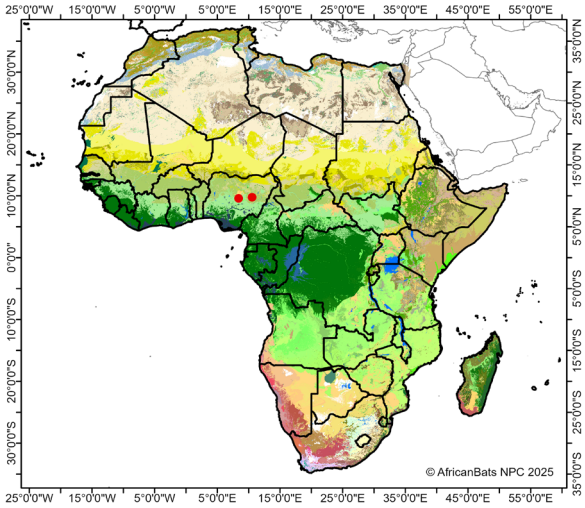

Figure 228. Distribution of *Miniopterus* cf. *fraterculus*.

Miniopterus cf. inflatus Monadjem, Shapiro, Richards, Karabulut, Crawley, Broman Nielsen, Hansen, Bohmann and Mourier, 2020

2020. *Miniopterus cf. inflatus* Monadjem, Shapiro, Richards, Karabulut, Crawley, Broman Nielsen, Hansen, Bohmann and Mourier, Acta Chiropt., 21 (2): 239.

TAXONOMY:
Monadjem *et al.* (2020e: 252) found that *M. inflatus* s.s. from the lower Guinea region isn't closely related fo *M.* cf. *inflatus* from eastern and southern Africa, which might indicate that these two forms represent different species, but further investigation remains necessary (see also Monadjem *et al.*, 2020b: 12).

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Monadjem *et al.* (2020e: 246) indicate that *M.* cf. *inflatus* from eastern and southern Africa has a light pelage

ECHOLOCATION:
For two caves in the Republic of Congo, Labadie *et al.* (2025b: 11) provided the following data for *Miniopterus* cf. *inflatus*: Boundou cave: 1 M: F_{pmax}: 55.5 kHz, F_{pmean}: 54.2 kHz, F_{ppeak}: 51.2 kHz, F_{max}: 105.3 kHz, F_{flat}: 98.8 kHz, F_{knee}: 104 kHz, F_{min}: 44 kHz, F_{mean}: 69.2 kHz, Duration: 2.2 ms; 7 FF: F_{pmin}: 39.6 ± 3.3 kHz, F_{pmax}: 69.6 ± 11.1 kHz, F_{pmean}: 54.6 ± 6.2 kHz, F_{ppeak}: 47.6 ± 2.7 kHz, F_{max}: 82 ± 17.8 kHz, F_{flat}: 53.5 ± 16.6 kHz, F_{knee}: 56.2 ± 16.2 kHz, F_{min}: 44.6 ± 2.9 kHz, F_{mean}: 58.7 ± 9 kHz, Duration: 4.1 ± 0.2 ms. Mont Belo cave: 24 MM: F_{pmin}: 37.3 ± 8.6 kHz, F_{pmax}: 62.5 ± 9.9 kHz, F_{pmean}: 52.5 ± 7.7 kHz, F_{ppeak}: 48.1 ± 7.5 kHz, F_{max}: 77.1 ± 14.5 kHz, F_{flat}: 47.3 ± 8.4 kHz, F_{knee}: 51 ± 8.2 kHz, F_{min}: 44.9 ± 5.2 kHz, F_{mean}: 55.4 ± 7.6 kHz, Duration: 2.8 ± 0.5 ms.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

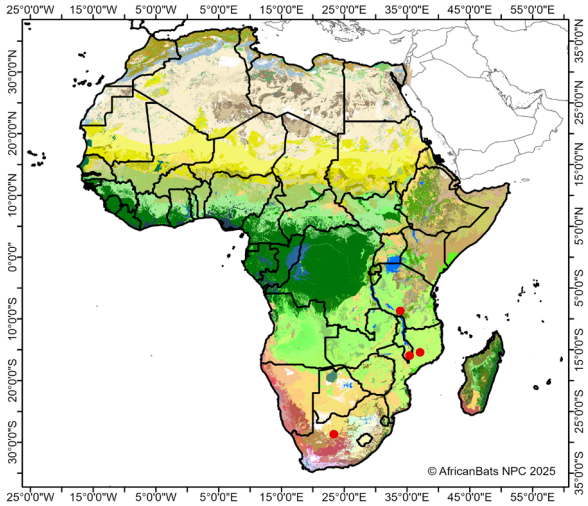

Figure 229. Distribution of *Miniopterus* cf. *inflatus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Malawi, Mozambique, South Africa, Tanzania.

Miniopterus egeri Goodman, Ramasindrazana, Maminirina, Schoeman and Appleton, 2011

*2011. *Miniopterus egeri* Goodman, Ramasindrazana, Maminirina, Schoeman and Appleton, Zootaxa, 2880: 1, 9, figs 3, 4, 5A, 6, 7. Publication date: 17 May 2011. Type locality: Madagascar: Toamasina Province: Sahafina forest: Brickaville, 9.5 km W [18 48 37 S 48 58 48 E, 50 m]. Holotype: FMNH 209160: ad ♀, skull and alcoholic. Collected by: Steven M. Goodman and Beza Ramasindrazana; collection date: 5 December 2009; original number: SMG 16602. - Etymology: In honour of Dr. Judith Eger, Senior Curator, Department of Mammalogy, Royal Ontario Museum, Toronto, for her contribution to taxonomic studies of Old World bats, including Madagascar (see Goodman *et al.*, 2011: 13). (Current Combination).

? *Miniopterus sp. BRA-2011*

COMMON NAMES:
English: Eger's long-fingered bat, Eger's Bent-winged Bat. French: Minioptère d'Eger. German: Eger-Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
This newly described species is known from numerous sites in the eastern portions of Madagascar (Goodman and Ramasindrazana, 2013), several of which are within existing protected areas. This species is apparently not forest-dependent and by extrapolation not subjected to any important habitat degradation or other human pressures (Goodman, 2017j).

Assessment History
Global
2016: LC ver 3.1 (2001) (Goodman, 2017j).

Regional
Endemic to Madagascar, therefore, see global assessment.

CONSERVATION ACTIONS:
Goodman (2017j) report that this species is known from several protected areas, which include Masoala, Sahafina, and Andohahela.

GENERAL DISTRIBUTION:
Based on current knowledge it is known from scattered sites occurring across two-thirds of Madagascar's lowland area from near sea level to 550 m (Goodman *et al.*, 2011: 15).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the eastern coastal part of the island (eastern humid forest or lowland forest region - humid).

Native: Madagascar (Goodman *et al.*, 2011: 15).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 63) could not find a baculum in the one specimen they examined.

ECHOLOCATION:
Low-duty cycle, frequency modulated/quasi constant (FM/QCF) echolocation call, with a peak frequency of 54.7 kHz (53.2 - 56.3 kHz) and a duration of 2.9 ms (2.5 - 3.4 ms) (Goodman *et al.*, 2011: 8).

Ramasindrazana *et al.* (2011: 294) recorded 16 calls from 2 *Miniopterus egeri* specimens, and found the following echolocation call values: Frequency of maximum energy: 54.7 ± 1.02 (53.2

- 56.3) kHz, Maximum frequency: 113.8 ± 3.62 (107.0 - 123.0) kHz, Minimum frequency: 49.0 ± 0.52 (48.0 - 50.0) kHz, Call duration: 2.9 ± 0.26 (2.5 - 3.4) ms, Inter pulse interval: 62.6 ± 12.57 (43.2 - 81.1) ms.

HABITAT:
Often associated with disturbed forests with mixed native and introduced trees or at the ecotone between degraded anthropogenic habitats and native forest (Goodman *et al.*, 2011: 15).

ROOST:
A day roost site of this species was found in a natural rock shelter in the Poste Forestier de Farankaraina surrounded by slightly disturbed natural lowland humid forest (Goodman *et al.*, 2011: 15).

DIET:
Rasoanoro *et al.* (2015: 63, 64) found that the diet of *M. egeri* mainly consisted of Coleoptera (51.5 vol %), Hymentoptera (28 %), Lepidoptera (10.8 %), and Isoptera (9.7 %).

POPULATION:
Structure and Density
Further information is needed (Goodman *et al.*, 2011: 15). Not known (Goodman, 2017j).

Trend
2016: Unknown (Goodman, 2017j).

In the short term this species does not appear to face a risk of dramatic population decline (Goodman *et al.*, 2011: 15).

PARASITES:
HAEMOSPORIDA
Referring to Rasoanoro *et al.* (2021), Minozzo *et al.* (2021: 8) report the presence of *Polychromophilus* in *M. egeri*.

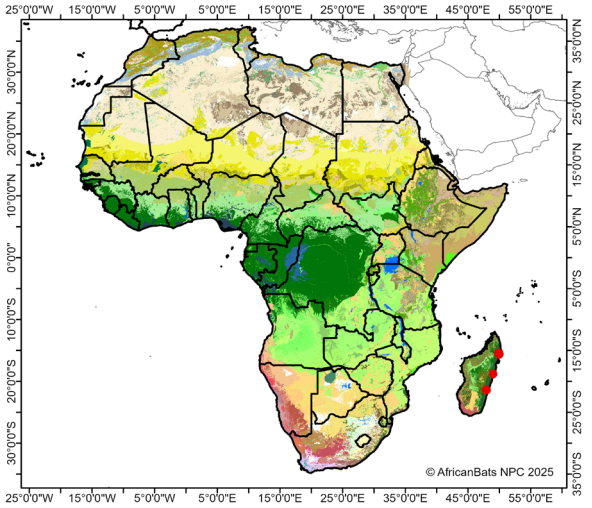

Figure 230. Distribution of *Miniopterus egeri*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus fraterculus Thomas and Schwann, 1906

*1906. *Miniopterus fraterculus* Thomas and Schwann, Proc. zool. Soc. Lond., 1906, I: 162. Publication date: 7 June 1906. Type locality: South Africa: Southern Cape Province: Knysna [33 53 S 22 59 E]. [Goto Description]. Holotype: NHMUK 1905.5.7.18: ad ♂, skin and skull. Collected by: Captain Claude Henry Baxter Grant; collection date: 3 October 1905; original number: 1073. See Thomas and Schwann (1906a: 162). - Comments: Coordinates mentioned as 35 56 S 23 06 E by Thorn *et al.* (2009: 49). - Etymology: From the Latin meaning "little brother" (see Goodman *et al.*, 2007b: 1222). (Current Combination).

1917. *Miniopterus breyeri vicinior* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 450. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Aba [03 53 N 30 17 E]. [Goto Description]. Holotype: AMNH 49019: ad ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 16 December 1911; original number: 1770. See Allen (1917: 450). - Comments: Considered a subspecies of *fraterculus* by Thorn *et al.* (2009: 49).

1978. *M[iniopterus] fraterreulus:* Herzit-Straschil and Robinson, Koedoe, 21: 104. (Lapsus).

? *Miniopterus fraterculus fraterculus:* (Name Combination).

TAXONOMY:
Meester *et al.* (1986) state that Harrison and Clancey (1952) and Harrison (1953) have demonstrated that Ellerman *et al.* (1953) are mistaken in regarding *fraterculus* as a synonym of *M. schreibersii natalensis*. Koopman (1966) regards *fraterculus* instead as a subspecies of the extralimital (to southern Africa) *M. minor* Peters, 1867, but Hayman and Hill (1971) disagree. Corbet and Hill (1980) retain *fraterculus* as species, as do Swanepoel *et al.* (1980) and Koopman (1982).

Specimens from Madagascar assigned to *M. fraterculus* by Peterson *et al.* (1995) and Simmons (2005: 519) are now considered to be a distinct species: *Miniopterus sororculus* (Goodman *et al.*, 2007b).

COMMON NAMES:
Afrikaans: Klein grotvlermuis. Chinese: 小长翼蝠. Czech: létavec jihoafrický. English: Lesser Long-fingered Bat, Black Clinging Bat, Lesser bent-winged bat. French: Minioptère d'Afrique

australe, Petit minioptère. German: Kleine Langflügelfledermaus. Portuguese: Morcego pequeno de dedos compridos. SiSwati: Lilulwane.

CONSERVATION STATUS:
Global Justification
Known from a number of discrete ranges. This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread distribution on the African mainland and its ability to live in a wide variety of habitat types (Schlitter *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bs). On Madagascar, it is quite rare and further surveys are required.

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bs). 2008: LC ver 3.1 (2001) (Schlitter *et al.*, 2008; IUCN, 2009). 2004: LC ver 3.1 (2001) (Schlitter, 2004g; IUCN, 2004). 1996: EN (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (MacEwan *et al.*, 2016c). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004).
Eswatini: 2003: NT B2ab(iv); D2 ver 3.1 (2001) (Monadjem *et al.*, 2003).

MAJOR THREATS:
There are no major threats to this species on the African mainland (Schlitter *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bs).

CONSERVATION ACTIONS:
Schlitter *et al.* (2008) [in IUCN (2009)] and Monadjem *et al.* (2017bs) report that this species is presumably present in a number of protected areas. In Tanzania it is present in the Manga Forest Reserve of Tanzania (Doggart *et al.*, 1999b). Further studies are needed to better define the range of this species.

GENERAL DISTRIBUTION:
Traditionally, *Miniopterus fraterculus* was considered to be present in Central Africa, East Africa and southern Africa, where it was known from a number of discrete ranges, the largest of which stretched along south-eastern Africa, from Malawi, Mozambique and Zimbabwe, down to South Africa (where it extended along the south coast and its distribution was mostly affected by the annual temperature range (Babiker Salata, 2012: 50)). It was also known from eastern Democratic Republic of Congo near the borders with Uganda and Rwanda (although this population needed to be confirmed as *Miniopterus fraterculus*), and recorded from localities in Tanzania, Zambia, and Kenya. A small recorded range in Kenya near the border with Tanzania probably does not represent *Miniopterus fraterculus*.

Taylor *et al.* (2018b: 62) mention *Miniopterus* cf. *fraterculus* from Angola, however based on acoustic evidence only. Beja *et al.* (2019: 388) believe the Angolan records to be misidentifications.

ROM has 28 specimens from two localities in Cameroon, which need verification as they are well outside the presently known distribution of the species. This is also the case for the specimens from DRC, Kenya and Nigeria.

Specimens from Madagascar assigned to *M. fraterculus* (Peterson *et al.* (1995; Russ *et al.*, 2001; Simmons, 2005: 519) are now considered to be a distinct species: *Miniopterus sororculus* (Goodman *et al.*, 2007b).

However, recent changed in the taxonomy of the genus *Miniopterus* have led to the recognition of several new species, which reduced the distribution of *M. inflatus* to the southern and eastern parts of the Republic of South Africa, Swaziland and possibly extreme southern Mozambique (Ibáñez and Juste, 2019: 706, Monadjem *et al.*, 2020e: 239).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 297,363 km^2. In the RSA, its distribution is most affected by the annual temperature range (Babiker Salata, 2012: 50).

Native: Eswatini (Monadjem *et al.*, 2010d: 539, Monadjem *et al.*, 2021: 5); Mozambique (Monadjem *et al.*, 2010d: 539; Monadjem *et al.*, 2010c: 385 as *M.* cf. *fraterculus*); South Africa (Monadjem *et al.*, 2010d: 539).

DENTAL FORMULA:
van der Merwe (1985b: 251) examined 44 skulls and found 95 % of them vestigial teeth between the upper canine and the first premolar. In 44 % of the skulls, the teeth were present on both sides.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 6.4 Pa, aspect ratio 6.3 for a wingspan of 29 cm and a wing area of 137 cm^2 and a body mass of 9 g.

ECHOLOCATION:
Schoeman and Waddington (2011: 291) mention a F_{peak}: 62.1 ± 1.7 kHz and a duration: 3.7 ± 0.6 ms for specimens from Durban, South Africa.

The 135 calls analysed by Eisenring *et al.* (2016: SI 2) from bats in the Aberdares Range in Kenya had the following values: F_{peak}: 56.2 ± 1.4 (53.3 - 60.0) kHz, F_{max}: 87.1 ± 15.9 (63.8 - 127.6) kHz, F_{min}: 52.2 ± 1.6 (47.4 - 56.2) kHz, duration: 34.9 ± 15.9 (11.5 - 80.1) ms, interpulse interval: 0.8 ± 0.6 (0.3 - 4.8) ms.

For calls from specimens from Swaziland, Monadjem *et al.* (2017c: 179) recorded: F_{min}: 58.5 ± 0.50 (58.1 - 58.8) kHz, F_{knee}: 63.6 ± 1.27 (62.7 - 64.4) kHz, F_c: 59.2 ± 0.40 (58.9 - 59.5) kHz and duration: 2.9 ± 0.32 (2.7 - 3.1) ms.

Weier *et al.* (2020: Suppl.) reported on 27 "*M.* cf. *fraterculus* calls from the Okavango River Basin with the following characteristics: F_{max}: 70.82 ± 8.03 kHz, F_{min}: 55.21 ± 14.04 kHz, F_{knee}: 62.13 ± 1.59 kHz, F_{char}: 59.99 ± 1.53 kHz, slope: 36.47 ± 32.94 OPS, duration: 3.88 ± 1.45 ms.

5 calls recorded at the Venatia mine (Limpopo province, RSA) by Cory-Toussaint and Taylor (2022: Table S1) had a duration of 3.14 ± 0.73 ms, F_{min}: 61.22 ± 2.88 kHz, F_{max}: 70.57 ± 3.36 kHz, F_{knee}: 65.56 ± 1.07 kHz and F_{char}: 63.43 ± 1.90.

950 calls of 52 bats from southern KwaZulu-Natal and Eastern Cape reported by Moir (2020: 29) and Moir *et al.* (2021a: 371) had the following parameters: F_{max}: 83.21 ± 8.26 (68.35 - 101.11) kHz, F_{min}: 58.59 ± 1.65 (53.43 - 61.19) kHz, F_{char}: 58.59 ± 1.65 (56.43 - 61.19) [identical to F_{min}?], F_{knee}: 59.35 ± 1.43 (57.80 - 61.46) kHz, and duration: 2.07 ± 0.51 (1.33 - 3.78) ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 62.30 ± 1.90 kHz.

MOLECULAR BIOLOGY:
Genetics
See Hoofer and Van Den Bussche (2003).

Karyotype
Rautenbach *et al.* (1993) described the karyotype as having a diploid number $2n$ = 46, aFN = 50, BA = 6, X = SM, Y = A.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 75 minutes, and the digestibility rate about 80.3 %.

POPULATION:
Structure and Density
It is common and widespread (Schlitter *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017bs).

Trend
2016: Unknown (Monadjem *et al.*, 2017bs).
2008: Unknown (Schlitter *et al.*, 2008; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Delayed implantation (lasting two-and-a-half months), insemination, ovulation and fertilization occur in the autumn. Embryogenesis proceeds to the blastocyst stage and development is then retarded until arousal in spring, when the blastocyst implants and embryogenisis resumes. The active foetal growth period takes about four months (Bernard, 1980a: 55; Bernard, 1980c).

Bernard (1980b: 111) found that the ovarian and uterine function is asymmetrical as ovulations occurred primarily in the left ovary (94 %), whereas all implantations occurred in the right uterine horn.

PARASITES:
HAEMOSPORIDA
Lutz *et al.* (2016: 9) examined 6 *M.* cf. *fraterculus* specimens from East Africa and found two of them infected with the haemosporidan parasite *Polychromophilus melanipherus* Dionisi, 1899.

ACARI
Myobiidae
Uchikawa (1985a: 16) reported mites belonging to *Calcarmyobia rhinolophia* (Radford, 1940) on bats identified as *M. fuscus fraterculus* from Natal, South Africa.

Trombiculidae
Leptotrombidium lawrencei Vercammen-Grandjean and Langston, 1976 (see Stekolnikov, 2018a: 143; Zajkowska *et al.*, 2018: 112).

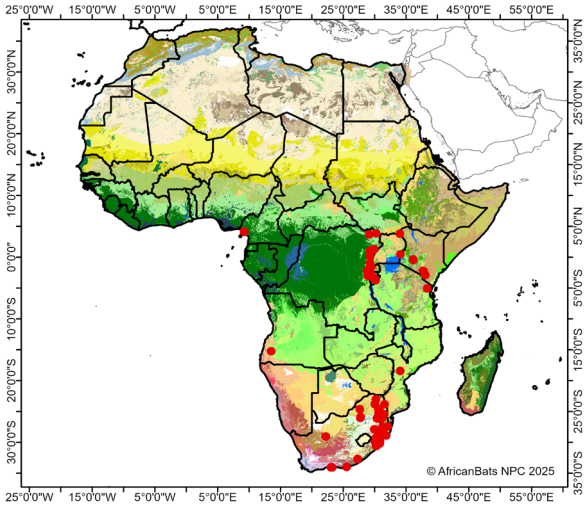

Figure 231. Distribution of *Miniopterus fraterculus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Burundi, Cameroon, Congo (Democratic Republic of the), Eswatini, Kenya, Madagascar, Mozambique, Rwanda, South Africa, Tanzania, Uganda.

Miniopterus gleni Peterson, Eger and Mitchell, 1995

*1995. *Miniopterus gleni* Peterson, Eger and Mitchell, Faune de Madagascar, Chiroptères, 84: 128, figs 60, 61. Type locality: Madagascar: 20 km S Tuléar: Sarodrano and Saint-Augustin, in a marine cave [23 33 S 43 45 E]. [Goto Description]. Holotype: ROM 42567: ad ♂, skin and skull. Collection date: 9 May 1967. (Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: létavec Glenův. English: Glen's Long-fingered Bat, Glen's Bent-winged Bat. French: Minioptère malgache, Minioptère de Glen. German: Glens Langflügelfledermaus.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Muldoon *et al.* (2009: 1114) report on subfossil remains from the Ankilitelo fauna (late Holocene, appr. 500 years ago).

Gunnell *et al.* (2014: 3) refer to Goodman and Junker (2013) who also report fossils from the Andrahomana cave.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread distribution in Madagascar. It may be locally threatened in parts of its range by hunting and roost disturbance, but is not thought to be declining fast enough to place it in a higher category of threat (Andriafidison *et al.*, 2008e; IUCN, 2009; Monadjem *et al.*, 2017ce).

Assessment History
Global
2016: LC ver 3.1 (Monadjem *et al.*, 2017ce). 2008: LC ver 3.1 (2001) (Andriafidison *et al.*, 2008e; IUCN, 2009). 2000: LR/nt (IUCN, 2000). 1994: LR/nt ver 2.3 (1994) (Groombridge, 1994).

Regional
None known.

MAJOR THREATS:
It is threatened by roost site disturbance. This species is locally hunted in the south-west and north-west of Antananarivo (Goodman, 2006; Goodman *et al.*, 2008d) and as a relatively large species may be subject to similar exploitation elsewhere. There is no evidence that hunting presents a major threat. It is unclear if this species is forest dependent (Andriafidison *et al.*, 2008e; IUCN, 2009; Monadjem *et al.*, 2017ce).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008e) [in IUCN (2009)] and Monadjem *et al.* (2017ce) report that this species is known to exist in a number of protected areas in the north-east (Eger and Mitchell, 2003) and many along the west coast (Goodman *et al.*, 2005a).

GENERAL DISTRIBUTION:
Miniopterus gleni is endemic to the island of Madagascar where it appears to be widely distributed (Eger and Mitchell, 2003; Goodman *et al.*, 2005a). The areas from where it has yet to be recorded may reflect low sampling effort rather than a genuine absence. North of Onilahy river (incl. Ile Sainte-Marie; Rakotonandrasana and Goodman, 2007: 6).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the coastal areas of northeast, north, west, and the south of the island (western or dry deciduous region).

Native: Madagascar (Eger and Mitchell, 2003; Goodman *et al.*, 2005a; Rakotonandrasana and Goodman, 2007: 6)

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
This is the largest *Miniopterus* species occurring on Madagascar (Garbutt, 2022: 106).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 63) could not find a baculum in the three males they examined.

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls of eight individuals, which were characterized by broadband FM/QCF pulses produced at low duty cycle with a frequency of maximum energy at about 44.8 kHz, while the fundamental was always the most intense call and pulses are short duration.

Ramasindrazana *et al.* (2011: 294) recorded 16 calls from 6 *Miniopterus gleni* specimens, and found the following echolocation call values: Frequency of maximum energy: 42.3 ± 1.29 (40.1 - 44.6) kHz, Maximum frequency: 82.6 ± 8.22 (70.0 - 93.2) kHz, Minimum frequency: 37.4 ± 0.94 (36.0 - 38.9) kHz, Call duration: 3.7 ± 0.49 (3.0 - 4.4) ms, Inter pulse interval: 88.9 ± 17.75 (66.7 - 124.1) ms.

HABITAT:
Dammhahn and Goodman (2013: 108) mention the lower portion of forest structure and partially open areas as the foraging habitat for this species. Garbutt (2022: 106) mentions this species occurs in all forest types and anthropogenic areas up to 1,250 m. Falimiarintsoa (2022: 28) found this species in a vanilla plantation.

ROOST:
On Madagascar, Wilkinson *et al.* (2012: 160) reported the typical roosting site to be caves, where the colony size is usually 2 to 8 bats, but in Ankarana 90 bats were found in a colony (Garbutt, 2022: 106).

DIET:
The fecal pellets of one individual from Sarahandrano contained primarily Diptera and much less Coleoptera (see Falimiarintsoa, 2022).

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 84 minutes, and the digestibility rate about 79.1 %.

POPULATION:
Structure and Density
There was a maximum of 90 individuals recorded at a roost in Ankarana (S. G. Cardiff *pers. comm.*), but otherwise this species always appears to roost in rather small colonies (Robinson *et al.*, 2006). Its relative abundance, as determined by mist netting, varies from rare (Kofoky *et al.*, 2007) to locally common (Robinson *et al.*, 2006).

Trend
2016: Unknown (Monadjem *et al.*, 2017ce).
2008: Unknown (Andriafidison *et al.*, 2008e; IUCN, 2009).

PARASITES:
Lagadec *et al.* (2012: 1696) and Dietrich *et al.* (2014: Suppl.) report the presence of spirochaetes bacteria of the genus *Leptospira*, and which were identified as *L. borgpetersenii* by Dietrich *et al.* (2018a: 3).

Ramasindrazana *et al.* (2016: 2) indicate that *Litomosa goodmani* Martin, Bain, Jouvenet, Raharimanga, Robert & Rousset, 2006 (Onchocercidae, Nematoda) was described from a *M. gleni* from northern Madagascar. They also recovered *Litomosa* Clade 1 from this bat species.

Perkins and Schaer (2016: Suppl.) report the presence of the haemosporidan *Polychromophilus* sp. Ramasindrazana *et al.* (2018: Suppl.) identified this parasite as *Polychromophilus melanipherus* Dionisi, 1899 (see also Bajić *et al.*, 2023: Suppl.).

Tortosa *et al.* (2013: 4) and Ramasindrazana *et al.* (2017: Suppl.) reported the following Nycteribiid bat flies: *Nycteribia stylidiopsis*, *Penicillidia leptothrinax*, and *Penicillidia* sp. The first one was also mentioned by Wilkinson *et al.* (2016) and Urushadze *et al.* (2017: 9), who reported that these flies carried Enterobacteriales and *Bartonella* bacteria, as well as the blood parasite *Polychromophilus melanipherus* (Szentiványi *et al.*, 2019a: Suppl.).
Rasoanoro *et al.* (2021: 8) mentions one *Nycteribia stylidiopsis* Speiser, 1908 specimen on a *Miniopterus gleni*.

VIRUSES:

Astroviridae

One of two *M. gleni* specimens tested by Lebarbenchon *et al.* (2017: Suppl.) was positive for Astroviridae.

Paramyxoviridae

Wilkinson *et al.* (2012: 160) tested 7 individuals from the Mauritius using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids.

Hoarau *et al.* (2021: Suppl.) reported two specimens from Madagascar carrying viruses of this family.

Mélade *et al.* (2016b: 4) found four out of 22 *M. gleni* specimens they tested to be infected with paramyxoviruses.

UTILISATION:

Goodman (2006) describes the hunting method used by local inhabitants. See also Goodman *et al.* (2008d) and Jenkins and Racey (2008).

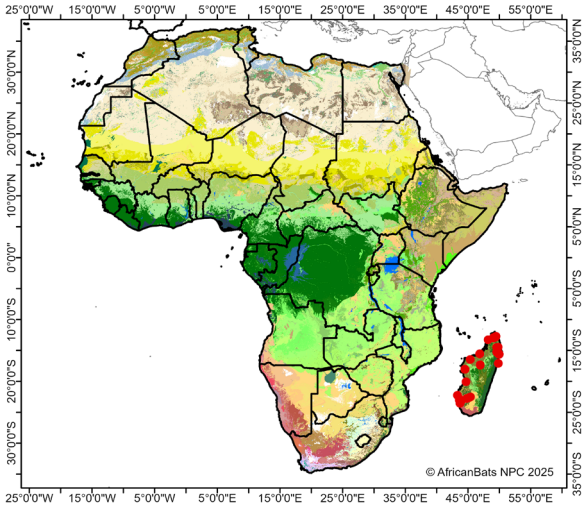

Figure 232. Distribution of *Miniopterus gleni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

Madagascar.

Miniopterus griffithsi Goodman, Maminirina, Bradman, Christidis and Appleton, 2009

*2009. *Miniopterus griffithsi* Goodman, Maminirina, Bradman, Christidis and Appleton, J. Syst. Evol. Res., 38: 75, 81, figs 4, 6. Publication date: prior to 25 October 2009. Type locality: Madagascar: Province de Toliara: Grotte d'Androimpano: 4.2 km NE Itampolo (village), on old road to Ejeda [24 39.012 S 43 57.797 E, 110m]. Holotype: FMNH 184214: ad ♂, skull and alcoholic. Collected by: Steven M. Goodman; collection date: 23 February 2005; original number: SMG 14593. Paratype: FMNH 184153: ad ♂. Grotte de Vitane (Vitany), 4.1 km SE Itampolo, 244208.5S 435749.4E, 25m. Paratype: FMNH 184154: ad ♂. Grotte de Vitane (Vitany), 4.1 km SE Itampolo, 244208.5S 435749.4E, 25m. Paratype: FMNH 184167: ad ♂. Grotte de Vitane (Vitany), 4.1 km SE Itampolo, 244208.5S 435749.4E, 25m. Paratype: FMNH 184215: ad ♂. same locatlity as the holotype. Paratype: FMNH 184216: ad ♂. Same locatlity as the holotype. Paratype: FMNH 184236: ad ♀. Same locatlity as the holotype. Paratype: USNM 577076. Fivondronana de Tolagnaro, 20 km WNW Ranopiso, 12 km ENE Amboasary, near Itaranta River, 2501S 4630E, 40m. Paratype: USNM 577077. Fivondronana de Tolagnaro, 20 km WNW Ranopiso, 12 km ENE Amboasary, near Itaranta River, 2501S 4630E, 40m. (Current Combination).

2021. *M[iniopterus] grifthsi:* Minozzo, da Silva Mathias, Riediger, de Oliveira Guimarães, dos Anjos, Monteiro, dos Santos, Biondo and Kirchgatter, Microorganisms, 9 (6): 7. Publication date: 7 June 2021. (Lapsus).

2022. *Miniopterus griffiths:* Esteves, Gaeta, Batista, Dias and Heinemann, Transb. Emerg. Dis., xxx (x): 9. Publication date: 9 May 2022. (Lapsus).

TAXONOMY:

Goodman *et al.* (2009b) examining the phylogeography of the *M. gleni* complex, found that the Onilahy River is a major barrier to gene flow. Subsequently, morphological characters (tragus shape, pelage coloration and skull proportions) were identified, that supported the separation of the populations found on either side of the Onilahy River (Goodman *et al.*, 2009b).

COMMON NAMES:

English: Griffiths' Long-fingered Bat, Griffiths's Bent-winged Bat. French: Minioptère de Griffiths. German: Griffiths Langflügelfledermaus.

ETYMOLOGY OF COMMON NAME:

In honour of Owen Griffiths, founder of Biodiversity Conservation Madagascar, who is a specialist on the terrestrial mollusc fauna of the western Indian Ocean and has been instrumental in preserving key important areas of habitat on Mauritius and Madagascar. He has generously supported many initiatives for documenting the rich Malagasy fauna (including genetic studies on *Miniopterus*) (see Goodman *et al.*, 2009a: 346).

CONSERVATION STATUS:

Global Justification

This species is known from few localities in the southern portion of Madagascar (Goodman and Ramasindrazana, 2013). Research is needed to

better define the geographical distribution of *Miniopterus griffithsi* and new field data are necessary to assess properly this taxon (Goodman, 2017k).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2016: DD ver 3.1 (2001) (Goodman, 2017k).
2009: EN (Goodman *et al.*, 2009b).

Regional
Endemic to Madagascar therefore global assessment should be used.

MAJOR THREATS:
Threats to this species are not known (Goodman, 2017k).

CONSERVATION ACTIONS:
Goodman (2017k) report that this species is not currently known from any protected area. Two of the three sites it has been documented are in degraded forested ecosystems (Goodman *et al.*, 2009b). If indeed it is not forest dependent, these human pressures may not directly impact this species.

GENERAL DISTRIBUTION:
Miniopterus griffithsii is endemic to Madagascar, where it seems to be restricted to the region between the southern banks of the Onilahy River and the Mandrare River (Itampolo east to near Ranopiso). It is actually known from three localities between 15 and 100 m of altitude (Garbutt, 2022: 109).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the south/southwestern coastal part of the island (south-west sub-arid or spiny bush).

Native: Madagascar.

ECHOLOCATION:
Ramasindrazana *et al.* (2011: 294) recorded 8 calls from 2 *Miniopterus griffithsi* specimens, and found the following echolocation call values: Frequency of maximum energy: 44.1 ± 0.67 (43.5 - 45.3) kHz, Maximum frequency: 80.4 ± 15.66 (61.0 - 99.0) kHz, Minimum frequency: 40.0 ± 0.0 (40.0 - 40.0) kHz, Call duration: 3.2 ± 0.29 (2.9 - 3.6) ms, Inter pulse interval: 89.2 ± 27.42 (56.4 - 128.5) ms.

ROOST:
Wilkinson *et al.* (2012: 160) indicate that caves are the typical roosting sites for these bats on Madagascar.

MIGRATION:
Reher *et al.* (2019: 121) found that *M. griffithsi* was only present in the Vintany Cave (southwestern Madagascar) during the wet season, whereas other species such as *Triaenops menamena* and *Miniopterus mahafaliensis* were present in both the dry and wet season.

POPULATION:
Structure and Density
Population size and trends are not known for this species (Goodman, 2017k).

Trends
2016: Unknown (Goodman *et al.*, 2009b).

PARASITES:
Lagadec *et al.* (2012: 1696), Dietrich *et al.* (2014: Suppl.) and Gomard *et al.* (2016: 5) report the presence of spirochaetes bacteria of the genus *Leptospira*, and which were further identified as *L. borgpetersenii* by Dietrich *et al.* (2018a: 3).

The haemosporidian *Polychromophilus melanipherus* Dionisi, 1899 was reported from this species by Ramasindrazana *et al.* (2018: Suppl.) (see also Bajić *et al.*, 2023: Suppl.).

Ramasindrazana *et al.* (2016: 6) recovered *Litomosa* Clade 2 (Nematoda: Onchocercidae) from this bat species.

VIRUSES:
Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 2 individuals from the Mauritius using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids.

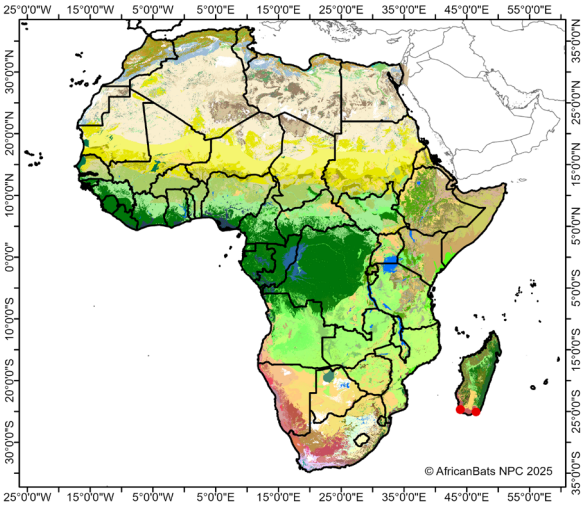

Figure 233. Distribution of *Miniopterus griffithsi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus griveaudi Harrison, 1959

*1959. *Miniopterus minor griveaudi* Harrison, Durban Mus. Novit., 5 (15): 192. Publication date: 30 April 1959. Type locality: Comoros: Grand Comoro [11 35 S 43 20 E]. [Goto Description]. Holotype: NHMUK 1967.1231: ad ♀, alcoholic (skull not removed). Collected by: Paul Griveaud; collection date: 10 August 1958. Formerly HZM 3.2803, see Harrison (1959a: 192). - Comments: The museum labels of the two other specimens, on which Harrison (1959a) based his description (HZM 4.2804 and 5.2805), have the following note by P. Griveaud: "couloir souterrain et grotte sous coulée de lave Niombadjée". Niombadjée is a toponym for Niombadjou (also spelled as Niumbadju), located on the western lower flank of Mt. Karthala at 11° 47′ 57" S, 43° 17′ 50" E (approximately 600 m) and where members of the expedition were based from 8 August 1958 to 23 August 1958: see Goodman *et al.* (2009a: 342). - Etymology: In honour of Mr. Paul Griveaud, the collector of the type specimen.

2022. *Miniopterus griveaud:* Esteves, Gaeta, Batista, Dias and Heinemann, Transb. Emerg. Dis., xxx (x): 8. Publication date: 9 May 2022. (Lapsus).

? *Miniopterus griveaudi (Clade 3):* Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, Zool. Scr., 38: 351 - 353, 362 - 363.

? *Miniopterus griveaudi:* (Current Combination).

TAXONOMY:
Originally synonymised with *Miniopterus minor*. Then moved as a synonym of *Miniopterus manavi* (Peterson *et al.*, 1995: 135; Simmons, 2005: 520). Peterson *et al.* (1995: 119) suggest that it may be a valid species, which Simmons (2005: 520) recognises as a valid subspecies. Juste [B.] *et al.* (2007: 32) consider *griveaudi* a valid species based on mtDNA data, a view supported by Weyeneth *et al.* (2008).

COMMON NAMES:
Czech: létavec komorský. English: Griveaud`s Long-fingered bat, Griveaud's Bent-winged Bat. French: Minioptère des Comores. French: Minioptère de Griveaud. German: Komoren-Langflügelfledermaus.

ETYMOLOGY OF COMMON NAME:
In honour of Mr. Paul Griveaud, the collector of the type specimen.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Juste, 2008a; IUCN, 2009; Juste, 2019a).

Assessment History
Global
2018: DD ver 3.1 (2001) (Juste, 2019a). 2008: DD ver 3.1 (2001) (Juste, 2008a; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Juste, 2008a; IUCN, 2009; Juste, 2019a).

CONSERVATION ACTIONS:
Juste (2008a) [in IUCN (2009)] and Juste (2019a) reports that it is not known if the species is present in any protected areas. Further studies

are needed into the distribution, abundance, natural history, and threats to this species.

GENERAL DISTRIBUTION:
Miniopterus griveaudi is endemic to Grand Comore Island and Anjouan in the Comoros.

O'Brien (2011: 289) also reports it from Madagascar. Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the northwestern part of the island (western or dry deciduous region) up to 400 m.

Native: Comoros (Koopman, 1993a: 231 [as *minor*], Simmons, 2005: 521 [as *minor*], Juste [B.] *et al.*, 2007: 32), Madagascar.

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls as *M. manavi s.l.*, these calls were broadband FM/QCF sweeps produced at low duty cycle with most energy at about 58.1 kHz in the fundamental, with pulses having a short duration of about 4 ms.
Ramasindrazana *et al.* (2011: 294) recorded 49 calls from 17 *Miniopterus griveaudi* specimens from Madagascar, and found the following echolocation call values: Frequency of maximum energy: 59.9 ± 1.73 (56.4 - 62.4) kHz, Maximum frequency: 105.6 ± 12.05 (82.0 - 130.0) kHz, Minimum frequency: 55.9 ± 1.36 (53.0 - 58.0) kHz, Call duration: 3.5 ± 0.54 (2.7 - 4.4) ms, Inter pulse interval: 85.7 ± 19.80 (40.0 - 123.6) ms.
For 27 calls of 8 specimens from the same species from Anjoun, Ramasindrazana *et al.* (2011: 294) reported the following echolocation call values: Frequency of maximum energy: 59.2 ± 0.73 (58.2 - 60.8) kHz, Maximum frequency: 104.3 ± 8.86 (86.0 - 123.0) kHz, Minimum frequency: 54.5 ± 1.22 (53.0 - 57.0) kHz, Call duration: 3.2 ± 0.53 (2.7 - 4.6) ms, Inter pulse interval: 83.8 ± 15.60 (57.6 - 128.1) ms.
And 22 calls of 6 specimens from Grande Comore gave the following echolocation call values: Frequency of maximum energy: 59.4 ± 0.78 (58.2 - 60.9) kHz, Maximum frequency: 110.0 ± 11.10 (74.0 - 124.0) kHz, Minimum frequency: 55.0 ± 0.76 (53.0 - 56.0) kHz, Call duration: 3.1 ± 0.34 (2.6 - 3.6) ms, Inter pulse interval: 83.5 ± 13.18 (66.1 - 123.9) ms.

MOLECULAR BIOLOGY:
Karyotype
Richards *et al.* (2010) reported one female with a 2*n*=46 and a FNa=50. The karyotype consists of two large metacentric, one medium metacentric and 19 acrocentric chromosomal pairs. As FISH with the complete set of *Myotis* probes was applied, the X chromosome could be identified as a submetacentric element. Volleth and Eick (2012: 167) also mention a segment number of 23.

HABITAT:
Dammhahn and Goodman (2013: 108) mention the lower portion of forest structure and partially open areas as the foraging habitat for this species.

ROOST:
Wilkinson *et al.* (2012: 160) indicated that caves are the typical roosting site for this species on the Comoros.

DIET:
Goodman *et al.* (2023b: 241) [referring to Falimiarintsoa (2022), Rafanomezanjanahary (2021), Manana (2022)] mentioned fecal pellets of four bats from Sarahandrano containing Coleoptera (54.0 %), Diptera (35.0 %), and Lepidoptera (9.5 %); pellets of 10 individuals from Antsahabe contained Coleoptera (50 %), Lepidoptera (33 %), and Diptera (11 %), and pellets of five bats from the eastern slopes of the Marojejy National Park contained Coleoptera (42.4 %), Lepidoptera (37.2 %), and Hymenoptera (25.4 %).

PREDATORS:
Razakaratrimo *et al.* (2019: 112) mention *Macheiramphus alcinus anderssoni* (Gurney, 1866) as predator of *M.* cf. *griveaudi*, which makes 4.6 % of its prey in the Mandrozo Protected Area.

POPULATION:
Structure and Density
The abundance and population size of this species are not known (Juste, 2008a; IUCN, 2009; Juste, 2019a).

Trend
2018: Unknown (Juste, 2019a). 2008: Unknown (Juste, 2008a; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Goodman *et al.* (2023b: 242) mentioned that eight females captured at Antsahabe between 29 September and 19 November 2019 of which three had small mammae and four carried embryos (crown-rump 4 to 18 mm). Of the 12 males, seven had abdominal testes and non-convoluted epididymes and five had abdominal testes and partially convoluted epididymes. Three bats collected at Andratsakala between 6 March and 25 April 2022 included two subadult females and one male with convoluted epididymes. This would indicate that the gestation period is at the end of the year when

the rainy season starts and the insects are available at their highest densities.

Goodman *et al.* (2025: 215) reported on three non-reproductive males and 31 (out of 39) pregnant females collected between mid November and early December. Two of the latter had single embryos with crown-rump lengths of 18 and 19 mm.

PARASITES:
Lagadec *et al.* (2012: 1696), Lei and Olival (2014: Suppl.) and Gomard *et al.* (2016: 5) found this species to be infected by *Leptospira* bacteria on the Comoro Islands. These were further identified as *L. borgpetersenii* by Dietrich *et al.* (2018a: 3).

The haemosporidian *Polychromophilus melanipherus* Dionisi, 1899 was reported from this species by Ramasindrazana *et al.* (2018: Suppl.), as wel as an unidentified *Haemosporida* sp.

Tortosa *et al.* (2013: 4) reported these bats to be parasitized by *Nycteribia stylidiopsis* on both the Comoro Islands and on Madagascar. On the latter island, two additional Nycteribiid bat flies were found: *Penicillidia leptothrinax* and *Penicillidia* sp. *N. stylidiopsis* and *P. leptothrinax* were also reported by Wilkinson *et al.* (2016) and Ramasindrazana *et al.* (2017: Suppl.). Wilkinson *et al.* (2016) furthermore reported the presence of "*Penicillidia* sp. (cf. *fulvida*)" (see also Attaullah *et al.*, 2023: 4). The *N. stylidiopsis* flies were found to carry Enterobacteriales, and the *P.* cf. *fulvida* was host for the blood parasite *Polychromophilus murinus* as well as Enterobacteriales and *Bartonella* bacteria, whereas *P. leptothrinax* was carrying Enterobacteriales and *Bartonella* and *Wolbachia* bacteria (Szentiványi *et al.*, 2019a: Suppl.).

Ramasindrazana *et al.* (2016: 6) recovered *Litomosa* Clades 1, 2 and 3 (Nematoda: Onchocercidae) from this bat species, as well as an unnamed filariod.

VIRUSES:
Astroviridae
26 bats were tested by Lebarbenchon *et al.* (2017: Suppl.) of which 15 were positive for Astroviridae.

Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 20 individuals from the Comoros using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 3 positive results for viral nucleic acids. Wilkinson *et al.* (2014) tested 17 individuals from Amabhibe in Madagascar with an RT-PCR specific for the *Respiro-*, *Morbilli-* and *Henipavirus* genera, four of the 17 individuals tested positive for paramyxovirus RNA.

18 out of 116 Madagascan specimens tested by Mélade *et al.* (2016b: 4) were positive for paramyxoviruses.

Rhabdoviridae
Mélade *et al.* (2016a: 6) tested 33 specimens for *Lagos bat lyssavirus* and two of them showed seroreactivity. This was also the case for 10 out of 29 specimens they tested for *Duvenhage lyssavirus*.

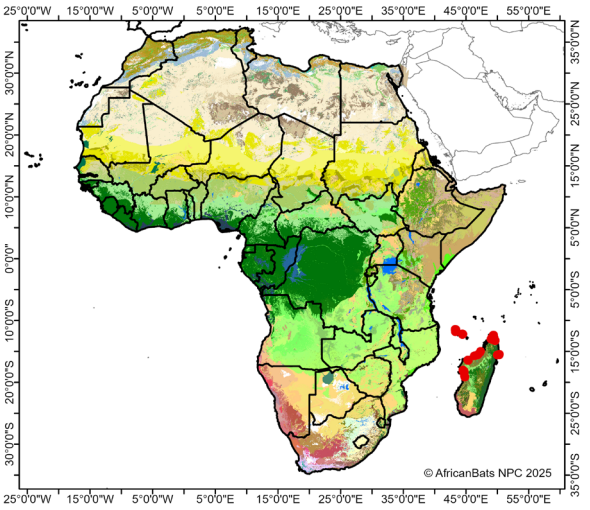

Figure 234. Distribution of *Miniopterus griveaudi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Comoros, Madagascar.

†*Miniopterus horaceki* Gunnell, Eiting and Geraads, 2011

*2011. *Miniopterus horaceki* Gunnell, Eiting and Geraads, N. Jb. Geol. Paläont. Abh., 260 (1): 63, figs 3B, 7C, 8D-F. Publication date: January 2011. Type locality: Morocco: Ahl al Oughlam [ca. 33 35 N 07 30 W]. Holotype: INSAP AaO 4605. Right dentary with p2-p4, m1 trigonid. - Etymology: In honour of Ivan Horáček, in recognition of his many contributions to the understanding of the evolutionary history of bats, and especially of vespertilionids (see Gunnell *et al.*, 2011: 63). (Current Combination).

TAXONOMY:
Gunnell *et al.* (2011: 63) describe it as larger than nearly all extant African and European *Miniopterus* species (including *M. gleni, M. inflatus, M. newtoni, M. fraterculus, M. natalensis, M. manavi, M. noreenae, M. minor, M. williamsi*, and *M. schreibersi*). Generally similar in size to *M. africanus* but differs in having PM_{3-4} relatively broader and more exodaenodont, PM_3 larger than PM_2, and in having relatively taller lower premolars. Larger than *M. schreibersi* with PM_2 smaller compared to PM_3, but *M. schreibersi* does possess relatively broad premolars similar to the Moroccan species.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Pliocene (Brown *et al.*, 2019: Suppl.).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Libya.

Miniopterus inflatus Thomas, 1903

*1903. *Miniopterus inflatus* Thomas, Ann. Mag. nat. Hist., ser 7, 12 (72): 634. Publication date: 1 December 1903. Type locality: Cameroon: Efulen [02 46 N 10 42 E]. [Goto Description]. Holotype: NHMUK 1903.2.4.8: ad ♂, skin only. Collected by: George Latimer Bates Esq. Collection date: 24 July 1901. - Etymology: From the masculine Latin adjective *inflatus*, meaning "inflated, swollen", referring to its inflated skull (see Lanza *et al.*, 2015: 329). (Current Combination).
? *Miniopterus infatus:* (Lapsus).

TAXONOMY:
Koopman (1975: 230) included *africanus*, but see Peterson *et al.* (1995: 120), Simmons (2005: 520) and Juste [B.] *et al.* (2007: 28).

Simmons (2005: 520) recognises *rufus* Sanborn, 1936 as a valid subspecies.

Based on cytochrome *b* and morphometric analyses, Monadjem *et al.* (2020b: 12; 2020e: 237) found that *M. inflatus* is paraphyletic with the populations from the central African rainforest (Cameroon, Gabon and possibly Congo, DRC and CAR) not being closely related to the savanna forms from eastern and southern Africa.

Until a more profound analysis is performed, Benda *et al.* (2025: 105-106) assigned their Kenyan specimens tentatively to *Miniopterus* aff. *Inflatus* as this is a parataxon, which covers multiple genetic lineages.

COMMON NAMES:
Afrikaans: Groot grotvlermuis. Castilian (Spain): Murciélago de Ala Larga. Chinese: 大长翼蝠. Czech: létavec větší. English: Greater Long-fingered Bat, High-crowned bat. French: Grand minioptère africain, Grand minioptère, Minioptère à couronne. German: Aufgeblasene Langflügelfledermaus. Italian: Miniòttero maggióre di Thòmas, Miniòptero maggióre di Thòmas. Portuguese: Morcego grande de dedos compridos.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Schlitter, 2008h; IUCN, 2009; Monadjem and Schlitter, 2017d).

Assessment History
Global
2016: LC ver 3.1 (2001) [includes *africanus* Sanborn, 1936] (Monadjem *et al.*, 2017cm). 2008: LC ver 3.1 (2001) [includes *africanus* Sanborn, 1936] (Schlitter, 2008h; IUCN, 2009). 2004: LC ver 3.1 (2001) (Schlitter, 2004j; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: NT D1 ver 3.1 (2001) (Richards *et al.*, 2016c).

MAJOR THREATS:
There do not appear to be any major threats to this species. Some roosting caves are disturbed by tourism activities (Schlitter, 2008h; IUCN, 2009; Monadjem and Schlitter, 2017d).

CONSERVATION ACTIONS:
Schlitter (2008h) [in IUCN (2009)] and Monadjem and Schlitter (2017d) report that this species has been recorded from a number of protected areas. There is a need to limit disturbance of important roosting caves. Further studies are needed into the distribution of this species in West Africa.

GENERAL DISTRIBUTION:
Patchily recorded over much of sub-Saharan Africa. It has been reported from Liberia and Guinea in West Africa; from Cameroon, Equatorial Guinea, Gabon, Central African Republic and the Democratic Republic of the Congo in Central Africa; from Ethiopia, Uganda, Kenya and Tanzania in East Africa; and from Namibia, Zimbabwe and Mozambique in southern Africa.

The distribution of this species is somewhat unclear in West Africa due to confusion with records of "*Miniopterus schreibersii*" (Hutterer *et al.*, 1992: 397: Simmons, 2005:520) and *M. villiersi* (Tanshi *et al.*, 2022a: 314). Additionally, Monadjem et al. () only recognize two species in West Africa: a larger *Miniopterus nimbae* and a smaller sized *M. villiersi*. The animals from Guinea and Liberia previously assigned to *M. inflatus* therefore rather represent *M. nimbae*.

Native: Burundi (Simmons, 2005: 520); Cameroon (Simmons, 2005: 520); Central African Republic; Congo (Bates *et al.*, 2013: 329 - 1st authenticated records); Congo (The Democratic Republic of the) (Schouteden, 1944; Hayman *et al.*, 1966; Simmons, 2005: 520; Monadjem *et al.*, 2010d: 539); Equatorial Guinea; Gabon (Simmons, 2005: 520); Kenya (Simmons, 2005: 520); Malawi (Monadjem *et al.*, 2010d: 539); Mozambique (Smithers and Lobão Tello, 1976; Simmons, 2005: 520; Monadjem *et al.*, 2010d: 539; Monadjem *et al.*, 2010c: 385); Namibia (Monadjem *et al.*, 2010d: 539); Nigeria (Tanshi *et al.*, 2022a: 317); South Africa (Monadjem *et al.*, 2010d: 539); Tanzania; Uganda (Kityo and Kerbis, 1996: 62; Simmons, 2005: 520); Zambia (Ansell, 1974; Monadjem *et al.*, 2010d: 539); Zimbabwe (Monadjem *et al.*, 2010d: 539).

Dental Formula:

van der Merwe (1985b: 251) examined three skulls and found vestigial teeth between the upper canine and the first premolar in all of them.

Functional morphology:

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 12.6 Pa, aspect ratio 8.7 and tip shape index of 2.15 for a wingspan of 29 cm and a wing area of 97 cm^2 and a body mass of 13 g.

Molecular Biology:

Genetics

See Hoofer and Van Den Bussche (2003).

Karyotype

Ruedas *et al.* (1990) described the karyotype as having a diploid number of 2*n* = 46, aFN = 50, BA = 6, X = M, Y = A.

Habitat:

In the Mount Nimba area, Monadjem *et al.* (2016y: 371) recorded this species from a variety of forested and disturbed habitats between 500 and 1,000 m.

Roost:

Monadjem *et al.* (2016y: 371) found a roost of this species in an old mine adit.

Happold and Happold (2023: 178) indicate that these bats generally roost singly and sometimes in small groups, but also that - in Gabon - females congregated in a maternity cave, which housed about 40,000 bats.

Diet:

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 106 minutes, and the digestibility rate about 76.6 %.

Population:

Structure and Density

This is generally considered to be a locally rare species, although it can be common in some areas (Schlitter, 2008h; IUCN, 2009; Monadjem and Schlitter, 2017d).

Trend

2016: Unknown (Monadjem and Schlitter, 2017d).
2008: Unknown (Schlitter, 2008h; IUCN, 2009).

Reproduction and ontogeny:

Brosset and Saint Girons (1980: 227) indicate that in Gabon all females were pregnant between August and September, and births were taking place in October. Between January and July, none of the females were either having any foetuses or young or were lactating. The males were non-reproductive between 9 October and 10 February.

Parasites:

Fain (1959b: 342) described *Nycteridocoptes miniopteri* (Acari: Sarcoptidae) from a *M. inflatus* specimen collected in Mulungu, Kivu, DRC.

Uchikawa (1985a: 22) reported *Calcarmyobia kenyaensis* Uchikawa, 1982 (Acari: Myobiidae) from *Miniopterus inflatus* specimens from Cameroon, Liberia, The Democratic Republic of Congo, Uganda and Kenya. Some Kenyan bats were identified as belonging to *Miniopterus inflatus africanus*, which might indicate that the host should actually be *M. africanus*.

Uchikawa (1985b: 52) further collected two paratypes of *Calcarmyobia producta* from a *M. inflatus* specimen from N Chyulu Hills, Kenya.

Uchikawa (1985c: 110) furthermore reported on several specimens from Kenya and The Democratic Republic of Congo, infected with four female *Pteracarus miniopteri* Uchikawa mites.

Justine (1989b: 555) described a new stomach parasite: *Capillaria magnova* from a *M. inflatus* from Belinga (Gabon).

Duval *et al.* (2012: 1559) indicate that the haemosporidan *Polychromophilus (Polychromophilus) corradetti* Landau et al., 1980 was described from *M. inflatus* specimens from Gabon (see Landau *et al.*, 1980b: 22). They also report (p. 1561) on five haplotypes belonging to the *Polychromophilus melanipherus* group and isolated during their study in Gabon (see also Bajić *et al.*, 2023: Suppl.).

Arnuphapprasert *et al.* (2020: Suppl.) refer to GenBank data for *Polychromophilus* sp. (haplotypes 3, 4, and 5) from Gabonese *M. inflatus*.

ARACHNIDA
Laelapidae
Neospinolaelaps Illiniopteri Zumpt and Patterson, 1952 was reported by Taufflieb (1962: 112).

Sarcoptidae
Fain (1959e: 157) described *Notoedres (Metanotoedres) miniopteri* from *M. inflatus* from Thysville (= Mbanza-Ngungu), DRC.

Spinturnicidae
Taufflieb (1962: 112) reported *Spinturnix semilunaris* de Meillon and Lavolplerre, 1944.

DIPTERA
Streblidae
Brachytarsina allaudi (Falcoz, 1923) in Gabon (Obame-Nkoghe *et al.*, 2016: 5). *Raymondia huberi* Frauenfeld 1856 in Guinea-Bissau (Haeselbarth *et al.*, 1966: 102). *Raymondia seminuda* Jobling, 1954 (Shapiro *et al.*, 2016: 255). *Raymondia tauffliebi* Theodor, 1968 in Congo (Shapiro *et al.*, 2016: 256).

Nycteribiidae
Nycteribia exacuta Theodor, 1957 from Dalaba, Guinea (Haeselbarth *et al.*, 1966: 108). *Nycteribia schmidlii* Schiner, 1853 (Haeselbarth *et al.*, 1966: 108; Tortosa *et al.*, 2013: 5; Duron *et al.*, 2014: 2108; Obame-Nkoghe *et al.*, 2016: 5; Ramasindrazana *et al.*, 2017: Suppl.), which was in Gabon carrying the blood parasite *Polychromophilus melanipherus* (Szentiványi *et al.*, 2019a: Suppl.). *Penicillidia fulvida* (Bigot, 1885) (Haeselbarth *et al.*, 1966: 114; Duron *et al.*, 2014: 2109; Obame-Nkoghe *et al.*, 2016: 5), which in Gabon was also carrying the same blood parasite as above (Szentiványi *et al.*, 2019a: Suppl.). *Eucampsipoda africana* Theodor, 1955 (Obame-Nkoghe *et al.*, 2016: 5; Júnior *et al.*, 2020: Suppl.).

VIRUSES:
Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested between 1986 and 1999, for antibody to SARS-CoV in sera in 34 individuals from Oriental Province, DRC, one tested positive (1/34, 2.9 %). Tong *et al.* (2009) tested 7/12 bats collected in Kenya during 2006 positive for the presence of coronavirus RNA in a fecal sample.

Anthony *et al.* (2017b: Suppl.) mention the alpha-coronaviruses: Kenya_Cov_KY33 and Predict_CoV_28. One out of two Kenyan specimens tested by Tao *et al.* (2017: Suppl.) was positive for CoV. One out of 249 Gabonese bats (0.4 %) tested by Maganga *et al.* (2020: 2) was found to be positive for an infection by *Alphacoronavirus*.

Filoviridae - Filoviruses
Marburgvirus
This virus is reported by Becquart *et al.* (2010: 1), Kuzmin *et al.* (2010b: 353), Luis *et al.* (2013: Suppl), Changula *et al.* (2014: 486), Simons *et al.* (2014: 2090), and Willoughby *et al.* (2017: Suppl.). Markotter *et al.* (2020: 6) mention the bat species as "*Miniopterus* cf. *inflatus*" (see also below).

Ebolavirus
On 24 January 2019, a series of newspaper articles was published, where several scientists from EcoHealth Alliance were quoted (Simon J. Anthony, Jonathan Epstein) stating that in a mouth swab one Liberian *Miniopterus inflatus* (out of 150 tested) RNA material of the Zaire Ebolavirus was found. Epstein, however, pointed out that if the bat was a natural host for the virus, it would have been found in more than one bat. He also pointed out that the bat could have become infected by another bat species living in the same habitat. Fabian Leendertz (veterinary epidemiologist at the Robert Koch Institute - not involved in the study) indicated that the virus itself wasn't isolated but only about one-fifth of its genome (Grady, 2019; Kupferschmidt, 2019; Su, 2019; Brainard, 2019).

Demos *et al.* (2019c: "11") pointed out that *M. inflatus* - as currently understood - has a very wide distribution, ad might be paraphyletic, indicating that further research is needed to confirm the true identity of the bat involved. Markotter *et al.* (2020: 6) therefore listed the bat as "*Miniopterus* cf. *inflatus*".

Nairoviridae
Orthonairovirus
9 out of 51 *M. inflatus* specimens from Gabon tested by Müller *et al.* (2016: 3) were positive for Crimean Congo haemorrhagic fever virus (CCHFV).

Paramyxoviridae
Orthorubulavirus
Drexler *et al.* (2012a: Suppl. Table S1) indicated that two of the 125 specimens they examined from Gabon tested positive for *Rubulavirus* (Human orthorubulavirus-related viruses according to Markotter *et al.*, 2020: 6).

Polyomaviridae
Nieto-Rabiela *et al.* (2019: Suppl.) mentioned the presence of Bat Polyomavirus.

In their overview table, Maganga *et al.* (2014a: 8) reported the following viruses were already found on *M. inflatus*: Marburg virus (MBGV), Coronavirus, Rubulavirus.

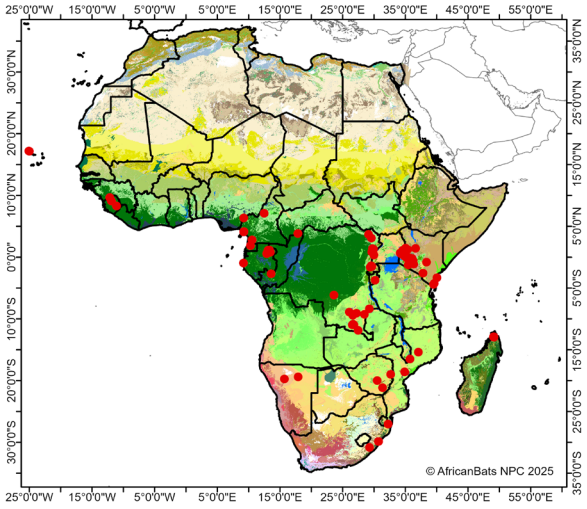

Figure 235. Distribution of *Miniopterus inflatus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Cameroon, Cape Verde, Central African Republic, Congo (Democratic Republic of the), Gabon, Kenya, Madagascar, Mozambique, Namibia, Nigeria, Rwanda, Sierra Leone, South Africa, Uganda, Zambia, Zimbabwe.

Miniopterus inflatus inflatus Thomas, 1903

*1903. *Miniopterus inflatus* Thomas, Ann. Mag. nat. Hist., ser 7, 12 (72): 634. Publication date: 1 December 1903. Type locality: Cameroon: Efulen [02 46 N 10 42 E]. [Goto Description]. - Etymology: From the masculine Latin adjective *inflatus*, meaning "inflated, swollen", referring to its inflated skull (see Lanza *et al.*, 2015: 329). (Current Combination).
? *Miniopterus inflatus inflatus:* (Name Combination).

Collected by: Petr Benda, Jaroslav Červený, Adam Konečný and Peter Vallo; collection date: 26 April 2008. Kef Azigza Cave. - Etymology: The name maghrebensis refers to the region (the Maghreb; the region of northern Africa located between the Atlantic Ocean, the Mediterranean Sea, and the Sahara) where the new species was discovered (see Puechmaille *et al.*, 2014a: 118). (Current Combination).

Taxonomy:

Bilgin *et al.* (2016: 330) calculated that the split between *M. maghrebensis* and *M. schreibersii* took place some 72,041 years ago (95 % HDP Interval = 5,637 - 139,570 years).

Common Names:

Castilian (Spain): Murrcielago de cueva magrebí. Czech: létavec maghrebský. Dutch: Maghrebijns langvleugelvleermuis. English: Maghrebian bent-wing bat. French: Minioptere du Maghreb. German: Maghreb-Langflügelfledermaus.

Conservation status:

Global Justification

This species is known from very few sites only, all representing underground spaces threatened by human activities. Listed as Near Threatened (NT ver 3.1 (2001)) because actual levels of disturbance are likely to lead the habitat of this species to decline of at least 30% in the next 15 years (Benda and Piraccini, 2017).

Assessment History

Global

2016: NT ver 3.1 (2001) (Benda and Piraccini, 2017).

Regional

None known.

Major threats:

Threats to the species are mainly human disturbance of roost sites, and perhaps the use of pesticides against insects (Benda and Piraccini, 2017).

Conservation actions:

Benda and Piraccini (2017) report that no specific measures are known to be in place for this species, but it occurs in protected areas across its range.

General distribution:

Northern Morocco to south of the High Atlas Mountains and northern Tunisia.

Gili *et al.* (2025: 533) report the first European record for this species from the Island of Lampedusa.

Based on cyt *b* sequences from GenBank, Derouiche *et al.* (2024: 34) conclude that this species hasn't been found in Algeria yet, but given its distribution in the surrounding countries, it probably is present in that country.

Native: Lampedusa (Gili *et al.*, 2025: 533); Morocco (Dbiba *et al.*, 2025: 7); Tunisia.

Sexual dimorphism:

Šrámek and Benda (2014: 222) found that most of the cranio-dental measurements in males were larger than in females, except for the dimensions associated with skull and rostral width. In dental characters, on the other hand, females were larger in 38 of 57 variables and the sexes highly diverged ($P < 0.001$) in the length of the lower canine; slightly diverged in widths of the second lower incisor, second upper molar (in central part) and third lower molar.

Echolocation:

Puechmaille *et al.* (2014a: 113) provide the following data [(avg ± sd (min - max)]: Peak

frequency: 52.89 ± 0.74 (51.00 - 54.78) kHz; Start frequency: 74.69 ± 7.66 (63.57 - 101.07) kHz; End frequency: 50.36 ± 0.81 (48.92 - 51.85) kHz; Duration: 4.48 ± 0.67 (3.20 - 5.60) ms; Interval between pulses: 107.14 ± 27.35 (67.20 - 239.20) ms.

MOLECULAR BIOLOGY:
Genetics
The GenBank sequence (partial Cytochrome *b*, tRNA-Threonine, tRNA-Proline, HV1) of the holotype corresponds to the accession numbers KJ535784 & KJ535824 (see Puechmaille *et al.*, 2014a: 117).

POPULATION:
This species has been found in the Mediterranean and steppe habitats of the Maghreb (Benda and Piraccini, 2017).

Trend:- 2016: Unknown (Benda and Piraccini, 2017).

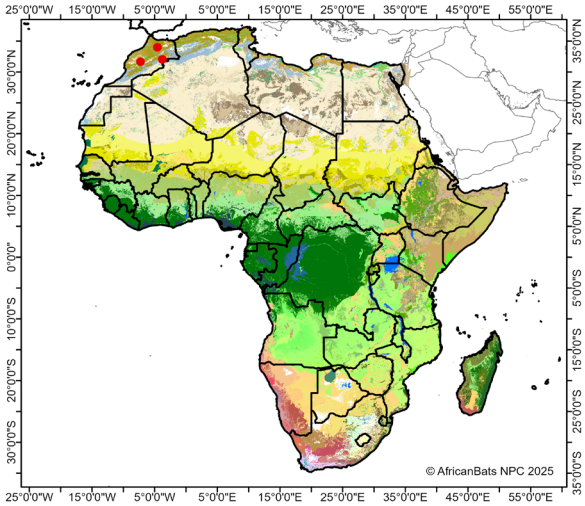

Figure 236. Distribution of *Miniopterus maghrebensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Morocco.

Miniopterus mahafaliensis Goodman, Bradman, Christides and Appleton, 2009

Betroka, 23°15'50" S, 46°05'30" E, 800 m. - Etymology: The name *mahafaliensis* is derived from the Malagasy word mahafaly, meaning ''to make taboos,'' but here specifically referring to one of the local cultural groups in southwestern Madagascar, the Mahafaly, and the Mahafaly Plateau, a limestone karst area, from whence many of the specimens of this taxon were collected. In the region of the Forêt des Mikea (see Goodman *et al.*, 2009c: 28). (Current Combination).

COMMON NAMES:
English: Mahafaly Long-fingered Bat, Mahafaly Bent-winged Bat. French: Minioptère Mahafaly. German: Mahafaly-Langflügelfledermaus. Malagasy: kitrotroke.

CONSERVATION STATUS:
Global Justification
This species is known from numerous sites in the dry southern portion of Madagascar (Goodman and Ramasindrazana, 2013); a few of these localities are within existing protected areas. This species is apparently not forest-dependant and may not be very sensitive to any important habitat degradation or other human pressures (Goodman, 2017l).

Assessment History
Global
2016: LC ver. 3.1 (2001) (Goodman, 2017l).

Regional
Endemic to Madagascar therefore global assessment should be used.

CONSERVATION ACTIONS:
Goodman (2017l) this species is known from several protected areas, which include: Isalo, Kirindy Mité, Mikea, and Tsimanampetsotsa.

GENERAL DISTRIBUTION:
Madagascar (known from numerous sites on or in close proximity to the limestone Mahafaly Plateau in the southwestern portion of the island, including the zone from Itampolo north across the Onilahy River to Sarodrano spanning the elevational range from sea level to 120 m. Its distribution then continues further north to the Forêt des Mikea (70 - 80 m) and based on current data ends in the Kirindy-Mite region (30 - 35 m). Further, it is known from the more inland and upland sites of Ihosy and near Betroka from 800 - 950 m and within the Isalo formation at 550 m.).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the southwestern quarter of the island (south-west sub-arid or spiny bush).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 63) could not find a baculum in the one specimen they examined.

ECHOLOCATION:
Ramasindrazana *et al.* (2011: 294) recorded 24 calls from 9 *Miniopterus mahafaliensis* specimens, and found the following echolocation call values: Frequency of maximum energy: 59.6 ± 1.46 (57.3 - 62.2) kHz, Maximum frequency: 113.7 ± 8.08 (95.0 - 123.0) kHz, Minimum frequency: 55.1 ± 1.47 (53.0 - 57.0) kHz, Call duration: 3.3 ± 0.25 (2.9 - 3.8) ms, Inter pulse interval: 68.7 ± 14.04 (43.5 - 95.3) ms.

HABITAT:
M. mahafaliensis is found in dry deciduous forests, spiny forests and open anthropogenic areas from sea level to 950 m (Garbutt, 2022: 108).

ROOST:
Wilkinson *et al.* (2012: 160) reported caves to be the typical roosting site for these bats on Madagascar, but it might possibly also use hollow trees.

DIET:
Ramasindrazana *et al.* (2012: 120-121) examined faecal pellets from bats in the Tsimanampetsotsa NP, and found them to contain 47.5 ± 5.5 volume percent Lepidoptera, 39.9 ± 5.5 Coleoptera, 6.9 ± 2.9 Hymenoptera, 3.4 ± 0.6 Psocoptera, 1.1 ± 0.4 Diptera, 1.0 ± 0.2 Aranea, and 0.1 ± 0.0 Homoptera/Hemiptera. During the dry season, 52.9 ± 6.1 volume percent Coleoptera were found and 35.2 ± 5.7 Lepidoptera. The latter order was represented by 82.3 ± 7.7 percent in the wet season, whereas the Coleoptera dropped to 3.2 ± 0.8 percent.

POPULATION:
Structure and Density
Not known (Goodman, 2017l).

Trends
Unknown (Goodman, 2017l).

PARASITES:
Lagadec *et al.* (2012: 4696), Dietrich *et al.* (2014: Suppl.), Lei and Olival (2014: Suppl.) and Gomard *et al.* (2016: 5) report the presence of spirochaetes bacteria of the genus *Leptospira*, which were identified as *L. borgpetersenii* by Dietrich *et al.* (2018a: 3).

The haemosporidian *Polychromophilus melanipherus* Dionisi, 1899 was reported from this species by Ramasindrazana *et al.* (2018: Suppl.), as wel as an unidentified *Haemosporida* sp. Rasoanoro *et al.* (2019: 67) refer to Raharimanga *et al.* (2003) who reported *Trypanomsoma* sp. from a "*Miniopterus manavi*".

Ramasindrazana *et al.* (2016: 6) recovered *Litomosa* Clade 2 (Nematoda: Onchocercidae) from *M. mahafaliensis*.

On Madagascar, Tortosa *et al.* (2013: 4) found Nycteribiid bat flies belonging to *Penicillidia leptothrinax*.

VIRUSES:
Astroviridae
Hoarau *et al.* (2021: Suppl.) reported the presence of these viruses in bats from Madagascar.

Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 11 individuals from the Mauritius using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids.

In their extensive study, Mélade *et al.* (2016b: 3) found that *M. mahafaliensis* was the least infected species of Madagascan bat, with only 4 out of 89 specimens (4.5 %) infected.

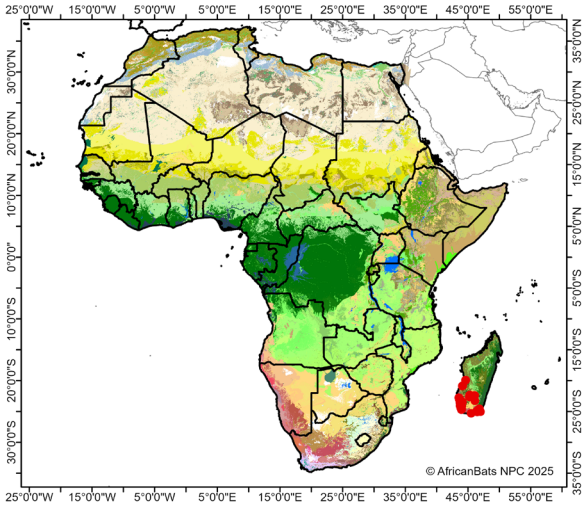

Figure 237. Distribution of *Miniopterus mahafaliensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus majori Thomas, 1906

*1906. *Miniopterus Majori* Thomas, Ann. Mag. nat. Hist., ser 7, 17 (98): 175. Publication date: 1 February 1906. Type locality: Madagascar: SE Betsileo: Imasindrary [=Sahamananina] [20 17 S 47 31 E, 1 600 m]. [Goto Description]. Holotype: NHMUK 1897.9.1.38: ad ♀, skin and skull. Collected by: Dr. Charles Immanuel Forsyth-Major; collection date: 3 July 1895; original number: 457. - Etymology: In honour of Dr. C.I. Forsyth Major, collector of the type specimen (see Thomas, 1906a: 176). (Current Combination).
? *Miniopterus majori majori:* (Name Combination).
? *Miniopterus majori:* (Current Spelling).

TAXONOMY:
Included in *schreibersi* by Koopman (1993a: 231), but considered a valid species by Peterson *et al.* (1995: 131), Hutson *et al.* (2001: 32), Russ *et al.* (2001), Simmons (2005: 520).

COMMON NAMES:
Czech: létavec východomadagaskarský. English: Major Long-fingered Bat, Major's Long-fingered Bat, Major's Bent-winged Bat. French: Grand minioptère malgache, Minioptère de Major. German: Majors Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its relatively wide range, ability to live in a wide variety of habitats from intact forests to heavily degraded areas, and because there is no evidence of a decline that would warrant listing in a higher category of threat (Jenkins and Rakotoarivelo, 2008a; IUCN, 2009; Monadjem *et al.*, 2017br).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017br). 2008: LC ver 3.1 (2001) (Jenkins and Rakotoarivelo, 2008a; IUCN, 2009). 2003: DD (IUCN, 2003). 2001: DD (IUCN/SSC Action Plan, 2001).

Regional
None known.

MAJOR THREATS:
The major threats to this species are not known. It could be susceptible to cave disturbance in some sites and it could perhaps be hunted in some areas (Jenkins and Rakotoarivelo, 2008a; IUCN, 2009; Monadjem *et al.*, 2017br).

CONSERVATION ACTIONS:
Jenkins and Rakotoarivelo (2008a) [in IUCN (2009)] and Monadjem *et al.* (2017br) report that this species is reported from a few protected areas, such as Parc National de Masoala and Parc National de Mantadia (Russ and Bennet, 1999; Randrianandrianana *et al.*, 2006). Some of these records may need to be reassessed in view of the ongoing taxonomy of this genus in Madagascar (Goodman and Maminirina, 2007).

GENERAL DISTRIBUTION:
Miniopterus majori is endemic to Madagascar and has a sympatric distribution with *Miniopterus*

sororculus in the highlands of Madagascar (Goodman *et al.*, 2007b) and is widely, but patchily, distributed across the island (Peterson *et al.*, 1995; Eger and Mitchell, 2003).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the eastern part of the island (higher elevations (< 1,200 m) of the Central Highlands - sub-humid region).

Goodman and Maminirina (2007) suggest that the only specimens known form the Comoro Islands were collected by M. Humbolt and may have been incorrectly provenanced. Until new material is available from the island to confirm that *M. majori* exists, it is removed from the known distribution of the species and is restricted at this time to Madagascar.

Native: Madagascar (Peterson *et al.*, 1995; Eger and Mitchell, 2003; Simmons, 2005: 520; Goodman and Maminirina, 2007).

Presence incorrectly assigned: Comoro Islands (Simmons, 2005: 520).

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls as *Miniopterus majori/sororculus*, which produced broadband FM/QCF echolocation calls at low duty cycle, but with a lower maximum energy, at about 48.5 kHz. The fundamental being most intense with short duration pulses of about 4.5 ms.

Ramasindrazana *et al.* (2011: 294) recorded 39 calls from 12 *Miniopterus majori* specimens, and found the following echolocation call values: F_{peak}: 48.5 ± 1.15 (46.1 - 52.0) kHz, F_{max}: 82.5 ± 11.78 (64.0 - 102.0) kHz, F_{min}: 44.4 ± 0.97 (43.0 - 46.0) kHz, duration: 3.6 ± 0.42 (2.8 - 4.5) ms, Inter pulse interval: 85.0 ± 16.34 (59.5 - 134.8) ms.

HABITAT:
M. majori is found in humid forest and spiny forest areas (Garbutt, 2022: 107).

ROOST:
This bat roosts in caves, often together with *M. gleni, M. manavi* and/or *M. sororculus*. Occasionally, it is also found in tree holes (Garbutt, 2022:107).

DIET:
Kemp *et al.* (2018: Suppl.) used DNA metabarcoding to detect insect pest species in the diet of these bats and found the following prey orders (in descending order): Lepidoptera (*Ericeia inangulata* (Guenée, 1852), *Pandemis* sp., *Celsumaria elongata* Brown, 2017, *Meyrickiella homosema* (Meyrick, 1887), *Emmalocera* sp., *Palpita* sp., *Pandemis retroflua* Diakonoff, 1960, *Achaea euryplaga* (Hampson, 1913), *Eublemma viettei* (Berio, 1954), *Herpetogramma licarsisalis* (Walker, 1859), *Chloroclystis androgyna* Herbulot, 1957, *Idiodes oberthuri* Dognin 1911, *Scopula* AH01Md, *Ectropis* AH27Md), Hemiptera, Blattodea, Trombidiformes, Diptera (*Simulium lineatum* (Meigen, 1804)), Coleoptera, Hymenoptera, Ephemeroptera, Trichoptera, Sarcoptiformes, Astigmata.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 84 minutes, and the digestibility rate about 79.1 %.

POPULATION:
Structure and Density
There is no information on its population status (Jenkins and Rakotoarivelo, 2008a; IUCN, 2009; Monadjem *et al.*, 2017br).

Trend
2016: Unknown (Monadjem *et al.*, 2017br). 2008: Unknown (Jenkins and Rakotoarivelo, 2008a; IUCN, 2009).

PARASITES:
Dietrich *et al.* (2014: Suppl.) and Gomard *et al.* (2016: 5) report the presence of spirochaetes of the genus *Leptospira* in bats from Fianarantsoa, Madagascar. These were identified as *L. borgpetersenii* by Dietrich *et al.* (2018a: 3).

Uchikawa (1985b: 45) reports *Calcarmyobia comoresensis* mites of bat specimens from Vobima and Bersroha, Madagascar. Uchikawa (1985c: 111) mentions the presence of *Pteracarus miniopteri* Uchikawa, 1978 mites on *M. schreibersi majori* specimens from Madagascar. Tortosa *et al.* (2013: 4), furthermore, reported the presence of Nycteribiid bat flies: *Nycteribia stylidiopsis* and *Penicillidia leptothrinax*. The *Nycteribia* is also reported by Ramasindrazana *et al.* (2017: Suppl.).

Ramasindrazana *et al.* (2016: 6) recovered *Litomosa* Clade 1 (Nematoda: Onchocercidae) from this bat species.

Ramasindrazana *et al.* (2018: 7) refer to Ramasindrazana *et al.* (2018) to report the presence of the Haemosporidian *Polychromophilus* in this bat species.

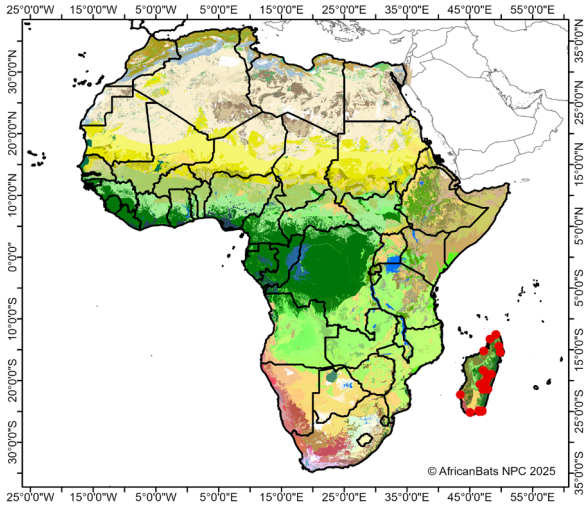

Figure 238. Distribution of *Miniopterus majori*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Madagascar.

Miniopterus manavi Thomas, 1906

*1906. *Miniopterus manavi* Thomas, Ann. Mag. nat. Hist., ser 7, 17 (98): 176. Publication date: 1 February 1906. Type locality: Madagascar: Eastern/Northeastern Betsileo: Fandriana region [20 17 S 47 31 E]. [Goto Description]. Holotype: NHMUK 1897.9.1.37: ad ♂, skin and skull. Collected by: Dr. Charles Immanuel Forsyth-Major; collection date: 3 July 1895; original number: 453. See Peterson *et al.* (1995: 135). Topotype: MCZ 45101: ♀, complete skeleton. Collected by: The Grandidier Collection; collection date: 3 July 1895. - Comments: [Imansindrary = ? Masindrary, 15 km ESE Fandriana, see Jenkins and Carleton, 2005 (in Goodman *et al.*, 2009a: 340)]. (Current Combination).
1993. *Miniopterus minor grivaudi:* Koopman, in: Wilson and Reeder, Mammal species of the World (2nd Edition): Chiroptera, 231. (Lapsus).
2001. *Miniopterus menavi:* Hutson, Mickleburgh and Racey, Microchiropteran bats, 89. (Lapsus).
2007. *Miniopterus (griveaudi) manavi:* Goodman and Maminirina, Mammalia, 71 (4): 151. (Name Combination).
2009. *Miniopterus manavi (Clade 1):* Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, Zool. Scr., 38: 346-351, 362.
? *Miniopterus manavi manavi:* (Name Combination).

TAXONOMY:
Included in *minor* by Koopman (1993a: 231), but considered a valid species by Peterson *et al.* (1995: 135), Hutson *et al.* (2001: 32), Russ *et al.* (2001), and Simmons (2005: 520).

Simmons (2005: 520) recognised *griveaudi* Harrison, 1959 as a valid subspecies of *M. manavi*, Juste [B.] *et al.* (2007: 33) elevated *griveaudi* as a separate species, which is followed in this account.

Weyeneth *et al.* (2008) used mitochondrial DNA markers to demonstrate that the specimens from the Comoro islands are not closely related to *M. minor* from the African mainland, and that these islands were probably populated as a result of two or three invasions originating from Madagascar.

COMMON NAMES:
Czech: létavec manavijský. English: Manavi Long-fingered Bat, Manavil Bent-winged Bat. French: Petit minioptère malgache. French: Minioptère manavi. German: Manavi-Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread distribution (near suitable caves) across Madagascar. While it is locally threatened by hunting, this is not thought to be a major threat of this species across its range (Andriafidison *et al.*, 2008f; IUCN, 2009; Monadjem *et al.*, 2017cf).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cf). 2008: LC ver 3.1 (2001) (Andriafidison *et al.*, 2008f; IUCN, 2009). 2003: DD [as *M. menavi*] (IUCN, 2003). 2001: DD [as *M. menavi*] (IUCN/SSC Action Plan, 2001). 2000: DD.

Regional
None known.

MAJOR THREATS:
There are no major threats to the species. In Makira, this species is eaten by people (Golden, 2005), but it is not known if this species is hunted

in other parts of its range. It is probably not forest dependent, but is rarely netted in areas without vegetation stands (Andriafidison *et al.*, 2008f; IUCN, 2009; Monadjem *et al.*, 2017cf).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008f) [in IUCN (2009)] and Monadjem *et al.* (2017cf) report that this species occurs in many of the forest protected areas in western and eastern Madagascar and as such does not require specific conservation measures. Additional information on its ecology would be helpful to better understand how it responds to deforestation and roost disturbance. There is some uncertainty about the taxonomy of *M. manavi* and that this taxon is actually a complex of new species (F. Ratromomanarivo *pers. comm.*). Further studies on morphology, acoustics and genetics are therefore needed.

GENERAL DISTRIBUTION:
Miniopterus manavi was originally reported from a wide area on Madagascar including the islands of Nosy Be and Nosy Komba (Rakotonandrasana and Goodman, 2007: 6), where it appeared to be widely distributed (Eger and Mitchell, 2003; Goodman *et al.*, 2005a) and occurreing over a wide elevational range, from 20 to 1,500 m above sea-level.

However, Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the eastern part of the island, but not along the coast (higher elevations of the Central Highlands - sub-humid region).

Due to the split off of several recently recognized species,.the above range has been restricted to the southern part of the Central Highlands, which also restricted the altitudinal range to between 900 and 1,500 m (Garbutt, 2022: 108).

Grand Comoro (Peterson *et al.*, 1995; Simmons, 2005: 520). Removed by Juste [B.] *et al.* (2007: 33), due to the removal of *griveaudi* as a separate species.

Native: Madagascar (Peterson *et al.*, 1995; Eger and Mitchell, 2003; Goodman *et al.*, 2005a; Simmons, 2005: 520; Rakotonandrasana and Goodman, 2007: 6).

ECHOLOCATION:
Russ *et al.* (2003) describe the echolocation as a frequency-modulated sweep that terminates in a constant-frequency portion with maximum energy around 57 kHz. Kofoky *et al.* (2009: 382) reported the calls as *M. manavi s.l.*, these calls were broadband FM/QCF sweeps produced at low duty cycle with most energy at about 58.1 kHz in the fundamental, with pulses having a short duration of about 4 ms. Low-duty cycle, frequency modulated/quasi constant (FM/QCF) echolocation call, with a peak frequency of 57.2 kHz (55.5 - 58.2 kHz) and a duration of 2.5 ms (2.1 - 3.0 ms) (Goodman *et al.*, 2011: 9).

Ramasindrazana *et al.* (2011: 294) recorded 9 calls from 2 specimens tentatively assigned to *Miniopterus 'manavi'*, and found the following echolocation call values: Frequency of maximum energy: 57.2 ± 0.77 (55.5 - 58.2) kHz, Maximum frequency: 98.4 ± 7.60 (89.0 - 110.0) kHz, Minimum frequency: 53.0 ± 0.0 (53.0 - 53.0) kHz, Call duration: 2.5 ± 0.32 (2.1 - 3.0) ms, Inter pulse interval: 66.0 ± 8.70 (54.1 - 84.7) ms.

HABITAT:
M. manavi is found In native forests, degraded forests and cultivated areas (rice paddies) (Garbutt, 2022: 108).

ROOST:
These bats roost in caves and large hollow trees (Garbutt, 2022: 108).

DIET:
Razakarivony *et al.* (2005) found Araneae in 2 % of stomachs examined. Rakotoarivelo *et al.* (2007), in Madagascar, found *M. manavi* to mainly consume Hemiptera.

Kemp *et al.* (2018: Suppl.) used DNA metacarcoding to detect insect pest species in the diet of these bats and found the following prey orders (in descending order): Lepidoptera (*Pandemis retroflua* Diakonoff, 1960), Hymenoptera, Coleoptera, Hemiptera, Blattodea, Diptera (*Simulium lineatum* (Meigen, 1804), *Anopheles squamosus* Theobald, 1901, *Coquillettidia* sp.), Ephemeroptera, Mesostigmata, Sarcoptiformes, Trombidiformes, Astigmata, Neuroptera.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 73 minutes, and the digestibility rate about 80.5 %.

POPULATION:
Structure and Density
It is locally abundant in cavities or rocky overhangs that provide suitable roosting features.

Bayliss and Hayes (1999) reported on a colony of approximately 4,000 found in Makira, but this locality is outside the currently accepted distribution area for this species.

Trend
2016: Unknown (Monadjem *et al.*, 2017cf). 2008: Unknown (Andriafidison *et al.*, 2008f; IUCN, 2009).

PARASITES:
Gomard *et al.* (2016: 5) reported the presence of *Leptospira* bacteria in 5 out of 7 tested bats (73.7 %).

Megali *et al.* (2010: 1042), Duval *et al.* (2012: 1563), and Arnuphapprasert *et al.* (2020: Suppl.) reported Genbank data for *Polychromophilus* sp. (*Haemosporida*) from *M. manavi*. Ramasindrazana *et al.* (2018: Suppl.) identified the parasite as *Polychromophilus melanipherus* Dionisi, 1899, and the bat as "*M. manavi* s.l." (see also Bajić *et al.*, 2023: Suppl.).

Raharimanga *et al.* (2003: 72) reported *Trypanosoma* sp. from *M. manavi*, but these bats were later re-identified as *M. mahafaliensis* and *M. brachytragos* (see Rasoanoro *et al.*, 2019: 67).

Uchikawa (1985b: 45) reported a mite belonging to *Calcarmyobia comoresensis* from the type specimen of *M. manavi*. From the same specimen, Uchikawa (1985c: 110) also reported mites belonging to *Pteracarus miniopteri* Uchikawa, 1978. Furtermore, he also described two mite subspecies: *Calcarmyobia steatosetae steatosetae* and *Calcarmyobia steatosetae rectipenis* from several other bat specimens.

The presence of the Nycteribiid bat fly *Penicillidia leptothrinax* was reported by Tortosa *et al.* (2013: 4), Ramasindrazana *et al.* (2017: Suppl.) and Urushadze *et al.* (2017: 10). Additionally, Ramasindrazana *et al.* (2017: Suppl.) reported both "*Penicillidia* sp. and *P. leptothrinax* from one and the same bat identified as "*Miniopterus* cf. *manavi*".

Ramasindrazana *et al.* (2016: 6) reported the presence of *Litosoma* Clade 1 (Nematoda: Onchocercidae) on this bat species.

VIRUSES:
Astroviridae
Hoarau *et al.* (2021: Suppl.) reported viruses of this family in organs of bats from Madagascar.

Picornaviridae
Zeghbib *et al.* (2019: Suppl.) refer to the presence of a Hepatovirus.

UTILISATION:
In Makira, this species is eaten by people (Golden, 2005), also see Goodman *et al.* (2008d).

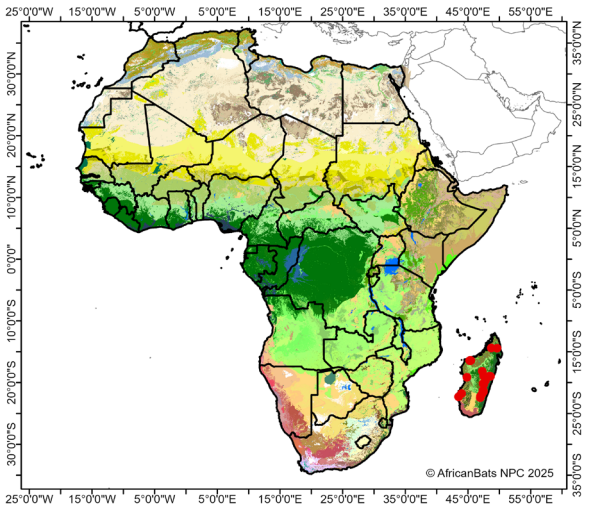

Figure 239. Distribution of *Miniopterus manavi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus minor Peters, 1867

*1867. *Miniopterus minor* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 870 (for 1866). Publication date: 1867. Type locality: Tanzania: Zanzibar Island. [Goto Description]. Holotype: ZMB 3268: ♂, skin and skull. Collected by: Baron Karl Klaus von der Decken. See Turni and Kock (2008: 52). - Comments: Peters (1867a: 885) mentions "Ein einziges ausgewachsenes Männchen von der Küste von Zanzibar". However, Benda *et al.* (2025: 32, 111-112 Footnote) suggest that the type locality is actually (the coast part of) Zanzibar Island itself. - Etymology: From the masculine Latin adjective *minor*, meaning "smaller", used as comparative of *parvus*, meaning "small", referring to the relatively small size of the species (see Lanza *et al.*, 2015: 334). (Current Combination).

1992. *Miniopterus minor occidentalis* Juste and Ibáñez, Bonn. zool. Beitr., 43 (3): 358, 362. Publication date: 21 October 1992. Type locality: Congo: Koilou, Meya-Nzouari Cave [03 53 S 14 31 E]. Holotype: MHNG 1074.013: ad ♀, skull and alcoholic. Collected by: M. Taufflieb; collection date: 1 July 1961. - Comments: (see Simmons, 2005). - Etymology: From the Latin for western. (Name Combination).

? *Miniopterus minor minor:* (Name Combination).

TAXONOMY:

Figure 240. *Miniopterus minor*, Zanzibar Island.

Koopman (1993a: 231) included *griveaudi* Harrison, 1959 and *manavi* Thomas, 1906, but Peterson *et al.* (1995: 119, 135) and Simmons (2005: 520) recognised *manavi* as a distinct species, with *griveaudi* as a subspecies. Juste [B.] *et al.* (2007: 33) elevated *griveaudi* as a separate species.

Simmons (2005: 521) recognised *newtoni* Bocage, 1889 and *occidentalis* Juste and Ibáñez, 1992 as vaild subspecies of *M. minor*. Juste [B.] *et al.* (2007: 33) elevated *newtoni* as a separate species.

Reviewed by Juste and Ibáñez (1992).

Morphometric analyses by Monadjem *et al.* (2020b: 12, 14) indicate that the specimens from Tanzania (*M. m. minor*) are clearly different from those from the Central African Republic and the Democratic Republic of the Congo (*M. m. occidentalis*) and possibly may represent different species. Although they do mention "*Miniopterus occidentalis*" throughout the text and in the appendix, they conclude that further investigation is needed to confirm its species status.

COMMON NAMES:

Chinese: 侏长翼蝠. Czech: létavec nejmenší. English: Least Long-fingered Bat. French: Petit minioptère africain, Minioptère minuscule. German: Zwerg-Langflügelfledermaus. Italian: Miniòttero minóre, Miniòptere minóre.

CONSERVATION STATUS:

Global Justification

Listed as Data Deficient (DD ver 3.1 (2001)) in view of continuing problems with its taxonomy as well as absence of recent information on its extent of occurrence, ecological requirements and threats (Jacobs *et al.*, 2008n; IUCN, 2009; Jacobs *et al.*, 2019j).

Assessment History

Global

2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019j). 2008: DD ver 3.1 (2001) [includes *occidentalis* Juste and Ibáñez, 1992] (Jacobs *et al.*, 2008n; IUCN, 2009). 2004: NT ver 3.1 (2001) (Jacobs *et al.*, 2004o; IUCN, 2004). 2003: LR/nt (IUCN, 2003). 2001: LR/nt (IUCN/SSC Action Plan, 2001). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional

None known.

MAJOR THREATS:

This species is presumably threatened in parts of its range by habitat loss resulting from logging operations and the conversion of land to agricultural use (Jacobs *et al.*, 2008n; IUCN, 2009; Jacobs *et al.*, 2019j).

CONSERVATION ACTIONS:

Jacobs *et al.* (2008n) [in IUCN (2009)] and Jacobs *et al.* (2019j) report that there appear to be no direct conservation measures in place. It has been recorded from the Kambai Forest Reserve in Tanzania by Cunneyworth (1996b). Further studies are needed into the taxonomy, distribution, natural history and threats to this poorly known species.

GENERAL DISTRIBUTION:

Miniopterus minor recorded from very few locations over a wide area. It has been reported from a small area on the border between Congo and the Democratic Republic of the Congo, a single locality in southwestern Democratic Republic of the Congo, and from a small area of coastal Kenya and Tanzania (including the island of Unguja [see O'Brien, 2011: 289]).

São Tomé (Koopman, 1993a: 231; Simmons, 2005: 521) removed by Juste [B.] *et al.* (2007: 33) due to the removal of *newtoni* as a separate species.

Native: Angola; Congo (Juste and Ibáñez, 1992: 363; Simmons, 2005: 521; Bates *et al.*, 2013: 337); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Juste and Ibáñez, 1992: 363; Van Cakenberghe *et al.*, 1999; Simmons, 2005: 521; Monadjem *et al.*, 2010d: 539); Kenya (Simmons, 2005: 521); Tanzania (Simmons, 2005: 521).

ECHOLOCATION:

For two caves in the Republic of Congo, Labadie *et al.* (2025b: 11) provided the following data for *Miniopterus* cf. *minor*: Boundou cave: 5 FF: F_{pmin}: 53.2 ± 1 kHz, F_{pmax}: 76.2 ± 6.7 kHz, F_{pmean}: 67.9 ±

5.8 kHz, F_{ppeak}: 64.8 ± 6 kHz, F_{max}: 107 ± 12.9 kHz, F_{flat}: 60 ± 3.2 kHz, F_{knee}: 64.4 ± 5.7 kHz, F_{min}: 58 ± 3.1 kHz, F_{mean}: 75 ± 6 kHz, Duration: 2.4 ± 0.4 ms; 10 MM: F_{pmin}: 52.5 ± 2.1 kHz, F_{pmax}: 78.1 ± 5 kHz, F_{pmean}: 68.9 ± 4.9 kHz, F_{ppeak}: 68.7 ± 13.1 kHz, F_{max}: 97.9 ± 21.9 kHz, F_{flat}: 60.3 ± 6.9 kHz, F_{knee}: 58.5 ± 21.5 kHz, F_{min}: 57.2 ± 2.7 kHz, F_{mean}: 73 ± 7.3 kHz, Duration: 2.9 ± 0.8 ms. Mont Belo cave: 10 FF: F_{pmin}: 46 ± 3.8 kHz, F_{pmax}: 71.1 ± 11.9 kHz, F_{pmean}: 62.7 ± 8.8 kHz, F_{ppeak}: 56.7 ± 5 kHz, F_{max}: 93 ± 15.1 kHz, F_{flat}: 55 ± 6.5 kHz, F_{knee}: 61.3 ± 8 kHz, F_{min}: 51.7 ± 4.6 kHz, F_{mean}: 66 ± 9 kHz, Duration: 2.8 ± 0.8 ms; 8 MM: F_{pmin}: 47.3 ± 3.2 kHz, F_{pmax}: 72.9 ± 7.6 kHz, F_{pmean}: 66.8 ± 7.3 kHz, F_{ppeak}: 61.1 ± 4 kHz, F_{max}: 96.4 ± 20.3 kHz, F_{flat}: 59 ± 6.6 kHz, F_{knee}: 68.6 ± 19.3 kHz, F_{min}: 55.3 ± 3.9 kHz, F_{mean}: 69.7 ± 8.7 kHz, Duration: 2.6 ± 0.5 ms.

ROOST:
McWilliam (1982: 176) found this bat to be roosting in caves.

MIGRATION:
In Kenya, McWilliam (1982: 175) found that most long-distance movements were made by females, whereas males showed a larger site specificity.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 73 minutes, and the digestibility rate about 80.5 %.

POPULATION:
Structure and Density
There are very few records of this species (Jacobs *et al.*, 2008n; IUCN, 2009; Jacobs *et al.*, 2019j).

Trend
2018: Unknown (Jacobs *et al.*, 2019j). 2008: Unknown (Jacobs *et al.*, 2008n; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
In Kenya, *M. minor* exhibits seasonal torpor between April and September, when the temperatures are lower (McWilliam, 1982: 184).

MATING:
McWilliam (1982: 176, 177) described a small "mating dome" within the Homa Lime cave in Kenya, which was almost exclusively occupied by mature males, which returned the following years. Immature males were excluded from the dome. During the mating period (May to July), the males produced a pungent odour (resembling rotting cocoa) in their urine (McWilliam, 1982: 181).

PARASITES:
Uchikawa (1985b: 50) described the mite *Calcarmyobia minoris* from *Miniopterus minor minor* from Similani Cave, 16 km S. of Mombasa, Coast Province, Kenya. Uchikawa (1985c: 110) also reported three female mites belonging to *Pteracarus miniopteri* Uchikawa, 1978 from bats from Kenya.

Adam and Landau (1973a: 5) and Landau and Adam (1973: 6) report on the presence of a protozoan parasite of the genus *Polychromophilus* (Haemoproteidae) in *M. minor minor* from the Republic of Congo. About 50 % of the specimens they examined, were found to be infected. Gametocytes were found year-round. The bats were also infested by the nycteribiids *Penicillidia fulvida* Bigot, 1885 and *Nycteribia schmidlii scotti* Falcoz, 1923, of which the prior was a major carrier of *Polychromophilus* sporozoites. Garnham (1973: 237) reports the parasite as *Polychromophilus melanipherus* Dinoisi, 1899 (see also Bajić *et al.*, 2023: Suppl.).

Polychromophilus sp. was also reported by Rosskopf *et al.* (2018: 31) from Gabonese *M. minor occidentalis*, where both examined specimens were infected.

Landau and Adam (1973: 6) also report on another protozoan parasite: *Hepatocystis*, of which schizonts were found in the liver and lungs.

Duval *et al.* (2012: 1559) and Landau *et al.* (2012: 142) indicate that the haemosporidan *Polychromophilus (Polychromophilus) adami* Landau *et al.*, 1980 was described from *M. minor minor* specimens in the Republic of Congo (see Landau *et al.*, 1980b: 27). Landau *et al.* (2012: 142) also mention this bat as the type host for *Bioccala murinus* (Dionisi, 1899).

Lutz *et al.* (2016: 9) examined 13 *M. minor* specimens from East Africa and found five of them infected with *Polychromophilus melanipherus* Dionisi, 1899.

11 out of 17 Kenyan bats examined by Lutz *et al.* (2021: Suppl.) were infected by *Polychromophilus* Haemosporidia.

BACTERIA
Bartonellae
McKee *et al.* (2021: Suppl.) reported *Bartonella* sp. from Kenyan bats.

ARACHNIDA
Spinturnicidae
Orlova *et al.* (2024: 153) mention this species as host for *Spinturnix semilunaris* de Meillon & Lavoipierre, 1944.

DIPTERA
Nycteribiidae
Nycteribia schmidlii Schiner, 1853 (Haeselbarth *et al.*, 1966: 108; Lutz *et al.*, 2021: Suppl.).

Lutz *et al.* (2021: Suppl.) also found *Penicillidia fulvida* (Bigot, 1885).

Dick *et al.* (2023) mentioned the following nycteribiid flies have been found on *Miniopterus minor*: *Eucampsipoda africana* Theodor, 1955, *Nycteribia schmidlii scotti* Falcoz, 1923 and *Penicillidia (Penicillidia) fulvida* (Bigot, 1885), but they also mention that *E. africana* might be an erroneous record.

VIRUSES:
In their country-wide survey of Kenyan bats, Waruhiu *et al.* (2017) found the following viruses in *Miniopterus minor*: Astroviruses, Coronaviruses, Paramyxoviruses and Polyomaviruses.

Coronaviridae - Coronaviruses
SARS-CoV
Tong *et al.* (2009) tested 1 bat collected in Kenya during 2006 positive for the presence of coronavirus RNA in a faecal sample. 22.6 % (66 out of 292) of the Kenyan bats tested by Tao *et al.* (2017: 3) were positive for CoV.

Paramyxoviridae
Paramyxovirus
Conrardy *et al.* (2014: 259) tested 16 bats from the Three Caves (Kenya) and found one of them to be positive. Mortlock *et al.* (2015: 1841) tested 151 Kenyan bats and found 14 to be positive.

Nieto-Rabiela *et al.* (2019: Suppl.) mention Bat paramyxovirus and Miniopterus paramyxovirus to be present.

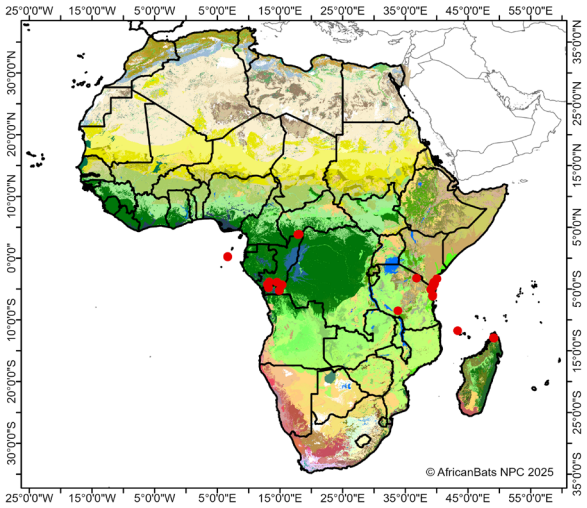

Figure 241. Distribution of *Miniopterus minor*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Central African Republic, Comoros, Congo, Congo (Democratic Republic of the), Kenya, Madagascar, São Tomé and Príncipe, Tanzania.

Miniopterus mossambicus Monadjem, Goodman, Stanley and Appleton, 2013

*2013. *Miniopterus mossambicus* Monadjem, Goodman, Stanley and Appleton, Zootaxa, 3746 (1): 123, 129, figs 3, 6, 7. Publication date: 10 December 2013. Type locality: Mozambique: Nampula province: outskirts of Nampula town: Bamboo Inn [15.10306 S 39.21748 E, 420 m]. Holotype: FMNH 213651: ad ♂, skull and alcoholic. Collected by: Steven M. Goodman and Ara Monadjem; collection date: 9 October 2010; original number: SMG-16875. Paratype: FMNH 213652: ad ♂, alcoholic (skull not removed). Collected by: Steven M. Goodman and Ara Monadjem; collection date: 9 October 2010; original number: SMG-16876. - Etymology: Refers to the country from which the species was collected (see Monadjem *et al.*, 2013a: 129). (Current Combination).

COMMON NAMES:
Chinese: 莫桑比克长翼蝠. English: Mozambique long-fingered bat. German: Mossambique-Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Native: Kenya (López-Baucells *et al.*, 2017: 20); Malawi; Mozambique; Zambia; Zimbabwe.

ECHOLOCATION:
Monadjem *et al.* (2013a: 139) mention a knee frequency of 55 kHz.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

REPRODUCTION AND ONTOGENY:
In a colony of about 2,000 bats at Bwarenunka Cave near Chisakila (Zambia), Benda *et al.* (2022: 322) found that all examined females were lactating on 1 December.

PARASITES:
BACTERIA
Dietrich *et al.* (2018a: 4) report the presence of *Leptospira borgpetersenii*.

DIPTERA
Streblidae
Raymondia aspera Maa, 1968 from Mozambique (Shapiro *et al.*, 2016: 254).

VIRUSES:
Astroviridae
Two out of 21 bats tested positive in the study by Hoarau *et al.* (2018: 2).

Coronaviridae
Hoarau *et al.* (2021: Suppl.) reported such viruses to be present in these bats.

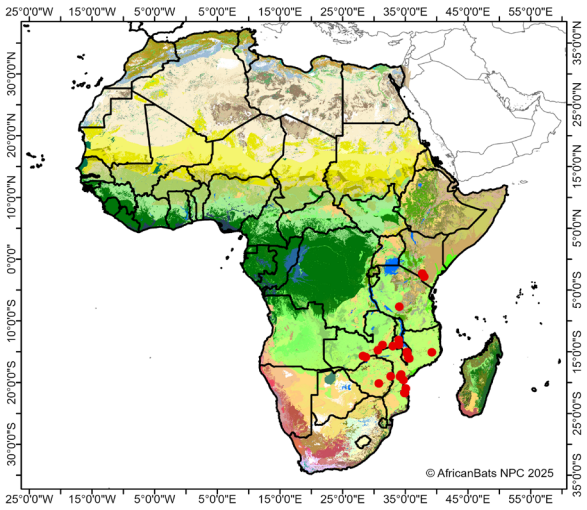

Figure 242. Distribution of *Miniopterus mossambicus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya, Malawi, Mozambique, Tanzania, Zambia, Zimbabwe.

Miniopterus natalensis (A. Smith, 1833)

*1833. *Vespertilio Natalensis* A. Smith, S. Afr. Quart. J., ser 2, 1 (2): 59. Publication date: November 1833. Type locality: South Africa: KwaZulu-Natal: Durban [29 52 S 31 00 E]. [Goto Description]. Syntype: NHMUK 1846.6.2.19. Shared cotype for *Vespertilio natalensis* and *Vespertilio scotinus* - this needs further investigation as it is unlikely that Sundeval examined material described by Andrew Smith. It is possible that this co-type should only be assigned to one of these species. Cotype: NHMUK 1848.6.12.19. - Comments: Concerning the type locality, Meester *et al.* (1986: 46) remark: "Durban nominated by Roberts (1951: 73)").

1840. *Vespertilio d'asythrix* Temminck, Monographies de mammalogie ou description de quelques genres de mammifères, dont les espèces ont été observées dans les différens musées de l'Europe. Tome Seconde, 2 (13): 268. Publication date: 1840. Type locality: South Africa: "Interior of Caffraria". [Goto Description]. Holotype: RMNH MAM.25093: ad, skin and skull. Collected by: Jean Baptiste Edouard Verreaux. The RMNH catalog mentions two numbers: 25093.a (skull + loose bones) and 25093.b (skin). - Comments: .

*1846. *Vesperugo scotinus* Sundevall, Öfvers. kongl. Sv. Vet.-Akad. Förhandl., 3 (4): 119. Publication date: 1846. Type locality: South Africa: KwaZulu-Natal: Durban [29 52 S 31 00 E]. [Goto Description]. Syntype: NHMUK 1846.6.2.19. Shared cotype for *Vespertilio natalensis* and *Vespertilio scotinus* - this needs further investigation as it is unlikely that Sundeval examined material described by Andrew Smith. It is possible that this co-type should only be assigned to one of these species. Syntype: NRM 631071:; collection date: 28 November 1843. Syntype: NRM 641070:; collection date: 28 June 1840. - Comments: Type locality originally mentioned as "variis Caffrariæ locis allata"; Meester *et al.* (1986: 46) state: "Durban nominated by Roberts (1951: 74)". .

1909. *Miniopterus breyeri* Jameson, Ann. Mag. nat. Hist., ser 8, 4 (23): 471. Publication date: 1 November 1909. Type locality: South Africa: N Transvaal province: Waterberg district: Gat(s)koppies. [Goto Description]. Holotype: NHMUK 1909.7.2.6: imm ♀. Collected by: Henry Paul William Lyster Jameson; original number: 398.

1927. *Miniopterus smitianus* Thomas, Proc. zool. Soc. Lond., 373. Publication date: 12 July 1927. Type locality: Namibia: E Damaraland, 40 mi (64 km) W of Gobabis: Witvlei. Holotype: NHMUK 1926.12.7.15.

2014. *Miniopterus 'natalensis':* Christidis, Goodman, Naughton and Appleton, PLoS ONE, 9 (3) e92440: Suppl. Publication date: 18 March 2014.

2018. *Miniopteris schriebersii:* Adams and Kwiecinski, Diversity, 10 (3) 103: 7. Publication date: 18 September 2018. (Lapsus).

2020. *Miniopterus cf. natalensis:* Monadjem, Guyton, Naskrecki, Richards, Kropff and Dalton, Acta Chiropt., 22 (1): 3. Publication date: 3 September 2020. (Name Combination).

2021. *Miniopterus nataliensis:* Hayward and Tachedjian, mBio, 12 (5) e0194-21: 3. Publication date: 7 September 2021. (Lapsus).

? *Miniopterus schreibersii natalensis A:*
? *Miniopterus schreibersii natalensis B:*
? *Miniopterus schreibersii natalensis:* (Name Combination).
? *Miniopterus schreibersii:*
? *Vespertilio scotinus:*

TAXONOMY:

Figure 243. *Miniopterus natalensis*.

Considered a synonym of *schreibersi* by Koopman (1993a: 231). O'Shea and Vaughan (1980), Koopman (1994), Peterson *et al.* (1995) and Horáček *et al.* (2006: 105) suggested that *natalensis* may be distinct from *schreibersi*. Considered a valid species by Simmons (2005: 521).

Simmons (2005: 521) recognised *arenarius* Heller, 1912 as valid subspecies. However, see Kruskop *et al.* (2014: 102), Kassahun *et al.* (2015: 168), Farkašová *et al.* (2017: Suppl.), Wilson and Mittermeier (2019: 704) and Monadjem *et al.* (2020e: 242, 255), who consider this to be a valid species.

Based on mitochondrial data, Demos *et al.* (2019c: "9") indicate that *natalensis* is sister to all of the other African and Madagascan forms, although this was not confirmed by the nuclear data.

COMMON NAMES:

Chinese: 纳塔尔长翼蝠. Czech: létavec natalský. English: Natal Long-fingered Bat, Natal Clinging Bat. French: Minioptère du Natal. German: Natal-Langflügelfledermaus, Südafrikanischen Sackfledermaus, Kaffern-Sackfledermaus. SiSwati: Lilulwane.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

This species is present in the latter half of the upper Pleistocene sequence and in the late Holocene at Border Cave, and probably at Nkupe during the middle and late Holocene (Avery, 1991: 6). Further Holocene material is reported by Avery and Avery (2011: 20) from Blinkklipkop, Limerock, and Zoovoorbij (Northern Cape province, South Africa), who also reported Pleistocene remains from Wonderwerk.

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008aj; IUCN, 2009; Monadjem *et al.*, 2017bg).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bg). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008aj; IUCN, 2009). 2004: NT ver 3.1 (2001) (Jacobs *et al.*, 2004ai; IUCN, 2004).

Regional

South Africa: 2016: LC ver 3.1 (2001) (MacEwan *et al.*, 2016b). 2004: NT ver 3.1 (2001) [assessed as *M. schreibersii*] (Friedmann and Daly, 2004:263).

Eswatini:- 2003: NT B2ab(iv); D2 ver 3.1 (2001) [assessed as *M. schreibersii*] (Monadjem *et al.*, 2003: 184).

MAJOR THREATS:

In view of its wide range, there appear to be no major threats to this species. In parts of the species distribution it is locally threatened by habitat loss resulting from conversion of land to agricultural use, incidental poisoning with insecticides, and the disturbance of roosting and maternity caves by tourist activities (Jacobs *et al.*, 2008aj; IUCN, 2009; Monadjem *et al.*, 2017bg).

Aronson (2022: 225) found this species to be the third most impacted species, with 5 % of the carcasses found near South African wind energy facilities.

CONSERVATION ACTIONS:
Jacobs *et al.* (2008aj) [in IUCN (2009)] and Monadjem *et al.* (2017bg) report that there appear to be no conservation measures in place for this species. There is a need to identify and protect important roost sites (especially maternity caves). In view of the species wide range, it is presumably present in some protected areas. There is a need to better determine the range of this species when compared to that of *Miniopterus schreibersii*.

GENERAL DISTRIBUTION:
Miniopterus natalensis is a widely distributed species, recorded from southern and East Africa, with some records from Central Africa. It ranges south from Angola and southern Democratic Republic of the Congo, into Namibia, Botswana, South Africa, Lesotho, Mozambique, Malawi, Zimbabwe and Zambia. Because of frequent misidentification between this species and *Miniopterus schreibersii*, there is a need to carefully review the distribution of *Miniopterus natalensis*.

Records from the Arabian Peninsula, Ethiopia, South Sudan and Uganda are currently assigned to *Miniopterus arenarius* (see Monadjem *et al.*, 2020e: 239; Ibáñez and Juste, 2019: 704). We also tentatively include the records from Kenya and Tanzania to this species.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,227,870 km^2. In the RSA, its distribution is best predicted by geology (Babiker Salata, 2012: 50).

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 539; Taylor *et al.*, 2018b: 62); Botswana (Smithers, 1971; Monadjem *et al.*, 2010d: 539); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 539); Eswatini (Monadjem *et al.*, 2010d: 540, Monadjem *et al.*, 2021: 5); Kenya?; Lesotho (Lynch, 1994: 191 [as "*M. schreibersii*"]; Monadjem *et al.*, 2010d: 539); Malawi (Happold *et al.*, 1988; Ansell and Dowsett, 1988: 35; Monadjem *et al.*, 2010d: 539); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 539; Monadjem *et al.*, 2010c: 385); Namibia (Monadjem *et al.*, 2010d: 340); South Africa (Simmons, 2005: 521, Seamark and Kearney, 2007: 4; Monadjem *et al.*, 2010d: 540); Tanzania? (Stanley and Goodman, 2011: 47 as *M. schreibersii*); Zambia (Ansell, 1974; Ansell, 1978; Monadjem *et al.*, 2010d: 540); Zimbabwe (Monadjem *et al.*, 2010d: 540).

Presence uncertain: Uganda, Kenya, Tanzania.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Schoeman and Jacobs (2002: 157) reported the following wing parameters for one "*M. schreibersii*" specimen from the Algeria Forestry Station (RSA): Fa: 46.6 mm, Wing area: 137.7 cm^2, Wing span: 30.9 cm, Wing loading: 7.8 N/m^2, and aspect ratio: 6.9.

DENTAL FORMULA:
The permanent dental formula is as follows: $I^2/_3$ $C^1/_1$ $PM^2/_3$ $M^3/_3$ = 36 (van der Merwe, 1985a: 73).

van der Merwe (1985a: 73) also indicates that the deciduous tooth replacement starts in the lower jaw and is completed prior to that of the upper jaw. The replacement starts at an age of one and a half weeks. In general, the replacement sequence is: I_3, I_1, C_1, I_2, PM_4, PM_3, and all teeth are replaced at week 5. In the upper jaw, the replacement starts two and a half weeks (PM^4, PM^3, I^2, I^3, C^1) and is generally completed in week 6.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
Camacho *et al.* (2019: "5") describe the facial profile of *M. natalensis* as convex ("airorhynchy"), with an extreme upward orientation in its snout.

FUNCTIONAL MORPHOLOGY:
Moussy *et al.* (2012: 189), referring to Miller-Butterworth *et al.* (2003), indicate that isolation of different populations in South Africa has led to local adaptation in *Miniopterus schreibersii natalensis*, which is strongly associated with four biomes and results in differences in wing morphology and migratory behaviour. The animals from the northeastern population have a higher wing aspect ratio, which forms an advantage for long-distance flight, allowing for migrations over longer distances.

Brown (1999: 170) found that "*M. schreibersii*" is able to thermoregulate in temperatures between 5 and 40°C.

Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 7.8 Pa, aspect ratio 6.4 for a wingspan of 31 cm and a wing area of 146 cm^2 and a body mass of 12 g.

ECHOLOCATION:
See Jacobs (1999) and Taylor (1999b).

Schoeman and Waddington (2011: 291) mention a F_{peak}: 51.1 ± 0.9 kHz and a duration: 6.8 ± 0.4 ms for specimens from Durban, South Africa.

For *Miniopterus natalensis* specimens from Swaziland and Namibia, Taylor *et al.* (2013b: 17) recorded the following parameters for 21 calls: F_{max}: 65.9 ± 5.76 (59.0 - 80.9) kHz, F_{min}: 53.7 ± 0.58 (52.5 - 54.9) kHz, F_{knee}: 56.5 ± 0.31 (55.7 - 57.0) kHz, F_{char}: 54.1 ± 0.78 (52.7 - 55.5) kHz, duration: 2.6 ± 0.48 (1.9 - 3.8) ms. Values for a further 11 specimens from Swaziland were reported by Monadjem *et al.* (2017c: 179): F_{min}: 53.2 ± 0.87 (51.3 - 54.8) kHz, F_{knee}: 57.0 ± 0.96 (55.5 - 58.5) kHz, F_c: 53.6 ± 0.83 (51.6, 55.0) kHz and duration: 2.8 ± 0.37(2.2 - 3.7) ms. They also indicated that the maximum detection distance for this species is 5 m.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 56 (56 - 57) kHz.

Schoeman and Jacobs (2002: 157) reported a F_{peak} of 53.6 kHz for one "*M. schreibersii*" from the Algeria Forestry Station (RSA). Linden *et al.* (2014: 40) reported the following parameters from the Soutpansberg area (RSA): F_{min}: 52 - 55 kHz, F_{char}: 45 - 62 kHz, F_{knee}: 56 - 57 kHz, slope: 235 - 622 OPS, duration: 2 - 4 ms.

In the Mapungubwe National Park (RSA), Parker and Bernard (2018: 57) recorded 15 calls with F_{char}: 49.91 ± 0.95 kHz, F_{max}: 67.84 ± 4.75 kHz, F_{min}: 49.39 ± 0.88 kHz, F_{knee}: 53.61 ± 2.27 kHz, duration: 4.96 ± 1.31 ms and 7.30 ± 2.65 calls/sec.

Moir (2020: 29) a,d Moir *et al.* (2021a: 371) registered 373 calls of 20 bats from southern KwaZulu-Natal and Eastern Cape: F_{max}: 71.72 ± 5.90 (62.55 - 85.55) kHz, F_{min}: 48.28 ± 1.65 (45.99 - 53.83) kHz, F_{char}: 50.37 ± 2.14 (47.26 - 53.25) kHz, F_{knee}: 52.79 ± 2.71 (49.07 - 61.60) kHz, and duration: 2.19 ± 0.49 (1.46 - 3.48) ms.

Eisenring *et al.* (2016: SI 2) reported for 17 calls of bats from the Aberdares Range in Kenya the follow values: F_{peak}: 44.1 ± 3.5 (41.5 - 54.8) kHz, F_{max}: 66.6 ± 17.7 (51.3 - 104.4) kHz, F_{min}: 40.4 ± 1.5 (38.5 - 44.0) kHz, DT: 0.1 ± 0.0 (0.1 - 0.1), duration: 26.1 ± 17.5 (12.5 - 63.9) ms, interpulse interval: 1.0 ± 0.5 (0.5 - 2.5) ms.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 27.90 ± 2.50 kHz, F_{max}: 33.20 ± 8.00 kHz, F_{min}: 25.70 ± 2.20 kHz.

10 calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 58.77 ± 2.45 kHz, F_{min}: 55.48 ± 1.10 kHz, F_{knee}: 57.07 ± 1.50 kHz, F_{char}: 55.90 ± 1.29 kHz, slope: 13.28 ± 20.65 OPS, duration: 3.92 ± 1.48 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 8) reported the following characteristics for 96 calls of 11 bats: F_{max}: 61.46 ± 7.55 kHz, F_{min}: 52.27 ± 5.9 kHz, F_{knee}: 55.55 ± 0.81 kHz, F_{char}: 54.08 ± 0.98 kHz, slope: -508.55 ± 3897.77 OPS, duration: 4.08 ± 1.61 ms. Three calls recorded at the Venatia mine by Cory-Toussaint and Taylor (2022: Tabls S1) had a duration: 3.91 ± 0.66 ms, F_{min}: 48.76 ± 0.31 kHz, F_{max}: 65.05 ± 11.73 kHz, F: 50.90 ± 0.74 kHz and F_{char}: 48.95 ± 0.24 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 23 *Miniopterus natalensis* calls from the Kruger Park (RSA): F_{min}: 50.5 ± 2.6 (46.6 - 54.2) kHz, duration: 3.2 ± 0.7 (2.4 - 4.6) ms, F_{max}: 65.8 ± 8.3 (51.5 - 85.9) kHz, F_{knee}: 53.8 ± 3.6 (48.5 - 60.3) kHz, F_{char}: 51.9 ± 2.9 (47.8 - 57.0) kHz.

28 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 52 - 55 kHz, F_{max}: 59 - 80 kHz, F_{char}: 53 - 56 kHz, F_{knee}: 56 - 57 kHz and duration 2 - 4 ms.

For 16 calls from 2 *Miniopterus natalensis* bats from Telperion Nature Reserve (RSA), De Jong *et al.* (2025: 322) reported the following parameters: F_{char}: 53.57 ± 0.50 kHz, F_{knee}: 58.78 ± 2.05 kHz, F_{min}: 53.26 ± 0.81 kHz, F_{max}: 73.89 ± 11.90 kHz, Bandwidth: 20.63 ± 11.92 kHz, Duration: 2.41 ± 0.27 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 49.91 ± 0.95 kHz, F_{max}: 67.84 ± 4.75 kHz and F_{min}: 49.39 ± 0.88 kHz.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 51.4 kHz and duration: 3.4 ms.

Molecular Biology:

Karyotype

M. schreibersii from Namibia and South Africa now assigned to *M. natalensis*, were karyotyped by Rautenbach *et al.* (1993) who described the karyotype as having a diploid number of 2*n* = 46, aFN = 50, BA = 6, X = SM, Y = A.

Genetics

Teeling *et al.* (2017: 32) mention the assembly size for *M. natalensis* to be 1.80 Gb.

Banerjee *et al.* (2017: 10) detected potential c-Rel binding sites in *M. natalensis*. This protein has a

potential role in the DNA repair pathway as a regulator of inflammatory gene expression.

Shao *et al.* (2023: 3) investigated the genome of *M. natalensis* and found the 15 most diverse microsatellite motifs in this species to be $(A)_n$, $(CT)_n$, $(AC)_n$, $(TA)_n$, $(G)_n$, $(TAT)_n$, $(TTTA)_n$, $(ATAG)_n$, $(CATT)_n$, $(CCTT)_n$, $(CAA)_n$, $(TGGA)_n$, $(AACAA)_n$, $(AAAC)_n$ and $(TTATT)_n$ comprising of 94.10 % of all microsatellites identified.

Wang *et al.* (2025b: 6) report that the total length of the genome is 1.9 Gb.

Isotope
Pretorius *et al.* (2022: 802) found that male *M. natalensis* had a broader isotopic niche (in both $\delta^{13}C$ and $\delta^{15}N$ ranges). This may indicated different migration strategies to that of females or feeding on prey from a broader geographic origin.

HABITAT:
Sirami *et al.* (2013: 34) recorded in the Western Cape Province, South Africa that *M. natalensis* activity was not significantly, nor positively influenced by size of wetland, while habitats 100 m surrounding wetlands were also significantly and positively influenced by the water body. *M. natalensis* preferred trees and orchards surrounding wetlands (Sirami *et al.*, 2013: 35).

Voigt *et al.* (2013: 751) investigated stable isotope ratios of carbon, nitrogen and hydrogen in the fur keratin of *M. natalensis* on the slopes of Mount Kilimanjaro and found that this species migrates seasonally between low and high elevations. They found that *M. natalensis* captured before and after the cold period at around 1,800 m above sea level originated from around 1,400 m a.s.l. or lower, which they suggest might be the result of a search for colder hibernacula at higher elevations.

HABITS:
van der Merwe (1973b: 380) indicates that in the Transvaal *M. natalensis* forms hibernating (winter) and maternity (summer) colonies, and he reports on maternity caves housing 50,000 to 100,000 animals. The bats usually form closely packed clusters, hanging from the roofs of caves, although some might be hanging against the walls. Hibernation started at the beginning of May and lasted until the end of July.

At De Hoop Nature Reserve (Western Cape Province, South Africa), Thomas and Jacobs (2013: 124) found that *M. natalensis* emerged significantly later during early summer than in late summer. Norton and van der Merwe (1978: 219) already found that juveniles returned later in the night than adults, probably because they needed more food as their fat reserves would be insufficient to get them over the winter.

At Madimatle cave (RSA), Pretorius *et al.* (2020b: 409) found that the magnitude of activity of *Miniopterus natalensis* is primarily affected by photoperiod rather than by climatic variables (including rainfall). Their activity increased as the night length decreased. Pretorius *et al.* (2020c: 755) found that the time of moonrise did not affect the activity of these bats. Moonlight did not affect the bat's activity during the maternity season, but bright moonlight during the non-breeding season did reduce the activity.

ROOST:
van der Merwe (1973b: 380) reports "*M. schreibersi natalensis*" to occur in colonies of hundreds or thousands of animals occupying a wide range of caves. At Peppercorn's cave and at Sandspruit Cave No. 1 clusters of 50,000 and 100,000 individuals were reported.

van der Merwe (1973a: 133) found that the bats preferred caves with lower temperature for hibernation. Norton and van der Merwe (1978: 220) also found that temperatures in the Long One Cave were probably too high and variable for prolonged hibernation, which resulted in fluctuating numbers of bats. By the end of the winter, however, temperatures decreased and the proportion of *M. natalensis* bats staying in the cave increased.

Bernard and Bester (1988: 921) describe the annual movements of "*M. schreibersi*" between three roosts in the Eastern Cape region (RSA). The maternity roost was warmer than the hibernation site. One of the sites was used as maternity and hibernaculum, but as these functions were at different times of the year, the temperatures were also different. The higher temperature at the maternity roost might increase prenatal and postnatal development rates.

Brown (1999: 171) reported the mean temperature in tunnel roosts is on average 19.5°C in summer (max: 22°C) and 14°C in winter. Czenze *et al.* (2021: 3) confirmed that these bats roost in sites where the maximum temperature is much lower than 30* C and where the maximum temperature was at least 10*C lower than outside.

MIGRATION:
Pretorius *et al.* (2020a: 1110) investigated potential migratory least-cost paths (LCPs) between maternity sites and winter hibernacula in South Africa. Most of the involved caves were

not located in formal protected areas, and the most prominent threat factors were onshore wind energy facilities and human settlements.

Markotter *et al.* (2023: 200) report on a wing-tattooed *M. natalensis* bat that was recaptured 200 km away from the site where it was originally marked.

DIET:
At the Umbilo River (KwaZulu Natal, RSA), Naidoo *et al.* (2011: 26) found the following percentage volume diet composition: Lepidoptera (35.7 ± 10.3), Coleoptera (11 ± 9.1), Hemiptera (28.3 ± 12.9), and Trichoptera (25.0 ± 13.9). No data were provided for the winter.

Schoeman and Jacobs (2002: 157) reported the following volume percentages found in 20 faecal pellets from one "*M. schreibersii*" from the Algeria Forestry Station (RSA): Diptera (49), Hemiptera (33), Lepidoptera (6), Coleoptera (6), and Trichoptera (6).

For 21 "*M. schreibersii*" specimens from Sudwala (RSA), Jacobs (2000: 201) reported the following prey proportions: Lepidoptera (23.1 ± 31.2), Coleoptera (4.5 ± 16.7), Isoptera (70.8 ± 32.2), Diptera (0.6 ± 2.3), Hemiptera (0.6 ± 2.3), and Mantodea (0.4 ± 0.3).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 90 minutes, and the digestibility rate about 78.3 %.

PREDATORS:
Avery *et al.* (2005: 1054) found this species (reported as *M. schreibersii*) to be present in pellets from *Tyto alba* (Scopoli, 1769) in South Africa. van der Merwe (1980a: 15) already reported the barn owl as a predator, but indicated that these bats do not rank high on its diet, although there was an increase when other terrestrial and subterrestrial preys are decreasing in availability. Swartz *et al.* (2025: 1) confirmed that the owl's selection of these bats was more determined by prey abundance than by preference.

Malan *et al.* (2022: 167) reported one individual found in a pellet from a bat hawk (*Macheiramphus alcinus* Bonaparte, 1850 in the RSA.

POPULATION:
Structure and Density
This species can be found in colonies of more than 2,500 animals (Jacobs *et al.*, 2008aj; IUCN, 2009; Monadjem *et al.*, 2017bg). Mason *et al.* (2010: 165) observed that the number of bats in the De Hoop maternity chamber increased from a few hundred to several thousand from 18th August to the 25 September 2006.

Trend
2016: Unknown (Monadjem *et al.*, 2017bg).
2008: Unknown (Jacobs *et al.*, 2008aj; IUCN, 2009).

LIFESPAN:
Based on mark-recapture techniques, van der Merwe (1989b: 87) determined the maximum life expectancy for this species in the wild to be 13 years.

REPRODUCTION AND ONTOGENY:
Delayed implantation, insemination, ovulation and fertilization occur in the autumn (April to May in South Africa, see Bernard *et al.* (1991: 31), as *M. schreibersii*). Embryogenesis proceeds to the blastocyst stage and development is then retarded until arousal in spring, when the blastocyst implants and embryogenisis resumes (van der Merwe, 1980b). van der Merwe (1982b: 319) also mentions that implantation is centric and superficial in the right uterine horn, as was already noticed by Ginther (1967: 580) and van der Merwe (1996: 154), who also indicated [referring to Matthews (1941)], that the implantation occurs in the uterine horn opposite to the ovary containing the corpus luteum. van der Merwe (1979a: 17) and Bernard (1980a: 55) indicated that the delayed implantation period for "*M. schreibersi natalensis*" lasted for four months (120 days), which is as long as the active foetal growth period, giving a gestation period of 240 days. van der Merwe (1981: 172) presented the following formula to calculate the embryo's age in days (t) based on its body mass (W): $t = W^{1/3}/0.0145 + 144$.

Bernard and Davison (1996: 218) investigated the relation between calcium availability (from the poor source that insects are) and the reproduction of "*M. schreibersii*" and found that seasonal changes in insect abundance could not explain the delayed implantation, but that lactating females nevertheless had the lowest bone calcium concentrations. This is probably the reason why parturition occurs in seasons with maximum insect availability.

Mason *et al.* (2010: 165) found at De Hoop that in mid-August 2006 the bats sampled were either not pregnant or at a very early stage of pregnancy and no embryos were present. However, on the 8th September the first bat sampled was pregnant and carried an embryo at the limb bud stage (CS13), this is found

approximately the same time of year as those of the KwaZulu Natal and Eastern Cape populations. No twins were observed, and pregnant bats collected on the same day never had embryos from only one stage of development (Mason *et al.*, 2010). Mason *et al.* (2010: 168) found that the period of early to mid-embryonic development (CS11 to CS21) occurred over a period of about two weeks in both years sampled, however this period appeared to occur about two weeks later in 2008 than in 2006, this delay in pregnancy may be due to environmental factors. Also the embryonic stages were not the same among individuals sampled on the same day, indicating that although reproductive events may be synchronous (within the period of a month) in this species, exact developmental events were not highly synchronized between individuals.

At the Gatkop cave (RSA), Dietrich *et al.* (2018b: 4) were only able to trap non-scrotal males in September 2015. In November 2015, 90 % of the females they trapped had given birth very recently, and in January 2016, large amounts of juveniles were present, together with post-lactating females.

The mass of pregnant females varied greatly and was not correlated to the developmental stage of the embryos that they carried (Mason *et al.*, 2010: 165). Pretorius *et al.* (2019: 319), however, found that lactating females with sclerotized nipples were 6 % heavier than non-reproductive females and pregnant females were 25 % heavier than non-reproductive females, a difference - which at least in part - was attributed to foetus mass. Over three successive years (2015 - 2017), the proportion of active breeding females was found to be 31 %, 33 % and 70 %.

Pretorius *et al.* (2021a: 1) investigated the seasonal variation in body mass and found that varied significantly between the two sexes and by reproductive category. Scrotal males had a higher body mass in summer compared to autumn, which was not the case nin non-scrotal males. The summer body mass of nonpregnant and post-lactating females was not significantly higher than the autumn body mass of nonpregnant females, indicating that females do not seem to store extra fat during the summer and before their migration.

Mason *et al.* (2015) studied the embryological development of the fore- and hindlimbs, and found that that the transcription factor *Meis2* has a significantly higher expression in bat forelimb autopods compared to hindlimbs. Eckalbar *et al.* (2016: 528) found over 7,000 genes and noncoding RNAs (incl. Tbx5-as1 and Hottip), that were differentially expressed between forelimb and hindlimb, and across different stages of development.

MATING:

van der Merwe (1973b: 384) reported that the period of mating was still uncertain, although he assumed that it occurred at the wintering caves prior to hibernation.

PARASITES:

BACTERIA

Dietrich *et al.* (2016b: 3) tested 17 bats from Irene (RSA) and found two testing positive for *Bartonella* and one for *Rickettsia*. Five out of 8 bats from Vanderkloof Dam (RSA) also tested positive for *Bartonella*.

Dietrich *et al.* (2015a: 3) reported the presence of the Enterobacteria *Hafnia* and *Nitrococcus*. They also found *Leptospira* in the urine sample, and *Bartonella* in urine and saliva samples. Dietrich *et al.* (2018a: 4;2018b: 4) reported the presence of bacteria related to *Leptospira borgpetersenii* and a second group closely related to *L. interrogans* and *L. kirschneri*.

Clément *et al.* (2019a: 5) reported on 97 southern African *M. natalensis* specimens of which 12 were infected by either *Trypanosoma* sp. 1_AF (2), *Trypanosoma* sp. 2_A (2), *Trypanosoma* sp. 2_B (3), *Trypanosoma dionisii*_AF1-AF4 (4) and *Trypanosoma* cf. *livingstonei*_likeH_G1 (1).

Federici *et al.* (2022: 5) [referring to Dietrich *et al.* (2016a)] mentions Proteobacteria *Burkholderia, Helicobacter* and *Bartonella*.

HAEMOSPORIDA

Minozzo *et al.* (2021: 7) refer to Lutz *et al.* (2016) to report the presence of *Polychromophilus* in *Miniopterus natalensis* (see also Chumnandee *et al.*, 2020: Suppl.; Lutz *et al.*, 2021: Suppl.). Bajić *et al.* (2023: Suppl.) and Ceballos-Pérez *et al.* (2024: 3) mention the parasites as *Polychromophilus melanipherus* (Dionisi, 1899). However, the bats referred to by Lutz *et al.* (2021) are most probably representatives of *Miniopterus arenarius*.

Gastro-intestinal Helminthes - See Ortlepp (1932) and Junker *et al.* (2008a).

NEMATODA

Genov *et al.* (1992) reported *Molinostrongylus omatus* (Mönnig, 1927) from *M. natalensis* from South Africa. Ramasindrazana *et al.* (2016: 2) indicate that *Litomosa chiropterorum* Ortlepp, 1932 (Onchocercidae) was redescribed from a *M. natalensis* population from South Africa. This

Nematode was already reported from a bat from Katanga (DRC) by Durette-Desset and Chabaud (1975: 304).

Krasnov *et al.* (2020: Suppl.) examined 96 *Miniopterus natalensis* specimens from the RSA and found the following Nematoda: *Aonchotheca* sp., *Molinostrongylus ornatus* (Mönnig, 1927), two unclassified *Molinostrongylus* species, *Litomosa chiropterorum* Ortlepp, 1932 and *Physaloptera* sp.

PLATYHELMINTHES

Krasnov *et al.* (2020: Suppl.) found the Trematodes *Anchitrema sanguineum* (Sonsino, 1894), *Paralecithodendrium khalili* (Saoud & Ramadan, 1977) and *Paralecithodenrium pyramidum* (Looss, 1896) as well as Cestoda belonging to the Hymenolepididae in bats from the RSA.

ARACHNIDA

Argasidae

Argas vespertilionis (Latreille, 1802) from a "*M. schreibersi*" from Pretoria (see Howard, 1908: 168).

Dermanyssidae

Zumpt and Till (1954: 49) report *Steatonyssus natalensis* Zumpt and Patterson, 1951 from bats from Natal. Zumpt (1950: 92) found a new mite of the genus *Bdellonyssus*.

Ixodidae

Krasnov *et al.* (2020: Suppl.) found *Ixodes simplex* Neumann, 1906 on bats in the RSA.

Macronyssidae

Zumpt (1950: 89) described *Hirstesia transvaalensis* from bats from the Sterkfontein cave (RSA). Krasnov *et al.* (2020: Suppl.) reported the presence of *Ichoronyssus miniopteri* (Zumpt & Patterson, 1952) as well as four unclassified species of *Macronyssus* and two of *Steatonyssus*.

Myobiidae

Uchikawa (1985a: 19) also reported that the type specimens of *Miniopterus breyeri*, *M. dasythrix*, and *M. scotinus* harboured the "atypical" form of *Calcarmyobia congoensis* Uchikawa, 1982, and he also (Uchikawa, 1985a: 22) mentioned *Calcarmyobia kenyaensis* Uchikawa, 1982 on "*Miniopterus schreibersi*" from Belgian Congo. Uchikawa (1985c: 110) furthermore reported on the presence of *Pteracarus miniopteri* Uchikawa, 1978 on bats from South Africa, Zambia, Namibia (as *M. schreibersi natalensis* or *M. smitianus*). *Calcarmyobia rhinolophia* (Radford, 1940) (see Krasnov *et al.*, 2020: Suppl.).

Myobia miniopterus Womersley, 1941 (see Zumpt, 1950: 92).

Rosensteiniidae

Fain (1979: 124) reported *Nycteriglyphus miniopteri* Fain, 1963 from a "*Miniopterus schreibersii natalensis*".

Spinturnicidae

Spinturnix semilunaris De Meillon and Lavoipierre, 1944 (see Zumpt, 1950: 92; Krasnov *et al.*, 2020: Suppl.; Orlova *et al.* (2024: 153).

Trombiculidae

Stekolnikov (2018a: 147) mentioned *Microtrombicula armata* Vercammen-Grandjean, 1965 from a South African "*M. schreibersi*". Zajkowska *et al.* (2018: 116) indicated that the host species was originally given as "*M. schreibersii natalensis*".

DIPTERA

Nycteribiidae

Nycteribia capensis Karaman, 1939 from the Cape and Pietermaritzburg, South Africa (Haeselbarth *et al.*, 1966: 108). *Nycteribia latiterga* Theodor, 1957 from Mt. Menengai, Kenya (Haeselbarth *et al.*, 1966: 108). *Nycteribia schmidlii* Schiner, 1853 (Zumpt, 1950: 97; Haeselbarth *et al.*, 1966: 108; Blackwell, 1980: 146 - infected by the fungus *Arthrorhynchus eucampsipodae* Thaxter, 1901 [see also Haelewaters *et al.*, 2018: 794; Szentiványi *et al.*, 2019a: Suppl.], de Groot *et al.*, 2020: Suppl.), *Penicillidia fulvida* (Bigot, 1885) (Haeselbarth *et al.*, 1966: 114; Blackwell (1980: 144 - infected by the fungus *Arthrorhynchus nycteribiae* (Peyritsch) Thaxter [see also Haelewaters *et al.*, 2018: 794; Szentiványi *et al.*, 2019a: Suppl.], de Groot *et al.*, 2020: Suppl.).

Szentiványi *et al.* (2020: 3) reported on *Nycteribia schmidlii scotti* Falcoz, 1923 on bats from the RSA (on average 1.4 ± 0.7 bat flies per bat).

Streblidae

Ascodipteron africanum Jobling, 1939 from Kapretwa and Mt. Kenya, Kenya, other records referred to this species are misidentification (Haeselbarth *et al.*, 1966: 106). *Ascodipteron theodori* Maa 1965 from Rooiberg, South Africa (Haeselbarth *et al.*, 1966: 106). Krasnov *et al.* (2020: Suppl.) also mentioned *Ascodipteron* sp. and *Brachytarsina* sp parasites from the RSA.

Raymondi waterstoni Jobling 1931 which may be accidental (Haeselbarth *et al.*, 1966: 104) (see also Shapiro *et al.*, 2016: 256).

HEMIPTERA
Cimicidae
Kock *et al.* (1998b: 236) mentioned the presence of *Cacodmus villosus* (Stål, 1855) on bats from South Africa.

SIPHONAPTERA
Ischnopsyllidae
Oxyparius isomalus (Waterston, 1915) known from several localities in southern Africa (Transvaal, Natal of South Africa, Botswana and Namibia) (Haeselbarth *et al.*, 1966: 188; Krasnov *et al.*, 2020: Suppl.).

VIRUSES:
In a limited study in Kenya (three caves), Kamau *et al.* (2022: 5) found Astroviridae, Circoviridae, Dicistroviridae and Retroviridae.

Bunyaviridae
Phlebovirus
Rift Valley Fever Virus (RVFV)
Oelofsen and Van der Ryst (1999) tested [as *M. schreibersi*] 49 individuals from one locality in the Free State Province, South Africa for RVFV antigen using an enzyme linked immunosorbet assay (ELISA), none tested positive.

Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested [as *M. schreibersi*] between 1986 and 1999, for antibody to SARS-CoV in sera in one individual from Limpopo Province, South Africa, none were tested positive (0/1). Tong *et al.* (2009) tested 1 bat collected in Kenya during 2006 positive for the presence of coronavirus RNA in a faecal sample. Nine out of 53 (17 %) Kenyan bats tested by Tao *et al.* (2017: Suppl.) was positive for CoV. One out of 14 specimens tested by Geldenhuys *et al.* (2013: 517) from Irene Caves, Gauteng, RSA tested positive for CoV.

Paramyxoviridae
Conrardy *et al.* (2014) detected a paramyxovirus sequence in one of eight bats sampled in Kenya. This virus does not group with the known paramyxoviruses and remains an unclassified paramyxovirus.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Duvenhage
van der Merwe (1982a) implicated *Miniopterus schreibersii*, as an isolate of the virus but the bat was never positively identified. This record was also referred to by Hayman *et al.* (2011a: 88), who indicated that the bas was possibly a *M. natalensis*.

Rabies
Oelofsen and Smith (1993) tested [as *M. schreibersi*] 137 individual brains, from 5 localities by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), none were tested positive.

Coertse *et al.* (2020: 3057) reported a new lyssavirus (distantly related to West Caucasian Bat Virus) from two bats from Matlapitsi and Madimatle caves in Limpopo, RSA. This virus was called Matlo Bat Lyssavirus (MBLV) and its entire genome sequence was given by Grobler *et al.* (2021).

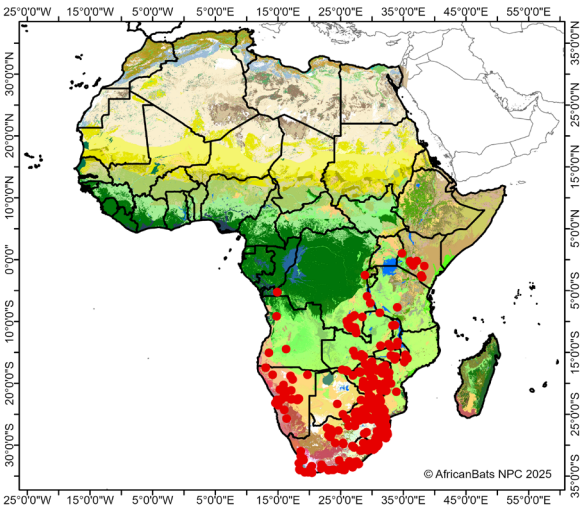

Figure 244. Distribution of *Miniopterus natalensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Botswana, Congo (Democratic Republic of the), Eswatini, Kenya, Lesotho, Malawi, Mozambique, Namibia, South Africa, Tanzania, Zambia, Zimbabwe.

Miniopterus newtoni Bocage, 1889

*1889. *Miniopterus Newtoni* Bocage, J. Sci. mat. phys. nat., ser 2, 1 (3): 198. Publication date: December 1889. Type locality: São Tomé and Príncipe: São Tomé Island. [Goto Description]. Neotype: EBD 17350M: ad ♂, skull and alcoholic. Collected by: Javier Juste and Carlos J. Ibáñez Uargui; collection date: 4 April 1988. São Tomé Island, Santa Catarina, in a cave near the seashore (00 16 N 06 29 E), designated as neotype by Juste and Ibáñez (1992: 361). (Current Combination).
? *Miniopterus newtoni:* (Current Spelling).

TAXONOMY:
Recognised as a synonym (Koopman, 1993a: 231) or a subspecies (Simmons, 2005: 521) of *M. minor* Peters, 1867. Removed from *minor* by Juste [B.] *et al.* (2007: 33), based on mtDNA analyses. Juste and Ibáñez (1992: 361) designated a neotype for *newtoni* Bocage, 1889.

COMMON NAMES:
Czech: létavec tomášský. English: Sao Thome Long-fingered bat. French: Minioptère de São Tomé. German: Sao Thome Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Juste, 2008b; IUCN, 2009; Juste, 2019b).

Assessment History
Global
2018: DD ver 3.1 (2001) (Juste, 2019b). 2008: DD ver 3.1 (2001) (Juste, 2008b; IUCN, 2009).

Regional
São Tomé: NT due to a probable decline in the number of individuals and locations because of the destruction and/or disturbance of underground roosts (Rainho *et al.*, 2022: 609).

MAJOR THREATS:
The threats to this species are not well known (Juste, 2008b; IUCN, 2009; Juste, 2019b).

CONSERVATION ACTIONS:
Juste (2008b) [in IUCN (2009)] and Juste (2019b) reports that it is not known if the species is present in any protected areas. Further studies are needed into the natural history and threats to this species.

GENERAL DISTRIBUTION:
Miniopterus newtoni is endemic to the island of São Tomé (São Tomé and Príncipe) where it is widespread (Juste [B.] *et al.*, 2007).

Native: São Tomé and Príncipe (Koopman, 1993a: 231 [as *minor*]; Simmons, 2005: 521 [as *minor*]; Juste [B.] *et al.*, 2007; Rainho *et al.*, 2010a: 33).

ECHOLOCATION:
Rainho *et al.* (2010a: 21) and Rainho *et al.* (2022: 605) reported the calls of 14 individuals from São Tomé with the following characteristics: F_{min}: 50.3 ± 1.3 (47.8 - 52.2) kHz, F_{max}; 101.7 ± 16.7 (69.6 - 119.0) kHz, F_{maxE}: 55.9 ± 2.7 (53.2 - 61.0) kHz, duration: 4.8 ± 2.1 (2.3 - 7.8) ms and interpulse interval: 61.4 ± 23.6 (31.8 - 105.7) ms.

HABITAT:
On Sáo Tomé, Castro-Fernandes *et al.* (2024: 1, 2) reported this bat to be an edge-forager, most active in oil palm plantations.

POPULATION:
Structure and Density
It is a common species (Juste B. and Ibáñez, 1994b; Juste, 2008b; IUCN, 2009; Juste, 2019b).

Trend
2018: Unknown (Juste, 2019b). 2008: Unknown (Juste, 2008b; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Araújo-Fernandes *et al.* (2025: 830) reported that the activity pattern of *Miniopterus newtoni* in rural areas shows two peaks: one at dusk and a second at dawn, whereas the activity in urban areas is continuous during the night. But it is not clear whether this is due to a higher light tolerance or to a limited availability of prey or to the activity patterns of the prey (p. 832).

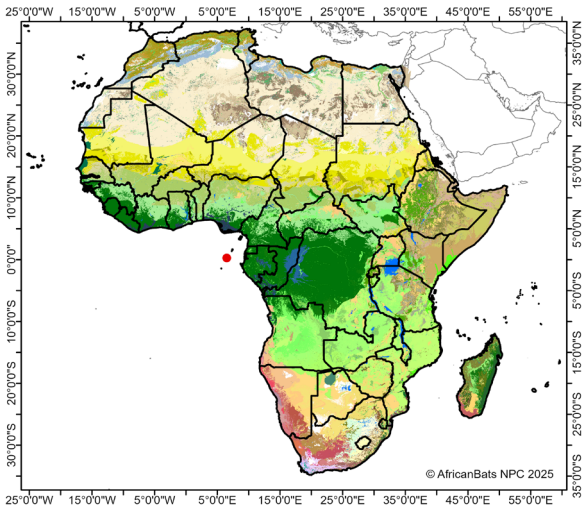

Figure 245. Distribution of *Miniopterus newtoni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
São Tomé and Príncipe.

Miniopterus nimbae Monadjem, Shapiro, Richards, Karabulut, Crawley, Nielsen, Hansen, Bohmann and Mourier, 2020

*2020. *Miniopterus nimbae* Monadjem, Shapiro, Richards, Karabulut, Crawley, Nielsen, Hansen, Bohmann and Mourier, Acta Chiropt., 21 (2): 239, 245, figs 6, 7A, 8, 9A. Type locality: Liberia: Nimba county: Mount Gangra:

10 km W Mount Nimba [07 33 16 N 08 37 44 W, 720 m]. Holotype: DNSM 12621: ad ♂, skull and alcoholic. Collected by: Dr. Ara Monadjem; collection date: 18 December 2010; original number: AM2010_12_18_1. Presented/Donated by: Dr. Ara Monadjem. Paratype: DNSM 12614: ad ♀. Collected by: Dr. Ara Monadjem; collection date: 17 December 2010. Presented/Donated by: Dr. Ara Monadjem. - Etymology: Referring to the type locality on Mount Nimba. (Current Combination).

COMMON NAMES:
English: Nimba long-fingered bat

CONSERVATION STATUS:
Monadjem *et al.* (2020e: 252) suggest this species might be assigned to the IUCN category Vulnerable or even Endangered.

GENERAL DISTRIBUTION:
Only known from Liberia (Mount Nimba and surrounding uplands, Wonegizi mountains) and Guinea (Mount Béro) (see Monadjem *et al.*, 2020e: 247).

ECHOLOCATION:
Monadjem *et al.* (2020e: 248) found that the knee frequency of the echolocation calls from four hand-released *M. nimbae* specimens ranged between 47.2 and 48.9 kHz (average 48.4 kHz).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

REPRODUCTION AND ONTOGENY:
Monadjem *et al.* (2020e: 248) found that five out of 13 females captured between late December and the end of March were pregnant, and three out of 10 males had scrotal testes.

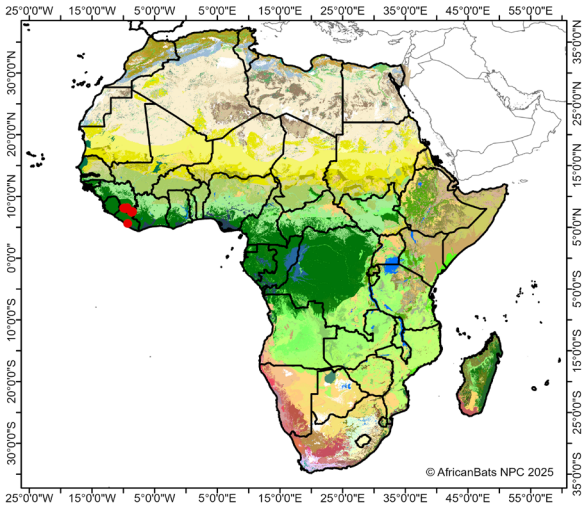

Figure 246. Distribution of *Miniopterus nimbae*.

Miniopterus petersoni Goodman, Bradman, Maminirina, Ryan, Christidis & Appleton, 2008

2007. *Miniopterus cf. sororculus:* Goodman, Ryan, Maminirina, Fahr, Christidis and Appleton, J. Mamm., 88 (5): 1229.
2008. *Miniopterus cf. petersoni:* Goodman, Bradman, Maminirina, Ryan, Christidis and Appleton, Mamm. biol., 73: 202.
*2008. *Miniopterus petersoni* Goodman, Bradman, Maminirina, Ryan, Christidis and Appleton, Mamm. biol., 73: 199, 200, 201, figs 2 - 5. Type locality: Madagascar: Province de Toliara: Cascade de Manantantely: Tolagnaro, 5.2km NW [2459.343S 4655.370E, 65m]. Holotype: FMNH 194136: ad ♂. Collected by: Steven M. Goodman; collection date: 20 February 2007; original number: SMG 15833. Paratype: USNM 577096. Paratype: USNM 577097. Paratype: USNM 577098: Collected by: G. Kenneth Creighton and E. Raholimavo; collection date: 19-30 October 1990. Paratype: USNM 577099. Paratype: USNM 577100. Paratype: USNM 577101. - Etymology: The name *petersoni* is a patronym in honour of Randolph L. Peterson of the Royal Ontario Museum, Toronto, Canada, who made pioneering contributions to the study of Malagasy bats, based on a 1967 collecting trip to the island, as well as other fields in mammalogy (Eger and Mitchell, 1990; Goodman *et al.*, 2008a). (Current Combination).

TAXONOMY:
See Goodman *et al.* (2008a).

COMMON NAMES:
Czech: létavec Petersonův. English: Peterson's Long-fingered Bat, Peterson's Bent-winged Bat. French: Minioptère de Peterson. German: Petersons Langflügelfledermaus.

SIMILAR SPECIES:
See Goodman *et al.* (2008a).

CONSERVATION STATUS:
Global Justification
This species is listed as Data Deficient (DD ver 3.1 (2001)) because although it appears to have a restricted range in the southeast of Madagascar and is associated with forest, there is taxonomic uncertainty about specimens from the north of Madagascar (which if proved valid would greatly extend the known range). There is also limited information on the population status and threats to this species (Jenkins and Rakotoarivelo,

2008b; IUCN, 2009; Jenkins and Rakotoarivelo, 2019).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2018: DD ver 3.1 (2001) (Jenkins and Rakotoarivelo, 2019). 2008: DD ver 3.1 (2001) (Jenkins and Rakotoarivelo, 2008b; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
Although robust data are lacking and there are still some taxonomic uncertainties of specimens from the north of Madagascar, the information on *M. petersoni* from the southeast suggests that this species is closely associated with natural forest formations and is therefore threatened by the loss or degradation of these habitats (Goodman *et al.*, 2008a). Threats to roosting colonies have not yet been documented (Jenkins and Rakotoarivelo, 2008b; IUCN, 2009; Jenkins and Rakotoarivelo, 2019).

CONSERVATION ACTIONS:
Jenkins and Rakotoarivelo (2008b) [in IUCN (2009)] and Jenkins and Rakotoarivelo (2019) report that none of the known collecting localities for verified specimens of this species are from within protected areas (Goodman *et al.*, 2008a). The taxonomic status of specimens from north Madagascar requires further study.

GENERAL DISTRIBUTION:
Miniopterus petersoni is endemic to the island of Madagascar and appears to be restricted to lowland (< 550 m elevation) habitats in the south-east (Goodman *et al.*, 2008a).

Schoeman *et al.* (2014: 28, 31) found the most suitable area for this species to be located in the southeastern part of the island, but reaching along the coast to the northeast, where the suitability seems to increase again (eastern humid forest or lowland forest region - humid).

The taxonomic status of specimens from the north of Madagascar remain unresolved (Goodman *et al.*, 2008a).

Native: Madagascar (Goodman *et al.*, 2008a).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Goodman *et al.* (2008a).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Goodman *et al.* (2008a).

ECHOLOCATION:
Low-duty cycle, frequency modulated/quasi constant (FM/QCF) echolocation call, with a peak frequency of 53.2 kHz (52.0 - 53.9 kHz) and a duration of 2.9 ms (2.5 - 3.3 ms) (Goodman *et al.*, 2011: 9).

Ramasindrazana *et al.* (2011: 294) recorded 6 calls from 1 *Miniopterus petersoni* specimen, and found the following echolocation call values: Frequency of maximum energy: 53.2 ± 0.75 (52.0 - 53.9) kHz, Maximum frequency: 106.5 ± 6.66 (95.0 - 115.0) kHz, Minimum frequency: 49.0 ± 0.63 (48.0 - 50.0) kHz, Call duration: 2.9 ± 0.32 (2.5 - 3.3) ms, Inter pulse interval: 71.0 ± 4.63 (63.8 - 76.7) ms.

MOLECULAR BIOLOGY:
Genetics
See Goodman *et al.* (2008a).

HABITAT:
See Goodman *et al.*, 2008a).

HABITS:
See Goodman *et al.* (2008a).

ROOST:
See Goodman *et al.* (2008a).

MIGRATION:
May be involved in seasonal migrations between cave roost sites (Goodman *et al.*, 2008a).

POPULATION:
Structure and Density
This species was only formally described in 2008 and there is no information on its population (Goodman *et al.*, 2008a).

Trend
2018: Unknown (Jenkins and Rakotoarivelo, 2019). 2008: Unknown (Jenkins and Rakotoarivelo, 2008b; IUCN, 2009).

PARASITES:
Tortosa *et al.* (2013: 4) and Ramasindrazana *et al.* (2017: Suppl.) reported the presence of the Nycteribiid bat flies *Nycteribia stylidiopsis* and *Penicillidia leptothrinax*. The latter is also reported by Wilkinson *et al.* (2016), and was found to be carrying *Rickettsia* bacteria Szentiványi *et al.*, 2019a: Suppl.).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

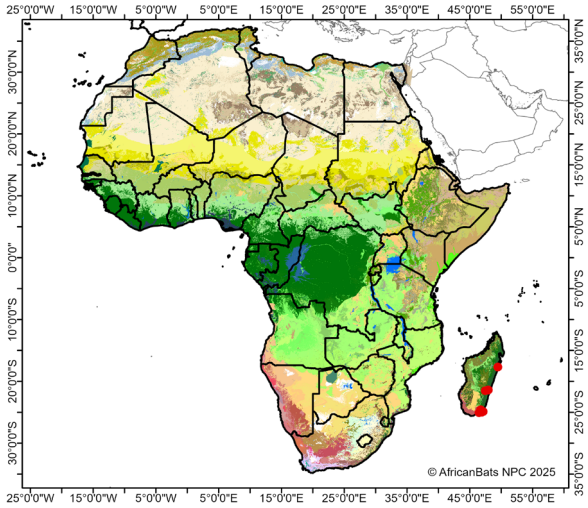

Figure 247. Distribution of *Miniopterus petersoni*.

Miniopterus schreibersii (Kuhl, 1817)

*1817. *Vespertilio schreibersii* Kuhl, Die Deutschen Fledermäuse, Hanau, 14. Type locality: Romania: S Ban(n)at Mnts, near Coronini, left bank Danube: Kolumbács Cave [=Kulmbazer cave] [ca. 44 37 N 21 40 E]. - Comments: Turni and Kock (2008) mention that the type and three "doublets" should have been present in the NMW, but are no longer found. - Etymology: In honour of Karl Franz Anton, Ritter von Schreibers (1775 - 1852), then director of the Vienna Museum (Flannery, 1995a: 378; 1995b: 452; Kozhurina, 2002: 17). - Phonetics: shrie'-berz-ee-ee, shribe'-er-zee-ee.
1827. *Vespertilio Screbersii:* Lesson, Manuel de Mammalogie, 89. (Lapsus).
1855. *V[espertilio] Schreibersi:* Giebel, Die Säugethiere, 950. (Name Combination).
1953. *Miniopterus schrebersii:* Harrison, Durban Mus. Novit., 4 (5): 65. Publication date: 30 June 1953. (Lapsus).
1995. *M[iniopterus] screibersi:* Pavlinov, Borissenko, Kruskop and Jahonton, Arch. Zool. Mus., Moscow State Univ., 133: 119. (Lapsus).
2013. *Miniopterus schreibersiias:* Shi, Sci. China Life Sci., 56 (8): 679. (Lapsus).
? *Miniopterus schreibersi schreibersi:* (Name Combination).
? *Miniopterus schreibersii dasythrix:* (Name Combination).
? *Miniopterus schreibersii schreibersii:* (Name Combination).
? *Miniopterus schreibersii villiersi:* (Name Combination).
? *Miniopterus schreibersii:* (Name Combination, Current Combination).

TAXONOMY:
Molecular systematics and biogeography are discussed by Appleton *et al.* (2004: 436 - 437), who indicate that based on their data *M. schreibersii* would be restricted to Europe and North Africa; the Ethiopian representatives would belong to a second species and the Oriental-Australian a third (see also Stadelmann *et al.*, 2004b: 188). Tian *et al.* (2004: 303) confirm the views presented by Appleton *et al.* (2004), and suggest *M. schreibersii* for the European specimens, *M. fuliginosus* for the Asian representatives and *M. oceanensis* for the Australian ones (which was already suggested by Maeda (1982), although he separated the specimens from Hainan from the other Asian representatives, which is no longer supported by Appleton *et al.* (2004).

Reviewed by Crucitti (1976) and Hill (1983).

If *Miniopterus schreibersii* is restricted to northern Africa, then *Miniopterus inflatus villiersi* Aellen, 1956 should possibly be assigned to *Miniopterus natalensis*, but as already indicated by Fahr *et al.* (2006a: 74) and Monadjem *et al.* (2016y: 371), *villiersi* represents a distinct species, restricted to the Upper Guinea forest zone.

COMMON NAMES:

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Gunnell *et al.* (2015a: 22) report skeletal remains from a Pleistocene deposit at Olduvai Gorge (Tanzania), which they assigned to *Miniopterus* cf. *M. schreibersi*.

CONSERVATION STATUS:
Global Justification
Listed as Near Threatened NT ver 3.1 (2001). Significant population declines and range contractions have been recorded in a number of range states and although it is stable in the Balkans and Turkey, overall the rate of population decline may approach 30 % (almost qualifies as VU under A2a) (Hutson *et al.*, 2008c; IUCN, 2009; Benda and Paunović, 2019).

Assessment History
Global
2016: NT ver 3.1 (2001) (Benda and Paunović, 2019). 2008: NT ver 3.1 (2001) (Hutson *et al.*, 2008c; IUCN, 2009). 2004: LC ver 3.1 (2001) [included *natalensis*] (Schlitter, 2004i; IUCN, 2004). 1996: LR/nt [included *M. natalensis*] (Baillie and Groombridge, 1996).

Regional
Mediterranean:- 2008: NT ver 3.1 (2001) (IUCN, 2009).

MAJOR THREATS:
The main threat in Africa is disturbance in roosts. In Europe, the disturbance and loss of underground habitats and pesticide use may threaten this species. In the Caucasus, disturbance caused by tourism in caves is a problem (K. Tsytsulina *pers. comm.,* 2005).

The cause of recent mass mortality events is unknown. In 2002 mass mortalities of this species were reported for populations in France, Spain and Portugal. There are also historical records for such mortalities in Italy, Australia and a possible incidence in Iran. A meeting was held at the 9th European Bat Research Symposium to discuss these incidents. Veterinary investigations in Spain did not identify any disease as the cause of the die offs, and there is increasing belief that the die offs are caused by bad weather in late winter/early spring (Hutson *et al.*, 2008c; IUCN, 2009).

The species' small range, cave/tree roosting and aerial hawking feeding style are believed to be the most important risk factors in view of climatic change (Sherwin *et al.*, 2012: 174).

CONSERVATION ACTIONS:
Hutson *et al.* (2008c) [in IUCN (2009)] and Benda and Paunović (2019) report that in Europe, it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention in parts of the range where these apply. It is included in Annex II (and IV) of the EU Habitats and Species Directive, and hence requires special measures for conservation including designation of Special Areas for Conservation. There is some habitat protection through Natura

2000, and some roosts are already protected by national legislation. There have been a number of LIFEfunded projects for this species in Spain, Italy, Romania and Germany.

The species is found in many protected areas throughout its range.

Care is required when fencing caves to minimise mortality. Further research is required into the causes of the recent mass mortality events.

GENERAL DISTRIBUTION:
Miniopterus schreibersii occurs from south-western Europe and North and West Africa through Anatolia and the Middle East to the Caucasus. In Africa it is known from records in North Africa (Morocco, Algeria, Tunisia, Libya), and West Africa (Guinea, Sierra Leone, Liberia, Nigeria, Cameroon). It is patchily distributed over its range in some huge and vulnerable colonies. It typically occurs at altitudes of up to 1,400 m asl (commuting up to 2,600 m asl).

Based on cyt b sequences from GenBank, Derouiche *et al.* (2024: 23) conclude that *Miniopterus schreibersii* is the only *Miniopterus* species occurring in Algeria, although *M. maghrebensis* is probably present too (p. 34).

Native: Afghanistan; Albania; Algeria; Armenia; Azerbaijan; Bosnia and Herzegovina; Bulgaria; Cameroon; Cape Verdian Islands (Borloti *et al.*, 2020: 2); Croatia; Cyprus; France [Corse]; Georgia; Gibraltar; Greece [East Aegean Islands; Kriti]; Holy See [Vatican City State]; Hungary; Israel; Italy [Sardinia, Sicily]; Jordan; Lebanon; Liberia; Macedonia, the former Yugoslav Republic of; Malta; Monaco; Montenegro; Morocco (Benda *et al.*, 2010a: 158; El Ibrahimi and Rguibi Idrissi, 2015: 364; Dbiba *et al.*, 2025: 7); Nigeria; Palestinian Territory, Occupied; Portugal; Romania; Russian Federation; San Marino; Serbia; Sierra Leone; Slovakia; Slovenia; Spain [Baleares]; Switzerland; Syrian Arab Republic; Tunisia (Dalhoumi *et al.*, 2014: 53; 2016b: 867; 2019b: 26); Turkey.

Possibly extinct: Austria.

Regionally extinct: Germany; Ukraine.

Presence uncertain: Libyan Arab Jamahiriya.

DETAILED MORPHOLOGY:
Bhide (1979: 1) described the anatomy, histology and histochemistry of this bat's stomach

In Korea, three types of lingual papillae were on the tongue by Park and Lee (2009: 267): filiform, fungiform, and circumvallate.

Cebesoy and Karakas (2013: 382) report on the muscle fiber types in primary flight muscles of specimens from Turkey, where they recognized three types: I, IIa, and IIb, which respectively make up 14 %, 70 % and 16 % of the *serratus ventralis*. In their study on take-off performance, Gardiner *et al.* (2014: 1059) determined a wing beat frequency of 11.95 ± 0.17 Hz.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 10.2 Pa, aspect ratio 7.0 and tip shape index of 1.03 for a wingspan of 31 cm and a wing area of 137 cm^2 and a body mass of 14 g.

ECHOLOCATION:
The data for 61 animals from Greece are the following: F_{start}: 93.0 ± 11.84 kHz, F_{end}: 50.8 ± 1.16 kHz, F_{peak}: 54.9 ± 5.32 kHz, bandwidth: 17.8 ± 14.30 kHz, duration: 6.7 ± 1.29 ms and interpulse interval: 94.1 ± 35.73 ms (Papadatou *et al.*, 2008b: 133). Walters *et al.* (2012: suppl.) report the following figures for 31 calls from France, Greece, Italy and Switzerland: duration: 6.37 ± 2.89 ms, F_{max}: 73.24 ± 12.13 kHz, F_{min}: 49.75 ± 1.33 kHz, bandwidth: 23.49 ± 11.29, F_{peak}: 52.02 ± 1.68 kHz. Davies *et al.* (2013b: Table S8) report a peak frequency of 56.07 kHz and a range between 52.1 and 85.2 kHz.

From Morocco, Disca *et al.* (2014: 226) indicate that the type of call is FM-QFC, with the following parameters: F_{start}: 97.3 ± 11.3 kHz, F_{end}: 50.6 ± 1.4 kHz, F_{peak}: 53.4 ± 1.2 kHz, $F_{QFC\text{-}peak}$: 52.3 ± 1.1 kHz, bandwidth: 43.2 ± 11.4 kHz, duration: 6.2 ± 1.2 ms.

Ait-Abdesselam *et al.* (2025: 40) reported an F_{max} value of 56.51 ± 0.6 kHz for Algerian bats.

For 3 calls from the Kalahari Desert, the characteristics were: F_{char}: 47.6 ± 6.5 kHz, F_{max}: 76.7 ± 7.7 kHz, F_{min}: 53.2 ± 4.9 kHz, duration: 2.6 ± 0.4 ms (Adams and Kwiecinski, 2018: 4).

Luo *et al.* (2019a: Supp.) reported the following data (from 2 calls): F_{peak}: 54.9, 54.2 kHz, F_{start}: 93, 85.2 kHz, F_{end}: 50.8, 52.1 kHz, Band width: 42.2, 33.1 kHz, and duration: 6.7, 5.8 ms.

MOLECULAR BIOLOGY:
Karyotype
Matthey and Bovey (1948) and Bovey (1949) described the karyotype from Switzerland as having a diploid number of $2n$ = 46, aFN = 48, X

= submetacentric, Y = acrocentric. Rushton (1970: 463) reported 2*n* = 46, FN = 50, X = metacentric, Y = minute. Capanna and Civitelli (1965 - Italy), Baker *et al.* (1974 - Tunisia), Bickham and Hafner, 1978 - Yugoslavia), Zima (1978 - Czechoslovakia), Pérez-Suárez *et al.* (1991 - Spain), Albayrak (2006 - Turkey) found the fundamental number to be aFN = 50, and X = metacentric for Zima (1978). The autosomal chromosomes contain two large metacentrics, one medium-sized metacentric, 17 acrocentric and two dot-like pairs (one of these pairs may be bi-armed) (Arslan and Zima, 2014: 14). In Turkey, Aşan Baydemir (2015: 350) found Nucleolus Organising Regions (NORs) on the secondary constriction in 2 pairs of chromosomes (pairs 18 and 20). Capanna and Civitelli (1965: 546) mention 22 pairs of autosomes, of which 3 are metacentric, 17 acrocentric, and two very small; the X chromosome is a medium sized metacentric and the Y chromosome is a very small one. Capanna and Manfredi Romanini (1971: 474) mention 2*n* = 45, aFN = 50, 2 pairs of metacentrics, 1 pair of submetacentrics, 19 pairs of acrocentrics.

Genetics
Barragán *et al.* (2002), Appleton *et al.* (2004), Tian *et al.* (2004), Bilgin *et al.* (2006, 2008).

Gürün *et al.* (2014: 73) confirmed the pattern of local differentiation previously detected in mitochondrial DNA as they also found significant differences in the nuclear DNA between bats from North Africa, Lebanon, Cyprus, Anatolia, Russia, Thrace-Balkans, Slovakia, Italy, France, and Iberia. Gürün *et al.* (2019: 1866), however, could not confirm the mitochondrial differences in the microsatellite markers they examined, which would suggest a male-biased dispersal.

HABITS:
In southern France, Vincent *et al.* (2011: 57) found that during pregnancy and lactation, females might switch roosts within a 30 km radius around the maternity colony. During the night, the females travelled between 4.1 and 29.2 km to their foraging areas. They also estimated the individual home-ranges for pregnant females to be 10,837 ha, and for lactating females 22,318 ha.

DIET:
Presetnik and Aulagnier (2013: 297) investigated the diet of *M. schreibersii* in Slovenia and found this to consist primarily of Lepidoptera (79 % by volume). Neuroptera (mostly Chrysopidae) accounted for 9.2 %), Diptera for 7.4 %, Trichoptera for 2.2 %, and Coleoptera for 1.4 %. This seems to indicate that *M. schreibersii* is an aerial hawker. Gardiner *et al.* (2014: 1058) assessed its foraging strategy as "high altitude fast aerial hawking".

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

Rihane *et al.* (2024: 223) indicate that Miniopterus schreibersii was the most frequently captured prey (22.1 %) of a Moroccan Magreb Owl (*Strix mauritanica* (Witherby, 1905)).

POPULATION:
Structure and Density
See Hutson *et al.* (2008c) [in IUCN (2009)] and Benda and Paunović (2019) for information of populations outside Africa.

Trend
2016: Decreasing (Benda and Paunović, 2019).
2008: Decreasing (Hutson *et al.*, 2008c; IUCN, 2009).

LIFESPAN:
Szekely *et al.* (2015: Supp.) and Lagunas-Rangel (2019: 2) reports a maximum longevity of 22 years.

REPRODUCTION AND ONTOGENY:
Tuttle and Stevenson (1982: 122) indicate that both sexes need about 16 months to attain sexual maturity.

Kurta and Kunz (1987: 82) report that, at birth, the young weights about 20.4 % of the mother's body mass (3.4 g versus 20.4 g), and that its forearm length is 35.5 % of its mother's (16.7 versus 47.0 mm).

Szekely *et al.* (2015: Suppl.) report that males become sexually mature after 730 days (24 months) and females after 577 days (19 months). The young is born after a gestation period of 100 days with a weight of 2.8 g (22 % of the adult). After weaning (66 days), its weight is increased to 12.8 g.

In central Tunisia, females can be gravid until mid-June (Dalhoumi *et al.*, 2019a: 160). In Malawi, births occurred early in the wet season (Happold and Happold, 1990b: 568).

Chari and Gopalakrishna (1984: 464) describe the development of the foetal membranes and the changes in the structure of the placenta in the Indian *Miniopterus schreibersii fuliginosus*, and they indicate that this bat has some unique embryological features.

MATING:
This species has a polygynandrous mating system (Webber *et al.*, 2017: Suppl.)

POSTNATAL DEVELOPMENT:
In Iran, Sharifi and Vaissi (2013: 1) found that new-borns had a mass of 3.74 ± 0.09 g and forearm length of 24.3 ± 0.31 mm. Both of these increased linearly over the first two weeks (at about 0.54 g/day and 1.39 mm/day), after which they remained rather stable. The epiphyseal gap of the fourth metacarpal phalangeal joint increased until the thirteenth day, then decreased linearly until the 70th day and thereafter fused. The eyes opened during the first week and the ears became erect. The pups also began to move by that time. At 21 days, their ability to fly improved, and they started to fly freely in the cave. At that time their average body mass was 11.32 g (91.6 % of adult weight).

PARASITES:
Lei and Olival (2014: Suppl.) mention this species to be a host for *Bartonella* bacteria.

Landau *et al.* (2012: 142) mention the Heamosporidians *Polychromophilus melaniferus* (Dionisi, 1899) and *Polychromophilus corradetti* Landau *et al.*, 1980.

In Europe, Genov *et al.* (1992) reported the following Nematodes: *Molinostrongylus panousei* Dollfus, 1954, *M. skrjabini* Skarbilovitch, 1934, *M. alatus* (Ortlepp, 1932), and *M. ornatus* (Mönning, 1927).

Uchikawa (1985a: 22) proposed the new name *Calcarmyobia dusbabeki* (Acari: Myobiidae) for a mite found on *Miniopterus schreibersii* from amongst others Tunisia and Algeria. The Spinturnicid mites *Spinturnix psi* (Kolenati, 1856) and *Spinturnix myoti* (Kolenati, 1856) were reported by Postawa and Furman (2014: 390) from Central Anatolia and the Levant.

Calcarmyobia ? parenzani Lombardini, 1956 was found on a *M. schreibersii* from Ras el Qued cave, Morocco.

Aellen (1955b) reported on the occurrence of the following nycteribid flies on *M. schreibersii* bats from Morocco and Algeria: *Nycteribia (Nycteribia) latreillei* (Leach, 1817), *Nycteribia (Nycteribia) schmidli* Schiner, 1853, *Nycteribia (Acrocholidia) vexata* Westwood, 1835, *Penicillidia dufouri* (Westwood, 1835), and *Penicillidia conspicua* Speiser, 1901.

Rhipicephalus sanguineus (Latreille, 1806) (Arachnidae: Ixodida: Ixodidae) were reported from Algerian bats by Bendjeddou *et al.* (2013: 325). Bendjeddou *et al.* (2017: 15), Bendjoudi *et al.* (2019: 71) and Khelfaoui *et al.* (2018: 67) reported the following ectoparasites from Algeria: Nycteribiidae: *Nycteribia (Nycteribia) pedicularia* Latreille, 1805, *Nycteribia schmidlii* Schiner, 1853, *Penicillidia (Penicillidia) dufourii* Westwood, 1835 and *Phthiridium biarticulatum* Hermann, 1804; Streblidae: *Brachytarsina (Brachytarsina) flavipennis* Macquart, 1851; and Siphonaptera: *Rhinolophopsylla unipectinata arabs* Jordan and Rothschild, 1921; Ixodidae: *Ixodes vespertilionis* Koch, 1844.

Khelfaoui *et al.* (2018: 69) also mentioned that *Nycteribia latreillii* (Leach, 1817) had been found earlier on bats from Morocco and Tunisia.

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Ischnopsyllidae: *Rhinolophopsylla unipectinata arabs* Jordan and Rothschild, 1921; Ixodidae: *Ixodes simplex* Neumann, 1906, *Ixodes vespertilionis* Koch, 1844; Spinturnicidae: *Spinturnix psi* (Kolenati, 1856); Nycteribiidae: *Nycteribia latreillii* (Leach, 1817), *Nycteribia pedicularia* Latreille, 1805, *Nycteribia schmidlii schmidlii* Schiner, 1853, *Nycteribia vexata* Westwood, 1835, *Penicillidia conspicua* Speiser, 1901, *Penicillidia dufourii* (Westwood, 1834), *Phthiridium biarticulatum* (Hermann, 1804); and Streblidae: *Brachytarsina flavipennis* Masquart, 1851.

In their key, Sun *et al.* (2022: 7) mention that the streblid flies *Ascodipteron minor* Theodor, 1973 and *Ascodipteron theodori* Maa, 1965 have been found on African *M. schreibersii*.

In Italy, Voyron *et al.* (2011: 193) reported the following fungal entities from *M. schreibersii* carcasses: *Aspergillus* sp., *Chrysosporium merdarium*, *Fusarium equiseti*, Ophiostomatacea, *Thielavia* sp., *Mucor hiemalis f. hiemalis*.

Ševčík *et al.* (2012: 35) report on the presence of the bat flies *Nycteribia schmidlii schmidlii* Schiner, 1853 and *Penicillidia conspicua* Speiser, 1901 on bats from Crete and Cyprus. These bat flies are vector hosts for the malaria parasite *Polychromophilus melanipherus* (see Witsenburg *et al.*, 2013: 169). Haelewaters *et al.* (2017: 1) furthermore reported *Nycteribia kolenati* Theodor & Moscona, 1954 from Hungary.

Additionally, Tortosa *et al.* (2013: 6) also reported the Nycteribiid bat fly *Penicillidia oceanica* (Bigot, 1885).

The bat flies *Nycteribia schmidlii* Schiner, 1853, *Penicillidia dufourii* (Westwood, 1834), and *Penicillidia conspicua* Speiser, 1901 were reported by Postawa and Furman (2014: 390) from Central Anatolia and the Levant. Haelewaters *et al.* (2018: 794) additionally reported the flies *Nycteribia parvula, Penicillidia indica, P. jenynsii*, and *P. oceanica* from non-specified areas.

In Europe, the tick *Ixodes simplex* Neumann, 1906 is highly specialized to *M. schreibersii* (see Hornok *et al.*, 2014: 1).

In Spain, Estrada-Peña and Serra-Cobo (1991: 346) found the following Acari: *Ixodes (Pomerantzevella) simplex* Neumann, 1906, *Ixodes (Eschatocephalus) vespertilionis* Koch, 1844, *Macronyssus longimanus* (Kolenati, 1856), *Macronyssus granulosus* (Kolenati, 1856), *Macronyssus cyclaspis* (Oudemans, 1906), *Macronyssus rhinolophi* (Oudemans, 1902), *Macronyssus diversipilis* (Vitzthum, 1920), *Macronyssus ellipticus* (Kolenati, 1857), *Spinturnix psi* (Kolenati, 1856), *Eyndhovenia euryalis euryalis* (Canestrini, 1884); and the bat flies *Nycteribia schmidlii* Schiner, 1853 and *Penicillidia dufouri* (Westwood, 1835).

VIRUSES:

Astroviridae

Luis *et al.* (2013: suppl.) mention the presence of an unassigned bat astrovirus.

Coronaviridae - Coronaviruses

Luis *et al.* (2013: suppl.) report the occurrence of various Coronaviruses (e.g., BatCoV HKU7, Miniopterus bat coronavirus 1, Miniopterus bat coronavirus HKU8).

Alphacoronavirus

Kohl and Kurth (2014: 3112) report this virus from Spain and Germany.

Betacoronavirus

Kohl and Kurth (2014: 3112) report this virus from Bulgaria and Germany.

Filoviridae - Filoviruses

Cuevavirus

Reported from Spain by Kohl and Kurth (2014: 3113).

Negredo *et al.* (2011: 1) described a new virus (Lloviu virus [LLOV]) from *M. schreibersii* in Spain.

Flaviviridae

Flavivirus

de Jong *et al.* (2011: 10), Luis *et al.* (2013: suppl.) report Japanese encephalitis virus. Luis *et al.* (2013) also mentions Kyasanur Forest disease virus and Yokose virus.

Orthomyxoviridae

Despite sampling and testing of 2 individuals of this species, no evidence of influenza A-like viruses (*Orthomyxoviridae*) were obtained (Fereidouni *et al.*, 2015).

Papillomaviridae

Dyolambda

A new papillomavirus (*Miniopterus schreibersii* papillomavirus type 1 [MscPV1]) was described by Tse *et al.* (2012: 5) from Hong Kong as the first member of the novel Dyolambda-papillomavirus genus.

Phenuiviridae

Phlebovirus - Rift Valley fever virus

de Jong *et al.* (2011: 11), Luis *et al.* (2013: suppl.) report the occurrence of Rift Valley fever virus.

Picornaviridae

Zeghbib *et al.* (2019: 3) reported a new *Mischivirus* from a bat from Algeria.

Rhabdoviridiae

Lyssavirus - Rabies related viruses

de Jong *et al.* (2011: 9) report the presence of West Caucasian bat virus.

van Eeden *et al.* (2011: 67) report an unconfirmed, but possible occurrence of Duvenhage virus in a specimen from the Limpopo province, South Africa.

In Algeria, Serra-Cobo *et al.* (2018: 2) found seven bats out of 63 testing seropositive for European bat lyssavirus 1.

"Various European bat lyssaviruses" were reported by Kohl and Kurth (2014: 3114) from a variety of European countries.

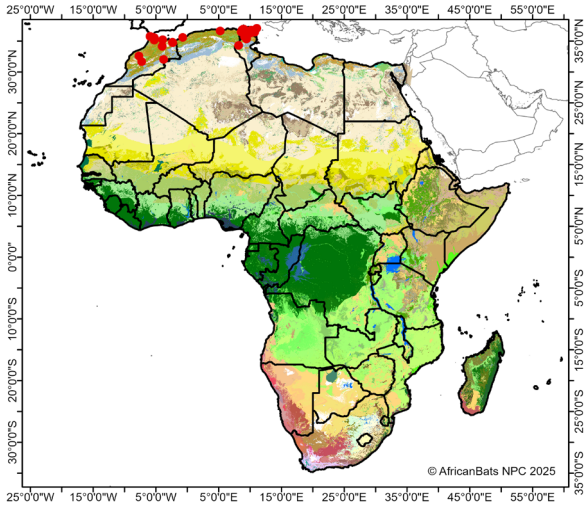

Figure 248. Distribution of *Miniopterus schreibersii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Algeria, Morocco, Tunisia.

Miniopterus sororculus Goodman, Ryan, Maminirina, Fahr, Christidis and Appleton, 2007

*2007. *Miniopterus sororculus* Goodman, Ryan, Maminirina, Fahr, Christidis and Appleton, J. Mamm., 88 (5): 1219, figs 2 - 6. Type locality: Madagascar: Province de Fianarantsoa: unnamed cave: Ambatofinandrahana, 3 km S [2034.321S 4648.530E, 1450 m]. Holotype: FMNH 177259: ad ♀, skull and alcoholic. Collected by: Steven M. Goodman; collection date: 23 March 2003; original number: SMG 13560. Paratype: FMNH 177255: Collected by: Steven M. Goodman; collection date: 23 March 2003. Paratype: FMNH 177256: Collected by: Steven M. Goodman; collection date: 23 March 2003. Paratype: FMNH 177257: Collected by: Steven M. Goodman; collection date: 23 March 2003. Paratype: FMNH 177258: Collected by: Steven M. Goodman; collection date: 23 March 2003. Paratype: FMNH 177260: Collected by: Steven M. Goodman; collection date: 23 March 2003. - Etymology: The name *sororculus* is derived from the Latin ("*sororcula*") and means "small sister" (Goodman *et al.*, 2007b: 1222). This epithet was chosen to contrast this taxon with its African counterpart *fraterculus*, which means "little brother", as well as this animal being slightly smaller than *M. majori* (Goodman *et al.*, 2007b: 1222). (Current Combination).

2017. *Miniopterus sorculus:* Yohe, Abubakar, Giordano, Dumont, Sears, Rossiter and Dávalos, Evolution, 71 (4): Suppl. Publication date: 7 March 2017. (Lapsus).

2018. *Miniopterus soroculus:* Kemp, López-Baucells, Rocha, Wangensteen, Andriatafika, Nair and Cabeza, Agric. Ecosyst. Environ., 369: 90 (for 2019). Publication date: 1 October 2018. (Lapsus).

? *Miniopterus sororculus fraterculus:* (Name Combination).

TAXONOMY:
Specimens from Madagascar assigned to *M. fraterculus* by Peterson *et al.* (1995) and Simmons (2005) are now considered to be a distinct species (Goodman *et al.*, 2007b).

COMMON NAMES:
Czech: létavec sesterský. English: Sororculus Long-fingered Bat, Sororcula Long-fingered Bat, Small sister Long-fingered Bat, Sororcula Bent-winged Bat. French: Minioptère petite soeur. German: Madagaskar-Langflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) as the species appears to have a broad distribution in the central highlands with a relatively wide elevational range. There are no obvious major threats, and based on current records seems to be at least somewhat adaptable to disturbed habitats (Jenkins *et al.*, 2008f; IUCN, 2009; Monadjem *et al.*, 2017t)).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017t).
2008: LC ver 3.1 (2001) (Jenkins *et al.*, 2008f; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
There are no known threats to this species and it exists in areas some distance from native forest (Goodman *et al.*, 2007b; Jenkins *et al.*, 2008f; IUCN, 2009; Monadjem *et al.*, 2017t).

CONSERVATION ACTIONS:
Jenkins *et al.* (2008f) [in IUCN (2009)] and Monadjem *et al.* (2017t) report that at present, there are no known records from protected areas. This is a recently described taxon that does not appear to rely on large tracts of intact forest for its survival (Goodman *et al.*, 2007b). Further studies

are needed to understand its adaptation to high elevations and extreme climate (Goodman *et al.*, 2007b).

GENERAL DISTRIBUTION:
Miniopterus sororculus is endemic to Madagascar where it has mainly been recorded from sites above 900 m elevation (Goodman *et al.*, 2007b) although there are a few records from sites at elevations < 50 m (Goodman *et al.*, 2008a). It is known from < 10 m confirmed localities ranging in elevation from 40 to 2,200 m above sea level. It is presumed to have a broad distribution spanning various portions of the Central Highlands (Goodman *et al.*, 2007b).

Schoeman *et al.* (2014: 28; 31) found the most suitable area for this species to be located in the central highland part of the island (higher elevations of the Central Highlands - sub-humid region).

Native: Madagascar (Goodman *et al.*, 2007b; Goodman *et al.*, 2008a).

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls as *Miniopterus majori/sororculus*, which produced broadband FM/QCF echolocation calls at low duty cycle, but with a lower maximum energy, at about 48.5 kHz. The fundamental being most intense with short duration pulses of about 4.5 ms.

Ramasindrazana *et al.* (2011: 294) recorded 20 calls from 7 *Miniopterus sororculus* specimens, and found the following echolocation call values: Frequency of maximum energy: 55.3 ± 0.92 (53.9 - 56.6) kHz, Maximum frequency: 103.2 ± 9.04 (83.0 - 121.0) kHz, Minimum frequency: 51.7 ± 1.08 (50.0 - 53.0) kHz, Call duration: 3.3 ± 0.29 (2.7 - 3.9) ms, Inter pulse interval: 79.3 ± 13.06 (50.8 - 99.8) ms.

HABITAT:
The holotype of *M. sororculus* was collected in a small limestone cave surrounded by pseudosteppe at 1,450 m (Goodman *et al.*, 2007b). This species is known to use rock crevices and deeper caves as day roosts (Goodman *et al.*, 2007b). At Antsampandrano, this species was found occupying a day roost in the attic of a building occupied by people. Further, it has been obtained in open dry savanna in the central west of Madagascar (Goodman *et al.*, 2007b).

ROOST:
Wilkinson *et al.* (2012: 160) mention that caves are the typical roosting sites for this species on Madagascar, although it is also found in rocky crevices (Garbutt, 2022: 108).

DIET:
Garbutt (2022: 108) states it presumably feeds on small insects like moths (Lepidoptera), bugs (Hemiptera) and beetles (Coleoptera).

POPULATION:
Structure and Density
There is no information available on the population status of this recently described endemic species (Jenkins *et al.*, 2008f; IUCN, 2009; Monadjem *et al.*, 2017t).

Trend
2016: Unknown (Monadjem *et al.*, 2017t). 2008: Unknown (Jenkins *et al.*, 2008f; IUCN, 2009).

PARASITES:
Dietrich *et al.* (2014: Suppl.) and Gomard *et al.* (2016: 5) report the presence of spirochaetes of the genus *Leptospira*, which Dietrich *et al.* (2018a: 3) identified as *L. borgpetersenii*.

Ramasindrazana *et al.* (2016: 6) recovered *Litomosa* Clade 1 and 2 (Nematoda: Onchocercidae) from this species.

Tortosa *et al.* (2013: 4) reported the presence of *Penicillidia leptothrinax*, a Nycteribiid bat fly. Ramasindrazana *et al.* (2017: Suppl.) mentioned the bat fly *Nycteribia stylidiopsis* (but the specimen on which this was found - UADBA 43264 - is here considered to be a *M. majori*).

Minozzo *et al.* (2021:7) refer to Ramasindrazana *et al.* (2018) to report the presence o the haemosporidian *Polychromophilus* in this bat species.

VIRUSES:
Astroviridae
Hoarau *et al.* (2021: Suppl.) reported these viruses in organs of bats from Madagascar.

Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 1 individuals from the Mauritius using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 1 positive results for viral nucleic acids.

2 out of 22 Madagascan specimens tested by Mélade *et al.* (2016b: 4) were positive for paramyxoviruses.

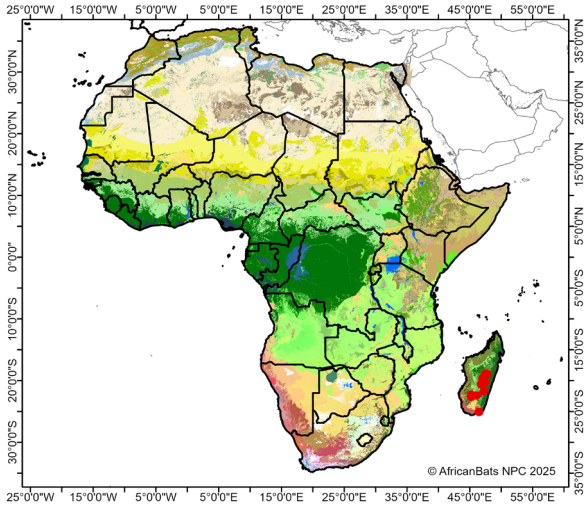

Figure 249. Distribution of *Miniopterus sororculus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Miniopterus villiersi Aellen, 1956

1956. *Miniopterus inflatus villiersi* Aellen, Bull. IFAN, (A) 18: 890. Type locality: Guinea: Dalaba: Grotte du Marché [10 42 N 12 15 W]. [Goto Description]. Holotype: MHNG IFAN 54-1-1: ad ♂. Collected by: Prof. André Villiers; collection date: 16 April 1954; original number: 2839. Former number IFAN: 54-1-1. Paratype: MHNG 983.044: ♂, alcoholic (skull not removed). Collected by: Prof. André Villiers; collection date: 16 April 1954. Paratype: MHNG 983.045: ♀, alcoholic (skull not removed). Collected by: Prof. André Villiers; collection date: 16 April 1954. - Comments: Considered a valid subspecies by Fahr and Ebigbo (2003: 128; 2004: 73), Fahr (2007a: 104). Aellen (1956a: 891) mentions 2 ♂♂ and 5 ♀♀ paratypes.

1965. *Miniopterus schreibersii villiersi:* Koopman, Am. Mus. Novit., 2219: 19. Publication date: 22 June 1965. (Name Combination).

2006. *Miniopterus (schreibersii) villiersi:* Fahr, Djossa and Vierhaus, Rapid assessment of bats (Chiroptera) in Déré, Diécké and Mt. Béro classified forests, southeastern Guinea; including a review of the distribution of bats in Guinée Forestière, 40: 74. (Name Combination).

2006. *Miniopterus villiersi:* Fahr, Djossa and Vierhaus, Rapid assessment of bats (Chiroptera) in Déré, Diécké and Mt. Béro classified forests, southeastern Guinea; including a review of the distribution of bats in Guinée Forestière: 74. (Current Combination).

2017. *Miniopterus screibersii villiersi:* Reardon and Schoeman, Acta Chiropt., 19 (2): Suppl. Publication date: December 2017. (Lapsus).

? *Miniopterus fraterculus villiersi:*

TAXONOMY:
For a long time, *villiersi* was considered to be a synonym or a subspecies of either *M. inflatus*, *M. schreibersii* or *M. natalensis*. Fahr *et al.* (2006a: 74), Weber and Fahr (2006: "4"), Jacobs *et al.* (2008x: 74) and Monadjem *et al.* (2016y: 371) indicated that *villiersi* represents a separate species (restricted to the Upper-Guinea forest zone), a view which is currently gaining support as detailed genetic analyses indicate the presence of multiple taxa in West Africa, and is confirmed by Monadjem *et al.* (2020e: 237, 248).

COMMON NAMES:
German: Lanflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Probably restricted to the Upper-Guinea forest zone, including Guinea (Decher *et al.*, 2016: 274).

ECHOLOCATION:
Monadjem *et al.* (2020e: 248) found that the knee frequency of the echolocation calls from five hand-released *M. villiersi* specimens ranged between 51.1 and 52.4 kHz (average 51.6 kHz).

HABITAT:
Monadjem *et al.* (2016y: 371) recorded *M. (schreibersii) villiersi* from altitudes between 460 and 900m in the Mount Nimba area.

ROOST:
Monadjem *et al.* (2016y: 371) found *Miniopterus (schreibersii) villiersi* roosting in old mine adits in the Mount Nimba area.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

PARASITES:
HAEMOSPORIDA
Schaer *et al.* (2013a: 17416) report the presence of hemosporidian parasites of the genus *Polychromophilus* in three out of 12 investigated *M. villiersi* specimens from West Africa. Rosskopf *et al.* (2018: Suppl.) and Arnuphapprasert *et al.* (2020: Suppl.) also reported *Polychromophilus* sp. in bats from Guinea. Sándor *et al.* (2021b: 7) identified this parasite as *P. melanipherus* Dionisi, 1899 (see also Bajić *et al.*, 2023: Suppl.).

ACARI
Uchikawa (1985a: 19) indicates that *Miniopterus villiersi* is one of the true hosts of "typical" *Calcarmyobia congoensis* Uchikawa, 1982 (Acari: Myobiidae).

DIPTERA
Nycteribiidae
Dick *et al.* (2023) mentioned the following nycteribiid flies have been found on *Miniopterus* cf. *viliersi* bats from the Mwaluganje Community Elephant Sanctuary: *Nycteribia schmidlii scotti* Falcoz, 1923 and *Penicillidia (Penicillidia) fulvida* (Bigot, 1885). However, given that these records are from Kenya, they most probably do not reprsent true *M. villiersi*.

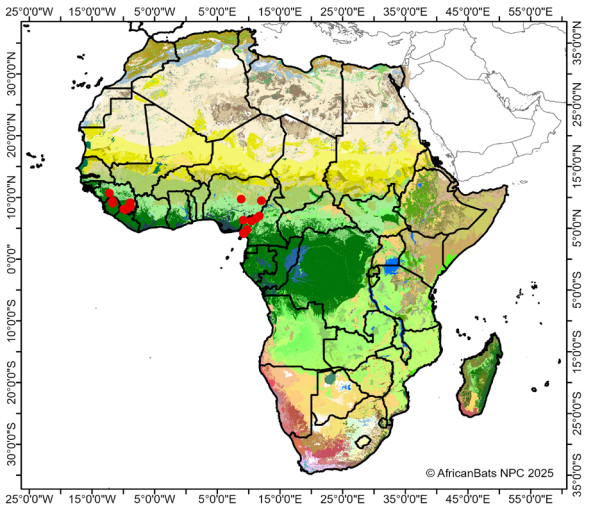

Figure 250. Distribution of *Miniopterus villiersi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Cameroon, Guinea, Liberia, Nigeria, Sierra Leone.

Miniopterus wilsoni Monadjem, Guyton, Naskrecki, Richards, Kropff and Dalton, 2020

*2020. *Miniopterus wilsoni* Monadjem, Guyton, Naskrecki, Richards, Kropff and Dalton, Acta Chiropt., 22 (1): 7, figs 5, 6, 7. Publication date: 3 September 2020. Type locality: Mozambique: Mount Gorongosa [18 28 59 S 034 02 41 E, 920 m]. Holotype: EOWL JAG444: ad ♂, skull and alcoholic. Collected by: Jennifer ("Jen") Anna Guyton; collection date: 22 April 2018. Paratype: EOWL JAG445: ad ♀. Collection date: 22 April 2018. - Etymology: In honour of Edward O. Wilson who has supported and facilitated biodiversity research at Gorongosa National Park over the past decade (Monadjem *et al.*, 2020b: 9).. (Current Combination).

COMMON NAMES:
English: Wilson's Long-fingered Bat

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Based on genetically confirmed specimens, Monadjem *et al.* (2020b: 10) restricted the range of this species to Mount Gorongosa (central Mozambique), but morphologically similar specimens were also recorded from northern Mozambique and southern Malawi. All of the localities are situated on mountains above 1,600 m.

ECHOLOCATION:
Monadjem *et al.* (2020b: 10) reported a F_{peak} of 56.8 ± 0.96 (56 - 58 kHz) for four calls recorded at the type locality and believed to be from this species.

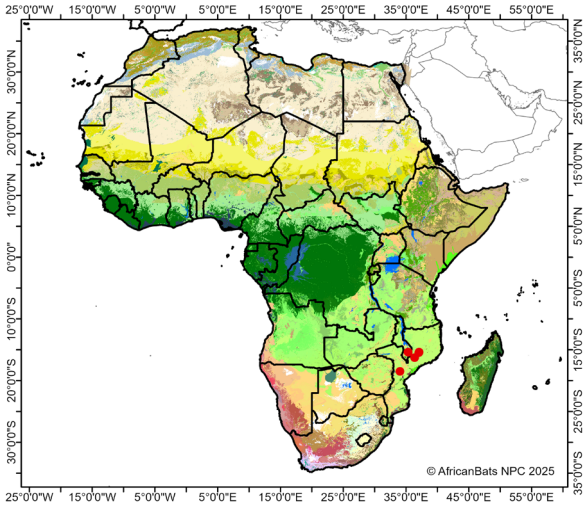

Figure 251. Distribution of *Miniopterus wilsoni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Malawi, Mozambique.

Family MYZOPODIDAE Thomas, 1904

*1904. *Myzopodidae* Thomas, Proc. zool. Soc. Lond., 1904, II, I: 5. Publication date: 1 October 1904. - Comments: Type genus: *Myzopoda* A. Milne-Edwards and A. Grandidier, 1878. (Current Combination).

TAXONOMY:
Although they are currently assigned to different superfamilies, karyotypic data suggest that the closest relatives of the Myzopodidae are the Nycteridae Volleth *et al.* (2020a: 279). Kruskop and Artyushin (2021: 119) assigned the Nycteridae to the Emballonuroidea and the Myzopodidae to an undefined (incertae sedis) superfamily.

Hao *et al.* (2023: 1) suggest that the Myzopodidae should be considered a basal lineage within the Emballonuroidea, having a sister relationship with the Nycteridae and the Emballonuridae.

The analysis of fossil material led Jones *et al.* (2024: 12) to conclude that the Myzopodidae occupy the basal extant branch of the Vespertilionoidea. This is based on three synapomorphies: myotodont lower molars, a tall entocristid on m1-2, and an m3 entocristid that is parallel to the long axis of the tooth.

Currently (Simmons and Cirranello, 2024a) recognized extant genus: ***Myzopoda*** A. Milne-Edwards and A. Grandidier, 1878.
Additionally, there is one extinct genus: †***Phasmatonycteris*** Gunnell, Simmons and Seiffert, 2014.

COMMON NAMES:
Czech: přísavkovcovití, myzopodovití, netopýrkové ušatí. Dutch: Madagassische hechtschijfvleermuizen. English: Sucker-footed Bats. French: Myzopodidés, Vespertilions dorés. German: Madagassische Haftscheibenfledermaus, Madagaskar-Haftscheibenfledermäuse. Norwegian: Sugeskålflaggermus.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Butler (1978: 67) suggests that the Myzopodidae are probably of African mainland origin but survive only in Madagascar.

Simmons *et al.* (2013: 146) indicate that one fossil species is known in this family. (Currently three species are known, see below).

The family-level stem and crown ages were calculated by Shi and Rabosky (2015: 1537) as 54.1 and 1.1 mya, respectively.

MOLECULAR BIOLOGY:
Karyotype
Sotero-Caio *et al.* (2017: 5) mention a 2*n* value of 26 for the two species in this family.

Genus ***Myzopoda*** Milne-Edwards and A. Grandidier, 1878

*1878. *Myzopoda* A. Milne-Edwards and A. Grandidier, Bull. Sci. Soc. Philom. Paris, sér 7, 2: 220. Publication date: 22 June 1878. - Comments: Type species: *Myzopoda aurita* A. Milne-Edwards and A. Grandidier, 1878. -

Etymology: From the Greek "*μύξάω*", meaning to suck (not from "*μύξα*", meaning mucus) and "*πούς*", meaning foot, referring to the sectional disk on the thumbs and feet (see Palmer, 1904: 446). (Current Combination).

1879. *Myxopoda:* Dobson, Proc. zool. Soc. Lond., 1878, IV: 871. Publication date: April 1879. - Comments: Lapsus (see Allen, 1939a: 82; Schliemann and Maas, 1978: 1) or emendation (see Palmer, 1904: 445). - Etymology: From the Greek "*μύξα*", meaning mucus, and "*πούς*", meaning foot, referring to the sectional disk on the thumbs and feet (see Dobson, 1879a: 281; Palmer, 1904: 445). (Lapsus).

TAXONOMY:

Currently Simmons and Cirranello, 2023b) recognized species of the genus *Myzopoda*: ***aurita*** A. Milne-Edwards and A. Grandidier, 1878; ***schliemanni*** Goodman, Rakotondraparany and Kofoky, 2007.

COMMON NAMES:

Czech: přísavkovci, myzopody. English: Sucker-footed Bats. French: Chauves-souris à ventouses. German: Madagaskar-Haftscheibenfledermäuse.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

Butler (1978) found a *Myzopoda* sp. at Olduvai, Kenya, in deposits of early Pleistocene age.

Goodman *et al.* (2022: 1903) indicate that fossils have been identified from the late Eocene and early Oligocene of Egypt, and from the early Pleistocene of Tanzania.

CONSERVATION STATUS:

Assessment History

Global

Assessed as *M. aurita* VU (World Conservation Monitoring Centre, 1993); LC ver 3.1 (2001) (Jenkins *et al.*, 2008h; IUCN, 2009).

Russell *et al.* (2008b: 219) suggests that *Myzopoda* sp. may be among the few Malagasy vertebrate species to benefit from rapid deforestation, due to the species utilizing *Ravenala* as a day roost. *Ravenala* is a dominating pioneering species, and dense stands are found in areas of primary lowland forest which have been cleared (Goodman *et al.*, 2007a).

BIOGEOGRAPHY:

Russell *et al.* (2008b) using coalescent analysis places the time of divergence of *M. aurita* and *M. schliemanni* at approximately 73,500 years ago.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:

A special feature in *Myzopoda* is the presence of adhesive organs on the ventral side of the thumb and the sole. These are flat, diskshaped sessile skin accessories becoming thinner distally and laterally. These pads work by wet adhesion, facilitated by a continuous glandular secretion (Ralisata *et al.* (2022: 1918, 1919)

DENTAL FORMULA:

The permanent dental formula is as follows: $I^2/_3$, $C^1/_1$, $PM^3/_3$, $M^3/_3$ = 38 (Ralisata *et al.* (2022: 1917).

DETAILED MORPHOLOGY:

Reproductive system

Carter and Enders (2016: 284) found *Myzopoda* sp. to have a smooth chorioallantois, suggesting that this genus belongs in the emballonurid clade.

†***Myzopoda africana*** Gunnell, Butler, Greenwood and Simmons, 2015

*2015. *Myzopoda africana* Gunnell, Butler, Greenwood and Simmons, Am. Mus. Novit., 3846: 1, 3, figs 2A, 2C, 3. Publication date: 16 December 2015. Type locality: Tanzania: Arusha province: Olduvai Gorge: Bed I, FLK NI, Layer 123. - Etymology: The name refers to the African continent as it is the only representative of the genus *Myzopoda* that is found on continental Africa.

SIMILAR SPECIES:

M. africana's humeri are on average 21 % larger than those of its living congeners (Gunnell *et al.*, 2015a: 5).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

Timeframe:

Pleistocene (Brown *et al.*, 2019: Suppl.).

Myzopoda aurita Milne-Edwards and A. Grandidier, 1878

*1878. *Myzopoda aurita* A. Milne-Edwards and A. Grandidier, Bull. Sci. Soc. Philom. Paris, sér 7, 2: 220. Publication date: 22 June 1878. Type locality: Madagascar: "Madagascar". Holotype: MNHN ZM-MO-1997-770: alcoholic (skull not removed). Number 223 in Rode (1941); see Peterson *et al.* (1995: 139). (Current Combination).

1879. *Myxopoda aurita:* Dobson, Proc. zool. Soc. Lond., 1878, IV: 879. Publication date: April 1879. (Lapsus).

TAXONOMY:
See Schliemann and Maas (1978: 116).

COMMON NAMES:
Czech: přísavkovec ušatý, netopýrek ušatý, myzopoda ušatá. English: Golden Bat, Old World Sucker-footed Bat, Sucker-footed Bat, Madagascar Sucker-footed Bat, Eastern Sucker-footed Bat. French: Chauve-souris malgache à pieds à ventouses, Chauve-souris à pieds à ventouses de Madagascar, Vespertilion Doré, Myzopoda oreillard, Chauves-souris à ventouses de Madagascar. German: Östliche Haftscheibenfledermaus.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) because it is widespread, thought to be locally common in areas of anthropogenic disturbance, and there are no obvious major threats (Jenkins *et al.*, 2008h; IUCN, 2009; Monadjem *et al.*, 2017p).

Ralisata *et al.* (2010) refute the suggestion that this species is rare (Hutson *et al.*, 2001).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017p). 2008: LC ver 3.1 (2001) (Jenkins *et al.*, 2008h; IUCN, 2009). 1996: VU A2c ver 2.3 (1994). 1994: VU (Groombridge, 1994). 1990: VU (IUCN, 1990).

Regional
None known.

MAJOR THREATS:
There are no known major threats to this species. It is occasionally eaten by people when harvesting *Ravenala madagascariensis* plants (Jenkins *et al.*, 2008h; IUCN, 2009; Monadjem *et al.*, 2017p). However, Ralisata *et al.* (2015: 95) do point out that this harvesting itself might lead to a loss of roosts, and as such has a negative impact on the bats.

CONSERVATION ACTIONS:
Jenkins *et al.* (2008h) [in IUCN (2009)] and Monadjem *et al.* (2017p) reported that *M. aurita* has only been recorded from a few protected areas: Parc National de Marojejy (Pont and Armstrong, 1990), Tampolo littoral forest (Ifticene *et al.*, 2005) and near to Parc National de Masoala (Russ and Bennet, 1999) and Réserve Spéciale d'Analamazaotra (Russ and Bennet, 1999). Additional study is needed to develop an understanding of local population densities and precise habitat requirements.

Ralisata *et al.* (2010) indicate that it used disturbed patches of vegetation and is not therefore threatened by deforestation, although it may be affected by loss of roosts for building materials.

GENERAL DISTRIBUTION:
Myzopoda aurita is endemic to the island of Madagascar (Goodman *et al.*, 2007a). It is found in the humid zone of eastern and north-eastern Madagascar and appears to be most common at elevations lower than 500 m (Schliemann and Goodman, 2003) although it has been recorded at Andasibe (ca. 970 m).

Garbutt (2022: 90) also indicated that these bats are found where there are large stands of Traveller's Tree (*Ravenala madagascariensis* - Strelitziaceae) and *Typhonodorum* spp. (Araceae). These trees are generally found in areas where deforestation is acute.

Native: Madagascar.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
For details, see a.o. Thomas (1904g).

DENTAL FORMULA:
The permanent dental formula is as follows: $I^2/_4$, $C^1/_1$, $PM^3/_3$, $M^3/_3$ (see Dobson, 1879a: 872).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 59) described the baculum from two specimens as being a small structure, triangular in shape, without a central shaft (length: 0.21, 0.26 mm; width: 0.15, 0.16 mm). In a third specimen they found a trace of a circular bone structure.

FUNCTIONAL MORPHOLOGY:
Schliemann (1970: 397; 1971; 78) and Schliemann and Goodman (2011: 313) studied the adhesive organs of *Myzopoda*, which are flat, disc-shaped skin duplications, primarily consisting of adipose tissue. He concluded that the static friction between these organs and a vertical surface is sufficient to enable the animals to hold on to this surface.

ECHOLOCATION:
Göpfert and Wasserthal (1995: 2 - 4) reported that this bat uses a complex frequency modulated (FM) echolocation call, consisting of two to four distinct elements of increasing amplitudes and long duration. The second harmonic decreases from 42 to 24 kHz with a shallow FM sweep of about 0.6 to 0.9 kHz/ms during the first three elements and a steeper sweep (2 kHz/ms) during the final element. The duration of the calls varied

between 12 and 23 ms, and call intervals were between 11 and 108 ms.

Altringham (2011: 95) mentioned that the functional value of such a complex call design is unknown.

MOLECULAR BIOLOGY:
Karyotype
Richards *et al.* (2010) examined two females showing a 2*n*=26 and a Fna=48, with all chromosomes being bi-armed. FISH with *Myotis* probes revealed a X-autosome translocation. However, the autosome translocated to the X chromosome has not been counted for the Fna. The number of autosomal arms would then be 50 instead of 48.

Genetics
See Hoofer and Van Den Bussche (2003) and Russell *et al.* (2008b).

HABITAT:
Myzopoda aurita is widespread in intact to degraded and fragmented forests, marshes, agricultural areas, and rice paddies at low to mid elevations in eastern Madagascar (Crowley and Goodman, 2025: 4).

HABITS:
Compositional analysis revealed that *M. aurita* males selected coffee plantations, degraded humid forest and wooded grasslands more than other habitats (Ralisata *et al.*, 2010).

ROOST:
Ralisata *et al.* (2010) found 133 roosts consisting of the partially unfurled leaves of *Ravenala madagascarensis* (Sonn, 1782) and housing between nine and 51 individuals, which changed roosts every 1 - 5 days. Ralisata *et al.* (2015: 95) found that the leaves of the tree became available as roost between one and 19 days after the unfurling started and were inhabited between one and 12 days. Males and females roost separately (Garbutt, 2022: 91).

Ralisata *et al.* (2022: 1921) report roosting groups of between 1 and 36 bats.

DIET:
Göpfert and Wasserthal (1995) noted that *M. aurita* - based on the analysis of faecal pellets of a single individual from north of Tolagnaro, southeast Madagascar - fed on smaller moths ("microlepidoptera"). Ralisata *et al.* (2010) found the diet comprised mainly of Lepidoptera and Coleoptera. The latter was confirmed by Rasoanoro *et al.* (2015: 64), who mention the following volume percentages: Aranea: 15.4 ± 2.38, Coleoptera: 26.7 ± 4.60, Diptera: 3.6 ± 3.59, Homoptera: 0.3 ± 0.33, Hymenoptera: 8.4 ± 3.58, Lepidoptera: 40.1 ± 7.31, and Neuroptera: 5.5 ± 5.07.

Ramasindrazana *et al.* (2009: 161) reported the following percentage frequency / percentage volume: Lepidoptera (100 / 60.4 ± 9.54), Coleoptera (54.5 / 19.4 ± 8.44), Blattaria (54.5 / 19.0 ± 6.32) and Aranea (9.1 / 1.2 ± 1.21).

POPULATION:
Structure
See Russell *et al.* (2008b: 219).

Density
Russell *et al.* (2008b) estimated an effective population size of between 100,054 and 132,742 individuals. In some areas, *M. aurita* is locally common (P. A. Racey, *pers. comm.*), but it is rarely trapped in large numbers during surveys (Russ and Bennet, 1999; Ifticene *et al.*, 2005; Rakotondraparany and Medard, 2005; Jenkins *et al.*, 2007b). Ralisata *et al.* (2010) caught on average of 5.7 (0 - 15) individuals per mist net night, at Kianjavato, where a total of 138 individiuals were captured on 24 nights of netting.

Trend
2016: Unknown (Monadjem *et al.*, 2017p). 2008: Unknown (Jenkins *et al.*, 2008h; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Ralisata *et al.* (2010) found that the foraging areas used by male bats varied between 7 and 108 ha (100 % minimum convex polygon), where the bats foraged close to the roost for the first hour after emergence, then travelled up to 1.8 km away and returned after 03h00.

REPRODUCTION AND ONTOGENY:
See Carter *et al.* (2008).
Ralisata *et al.* (2010) suggest that juvenile males leave their mothers after weaning and join adult males. During October-November, the testes of males appeared larger than at other times of the year, although seasonal variation was not pronounced (Ralisata *et al.*, 2010). Juveniles were caught in February-March and October-November (Garbutt, 2022: 91).

PARASITES:
Ralisata *et al.* (2010) did not observe any parasties on the 138 individual males captured.

UTILISATION:
In the area around Tampolo forest, people collecting leaves of the Traveller's palm (*Ravenala madagascariensis*) for housing materials often encounter *M. aurita* roosting in the

leaves, although no evidence that the bats were deliberately sought, they were collected and taken back to the village where they were cooked and eaten (Jenkins and Racey, 2008).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

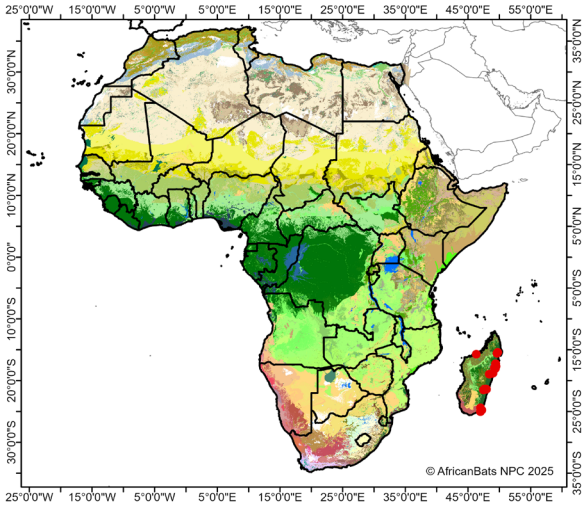

Figure 252. Distribution of *Myzopoda aurita*.

Myzopoda schliemanni Goodman, Rakotondraparany and Kofoky, 2007

*2007. *Myzopoda schliemanni* Goodman, Rakotondraparany and Kofoky, Mamm. biol., 72 (2): 65, 68, figs 2 - 5. Publication date: 26 March 2007. Type locality: Madagascar: Mahajanga province: Parc National d'Anarafantsika: Ampijoroa, forestry station: Jardin Botanique A [16 19.4 S 46 48.4 E, 160 m]. Holotype: FMNH 177327: ad ♂, skin and skeleton and skull and tissue. Collected by: Steven M. Goodman; collection date: 18 April 2003; original number: SMG-13624. 3 male and 4 female paratypes listed. - Etymology: The species name was chosen to honour Professer Dr. Harald Schliemann, University of Hamburg, in recognition of his long interest in sucker-footed bats, including several important anatomical studies (e.g. Schliemann, 1971; 2003). (Current Combination).

2016. *Myz[opoda] schleimanni:* Cardiff and Jenkins, Less. Conserv., 6: 90. Publication date: January 2016. (Lapsus).

2016. *Myzopoda scliemanni:* Amador, Moyers Arévalo, Almeida, Catalano and Giannini, J. mamm. Evolut., 25 (1): Suppl (for 2018). (Lapsus).

TAXONOMY:
Described by Goodman *et al.* (2007a) using external measurements and pelage coloration and supported by population genetics (Russell *et al.*, 2008b).

COMMON NAMES:
Czech: přísavkovec bělobřichý. English: Schliemann's Sucker-footed Bat. French: Chauve-souris à ventouses de Schliemann. German: Schliemanns Haftscheibenfledermaus.

ETYMOLOGY OF COMMON NAME:
The species name was chosen to honour Professor Dr. Harald Schliemann, University of Hamburg, in recognition of his long interest in sucker-footed bats, including several important anatomical studies (e.g., Schliemann, 1970, 1971).

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) as it has a relatively large geographic range and population size, and like other *Myzopoda* is thought to do well in highly modified habitats. It is unlikely to have been negatively impacted by deforestation (Jenkins *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017q). However, it will be important to obtain information on the local abundance of this species (Monadjem *et al.*, 2017q).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017q). 2008: LC ver 3.1 (2001) (Jenkins *et al.*, 2008l; IUCN, 2009). 2004: Not assessed but see Goodman *et al.* (2007a), who discuss the possible conservation status.

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known because of a lack of information on habitat preferences (Jenkins *et al.*, 2008l; IUCN, 2009). Russell *et al.* (2008b) consider bats of the genus *Myzopoda* to benefit from deforestation.

CONSERVATION ACTIONS:
Myzopoda schliemanni has been trapped in Parc National de Namoroka and Parc National

d'Ankarafantsika (Goodman *et al.*, 2007a) as well as a recently created protected area in the Lac Kinkony - Mahavay area (Rakotoarivelo and Randrianandrianina, 2007). Based on current information this is a restricted-range species for which there are few data on natural history or ecology and basic field research is clearly needed to obtain information on the local abundance of this species (Jenkins *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017q).

It was not found during surveys of Parc National du Tsingy de Bemaraha (Kofoky *et al.*, 2007), Parc National de Kirindy-Mité (Goodman *et al.*, 2005a; Andriafidison *et al.*, 2006a) or Kirindy CFPF (Goodman *et al.*, 2005a).

GENERAL DISTRIBUTION:
Myzopoda schliemanni is known from central western Madagascar in lowland areas from Ankaboka in the north (Goodman *et al.*, 2007a) to Andranomanintsy in the south (Russell *et al.*, 2008b). Goodman *et al.* (2007a) suggested that the distribution of range of *M. schliemanni* is broader than currently known and may extend north as far as Ambanja. They are found at altitudes of up to 200 m and in marshes dominated by *Bismarckia* palms (Garbutt, 2022: 92).

Native: Madagascar.

GEOGRAPHIC VARIATION:
See Goodman *et al.* (2007a).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Goodman *et al.* (2007a).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Goodman *et al.* (2007a).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 59) found in four specimens a triangular-shaped baculum, which was slightly more elongated than in *M. aurita* (length: 0.26 ± 0.078 mm, width: 0.12 ± 0.017 mm) and in a fifth specimen, the baculum was morphologically similar to that of the latter species.

Other
For a description of the crania, teeth, postcranial skeleton, ears and tragus see Goodman *et al.* (2007a).

SEXUAL DIMORPHISM:
Goodman *et al.* (2007a) found there is no sexual dimorphism in *M. schliemanni*.

MOLECULAR BIOLOGY:
Genetics
Russell *et al.* (2008b).

HABITAT:
There are few accounts of its foraging habitats, although Rakotoarivelo and Randrianandrianina (2007) mist-netted 16 individuals in relatively disturbed forest.

HABITS:
See Goodman *et al.* (2007a).

ROOST:
Kofoky *et al.* (2006) observed *M. schliemanni* roosting in a cave. There are no other published observations of this species' roosting preferences, although it is assumed to also use broad-leaved plants such as *Ravenala madagascariensis* (Strelitziaceae) (Goodman *et al.*, 2007a; Russell *et al.*, 2008b). Garbutt (2022: 92) mention they primarily roost in furled fronds of Bismarck Palms (*Bismarckia nobilis*), and frequently change roosts. Each palm tree can house 1 to 12 bats.

Ralisata *et al.* (2022: 1921) mention roosting groups of between 1 and 32 individuals.

DIET:
Rajemison and Goodman (2007) collected feacal samples from 18 individuals during mid-October from Andranomanitsy Forest, western Madagascar, where they reported four different insect orders. Prey belonging to the orders Lepidoptera and Blattaria were the most common in the samples and were more or less equally represented (Rajemison and Goodman, 2007).

PREDATORS:
Goodman *et al.* (2015c: 78) found the remains of one individual in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar.

POPULATION:
Structure
In Andranomanintsy forest, 8 of the 18 bats captured were males indicating a sex ratio of 1 : 1.25 (Goodman *et al.*, 2007a: 312).

Density
Estimated effective population size using demographic models from two sites was between 61,453 and 134,630 individuals (Russell *et al.*, 2008b). A roosting colony of 4 individuals was reported from a cave in Parc National de Namoroka (Kofoky *et al.*, 2006).

Trend
2016: Unknown (Monadjem *et al.*, 2017q). 2008: Unknown (Jenkins *et al.*, 2008l; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Rajemison and Goodman (2007) suggest that *M. schliemanni* is capable of gleaning prey from vegetation (see Diet).

REPRODUCTION AND ONTOGENY:
See Goodman *et al.* (2007a) and Carter *et al.* (2008).

Pregnant females were captured between late October and mid December, and births occurred between late November and early December (Garbutt, 2022: 92).

PARASITES:
Ralisata *et al.* (2022: 1921) mention the presence of unidentified bat flies.

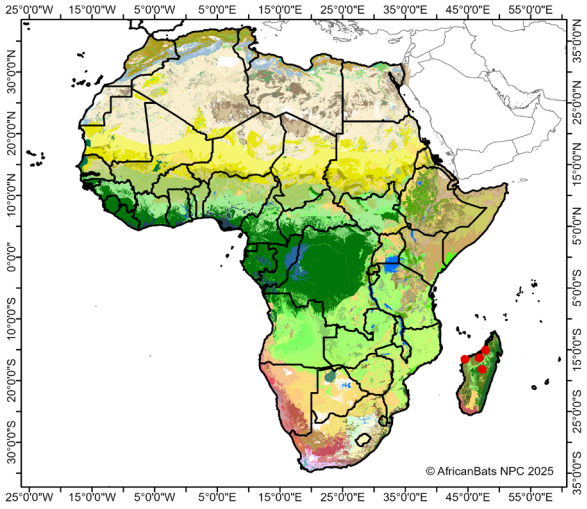

Figure 253. Distribution of *Myzopoda schliemanni*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

†Genus ***Phasmatonycteris*** Gunnell, Simmons and Seiffert, 2014

*2014. *Phasmatonycteris* Gunnell, Simmons and Seiffert, PLoS ONE, 9 (2): e86712: 6. Publication date: 4 February 2014. - Etymology: From the Greek "Phasma(to)" for apparition or spectre, in reference to the long ghost lineage connecting Fayum myzopodids with extant forms, and the Greek "Nykteris" for bat (see Gunnell *et al.*, 2014: 7). - ZooBank: 693EEE77-DD52-408B-B404-B689A43706AC. (Current Combination).

TAXONOMY:
Currently recognized species of the genus *Phasmatonycteris*: ***†butleri*** Gunnell, Simmons and Seiffert, 2014. ***†phiomensis*** Gunnell, Simmons and Seiffert, 2014.

†***Phasmatonycteris butleri*** Gunnell, Simmons and Seiffert, 2014

*2014. *Phasmatonycteris butleri* Gunnell, Simmons and Seiffert, PLoS ONE, 9 (2): e86712: 1, 7, figs 3A, 4. Publication date: 4 February 2014. Type locality: Egypt: Western Desert: Fayum Depression: Birket Qarun Formation: Fayum Quarry BQ-2 (23 metre level). - Etymology: In honour of Percy Butler, in recognition of his work on fossil bats from Africa and of his 75 year publishing career (see Gunnell *et al.*, 2014: 7). - ZooBank: E6B5FFD8-5250-4C2A-B83F-CC469DD32557. (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
The type specimen was found in the 23 metre level layer at Fayum Quarry BQ-2. This layer is about 37 million year old (Late Eocene, Priabonian - Brown *et al.*, 2019: Suppl.).

GENERAL DISTRIBUTION:
Native: Egypt.

†***Phasmatonycteris phiomensis*** Gunnell, Simmons and Seiffert, 2014

*2014. *Phasmatonycteris phiomensis* Gunnell, Simmons and Seiffert, PLoS ONE, 9 (2): e86712: 1, 6, figs 2A–D, 3C, E–G. Publication date: 4 February 2014. Type locality: Egypt: Western Desert: Fayum Depression: Fayum Quarry I (242 m level). - Etymology: From "Phiom," Greek for the Fayum Region of Egypt's Western Desert (see Gunnell *et al.*, 2014: 7). - ZooBank: 94812861-7911-438E-BD80-AB849541605B. (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
The type material was found in the 242 meter level Fayum Quarry I, in a layer of about 30 million years old (Early Oligocene, Rupelian - Brown *et al.*, 2019: Suppl.).

GENERAL DISTRIBUTION:
Egypt.

†Family PHILISIDAE Sigé, 1985

1985. *Philisidae* Sigé, 19: ?.

TAXONOMY:
Ravel *et al.* (2014) confirmed the family status of the Philisidae within the superfamily Vespertilionoidae based on a cladistic assessment of the dental data, and that they represent the earliest offshoot of this superfamily (p. 698).

Sigé (1985) [in Ravel *et al.* (2014: 696)] concluded that the Philisidae could have originated in Late or Middle Eocene from a generalized Vespertilionidae after the divergence between the Molossidae and the Vespertilionidae *sensu lato*.

Ravel *et al.* (2012) suggested that *Philisis* and *Dizzya* were probably split of from the third genus of the family (*Witwatia*) in the Early Eocene. Ravel *et al.* (2012: 699), however, doubt the close relationship between the two former genera.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
According to Ravel *et al.* (2014: 691), Philisids were among the most common African bats in the Palaeogene (66 to 23.03 mya). They were found in the Late Eocene - Early Oligocene deposits of the Fayum Depression in Egypt, together with extant bat families, such as Rhinopomatidae, Megadermatidae, Emballonuridae and Myzopodidae (Sigé, 1985; Gunnell *et al.*, 2008, 2014).

†Genus ***Dizzya*** Sigé, 1991

*1991. *Dizzya* Sigé, N. Jb. Geol. Paläont. Abh., 182: ?. - Comments: Type species - *Dizzya exultans* Sigé, 1991.

TAXONOMY:
Currently recognized species of *Dizzya*: ***†exsultans*** Sigé 1991.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Early. Eocene.

DENTAL FORMULA:
Ravel *et al.* (2011: 402) indicate that *Dizzya* differs from the other Philisidae in showing a nyctalodont molar structure.

†***Dizzya exsultans*** Sigé, 1991

*1991. *Dizzya exsultans* Sigé, N. Jb. Geol. Paläont. Abh., 182: ?. Type locality: Tunisia: Chambi. - Comments: Marandat (1994: 62) mentions the holotype to consist of a right M^1 or M^2.

. (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Early Eocene (Ypresian - Brown *et al.*, 2019: Suppl.).

DETAILED MORPHOLOGY:
Ravel *et al.* (2014: 694) indicate that *Dizzya exsultans* is the smallest representative of the Philisidae. Together with *Witwatia sigei*, it is also the oldest. Based on data from Gunnell *et al.* (2009), Ravel *et al.* (2014: 702) estimated the body weight for this bat to be about 8.6 to 9.1 g.

†Genus ***Khonsunycteris*** Gunnell, Simons and Seiffert, 2008

*2008. *Khonsunycteris* Gunnell, Simons and Seiffert, J. Vert. Paleont., 28 (1): 3, 8. - Comments: Type species - *Khonsunycteris aegypticus* Gunnell, Simons and Seiffert, 2008. - Etymology: Khonsu, Egyptian God of the Moon, in reference to the nocturnal habits of vesper bats (Gunnell *et al.*, 2008).

TAXONOMY:
See Gunnell *et al.* (2008).

Jones *et al.* (2024: 14) transferred this genus from the Vespertilionidae to the Philisidae based on synapomorphies (with *Witwatia*) including a lower

† Phasmatonycteris phiomensis

canine lacking a posterobasal cusp, myotodont lower molars, and m1-2 with large hypoconulids. However, they also point out that this genus' position within either the Philisidae, Vespertilioinidae (or wherever within the Chiroptera) will need additional material, including the upper molars.

SIMILAR SPECIES:
See Gunnell *et al.* (2008).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
See Gunnell *et al.* (2008).

Gunnell *et al.* (2017: 9) indicate that *Khonsunycteris* might be the earliest known myotine bat.

GENERAL DISTRIBUTION:
Egypt (Gunnell *et al.*, 2008).

DENTAL FORMULA:
Jones *et al.* (2024: 14) mention that *Khonsunycteris* possesses myotodont lower molars and three premolars, including a large, single-rooted p2 and reduced, double-rooted p3.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Gunnell *et al.* (2008).

†***Khonsunycteris aegypticus*** Gunnell, Simons and Seiffert, 2008

*2008. *Khonsunycteris aegypticus* Gunnell, Simons and Seiffert, J. Vert. Paleont., 28 (1): 3, 8, fig 8. Type locality: Egypt: Fayum Depression: Quarry L-41: Lower Sequence, Jebel Qatrani Formation. Holotype: CGM 83673. Left dentary c1-m2. - Comments: latest Eocene, Priabonian. - Etymology: Name for Egypt (Gunnell *et al.*, 2008). (Current Combination).
2016. *Khonsunycteris aegyptiacus:* Hand, Sigé, Archer and Black, Palaeovert., 40 (2) e2: 7. Publication date: 1 August 2016. (Lapsus).

TAXONOMY:
See Gunnell *et al.* (2008).

SIMILAR SPECIES:
See Gunnell *et al.* (2008).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
See Gunnell *et al.* (2008).

Timeframe:
Late Eocene (Priabonian - 37.97 - 33.23 - Brown *et al.*, 2019: Suppl.).

GENERAL DISTRIBUTION:
Native: Egypt (Gunnell *et al.*, 2008).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Gunnell *et al.* (2008).

†Genus ***Philisis*** Sigé, 1985

*1985. *Philisis* Sigé, Geol. Palaeontol., 19: ?. - Comments: Type species - *Philisis sphingis* Sigé, 1985. (Current Combination).

TAXONOMY:
May be a junior synonym of *Provampyrus*.

Ravel *et al.* (2014: 699) indicate that the genus might be paraphyletic.

Currently recognized species of *Philisis*: †*sevketi* Sigé, Thomas, Sen, Gheerbrant, Roger & Al-Sulaimani 1994 - Oman; †***sphingis*** Sigé 1985.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Ravel *et al.* (2014: 699) indicate that fossils of this genus were only found in deposits dating from the Early Oligocene.

†***Philisis sphingis*** Sigé, 1985

*1985. *Philisis sphingis* Sigé, Geologica et Palaeontologica, 19: ?. Holotype: YPM MAM 034488. Right maxilla (P^4-M^3): see Gunnell *et al.* (2008: 2). (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Early Oligocene (Rupelian - 32.46 - 29 mya) (see Brown *et al.*, 2019: Suppl.).

DETAILED MORPHOLOGY:
Based on data from Gunnell *et al.* (2009), Ravel *et al.* (2014: 702) estimated the body weight for this bat to be between 36 to 74 g.

†Genus ***Witwatia*** Gunnell, Simons and Seiffert, 2008

*2008. *Witwatia* Gunnell, Simons and Seiffert, J. Vert. Paleont., 28 (1): 2. - Comments: Type species - *Witwatia schlosseri* Gunnell, Simons and Seiffert, 2008. - Etymology: *Wit Wat*, Egyptian Arabic for large, flapping wings (Gunnell *et al.*, 2008). (Current Combination).

TAXONOMY:
See Gunnell *et al.* (2008).

Ravel *et al.* (2014: 702) mention that the differences between *W. schlosseri* and *W. eremicus* (both found in the same locality: BQ2, Fayum, Egypt), might be attributed to the presence of a sexual dimorphism, where the former might represent the larger female and he latter the smaller male. But they also indicate that this is currently speculative.

Jones *et al.* (2024: 17) indicate that there might still be some uncertainty to its association with the Philisidae

Currently recognized species of the genus *Witwatia*: †***eremicus*** Gunnell, Simons and Seiffert, 2008; †***schlosseri*** Gunnell, Simons and Seiffert, 2008; †***sigei*** Ravel, Marivaux, Tabuce, Bel Haj Ali, Essid, and Vianey-Liaud, 2012.

SIMILAR SPECIES:
See Gunnell *et al.* (2008).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
See Gunnell *et al.* (2008).

Timeframe - Ravel *et al.* (2014: 699) indicate that fossils were found dating back between the early and latest Eocene.

GENERAL DISTRIBUTION:
Egypt (Gunnell *et al.*, 2008).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Simmons and Jones (2024: 16) estimated that some members of this genus might have attained a weight between 40 and 116 g.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Gunnell *et al.* (2008).

DIET:
Simmons and Jones (2024: 16) [referring to Ravel *et al.* (2011,2014)] indicate that Witwatia species could possibly have fed on small vertebrates, at least opportunistic. Similarly, they might have consumed fruits too.

†***Witwatia eremicus*** Gunnell, Simons and Seiffert, 2008

*2008. *Witwatia eremicus* Gunnell, Simons and Seiffert, J. Vert. Paleont., 28 (1): 3, 4, 5. Type locality: Egypt: Fayum Depression: Quarry BQ-2: Umm Rigl Member of the Birket Qurun Formation. - Etymology: *Eremikos*, Greek for solitude, in reference to the vast solitude of the Egyptian Western Desert (Gunnell *et al.*, 2008). (Current Combination).

TAXONOMY:
See Gunnell *et al.* (2008).

SIMILAR SPECIES:
See Gunnell *et al.* (2008).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
See Gunnell *et al.* (2008).

Timeframe:
Earliest Late Eocene (Priabonian - Brown *et al.*, 2019: Suppl.), Umm Rigl Member of the Birket Qarum formation.

GENERAL DISTRIBUTION:
Egypt (Gunnell *et al.*, 2008).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Gunnell *et al.* (2008).

DETAILED MORPHOLOGY:
Based on data from Gunnell *et al.* (2009), Ravel *et al.* (2014: 702) estimated the body weight for this bat to be about 40 to 98 g.

†*Witwatia schlosseri* Gunnell, Simons and Seiffert, 2008

*2008. *Witwatia schlosseri* Gunnell, Simons and Seiffert, J. Vert. Paleont., 28 (1): 2, 3, fig 3D. Type locality: Egypt: Fayum Depression: Quarry BQ-2: Umm Rigl Member of the Birket Qarun Formation. Holotype: CGM 83668. Left dentary (c1-m3): see Gunnell *et al.* (2008: 3). - Etymology: Specific name for Max Schlosser who described the first fossil bat from the Fayum (Gunnell *et al.*, 2008). (Current Combination).

TAXONOMY:
See Gunnell *et al.* (2008).

SIMILAR SPECIES:
See Gunnell *et al.* (2008).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
See Gunnell *et al.* (2008).

Timeframe:
Earliest Late Eocene (Priabonian - Brown *et al.*, 2019: Suppl.), Umm Rigl Member of the Birket Qarum formation.

GENERAL DISTRIBUTION:
Native: Egypt (Gunnell *et al.*, 2008).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Gunnell *et al.* (2008).

DETAILED MORPHOLOGY:
Based on data from Gunnell *et al.* (2009), Ravel *et al.* (2014: 702) estimated the body weight for this bat to be between 57 and 116 g.

†*Witwatia sigei* Ravel, Marivaux, Tabuce, Bel Haj Ali, Essid and Vianey-Liaud, 2012

*2012. *Witwatia sigei* Ravel, Marivaux, Tabuce, Bel Haj Ali, Essid and Vianey-Liaud, Palaeontology, 55 (5): 1035, 1036, fig 2. Publication date: 18 September 2012. Type locality: Tunisia: Kasserine area: Chambi. Holotype: ONM CB1-230: unknown / no information. Left upper molar (M2), see Ravel *et al.* (2012: 1036). - Etymology: In honour of Bernard Sigé, who first extensively described Paleogene bats remains, including those from Chambi (see Ravel *et al.*, 2012: 1036). (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Early Eocene (Ypresian - Brown *et al.*, 2019: Suppl.).

DETAILED MORPHOLOGY:
Based on data from Gunnell *et al.* (2009), Ravel *et al.* (2014: 702) estimated the body weight for this bat to be about 100 g.

Family VESPERTILIONIDAE J. E. Gray, 1821

1815. *Vespertilia* Rafinesque, Analyse de la Nature, 54. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Conserved by Direction 98 (IUCN , 1958), which also corrected the name to Vespertilionidae. Originally included the subfamilies Lophinia (Rafinesque, 1815) [including the genera *Rhinolophus* Lacépède, 1799; *Phyllostoma* G. Cuvier, 1800 [= *Phyllostomus* Lacépède, 1799]; *Vampyrum* Rafinesque, 1815; and *Megaderma* É. Geoffroy, 1810]; and Nycteria (Rafinesque, 1815) [including the genera *Pteropus* Brisson, 1762; *Eidolon* Rafinesque, 1815; *Pteronotus* Rafinesque, 1815; *Cephalotes* É. Geoffroy, 1810 [= *Nyctimene* Borkhausen, 1797]; *Tadaris* [sic = *Tadarida*] Rafinesque, 1814; *Vespertilio* Linnaeus, 1758; *Nycterus* [sic = *Nycteris*] É. Geoffroy and G. Cuvier, 1795; *Noctilio* Linnaeus, 1766; *Molossus* É. Geoffroy, 1805; and *Atalapha* Rafinesque, 1814 [= *Nyctalus* Bowdich, 1825: 36]] (see Jackson and Groves, 2015: 264).

*1821. *Vespertilionidæ* J. E. Gray, London Med. Repos., 15: 299. Publication date: 1 April 1821. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Dobson (1878: 167) refers to Dobson, 1875 (p. 347), indicating that Gray's (1866) definition includes genera beloning to very distinct families. Originally included the genera *Megadermes* [sic = *Megaderma*] É. Geoffroy, 1810; *Rhynolophus* [sic = *Rhinolophus*] Lacépède, 1799; *Nycterus* [sic = *Nycteris*] É. Geoffroy and G. Cuvier, 1795; *Rhynopoma* [sic = *Rhinopoma*] É. Geoffroy, 1818; *Thaphosores* [sic = *Taphozous*] É. Geoffroy, 1818; *Vespertilio* Linnaeus, 1758; *Pecotus* [sic = *Plecotus*] É. Geoffroy, 1818; and *Barbastella* J. Gray, 1821 (see Jackson and Groves, 2015: 264). The name was conserved by Direction 98 (ICZN, 1958: 131). (Current Combination).

1825. *Vespertilionina* J. E. Gray, Ann. Philos., 10 (5): 339. Publication date: November 1825. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Originally include the genera *Vespertilio* Linnaeus, 1758; *Plecotus* É. Geoffroy, 1818; *Barbastellus* J. Gray, 1825 [= *Barbastella* J. Gray, 1821]; *Proboscidea* Spix, 1823 [= *Rhynchonycteris* Peters, 1867; *Thyroptera* Spix, 1823; and *Caelano* [sic = *Celaeno*] Leach, 1821 [= *Noctilio* Linnaeus, 1766: 88] (see Jackson and Groves, 2015: 264).

1843. *Gymnorhina* Wagner.

1855. *Nycticeina* Gervais, in: F. Comte de Castelnau, Exped. Partes Cen. Am. Sud., Zool, ???. Publication date: 23 July 1856.

1866. *Nyctophilina* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 91. Publication date: 1 February 1866.

1866. *Plecotina* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 91. Publication date: 1 February 1866.

1866. *Romiciana* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 90. Publication date: 1 February 1866.

1866. *Vespertiliones* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 1865: 524. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Originally included the genera *Synotus* Keyserling & Blasius, 1839 [= *Barbastella* J. Gray, 1821]; *Plecotus* É. Geoffroy, 1818; *Histiotus* Gervais, 1855; *Otonycteris* Peters, 1859; *Miniopterus* Bonaparte, 1837; *Vespertilio* Linnaeus, 1758; *Vesperugo* Keyserling and Blasius, 1839 [= *Vespertilio* Linnaeus, 1758]; *Vesperus* Keyserling and Blasius, 1839 [= *Vespertilio* Linnaeus, 1758]; *Murina* J. Gray, 1842; *Harpiocephalus* J. Gray, 1842; *Nycticejus* [sic = *Nycticeius*] Rafinesque, 1819]; *Atalapha* Rafinesque, 1814 [= *Nyctalus* Bowdich, 1825]; *Thyroptera* Spix, 1823; and *Antrozous* H. Allen, 1862 (see Jackson and Groves, 2015: 265). Jackson and Groves (2015: 227) consider this (family) name a homonym of Vespertiliones Pallas, 1767, and indicated that it covers the Vespertionidae family, rather than the Vespertilioninae subfamily. Not Vespertiliones Dobson, 1878, a group name for the subfamily Vespertilioninae.

1869. *Gymnorhinidæ* Fatio, Faune des Vertébrés de la Suisse.

1872. *Vespertilionidae:* Gill, Smiths. Misc. Coll., 11 (1): 17. Publication date: November 1872. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Originally included the subfamilies Vespertilioninae J. Gray, 1821 and Nycticejinae Gill, 1872 (see Jackson and Groves, 2015: 265).

1893. *Nycteridae:* Schulze. - Comments: Not of Van der Hoeven, 1855. Not of Dobson, 1875 (see Pavlinov *et al.*, 1995: 93).

1893. *Vespertilionini:* Winge, Samling af Afhandlinger. E Museo Lundii, 2 (1): 24. - Comments: Introduced as tribe (?). Jackson and Groves (2015: 265) (erroneously?) mention *Emballonura* Temminck, 1838 as type genus. Originally included the genera *Vespertilio* Linnaeus, 1758 [including the subgenera *Kerivoula* J. Gray, 1842; *Natalus* J. Gray, 1838; and *Nyctiellus* Gervais, 1855]; *Plecotus* É. Geoffroy, 1818; *Minyopterus* Agassiz, 1846 [= *Miniopterus* Bonaparte, 1837]; *Lasionycteris* Peters, 1865; *Vesperugo* Keyserling and Blasius, 1839 [= *Vespertilio* Linnaeus, 1758]; *Harpyiocephalus* J. Gray, 1866 [= *Harpiocephalus* J. Gray, 1842]; *Synotus* Keyserling & Blasius, 1839 [= *Barbastella* Gray, 1821]; *Chalinolobus* Peters, 1865; *Otonycteris* Peters, 1859; *Nyctophilus* Leach, 1821; *Atalapha* Rafinesque, 1814 [= *Nyctalus* Bowdich, 1825]; and *Antrozous* H. Allen, 1862 (see Jackson and Groves, 2015: 265).

1907. *Nyctophilinæ* Miller, Bull. U.S. natl. Mus., 57: xi, *234*. Publication date: 29 June 1907. - Comments: Type genus: *Nyctophilus* Leach, 1821. Originally included the genera *Antrozous* H. Allen, 1862 and *Nyctophilus* Leach (see Jackson and Groves, 2015: 270).

1942. *Myotini* Tate, Bull. Am. Mus. Nat. Hist., 80 (7): 221, 229. Publication date: 27 November 1942. - Comments: Type genus: *Myotis* Kaup, 1829. Introduced as tribe, and originally included the genera *Myotis* Kaup, 1829; *Lasionycteris* Peters, 1865; *Plecotus* É. Geoffroy, 1818; *Corynorhinus* H. Allen, 1865; *Idionycteris* Anthony, 1923; and *Euderma* H. Allen, 1891 (see Jackson and Groves, 2015: 280).

2008. *Vespertolionidae:* Selim, Nahla and Shelfeh, Tishreen Univ. J. Res. Sci. Stud. - Biol. Sci. Ser., 30 (1): 247. (Lapsus).

2018. *Vespertilionnidae:* Malekani, Musaba, Gembu, Bugentho, Toengaho, Badjedjea, Ngabu, Mutombo, Laudisoit, Ewango, Van Cakenberghe, Verheyen, Asimonyo, Masudi, Bongo and Ngbolua, Nat. Conserv. Res., 3 (1): 67. Publication date: January 2018. (Lapsus).

2024. *Vespertlionidae:* Rihane, Nahli, Laghzaoui, Dbiba, Radi, Dakki, El Mouden and El Hamoumi, Ostrich, 95 (3): 224. Publication date: 11 October 2024. (Lapsus).

2025. *Vespertiliondae:* Guan, Huang, Huang, Zhou, Yang, Yu, Guo, Feng, Wu, Hu and Wei, Sci. China Life Sci., xxx: 1. Publication date: 18 July 2025. (Lapsus).

? *Vespertilioninae sp.:*

TAXONOMY:

Systematicians have long recognized that Vespertilionidae as so defined, is diagnosed by few if any apomorphies, and some data have been cited as evidence that the family is not monophyletic. For example, *Tomopeas ravus* (the only member of the subfamily Tomopeatinae) shares immunological affinities and several derived morphological and molecular traits with molossidis (Miller, 1907; Davis, 1970; Barkley, 1984; Pierson, 1986; Sudman *et al.* (1994). Miniopterines, which differ from other vespertilionids in several aspects of foetal development and adult morphology, show immunological affinity with molossids (Mein and Tupinier, 1977; Gopalakrishna and Chari, 1983; Pierson, 1986). Kerivoulines share derived morphological traits with Natalidae, Thyropteridae, Furipteridae, and Myzopodidae (Sigé, 1974; Van Valen, 1979). These patterns have lead various workers to suggest removal of one or more subfamilies from Vespertilionidae (Davis, 1970; Sigé, 1974; Mein and Tupinier, 1977; Van Valen, 1979; Gopalakrishna and Chari, 1983; Barkley, 1984; Sudman *et al.*, 1994). Each of the eight vespertilionid subfamilies just listed appears to be monophyletic, with the exception of Vespertilioninae, which may be paraphyletic. In morphology, Vespertilioninae is "perhaps best characterized by absence of the special modifications that distinguish the other groups" (Miller, 1907: 197). Volleth and Heller, 1994) describe several derived karyotype features that diagnose Vespertilioninae (including Nyctophilinae but exclude Myotinae), but their study did not include any members of Antrozoinae or Lasiurini.

Molecular phylogenetics reviewed by Hoofer and Van Den Bussche (2003).

Roehrs *et al.* (2011: 24) suggest the following subdivision in tribes/groups:
Vespertilionini (*Nyctalus, Pipistrellus, Scotoecus, Vespertilio*)
Hypsugine group (*Chalinolobus, Vespadelus, Hypsugo, Nycticeinops, Neoromicia, Laephotis, Tylonycteris*)

Eptesicini / Nycticeiini (*Arielulus, Lasionycteris, Glauconycteris, Nycticeius, Eptesicus, Scotomanes*)
Perimyotine group (*Parastrellus, Perimytois*)
Scotophilini (*Scotophilus*)
Antrozini (*Antrozous, Rhogeessa, Baeodon*)
Lasiurini (*Lasiurus*)
Plecotini (*Corynorhinus, Otonycteris, Barbastella, Plecotus, Idionycteris*).

Known genera in the subfamily Vespertilioninae:
Tribe Eptesicini Volleth and Heller, 1994 - *Arielulus* Hill and Harrison, 1987; ***Eptesicus*** Rafinesque, 1820; *Hesperoptenus* Peters, 1868.
Tribe Lasiurini Tate, 1942 - *Lasiurus* Gray, 1831.
Tribe Nycticeiini Gervais, 1855 - ***Nycticeinops*** Hill and Harrison, 1987; *Nycticeius* Rafinesque, 1819; *Rhogeessa* H. Allen, 1866; *Scoteanax* Troughton, 1943; ***Scotoecus*** Thomas, 1901; *Scotomanes* Dobson, 1875; ***Scotophilus*** Leach, 1821; *Scotorepens* Troughton,1943.
Tribe Nyctophilini Peters,1865 - *Nyctophilus* Leach, 1821; *Pharotis* Thomas, 1914.
Tribe Pipistrellini Tate, 1942 - *Glischropus* Dobson, 1875; *Nyctalus* Bowditch, 1825; ***Pipistrellus*** Kaup, 1829; *Scotozous* Dobson, 1875.
Tribe Plecotini Gray, 1866 - *Barbastella* Gray, 1821; *Corynorhinus* H. Allen, 1865; *Euderma* H. Allen, 1892; *Idionycteris* Anthony, 1923; ***Otonycteris*** Peters, 1859; ***Plecotus*** E. Geoffroy Saint-Hilaire, 1818.
Tribe Vespertilionini Gray, 1821 - *Chalinolobus* Peters, 1867; *Eudiscopus* Conisbee, 1953; *Falsistrellus* Troughton, 1943; ***Glauconycteris*** Dobson, 1875; *Histiotus* Gervais, 1856; ***Hypsugo*** Kolenati, 1856; *Ia* Thomas, 1902; ***Laephotis*** Thomas, 1901; ***Mimetillus*** Thomas, 1904; ***Neoromicia*** Roberts, 1926; *Philetor* Thomas, 1902; *Tylonycteris* Peters, 1872; *Vespadelus* Troughton, 1943; *Vespertilio* Linnaeus, 1758.

Currently, Simmons and Cirranello (2024a) do not recognize subdivision (subfamilies/tribes) of the family Vespertionidae, but they do recognize the following genera:
- Kerivoulinae Miller, 1907: ***Kerivoula*** Gray, 1842; *Phoniscus* Miller, 1905.
- Murininae Miller, 1907: *Harpiocephalus* Gray, 1842; *Harpiola* Thomas, 1915; *Murina* Gray, 1842.
- Myotinae Tate, 1942: *Eudiscopus* Conisbee, 1953; ***Myotis*** Kaup, 1829; *Submyotodon* Ziegler, 2003.
- Scotophilinae Leach, 1821: ***Scotophilus*** Leach, 1821.
- Vespertilioninae Gray, 1821:
Antrozoini Miller, 1897: *Antrozous* H. Allen, 1863; *Baeodon* Miller, 1906; *Bauerus* Van Gelder, 1959; *Rhogeessa* H. Allen, 1866.
Lasiurini Tate, 1942: *Lasiurus* Gray, 1831.
Nycticeiini Gervais, 1866: *Arielulus* Hill and Harrison, 1987; ***Cnephaeus*** Kaup, 1829; *Eptesicus* Rafinesque, 1820; ***Glauconycteris*** Dobson, 1875; *Hesperoptenus* Peters, 1869; *Histiotus* P. Gervais, 1855; *Ia* Thomas, 1902; *Lasionycteris* Peters, 1866; *Neoeptesicus* Cláudio, Novaes, Gardner, Nogueira, Wilson, Maldonado, Oliveira and Moratelli6, 2023 [described after Simmons and Cirranello (2023b)]; *Nycticeius* Rafinesque, 1819; *Scoteanax* Troughton, 1944; *Scotomanes* Dobson, 1875; *Scotorepens* Troughton, 1944; *Thainycteris* Kock and Storch, 1996.
Pipistrellini (Tate, 1842): *Glischropus* Dobson, 1875; ***Nyctalus*** Bowdich, 1825; ***Pipistrellus*** Kaup, 1829; ***Scotoecus*** Thomas, 1901; *Scotozous* Dobson, 1875, ***Vansonia*** Roberts, 1946.
Plecotini: ***Barbastella*** Gray, 1821; *Corynorhinus* H. Allen, 1865; *Euderma* H. Allen, 1892; *Idionycteris* Anthony, 1923; ***Otonycteris*** Peters, 1860; ***Plecotus*** E. Geoffroy Saint Hilaire, 1818.
Vespertilionini Gray, 1821: ***Afronycteris*** Monadjem, Patterson and Demos, 2020; *Cassistrellus* Ruedi, Eger, Lim and Csorba, 2017; *Chalinolobus* Peters, 1867; *Falsistrellus* Troughton, 1944; ***Hypsugo*** Kolenati, 1856; ***Laephotis*** Thomas, 1901; ***Mimetillus*** Thomas, 1904; *Mirostrellus* Görföl, Kruskop, Tu, Estók, Son and Csorba, 2020; ***Neoromicia*** Roberts, 1926; ***Nycticeinops*** Hill and Harrison, 1987; *Nyctophilus* Leach, 1821; *Pharotis* Thomas, 1914; *Philetor* Thomas, 1902; ***Pseudoromicia*** Monadjem, Patterson, Webala and Demos, 2020; *Tylonycteris* Peters, 1872; *Vespadelus* Troughton, 1944; *Vespertilio* Linnaeus, 1758.
Unassigned to tribe: *Parastrellus* Hoofer, Van Den Bussche and Horáček, 2006; *Perimyotis* Menu, 1984; *Rhyneptesicus* Bianchi, 1917.

Common Names:
Castilian (Spain): Murcielagos chicos, Murciélagos de cola envainada. Czech: netopýrovití, netopýři holonosí. Dutch: Gladneusvleermuizen. English: Evening bats, Vespertilionid bats, Vesper Bats, Plain-faced Bats, Simple-nosed Bats. Finnish: Siipat. French: Vespertilionidés, Chauve-souris vesper. German: Glattnasen, Glattnasen-Fledermäuse. Italian: Vespertiliònidi. Norwegian: Glattneser, Glattneseflaggermus. Polish: mroczkowate. Romanian: Lilieci cu tragus. Russian: Гладконосые. Ukrainian: Лиликові [= Lylykovi]. Vietnamese: Họ dơi muỗi.

Etymology of common name:
Rosevear (1965) uses the colloquial name vesper bats, borrowing it from the name for the family, which is derived from the Latin for a bat,

vespertilio. They are sometimes called 'evening bats' because of their time of activity (Taylor, 2005).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Shi and Rabosky (2015: 1537) report the family-level stem ages/crown ages for the Vespertilionidae (including Miniopteridae and Cistugidae) to be 52.1 and 51.1 million years ago, respectively.

The oldest African fossil assigned to this family is *Khonsunycteris aegypticus* from the late Eocene (ca. 34 MYA) of the Fayum, Egypt (Hand *et al.*, 2016: 7).

GENERAL DISTRIBUTION:
Luo *et al.* (2019b) investigated the geographic range of 126 vespertilionid bat species (including 20 African) in relation to their wing morphology and found that species with higher wing loading have larger distribution ranges than those with lower wing loading, and that the size of geographic ranges was associated with wing aspect ratio.

DENTAL FORMULA:
Esquivel *et al.* (2021: 1093) found that the Vespertilionidae are one of the families where dental anomalies appear to occur to a greater extent, possibly as they have more complex taxonomic histories and their correct identification heavily depends on dental characters.

MOLECULAR BIOLOGY:
Karyotype
Sotero-Caio *et al.* (2017: 5) indicate that familywide the karyotype has a 2*n* value between 18 and 52.

ROOST:
López-Baucells *et al.* (2018: 30) examined the roost selection by synanthropic bats in rural Madagascar and found that small colonies of vespertilionid bats had a preference for small, traditional houses made of mud and wood, especially if the roof was made from leaves.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention a Vespertiliondae bat taken as prey by a Swamp boubou (*Laniarius bicolor* (Hartlaub, 1857)) in Botswana.

PARASITES:
Fain (1994: 1280) reports that three genera of Myobiidae (Acari) are occurring on members of the Vespertilionidae: *Acanthophthirius*, with 4 subgenera (*Acanthophtirius, Myotimyobia, Chiromyobia, Mimetillobia*) and 47 species, *Pteracarus* with 21 species, and *Calcarmyobia* with 18 species and 8 subspecies. The latter genus is restricted to bats of the genus *Miniopterus*, and since this genus is currently included in a family of its own, this implies that only two genera of Myobiidae parasite on Vespertilionidae.

VIRUSES:
Gutiérrez-Guerrero *et al.* (2020: Suppl. Fig 3A) report that worldwide 33 % of the species belonging to this family are confirmed viral carriers.

A paramyxovirus was detected in one out of nine Vespertilionidae bats sampled in Kirindy in Madagascar (Wilkinson *et al.*, 2014).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Algeria, Angola, Botswana, Congo (Democratic Republic of the), Ethiopia, Kenya, Morocco, Namibia, South Africa, South Sudan, Sudan, Tanzania, Togo, Uganda, Zambia.

Subfamily Kerivoulinae Miller, 1907

*1907. *Kerivoulinae* Miller, Bull. U.S. natl. Mus., 57: 232. Publication date: 29 June 1907. - Comments: Type genus: *Kerivoula* Gray, 1842. Originally included the genera *Kerivoula* J. Gray, 1842 and *Phoniscus* Miller, 1905 (see Caron *et al.*, 2018: 265).

TAXONOMY:
Known genera in the Kerivoulinae: †***Chamtwaria*** Butler, 1884; ***Kerivoula*** Gray, 1842; *Phoniscus* Miller, 1905.

COMMON NAMES:
Czech: vlnouškové, kerivuly. English: Forest Bats, Woolly bats.

†Genus *Chamtwaria* Butler, 1984

*1984. *Chamtwaria* Butler, Palaeovert., 14 (3): 117, 187. Publication date: 15 November 1984 [Goto Description].

TAXONOMY:
Was assigned to the Vespertilionidae by Beard *et al.* (1992).

Currently recognized species of the genus *Chamtwaria*: †***pickfordi*** Butler, 1984.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe- Early Miocene (Burdigalian).

†***Chamtwaria pickfordi*** Butler, 1984

*1984. *Chamtwaria pickfordi* Butler, Palaeovert., 14 (3): 118, 187, figs 25 A, A'. Publication date: 15 November 1984. Type locality: Kenya: Tinderet (volcano) Region, Songhor, Kapurtay agglomeration: Chamtwara. [Goto Description]. - Etymology: Named after Dr. Martin Pickford. (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Early Miocene (Burdigalian - Brown *et al.*, 2019: Suppl.).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola.

Genus ***Kerivoula*** J. E. Gray, 1842

*1842. *Kerivoula* J. E. Gray, Ann. Mag. nat. Hist., [ser 1], 10 (65): 258. Publication date: 1 December 1842. - Comments: Type species: *Vespertilio pictus* Pallas, 1767. Gray (1842: 258) mentions *Vesp. Hardwickii Horsfield, V. picta* Pallas, *V. tenuis*, G. Gärtneri [and *Kerivoula griseus, Kerivoula Poensis*]. Type species by subsequent designation (Peters, 1867c) (see Corbet and Hill, 1992: 153). Allen (1939a: 100) mentioned *Vespertilio hardwickii* Horsfield as genotype. - Etymology: Rosevear suggested that *Kerivoula* was derived from the Cingalese name for the Painted Bat, kehel vuhla. Flannery (1995a: 369) indicates that it was derived from the Ceylonese for plantain (banana) bat. - Phonetics: ke'-ree-vue'-lah, ke-ree-vool'-ah.

1849. *Kirivoula* Gervais, Dictionnaire Universelle d'Histoire naturelle, 13: 213. Publication date: 1849. - Comments: Emendation (see Meester *et al.*, 1986: 63). (Emendation).

1861. *Nyctophylax* Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 42: 390 (for 1860). Publication date: 1861. - Comments: "Apparently based on *Vespertilio tralatitius*, Temminck, 1840 =*V. tralatitius* Horsfield, 1824, an indeterminable name according to Laurie and Hill (1954: 66). According to Palmer (1904), *Nyctophylax* was 'a new name for the barbaric *Kerivoula* Gray, 1842'" (see Corbet and Hill, 1992: 153). Mentioned as a possible synonym (question mark) by Pavlinov *et al.* (1995: 93). - Etymology: From the Greek "*νύξ*" or "*νυκτός*", meaning night and "*φύλαξ*", meaning watcher (see Palmer, 1904: 467).

1870. *Nyctophilax:* Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 62 (1): 544. Publication date: November 1870. (Lapsus).

1891. *Cerivoula* Blanford, The fauna of British India, including Ceylon and Burma. Part II, 338. Publication date: 1891. - Comments: Emendation (see Meester *et al.*, 1986: 63). (Emendation).

1904. *Kehelvoulha* Jentink, Notes Leyden Mus., 24 (4): 175 (for 1902). Publication date: 15 Jul 1904. - Comments: *Nomen nudum*. Jentink (1904: 175) suggests that this should be the etymologically correct name, but adds immediately that this name has no taxonomical value whatsoever.

2005. *Keivoula:* Struebig, Rossiter, Bates, Kingston, Sai Sein Lin Oo, Aye Aye Nwe, Moe Moe Aung, Sein Sein Win and Khin Mya Mya, Acta Chiropt., 7 (1): 14. (Lapsus).

? *Kerivoula sp.:*

TAXONOMY:
Phoniscus Miller, 1906, has been included in *Kerivoula* as either a subgenus (Ellerman and Morrison-Scott, 1951; Ellerman *et al.*, 1953) or a synonym (Ryan, 1965). Hill (1965) argues for the generic separation of *Phoniscus* from *Kerivoula*, and this view appears to be widely accepted (Rosevear, 1965; Hayman and Hill, 1971; Corbet and Hill, 1992), but see Koopman (1982).

The species *aerosa* Tomes, 1858, was described from the east coast of South Africa, but Roberts (1951: 76) questions whether the description is not that of an immature *argentata*, although the colour is reminiscent of *lanosa*; Ellerman *et al.* (1953) point out that the type specimen resembles the Oriental species of *Kerivoula* (in which they include *Phoniscus*) rather than *argentata* or *lanosa*; Hill (1965: 553) has shown that *aerosa* should be transferred to the Asiatic *Phoniscus*. Hayman and Hill (1971) question the African origin of *aerosa*, and Corbet and Hill (1980) dubiously place it in Southeast Asia, while Koopman (1982) cite the provenance as 'possibly Africa'. In view of the considerable doubt about the status and origin of this species it is not treated as a member of the southern African fauna.

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Kerivoula*: ***africana*** Dobson, 1878; *agnella* Thomas, 1908 – Louisiade Arch., Woodlark and D'Entrecasteaux Isls (Papua New Guinea) (Simmons, 2005: 526);

argentata Tomes, 1861; *crypta* Wroughton and Ryley, 1913 – S India; ***cuprosa*** Thomas, 1912; *depressa* Miller, 1906 – Indochina, India, Burma [=Myanmar]; *dongduongana* Tu, Hassanin, Furey and Csorba, 2018 – Vietnam; ***eriophora*** (Heuglin, 1877); *flora* Thomas, 1914 – Borneo, Lesser Sunda Isls, Bali, Sumbawa and Sumba (Indonesia), Vietnam and Thailand (Simmons, 2005: 526); *furva* Kuo, Soisook, Ho, Csorba, Wang and Rossiter, 2017 – Taiwan, India, Myanmar, China; *hardwickii* (Horsfield, 1824) – India and Sri Lanka, Burma, Laos, Cambodia, Vietnam, Thailand, China, western Malaysia, Borneo, Java, Sumatra, Nusa Penida, Mentawai Isls, Sulawesi, Bali, Lesser Sundas, Kangean Isl and Talaud Isl (Indonesia), Philippines (Simmons, 2005: 526); *intermedia* Hill and Francis, 1984 – Borneo, western Malaysia (Simmons, 2005: 527); *kachinensis* Bates, Struebig, Rossiter, Kingston, Oo and Mya, 2004 – Myanmar, Vietnam, Cambodia; *krauensis* Francis, Kingston and Zubaid, 2007 – Peninsular Malaysia; S Peninsular Thailand; ***lanosa*** (A. Smith, 1847); *lenis* Thomas, 1916 – northeastern and southern India, western Malaysia, Sabah (Simmons, 2005: 527); *malpasi* Thomas, 1916 – India (Calcutta and Tamil Nadu), (Sabah, Sepilok) Malaysia (incl. Sarawak); Indonesia (S Borneo); *minuta* Miller, 1898 – western Malaysia, southern Thailand, Borneo (Simmons, 2005: 527); *muscina* Tate, 1941 – central New Guinea (Simmons, 2005: 527); *myrella* Thomas, 1914 – Bismarck Arch. (Simmons, 2005: 527); *oreias* (Temminck, 1840) – Known only from the type locality in Singapore; *papillosa* (Temminck, 1840) – Thailand, Cambodia, Vietnam, western Malaysia, Sumatra, Java, Sulawesi, Borneo (Simmons, 2005: 527); *pellucida* (G.R. Waterhouse, 1845) – Borneo, Philippines, Java and Sumatra, western Malaysia (Simmons, 2005: 528); ***phalaena*** Thomas, 1912; *picta* (Pallas, 1767) – Sri Lanka; India and Nepal to Vietnam, western Malaysia and southern China, Borneo, Sumatra, Java, Bali, Lombok and Molucca Isls (Simmons, 2005: 528); *pusilla* Thomas, 1894 – Mindanao (Philippines), Sarawak (Borneo); ***smithii*** Thomas, 1880; *titania* Bates, Struebig, Hayes, Furey, Mya, Thong, Tien, Son, Harrison, Francis and Csorba, 2007 – Myanmar, Thailand, Laos, Cambodia, Vietnam; Taiwan; China (Hainan Island); *whiteheadi* Thomas, 1894 – Philippines, Borneo, southern Thailand, western Malaysia (Simmons, 2005: 528).

COMMON NAMES:
Czech: praví vlnouškové. English: Woolly Bats, Trumpet-eared Bats. French: Chauves-souris peintes. German: Wollfledermäuse. Italian: Cherìvoule.

ECHOLOCATION:
Keeley *et al.* (2018: 13) indicate that some *Kerivoula* species have fundamental frequencies up to 295 kHz and bandwidths up to 155 kHz, which they link to the absence of grooves in the external ear.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Tanzania.

Kerivoula africana Dobson, 1878

*1878. *Kerivoula africana* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, p xl, 331, ul 335. Publication date: 15 June 1878. Type locality: Tanzania: Coast opposite Zanzibar Island. [Goto Description]. Holotype: MNHN ZM-MO-1985-1063: ♂, skull and alcoholic. Collected by: Achille Raffray; collection date: 1875. - Comments: Type specimen: MNHN ???, ad ♂, alcoholic. (Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: vlnoušek východoafrický, netopýr vlnatý, kerivula africká. English: African Woolly Bat, Tanzanian Woolly Bat. French: Kérivoule de Tanzanie, Chauve-souris peinte de Tanzanie. German: Tanzania-Wollfledermaus.

CONSERVATION STATUS:
Global Justification
MacPhee and Flemming (1999) considered this species to be extinct, followed by Simmons (2005), but it was recently rediscovered, see (Burgess *et al.*, 2000). Listed as Endangered under criterion B2ab(ii, iv) because its area of occupancy is estimated at 16 km^2 (the species has only been captured from four sites). The forests of the region are continuing to decline as it is converted to subsistence agriculture and is harvested as timber and firewood for local use (Cooper-Bohannon *et al.*, 2020a).

Assessment History
Global
2019: EN B2ab(iii, iv) ver 3.1 (2001) (Cooper-Bohannon *et al.*, 2020a). 2008: EN B2ab(iii) ver 3.1 (2001) (Fahr and Jacobs, 2008; IUCN, 2009). 2004: EN B2ab(iii) ver 3.1 (2001) (Fahr and Jacobs, 2004; IUCN, 2004). 1996: DD (Baillie and Groombridge, 1996). 1994: Ex (Groombridge, 1994). 1993: Ex (World Conservation Monitoring Centre, 1993). 1990: Ex

(IUCN 1990). 1988: Ex (IUCN Conservation Monitoring Centre 1988).

Regional
None known.

MAJOR THREATS:
It is threatened by the loss of coastal forests, largely through conversion of land to subsistence agriculture and harvesting of timber and firewood for local use (Fahr and Jacobs, 2008; IUCN, 2009; Cooper-Bohannon *et al.*, 2020a).

CONSERVATION ACTIONS:
Fahr and Jacobs (2008) [in IUCN (2009)] and Cooper-Bohannon *et al.* (2020a) report that it has been recorded from Morogoro (presumably within the Morogoro State Forest Reserve) and Genda Genda (possibly in a Forest Reserve). There is a need to prevent further loss of coastal forest habitat. Research is also needed into population size and trends, species' ecology and threats (Cooper-Bohannon *et al.*, 2020a).

GENERAL DISTRIBUTION:
Endemic to eastern Tanzania, where it has only been recorded from Morogoro; the Genda Genda coastal forest; and the Tong'omba coastal forest.

Native: Tanzania (Matschie, 1895; Swynnerton and Hayman, 1951; Cockle *et al.*, 1998; Burgess *et al.*, 2000).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 61 minutes, and the digestibility rate about 82.5 %.

POPULATION:
Structure and Density
Very little is known about the population of this rarely recorded species (Fahr and Jacobs, 2008; IUCN, 2009). It has been recorded at four times [sites], its global population is suspected to be declining due to extensive and continued deforestation (Cooper-Bohannon *et al.*, 2020a).

Trend
2019: Decreasing (Cooper-Bohannon *et al.*, 2020a). 2008: Decreasing (Fahr and Jacobs, 2008; IUCN, 2009).

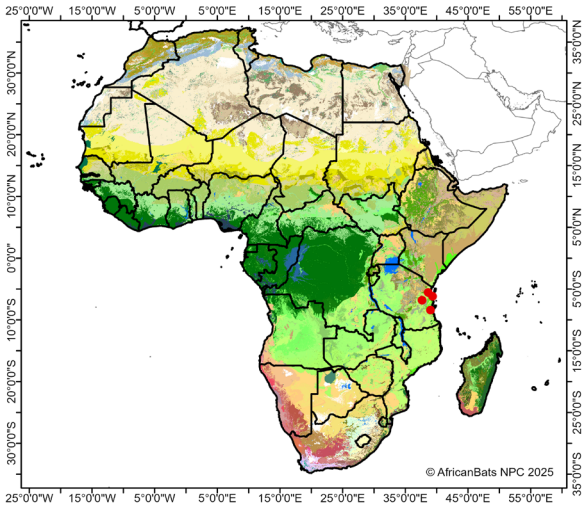

Figure 254. Distribution of *Kerivoula africana*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Tanzania.

Kerivoula argentata Tomes, 1861

*1861. *Kerivoula argentata* Tomes, Proc. zool. Soc. Lond., 1861, I: 31, 32. Publication date: May 1861. Type locality: Namibia: Ovamboland: Otjoro [=Otjihoro] [ca. 17 54 S 15 38 E]. [Goto Description]. Holotype: [Unknown] |TS171|: ♀. Collection date: 1 December 1859. See Tomes (1861b: 33). Holotype: NHMUK 1907.1.1.540: ♀. Collection date: 1 December 1859. - Comments: Ansell and Dowsett (1988: 44) indicate the type locality is probably Otjihoro, according to Shortridge (1934: 70). (Current Combination).

1865. *Nycticejus nidicola* Kirk, Proc. zool. Soc. Lond., 1864, III: 651. Publication date: May 1865. Type locality: Mozambique: Zambesi River: Shupanga [=Chupanga] [18 02 S 35 37 E]. [Goto Description]. Syntype: NHMUK 1864.1.9.37: ad. Collected by: Dr. Kirk. Syntype: NHMUK 1864.1.9.38: ad. Collected by: Dr. Kirk. Syntype: NHMUK 1864.1.9.39: ad. Collected by: Dr. Kirk. - Comments: (1 ad ♂ + 2 ad ♀♀). Considered a valid subspecies by Ansell and Dowsett (1988: 44.

1924. *Kerivoula nidicola zuluensis* Roberts, Ann. Transv. Mus., 10: 61. Publication date: 31 January 1924. Type locality: South Africa: KwaZulu-Natal: White Umfolosi River [28 19 S 31 50 E]. [Goto Description]. Holotype: TM 3025: ad ♂, skin and skull. Collected by: Austin Roberts; collection date: 17 July 1922. Note: In weaver nest with two others. - Comments: Considered a valid subspecies by Taylor (1998: 57).

? *Kerivoula argentata argentata:* (Name Combination).

? *Kerivoula argentata zuluensis:* (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Afrikaans: Damara-wolhaarvlermuis, Damaralandse Wolhaarvlermuis. Chinese: 银彩蝠. Czech: vlnoušek damarský. English:

Silvery Woolly Bat, Silvered Woolly Bat, Silver Woolly Bat, Damara Woolly Bat. French: Chauve-souris peinte argentée, Chauve-souris laineuse du Damara. German: Bunte Wollfledermaus. Kiluba (DRC): Kasusu. Portuguese: Morcego lanoso da Damaralandia.

ETYMOLOGY OF COMMON NAME:
This species was originally described from a specimen from Damaraland, Namibia (Taylor, 2005).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
K. argentata may be represented in the late Holocene at Nkupe, South Africa (Avery, 1991: 6).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008k; IUCN, 2009; Monadjem *et al.*, 2017ch).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017ch). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008k; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004h; IUCN, 2004). 1996: Lower Risk/least concern (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: NT C2a(i) ver 3.1 (2001) (Monadjem *et al.*, 2016f). 2004: EN B1ab(iii)+2ab(iii) ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Jacobs *et al.*, 2008k; IUCN, 2009; Monadjem *et al.*, 2017ch).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008k) [in IUCN (2009)] and Monadjem *et al.* (2017ch) report that there appear to be no direct conservation measures in place. It has been recorded from the Kambai Forest Reserve in Tanzania by Cunneyworth (1996b), and seems likely to be present in a number of protected areas within its range. Further studies are needed to determine if the species is truly present in Angola.

GENERAL DISTRIBUTION:
Kerivoula argentata is distributed in East Africa and southern Africa, with some records in southern parts of the Democratic Republic of the Congo and possibly northern Angola in Central Africa (records are uncertain from this country). In East Africa it has been recorded from Kenya and Tanzania in the north, through Zambia, Malawi and Mozambique. In southern Africa, it appears to be widespread in Zimbabwe, with additional scattered records from northeastern South Africa and central Namibia.

For southern Africa, Cooper-Bohannon *et al.* (2016: "5") calculated a potential distribution area of 752,853 km^2.

Native: Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 563); Eswatini (Monadjem *et al.*, 2021: 5); Kenya (Aggundey and Schlitter, 1984); Malawi (Happold and Happold, 1997b: 822; Monadjem *et al.*, 2010d: 563); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 563; Monadjem *et al.*, 2010c: 383); Namibia (Monadjem *et al.*, 2010d: 563); Rwanda (Flanders *et al.*, 2022: 3); South Africa (Roberts, 1951; Smithers, 1983; Skinner and Smithers, 1990; Taylor, 2000; Skinner and Chimimba, 2005; Monadjem *et al.*, 2010d: 563); Tanzania, United Republic of (Cunneyworth, 1996b); Zambia (Ansell, 1974; Monadjem *et al.*, 2010d: 563); Zimbabwe (Smithers and Wilson, 1979; Monadjem *et al.*, 2010d: 563).

Presence uncertain: Angola (Hill and Carter, 1941), although Taylor *et al.* (2018b: 63) predict it might occur in that country.

ECHOLOCATION:
See Taylor (1999b).

Schoeman and Waddington (2011: 291) mention a F_{peak}: 99 kHz and a duration: 1.7 ms for a specimen from the Mkuze Game Reserve, South Africa.

Moir (2020: 30) and Moir *et al.* (2021a: 371) reported six calls from one bat from southern KwaZulu-Natal or Eastern Cape (RSA), with the following features: F_{max}: 151.48 ± 6.60 (141.22 - 157.871) kHz, F_{min}: 84.06 ± 4.29 (77.67 - 90.28) kHz, F_{char}: 108.02 ± 12.76 (93.81 - 122.56) kHz, F_{knee}: 104.50 ± 3.69 (100.37 - 110.46) kHz, and duration: 1.55 ± 0.70 (0.70 - 2.54) ms.

28 calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 87.09 ± 10.39 kHz, F_{min}: 75.29 ± 9.80 kHz, F_{knee}: 77.89 ± 6.38 kHz, F_{char}:

77.44 ± 6.73 kHz, slope: 7.86 ± 28.41 OPS, duration: 3.37 ± 1.01 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 35 calls of 11 bats: F_{max}: 159.23 ± 6.03 kHz, F_{min}: 135.12 ± 15.89 kHz, F_{knee}: 142.39 ± 7.02 kHz, F_{char}: 140.26 ± 16.47 kHz, slope: 46.99 ± 7660.2 OPS, duration: 1.98 ± 1.33 ms.

ROOST:
Kerivoula argentata was found to be roosting in nests of weaver birds, but also among clusters of dead leaves, on bark of trees, under eaves of huts or on walls. They roost singly, in twos or in small groups of up to six animals (Happold and Happold, 2023: 139).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 88 minutes, and the digestibility rate about 78.5 %.

POPULATION:
Structure and Density
Although this species is rarely encountered, it is not thought to be especially uncommon (Jacobs *et al.*, 2008k; IUCN, 2009; Monadjem *et al.*, 2017ch).

Trend
2016: Unknown (Monadjem *et al.*, 2017ch). 2008: Unknown (Jacobs *et al.*, 2008k; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Trentin and Rovero (2011: 51) reported two lactating females, captured at Uzungwa Scarp Forest Reserve, Tanzania, at the end of November 2005.

VIRUSES:
Paramyxoviridae
Mortlock *et al.* (2015: 1841) reported that the one specimen they examined from South Africa tested positive for *Paramyxovirus* sequences.

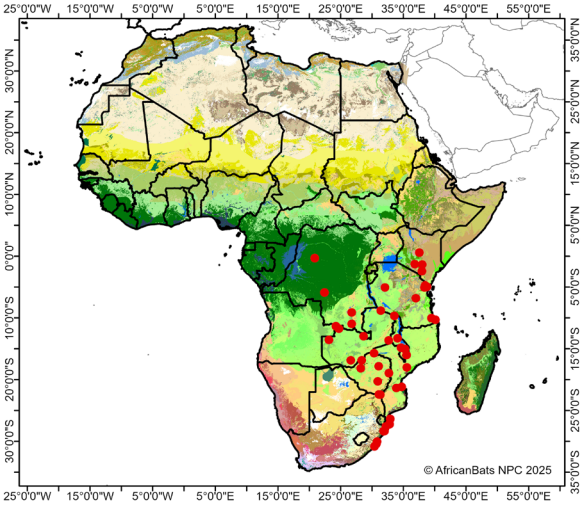

Figure 255. Distribution of *Kerivoula argentata*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Congo (Democratic Republic of the), Kenya, Malawi, Mozambique, Namibia, Senegal, South Africa, Tanzania, Zambia, Zimbabwe.

Kerivoula cuprosa Thomas, 1912

*1912. *Kerivoula cuprosa* Thomas, Ann. Mag. nat. Hist., ser 8, 10 (55): 41. Publication date: 1 July 1912. Type locality: Cameroon: Ja River: Bitye [03 13 N 12 22 E, 2 000 ft]. [Goto Description]. Holotype: NHMUK 1912.10.25.1: ad ♂. Collected by: George Latimer Bates Esq. Collection date: 17 October 1911; original number: 564. (Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: vlnoušek bronzový. English: Copper Woolly Bat. French: Chauve-souris laineuse cuivrée, Chauve-souris peinte cuivrée. German: Kupferfarbene Wollfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of continuing problems with its taxonomy as well as absence of recent information on its extent of occurrence, ecological requirements and threats (Fahr, 2008b; IUCN, 2009; Fahr, 2019a).

Assessment History
Global
2018: DD ver 3.1 (2001) (Fahr, 2019a). 2008: DD ver 3.1 (2001) (Fahr, 2008b; IUCN, 2009). 2004: NT ver 3.1 (2001) (Fahr, 2004m; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are not well known. In parts of its range it is presumably threatened to some degree by habitat loss resulting from conversion of land to agricultural use, and

harvesting of timber and firewood (Fahr, 2008b; IUCN, 2009; Fahr, 2019a).

CONSERVATION ACTIONS:
Fahr (2008b) [in IUCN (2009)] and Fahr (2019a) reports that it is unclear if this species is present in any protected areas. Additional studies are needed into the taxonomy, distribution, natural history and threats to this little-known bat.

GENERAL DISTRIBUTION:
Scattered records from West and Central Africa. It has apparently been reported from Guinea, Côte d'Ivoire, Liberia, possibly Ghana (see Koopman *et al.*, 1995; Grubb *et al.*, 1998), Cameroon and the Democratic Republic of the Congo (see Hayman and Hill, 1971). It is found up to 600 m asl.

Grubb *et al.* (1998: 92) indicate that records west of Cameroon are erroneous and probably refer to a specimen from Oda, Ghana in the FMNH that was re-identified as *K. lanosa muscilla*. A record of this species from Kenya was based on a specimen subsequently reidentified as *Kerivoula smithii* (J. Fahr *pers. Comm.,* in Simmons, 2005: 526; and also in Fahr (2008b) [in IUCN (2009)]).

Native: Cameroon; Congo (The Democratic Republic of the); Côte d'Ivoire; Guinea (Fahr and Ebigbo, 2004: 69); Kenya (Harrison, 1957b); Liberia (Koopman, 1989b; Koopman *et al.*, 1995); Nigeria (Tanshi *et al.*, 2022a: 317); Uganda (Kityo *et al.*, 2009b: 135).
Presence uncertain: Ghana.

ECHOLOCATION:
Sound files are available at the Chirovox website (https://www.chirovox.org/), e.g.: https://chirovox.elte.hu/sounds/A003669_PWGCLEZAOQ.WAV, https://chirovox.elte.hu/sounds/A003670_BBNOKVNQBS.WAV, https://chirovox.elte.hu/sounds/A003671_QTREJYLLLY.WAV

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 62 minutes, and the digestibility rate about 82.4 %.

POPULATION:
Structure and Density
It appears to be a rare, or rarely recorded, species (Fahr, 2008b; IUCN, 2009; Fahr, 2019a).

Trend
2018: Unknown (Fahr, 2019a). 2008: Unknown (Fahr, 2008b; IUCN, 2009).

PARASITES:
ACARI
Psorergatidae
Cierocka *et al.* (2022: 10) mention the presence of *Psorergatoides kerivoluae* Fain, 1959 on *Kerivoula cuprosa* specimens from the DRC.

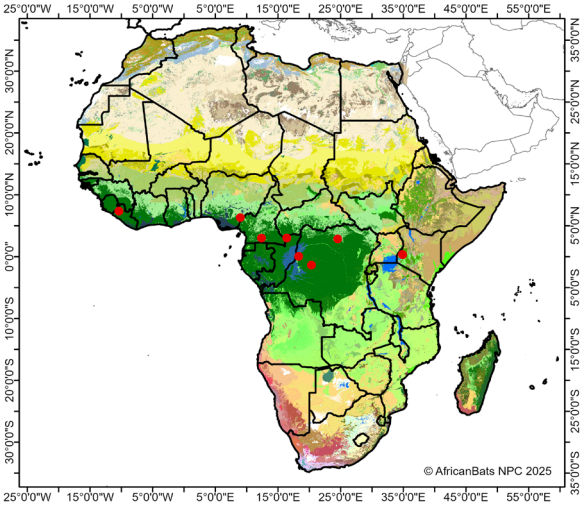

Figure 256. Distribution of *Kerivoula cuprosa*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Kenya, Liberia, Nigeria.

Kerivoula eriophora (Heuglin, 1877)

*1877. *Nycticejus eriophorus* Heuglin, Reise in Nordost Afrika, 2: 34. Publication date: 1877. Type locality: Ethiopia: Begemdir province: Belegaz Valley: Semian and Wogara, between [ca. 12 50 N 38 20 E]. [Goto Description]. - Etymology: From the Greek "*eriophora*" meaning wool-bearing.
? *Kerivoula eriophora:* (Current Combination).

TAXONOMY:
May be conspecific with *africana* which it antedates; see Hayman and Hill (1971: 53) and Simmons (2005: 526).

COMMON NAMES:
Czech: vlnoušek habešský. English: Ethiopian Woolly Bat. French: Chauve-souris laineuse d'Ethiopie, Chauve-souris peinte d'Ethiopie. German: Heuglins Wollfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of continuing problems with its taxonomy as well as absence of recent information on its extent of occurrence, ecological requirements and threats (Fahr, 2008c; IUCN, 2009; Fahr, 2019e).

Assessment History
Global
2008: DD ver 3.1 (2001) (Fahr, 2008c; IUCN, 2009). 2004: DD ver 3.1 (2001) (Fahr, 2004p; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Fahr, 2008c; IUCN, 2009; Fahr, 2019e).

CONSERVATION ACTIONS:
Fahr (2008c) [in IUCN (2009)] and Fahr (2019e) reports that it is not known if the species is present in any protected areas. Further research is needed into the systematic status, distribution, natural history and possible threats to this species.

GENERAL DISTRIBUTION:
Kerivoula eriophora has only been recorded at the type locality of 'between Semian and Wogara, Belegaz Valley, Ethiopia'.

Native: Ethiopia (Heuglin, 1877: 34), South Sudan (SMF record)

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 62 minutes, and the digestibility rate about 82.4 %.

POPULATION:
Structure and Density
It is known only from the holotype (Fahr, 2008c; IUCN, 2009; Fahr, 2019e).

Trend
2018: Unknown (Fahr, 2019e). 2008: Unknown (Fahr, 2008c; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
South Sudan.

Kerivoula lanosa (A. Smith, 1847)

*1847. *Vespertilio lanosus* A. Smith, Illustrated Zoology of South African Mammals, pl 50 and text. Publication date: December 1847. Type locality: South Africa: Cape province: Cape Town, 200 mi (332 km) E. Syntype: NHMUK 1907.1.1.538: ♂. Syntype: NHMUK 1907.1.1.539. - Comments: Thorn *et al.* (2009: 50) indicate that Roberts (1951: 75) designated Knysna as type locality. - Etymology: From the Greek "*lanosa*" meaning woolly.

1878. *Kerivoula brunnea* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, xl, 331, 334. Publication date: 15 June 1878. Type locality: South Africa: "South Africa or Madras". [Goto Description]. Holotype: NHMUK 1852.8.12.9: sad ♂, alcoholic (skull not removed). Presented/Donated by: Sir Andrew Smith. - Comments: Roberts (1951: 75) mentioned "Madras or South Africa as type locality. Sir A. Smith (Obviously the type of Smith's *V. Lanosus*, cf. Roberts, 1913: Knysna)". Meester *et al.* (1986: 64) mention "South Africa or Madras").

1901. *Kerivoula harrisoni* Thomas, Proc. zool. Soc. Lond., 1900, IV: 802, footnote. Publication date: April 1901. Type locality: Ethiopia: between Lakes Zwai and Margherita [=Lake Abaya]: Walamo [c. 07 00 N 38 00 E,, 6 700 ft]. [Goto Description]. Holotype: NHMUK 1900.11.4.1: Collected by: J.J. Harrison; collection date: 21 February 1900. Presented/Donated by: J.J. Harrison.

1906. *Kerivoula muscilla* Thomas, Ann. Mag. nat. Hist., ser 7, 18 (106): 294. Publication date: 1 October 1906. Type locality: Cameroon: Ja River [ca. 03 00 N 13 00 E]. [Goto Description]. Holotype: NHMUK 1908.6.23.10: ad ♂. Collected by: George Latimer Bates Esq. Collection date: 22 December 1905. - Comments: Considered a valid subspecies by Fahr and Ebigbo (2003: 128; 2004: 73).

1920. *Kerivoula lucia* Hinton, Ann. Mag. nat. Hist., ser 9, 6 (32): 240. Publication date: 1 August 1920. Type locality: Zambia: N'dola. [12 58 00 S 28 38 00 E, 1304 m]. [Goto Description]. Holotype: NHMUK 1920.11.3.27: ad ♂. Collected by: Captain Guy Chester Shortridge; collection date: 26 September 1919; original number: 472.

1922. *Kerivoula lueia* Kershaw, Ann. Mag. nat. Hist., ser 9, 10 (55): 99. Publication date: 1 July 1922. - Comments: Erratum (see Meester *et al.*, 1986: 64).

1959. *Kerivoula harrisoni bellula* Aellen, Archs Sci. Genève, 12 (2): 221. Type locality: Côte d'Ivoire: NW of Abidjan: Adiopodoumé [05 19 N 04 08 W, 0 - 30 m]. [Goto Description]. Holotype: MHNG 965.038: ad ♂, alcoholic (skull not removed). Collected by: Dr. Villy Aellen; collection date: 20 July 1953; original number: 622. Paratype: MHNG 965.039: ♀, alcoholic (skull not removed). Collected by: Dr. Villy Aellen; collection date: 21 December 1953; original number: 622.

TAXONOMY:
Includes *harrisoni* and *muscilla*; see Hill (1977b), but see Fahr and Ebigbo (2003: 128; 2004: 73).

COMMON NAMES:
Afrikaans: Klein wolhaarvlermuis. Chinese: 小彩蝠. Czech: vlnoušek malý. English: Lesser Woolly Bat. French: Petite Chauve-souris laineuse, Chauve-souris laineuse. German: Kleine Wollfledermaus. Portuguese: Morcego lamoso Harrison.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017ci).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017ci). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008l; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004a; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016g). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species (Jacobs *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017ci).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008l) [in IUCN (2009)] and Monadjem *et al.* (2017ci) report that it is not known if the species is present in any protected areas. Further studies are needed to better understand the taxonomic status of *Kerivoula lanosa*.

GENERAL DISTRIBUTION:
Kerivoula lanosa has been recorded across sub-Saharan Africa, from Liberia and Guinea in the west, to Ethiopia and Kenya in the east, and ranging as far south as southern South Africa. In the latter country, its distribution is mainly affected by temperature seasonality (Babiker Salata, 2012: 49).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 636,522 km^2.

Native: Angola (Monadjem *et al.*, 2010d: 563; Taylor *et al.*, 2018b: 63); Botswana (Monadjem *et al.*, 2010d: 563); Central African Republic; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 563); Côte d'Ivoire; Eswatini (Monadjem *et al.*, 2010d: 563, Monadjem *et al.*, 2021: 5); Ethiopia (Kruskop and Lavrenchenko, 2009: 72 - first record in over a 100 years); Gabon; Ghana; Guinea (Fahr and Ebigbo, 2003: 128); Kenya; Liberia; Malawi (Ansell and Dowsett, 1988; Monadjem *et al.*, 2010d: 563); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 563; Monadjem *et al.*, 2010c: 383); Nigeria (Happold, 1987); South Africa (Roberts, 1951; Smithers, 1983; Skinner and Smithers, 1990; Taylor, 1998; Skinner and Chimimba, 2005; Monadjem *et al.*, 2010d: 563); Tanzania; Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 563); Zimbabwe (Cotterill, 1996a; Monadjem *et al.*, 2010d: 563).

Presence uncertain: Namibia (Cotterill, 2004a: 262; Monadjem *et al.*, 2010d: 563).

ECHOLOCATION:
Moir (2020: 30) and Moir *et al.* (2021a: 371) reported 10 calls from one bat from southern KwaZulu-Natal or Eastern Cape (RSA) with the following characteristics: F_{max}: 147.28 ± 5.53 (137.19 - 152.32) kHz, F_{min}: 70.28 ± 2.95 (67.59 - 74.65) kHz, F_{char}: 95.41 ± 3.31 (89.28 - 98.86) kHz, F_{knee}: 95.58 ± 5.68 (90.79 - 107.94) kHz, and duration: 1.22 ± 0.2 (0.66 - 1.60) ms.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 28, FN = 50, BA = 24, a metacentric X chromosome, and an acrocentric Y chromosome, for specimens from South Africa.

ROOST:
In the southern part of the Kruger Park, Pienaar (1964: 12) indicated that it is said that it often used disused nests of weaver birds, but he could not confirm this without doubt.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 71 minutes, and the digestibility rate about 80.9 %.

POPULATION:
Structure and Density
There appears to be little information available on the population abundance of this species (Jacobs *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017ci).

Trend
2016: Unknown (Monadjem *et al.*, 2017ci). 2008: Unknown (Jacobs *et al.*, 2008l; IUCN, 2009).

PARASITES:
ACARI
Psorergatidae
Cierocka *et al.* (2022: 10) mention the presence of *Psorergatoides kerivoluae* Fain, 1959 on *Kerivoula lanosa* specimens from the DRC (Mentioned as "*Kerivoula harrisoni bellula*" by Fain, 1959a).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Botswana, Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Eswatini, Ethiopia, Gabon, Ghana, Guinea, Kenya, Liberia, Malawi, Mozambique, Namibia, Nigeria, South Africa, Tanzania, Zambia, Zimbabwe.

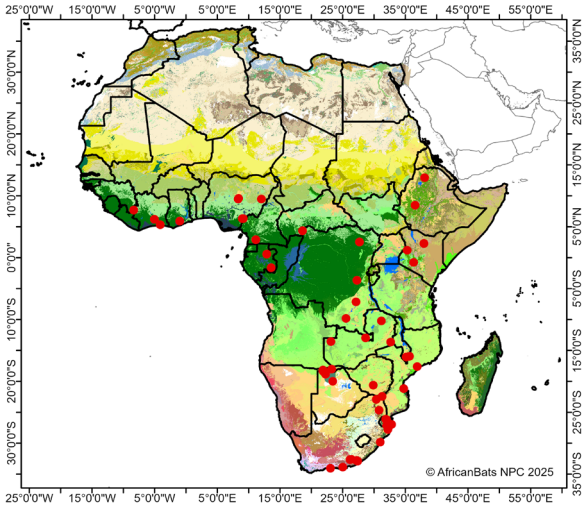

Figure 257. Distribution of *Kerivoula lanosa*.

Kerivoula phalaena Thomas, 1912

*1912. *Kerivoula phalæna* Thomas, Ann. Mag. nat. Hist., ser 8, 10 (57): 281. Publication date: 1 September 1912. Type locality: Ghana: Western province: Inland from Denkwa: Bibianaha [=Bibiani] [06 28 N 02 20 W, 720 ft]. [Goto Description]. Holotype: NHMUK 1912.6.20.3: ad ♀. Collected by: Dr. H.G.F. Spurrell; collection date: 24 April 1912; original number: 224. Presented/Donated by: Dr. H.G.F. Spurrell. - Etymology: From the Greek "*phalaena*" meaning whale. (Current Combination).
1973. *Kerivoula phalaema:* Eisentraut, Bonn. zool. Monogr., 3: 46. (Lapsus).
2010. *Kerivoula cf. phalaena:* Monadjem, Schoeman, Reside, Pio, Stoffberg, Bayliss, Cotterill, Curran, Kopp and Taylor, Acta Chiropt., 12(2): 383.
? *Kerivoula phalaena:* (Current Spelling).

TAXONOMY:
See Simmons (2005: 528).

COMMON NAMES:
Czech: vlnoušek západoafrický. English: Spurrell's Woolly Bat, Spurell trumpet-eared bat. French: Chauve-souris à oreilles en trompette de Spurell, Chauve-souris peinte phalène, Chauve-souris à oreilles en trompette de Spurell. German: Spurrells Wollfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Fahr, 2008d; Fahr, 2008d; Monadjem and Fahr, 2017a).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Fahr, 2017a). 2008: LC ver 3.1 (2001) (Fahr, 2008d; Fahr, 2008d). 2004: NT ver 3.1 (2001) (Fahr, 2004l; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known. Koopman *et al.* (1995) mention that this one of seven bat species from Liberia that have not been recorded from the lowland since 1965, and that it might have declined because of deforestation, although this may instead just indicate vagaries of collection within this country (Fahr, 2008d; IUCN, 2009; Monadjem and Fahr, 2017a).

CONSERVATION ACTIONS:
Fahr (2008d) [in IUCN (2009)] and Monadjem and Fahr (2017a) reports that it is not known if the species is present within any protected areas. Additional studies are needed into the distribution, abundance, natural history and threats to this little known species.

GENERAL DISTRIBUTION:
Recorded from Guinea, Liberia, Côte d'Ivoire and Ghana in West Africa; and from Cameroon, the Democratic Republic of the Congo to western Uganda in Central Africa.

Native: Cameroon; Congo (The Democratic Republic of the); Côte d'Ivoire; Ghana; Guinea (Fahr and Ebigbo, 2004: 69); Liberia (Kuhn, 1965; Koopman *et al.*, 1995); Nigeria (Tanshi *et al.*, 2022a: 317); Rwanda; Uganda.

Presence uncertain: Mozambique (Monadjem *et al.*, 2010c: 383, recorded as *K.* cf. *phalaena*).

HABITAT:
Monadjem *et al.* (2016y: 368) collected this bat in forested habitats in the Mount Nimba area, at altitudes between 450 and 700 m.

POPULATION:
Structure and Density
It appears to be a rare species that is known only from 14 localities (Fahr, 2008d; IUCN, 2009; Monadjem and Fahr, 2017a).

Trend
2016: Unknown (Monadjem and Fahr, 2017a).
2008: Unknown (Fahr, 2008d; IUCN, 2009).

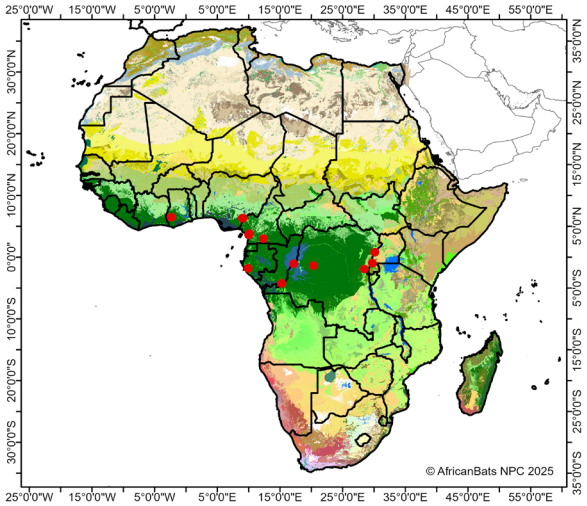

Figure 258. Distribution of *Kerivoula phalaena*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Gabon, Ghana, Liberia, Nigeria, Uganda.

Kerivoula smithii Thomas, 1880

*1880. *Kerivoula Smithii* Thomas, Ann. Mag. nat. Hist., ser 5, 6 (32): 166, text-fig. Publication date: 1 August 1880. Type locality: Nigeria: Eastern region: Old Calabar [04 56 N 08 22 E]. Holotype: NHMUK 1880.7.21.9: Collected by: Dr. A. Robb. Presented/Donated by: Dr. J.A. Smith. - Etymology: In honour of Dr. J.A. Smith, who presented to the type specimen to the British Museum of Natural History. (Current Combination).
? *Kerivoula smithi:* (Alternate Spelling).
? *Kerivoula smithii:* (Current Spelling).

TAXONOMY:
See Simmons (2005: 528).

COMMON NAMES:
Chinese: 史密斯彩蝠. Czech: vlnoušek guinejský. English: Smith's Woolly Bat. French: Chauve-souris peinte de Smith. German: Smith's Wollfledermaus. Italian: Cherìvoula di Smith.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Fahr, 2008e; IUCN, 2009; Monadjem and Fahr, 2017b).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Fahr, 2017b). 2008: LC ver 3.1 (2001) (Fahr, 2008e; IUCN, 2009). 2004: LC ver 3.1 (2001) (Fahr, 2004a; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this species (Fahr, 2008e; IUCN, 2009; Monadjem and Fahr, 2017b).

CONSERVATION ACTIONS:
Fahr (2008e) [in IUCN (2009)] and Monadjem and Fahr (2017b) reports that it is not known if the species is present within any protected areas. Further studies are needed into the distribution, abundance, and general ecology of this apparently rare species.

GENERAL DISTRIBUTION:
Kerivoula smithii is known from scattered records in a distribution band ranging from Nigeria and Cameroon in the west, through the Democratic Republic of the Congo, to Uganda and Kenya in the east. It has been recorded at elevations of 900 to 2,800 m asl.

Fahr (2007a: 105) indicates that the specimens from Liberia mentioned by Happold (1987: 349) and Koopman *et al.* (1995) are actually

representatives of *K. phalaena*. J. Fahr *pers. comm.* [in Simmons (2005: 528)] also suggests that records from Côte d'Ivoire (Happold, 1987: 349) appear to be in error.

Native: Cameroon; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966); Kenya (Harrison, 1963c; Aggundey and Schlitter, 1984) ; Nigeria (Happold, 1987: 77); Uganda.

Presence uncertain: Côte d'Ivoire (Happold, 1987: 349).

ECHOLOCATION:
Eisenring *et al.* (2016: SI 2) reported the following values for 14 calls from the Aberdares Range in Kenya: F_{peak}: 95.9 ± 6.2 (81.5 - 104.9) kHz, F_{max}: 126.3 ± 7.2 (115.6 - 137.2) kHz, F_{min}: 65.3 ± 13.2 (44.9 - 91.8) kHz, duration: 61.0 ± 16.5 (25.1 - 85.5) ms, interpulse interval: 0.2 ± 0.1 (0.1 - 0.6) ms.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 62 minutes, and the digestibility rate about 82.4 %.

POPULATION:
Structure and Density
This species has been very rarely recorded (Happold, 1987: 77; Fahr, 2008e; IUCN, 2009; Monadjem and Fahr, 2017b).

Trend
2016: Unknown (Monadjem and Fahr, 2017b).
2008: Unknown (Fahr, 2008e; IUCN, 2009).

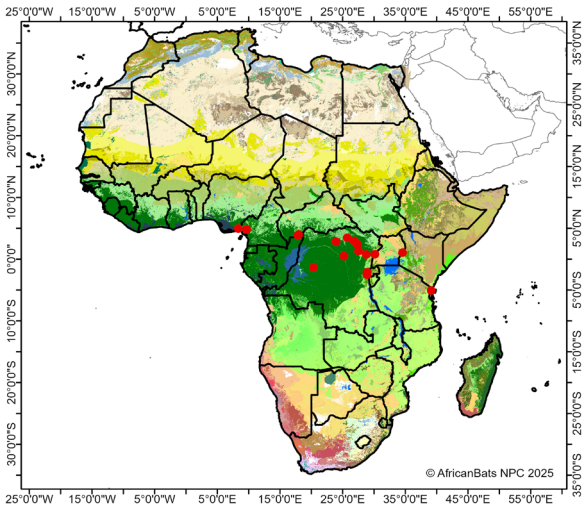

Figure 259. Distribution of *Kerivoula smithii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Central African Republic, Congo (Democratic Republic of the), Kenya, Nigeria, Tanzania, Uganda.

Subfamily Myotinae Tate, 1942

*1942. *Myotinae* Tate, Bull. Am. Mus. Nat. Hist., 80 (7): 221, 229. Publication date: 27 November 1942. - Comments: Type genus: *Myotis* Kaup, 1829. (Current Combination).

1942. *Myotini* Tate, Bull. Am. Mus. Nat. Hist., 80 (7): 221, 229. Publication date: 27 November 1942. - Comments: Type genus: *Myotis* Kaup, 1829. Introduced as tribe, and originally included the genera *Myotis* Kaup, 1829; *Lasionycteris* Peters, 1865; *Plecotus* É. Geoffroy, 1818; *Corynorhinus* H. Allen, 1865; *Idionycteris* Anthony, 1923; and *Euderma* H. Allen, 1891 (see Jackson and Groves, 2015: 280).

1987. *Leuconoformes* Menu, Palaeovert., 17 (3): 77, 7312, 133. Publication date: 31 March 1987. - Comments: Type genus: *Leuconöe* Boie, 1830. Introduced with unclear rank, and originally included the genera *Leuconöe* Boie, 1830 [= *Myotis* Kaup, 1829]; *Pizonyx* Miller, 1906 [= *Myotis* Kaup, 1829]; and *Perimyotis* Menu, 1984 (see Jackson and Groves, 2015: 280).

1998. *Myotinae:* Simmons, in: Kunz, T. H.; Racey, P. A., A reappraisal of interfamilial relationships of bats, 12. - Comments: Type genus: *Myotis* Kaup, 1829.

2005. *Myotiinae:* Ramírez-Pulido, Arroyo-Cabrales and Castro-Campillo, Acta Zool. Mex. (ns), 21 (1): 31. - Comments: Ramírez-Pulido *et al.* (2005) refer to Simmons (1998) for Myotiinae, but Simmons (1998: 5) uses the correct spelling (Myotinae). (Lapsus).

TAXONOMY:
Tate (1942: 229) originally named Myotini as a tribe within Vespertilioninae, in which he included the genera *Myotis*, *Lasionycteris*, *Plecotus*, *Corynorhinus*, *Idionycteris* and *Euderma*. Although Tate (1942: 230) noted that the latter four genera might alternatively be referred to their own tribe Plecotini. This suggestion was followed by subsequent authors, and Myotini has been restricted to *Myotis* and *Lasionycteris* in recent classifications (e.g., Hill and Harrison, 1987; Koopman, 1994). Volleth and Heller (1994) described karyological data which indicate that Myotini represents a lineage distinct from Vespertilioninae, and therefore they suggested that Myotini be raised to the rank of subfamily. Despite their suggestion, Volleth and Heller (1994) did not use the name Myotinae in their publication, so formal usage of the name at the subfamily rank dates from Simmons (1998: 3, 5),

who raised it to the subfamily level, and followed in recent classifications (e.g., Bannikova *et al.*, 2002: 722; Hoofer and Van Den Bussche, 2003: 21; Guan *et al.*, 2025: 3).

May not be monophyletlic; see Hoofer and Van Den Bussche (2001), and Simmons (2005). Hoofer and Van Den Bussche (2003: 21) and Roehrs *et al.* (2010: 1081) only include the members of the genus *Myotis*, (not *Lasionycteris* nor *Cistugo*).

Known genera of the subfamily Myotinae: †***Khonsunycteris*** Gunnell, Simons and Seiffert, 2008; ***Myotis*** Kaup, 1829.

COMMON NAMES:
Czech: netopýrcové. Ukrainian: Нічниці [= Nichnytsi]

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS: Ruedi *et al.* (2013: 446-447) doubt the African origin of the Myotinae as proposed by Gunnell *et al.* (2012), and their molecular phylogeny points to eastern Asia as the cradle of *Myotis* evolution.

Gunnell *et al.* (2017: 14) suggest that the basal myotines (e.g., *Khonsunycteris*) originated in northern Africa in the Late Eocene, followed by the appearance of *Myotis* in the early Oligocene of Europe. The fact that they found a plecotine bat (*Quinetia misonnei*) in the same Belgian location, furthermore, suggests that the vespertilionid subfamilies Vespertilioninae and Myotinae had already diverged by 33.5 MYA.

The discovery of the southernmost and oldest record of *Myotis podlesicensis* Kowalski, 1956 in Europe (Spain; Late Miocene) by Crespo *et al.* (2017: 324) provides support for an African origin of this taxon.

Genus ***Myotis*** Kaup, 1829

*1829. *Myotis* Kaup, Skizzierte Entwicklungs-Geschichte Natürliche Systematik der Europäische Thierwelt, 1: 106. Publication date: 1829. - Comments: Type species: *Vespertilio myotis* Borkhausen, 1797, by subsequent designation by Miller (1912: 167). Kaup (1829: 106) mentioned *Vespertilio murinus*, but for a discussion on the type species, see Jackson and Groves (2015: 280). - Etymology: From the Greek "*μύς*" or "*μυός*", meaning mouse and "*ούς*" or "*ώτός*" meaning ear (see Palmer, 1904: 442). Gardner (2005:184) considers the name to be masculine (My = mouse + ot = ear(ed) + is (Latin third declension ending)). - Phonetics: mie-oh′-tis.

1829. *Nystactes* Kaup, Skizzirte Entwicklungs-Geschichte Natürliche Systematik der Europäische Thierwelt, 1: 108. Publication date: 1829. - Comments: Type species: *Vespertilio bechsteini* Kuhl, 1819. Jackson and Groves (2015: 281) indicate that this name is an objective synonym of *Paramyotis* Bianchi. Not *Nystactes* Gloger, 1827 (Aves, Piciformes, Bucconidae). - Etymology: From the Greek "*νυστακτής*", meaning the one who nods, a sleeper (see Palmer, 1904: 467).

1830. *Leuconoe* Boie, Isis oder Encyclopädische Zeitung von Oken, 256. Publication date: 1830. - Comments: Type species: *Vespertilio daubentonii* Kuhl, 1817. Considered a valid genus based on tooth morphology: see Menu (1985, 1987) in Menu *et al.* (2002: 320).

1841. *Capaccinius* Bonaparte, Iconografia Fauna italiana, 1: Indice Distributivo: 1. - Comments: Type species: *Vespertilio megapodius* Temminck, 1840 [=*Vespertilio capaccinii* Bonaparte, 1837], by tautonomy (see Jackson and Groves, 2015: 281). - Etymology: In honour of Francesco Capaccini, under secretary of state of Rome about 1833-34, and a patron of Bonaparte's "Iconografia della Fauna Italica," published in 1832-1841 (see Palmer, 1904: 49).

1841. *Selysius* Bonaparte, Iconografia Fauna italiana, 1: Mamm, Introd: 3. Publication date: 1841 [Goto Description]. - Comments: Type species: *Vespertilio mystacinus* Kuhl, 1817, by monotypy (see Jackson and Groves, 2015: 281). - Etymology: In honour of Baron Edmond de Selys-Longchamps, 1813 - 1900, an eminent naturalist and statesman, some time president of the Belgian Senate; author of "Etudes de Micromammalogie," 1839, and "Faune Belge," 1844 (see Palmer, 1904: 51).

1842. *Trilatitus* J. E. Gray, Ann. Mag. nat. Hist., [ser 1], 10 (65): 258. Publication date: 1 December 1842. - Comments: type species: *Vespertilio hasseltii* Temminck, 1840, by subsequent designation (see Jackson and Groves, 2015: 281). Included *Vespertilio hasselti* Temminck, *M. macellus* Temminck, and *V. blepotis* Temminck (a *Miniopterus*) (see Hall and Kelson, 1959: 159; Hall, 1981: 183; Corbet and Hill, 1992: 119).

1843. *Vespertilio* J. E. Gray, Cat. specs mamm, xix, 26. Publication date: 13 May 1843. - Comments: Type species: *Vespertilio mystacinus* Kuhl, 1817, by monotypy according to Jackson and Groves (2015: 281). Not iVespertilio Linnaeus, 1758, nor *Vespertilio* Mörch, 1852 (Mollusca, Neogastropoda, Volutidae) (see Jackson and Groves, 2015: 281).

1849. *Tralatitus:* Gervais, Dictionnaire Universelle d'Histoire naturelle, 13: 213. - Comments: A lapsus for *Trilatitus* (see Hall, 1981: 183). Modification of *Trilatitus* (see Ellerman and Morrison-Scott, 1951: 137; Meester *et al.*, 1986: 47). Incorrect subsequent spelling (see Jackson and Groves, 2015: 281). (Lapsus).

1856. *Brachyotus* Kolenati, Allg. deutsche naturh. Zeitung, NF, 2 (2): 131. Publication date: 1856. - Comments: Type species: *Vespertilio mystacinus* Kuhl, 1817, by subsequent designation by Ellerman and Morrison-Scott (1951: 137) (see Jackson and Groves, 2015: 281). Preoccupied by *Brachyotus* Gould, 1837 (Aves, Strigiformes, Strigidae) (see Allen, 1939a: 89; Hall, 1981: 183; Corbet and Hill, 1992: 119; Pavlinov *et al.*, 1995: 95; Jackson and Groves, 2015: 281). Based on *V. mystacinus*, *daubentonii* and *dascyneme* (see Allen, 1939a: 89).

1856. *Isotus* Kolenati, Allg. deutsche naturh. Zeitung, NF, 2 (2): 131. Publication date: 1856. - Comments: Type species: *Vespertilio nattereri* Kuhl, 1817. Considered a valid subgenus by Pavlinov *et al.* (1995: 95). - Etymology: From the Greek "*ίσος*", meaning equal and "*ούς*" or "*ώτός*", meaning ear (see Palmer, 1904: 354).

1856. *Myotus:* Kolenati, Allg. deutsche naturh. Zeitung, NF, 2 (2): 131. Publication date: 1856. - Comments: Incorrect subsequent spelling (see Palmer, 1904: 442; Jackson and Groves, 2015: 282). (Lapsus).
1866. *Tralatitius:* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 90. Publication date: 1 February 1866. - Comments: Lapsus for *Trilatitus* Gray (seeHall, 1981: 183). Modification of *Trilatitus* (see Ellerman and Morrison-Scott, 1951: 137; Meester *et al.*, 1986: 47). (Lapsus).
1867. *Vespertilio (Pternopterus)* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 706. Publication date: 1867. - Comments: Type species: *Vespertilio (Pternopterus) lobipes* Peters, 1867 (=*Vespertilio muricola* Gray, 1846).
1868. *Pternopterus* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 1867: 706. - Comments: Type species: *Vespertilio (Pternopterus) lobipes* Peters, 1867 [= *Myotis muricola* (J. Gray, 1846)] by monotypy (see Jackson and Groves, 2015: 282).
1870. *Aëorestes* Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 62 (1): 427. Publication date: October 1870. - Comments: Based upon *Vespertilio villosissimus* E. Geoffroy, 1806, *albescens* E. Geoffroy, 1806, *laevis* I. Geoffroy, 1824 and *nigricans* Schinz, 1821 (see Allen, 1939a: 90; Hall, 1981: 183 [who excludes *laevis*]). Hill (in litt. In Meester *et al.*, 1986: 48) pointed out that *villosissimus* is a member of *Lasiurus* Gray, 1831, but all others are indeed *Myotis* representatives. If *villosissimus* can be regarded as the type species of *Aeorestes*, it should instead be included in *Lasiurus* (Meester *et al.*, 1986: 48). Hoofer and Van Den Bussche (2003: 25) consider *Aeorestes* a valid subgenus, including all of the New World species.
1870. *Comastes* Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 62 (1) 9: 565. Publication date: 1870. - Comments: Type species: *Vespertilio capaccinii* Bonaparte, 1837, by subsequent designation (see Jackson and Groves, 2015: 282). Based upon *Vespertilio capaccinii* Bonaparte, *megapodius*, *dasycneme* Boie, *limnophilus* (see Allen, 1939a: 90). Based upon *Vespertilio capaccinii* and *dasycneme* according to Hall and Kelson (1959: 159) and Hall (1981: 183). Not *Comastes* Jan, 1863 (Reptilia, Squamata, Colubridae) (see Jackson and Groves, 2015: 282). - Etymology: From the Greek "*κωμαστής*", meaning reveler, probably referring to the animal's nocturnal habits (see Palmer, 1904: 197).
1870. *Exochurus* Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 62 (1) 6: 75. Publication date: 1870. - Comments: Type species: *Vespertilio macrodactylus* Temminck, 1840, by subsequent designation (see Jackson and Groves, 2015: 282). Not of Kolenati (1858). Based upon *Vespertilio macrodactylus* Temminck, *V. horsfieldii* Temminck, and *V. macrotarsus* Waterhouse (see Hall, 1981: 183; Corbet and Hill, 1992: 119). Not of Kolenati, 1858: see Cabrera (1914: 91). - Etymology: From the Greek "*εξοχος*", meaning standing out and "*ούρά*", meaning tail (see Palmer, 1904: 284).
1899. *Euvespertilio* Acloque, Faune de France, Mammifères, 38. - Comments: Includes *Vespertilio emarginatus* Geoffroy, *murinus* Schreber =*myotis* Borkhausen, *mystacinus* Kuhl, *nattereri* Kuhl, and *bechsteinii* Kuhl. Hall and Kelson (1959: 159) and Hall (1981: 183) state that *Euvespertilio* includes *emarginatus* and *murinus* in a composite sense.
1906. *Pizonyx* Miller, Proc. Biol. Soc. Wash., 19: 85. Publication date: 4 June 1906. - Comments: Type species: *Myotis vivesi* Menegaux, 1901, by original designation (see Jackson and Groves, 2015: 282). Considered a valid genus by Hall and Kelson (1959), but only as a subgenus of *Myotis* by Hall (1981: 183).
1917. *Dichromyotis* Bianchi, Ann. Mus. zool. Acad. Impér. Sci. St. Petersbourg, 21: lxxviii (for 2016). Publication date: 14 May - 13 Jun 1917. - Comments: Type species: *Vespertilio formosus* Hodgson, 1835, by original designation according to Csorba *et al.* (2014: 668), by monotypy according to Jackson and Groves (2015: 283).
1917. *Megapipistrellus* Bianchi, Ann. Mus. zool. Acad. Impér. Sci. St. Petersbourg, 21: lxxvii (for 2016). Publication date: 14 May - 13 June 1917. - Comments: Type species: *Pipistrellus annectans* Dobson, 1871, by monotypy (see Jackson and Groves, 2015: 282). Considered a valid subgenus by Pavlinov *et al.* (1995: 95).
1917. *Paramyotis* Bianchi, Ann. Mus. zool. Acad. Impér. Sci. St. Petersbourg, 21: lxxix (for 2016). Publication date: 14 May - 13 Jun 1917. - Comments: Type species: *Vespertilio bechsteinii* Kuhl, 1817. New name for *Nystactes* Kaup, 1829, preoccupied (see Hall and Kelson, 1959: 159; Hall, 1981: 183). Considered a valid subgenus by Pavlinov *et al.* (1995: 95).
1917. *Rickettia* Bianchi, Ann. Mus. zool. Acad. Impér. Sci. St. Petersbourg, 21: lxxvii (for 2016). Publication date: 14 May - 13 Jun 1917. - Comments: Type species: *Vespertilio (Leuconoe) ricketti* Thomas, 1894, by monotypy (see Jackson and Groves, 2015: 282). Valid as a subgenus (see Hall and Kelson, 1959: 159; Hall, 1981: 183).
1929. *Anamygdon* Troughton, Rec. Austr. Mus., 17 (2): 87. Publication date: 26 Jun 1929. - Comments: Type species: *Anamygdon solomonis* Troughton, by original designation (see Jackson and Groves, 2015: 283) [=*Vespertilio adversus* Horsfield, 1824 or *Leuconoe moluccarum* Thomas, 1915 ?].
1934. *Brachyotis:* Taylor, Monographs of the Bureau of Science, Manila, 30: 278. (Lapsus).
1958. *Hesperomyotis* Cabrera, Rev. Mus. Arg. Cienc. Nat., Zool., 4: 103. - Comments: Type species: *Myotis simus* Thomas, 1901, by original designation (see Jackson and Groves, 2015: 283).
1982. *Myottis:* Alberico and Orejuela, Cespedesia, 3 (suppl): 103. (Lapsus).
1995. *Capaccinus:* Pavlinov, Borissenko, Kruskop and Jahonton, Arch. Zool. Mus., Moscow State Univ., 133: 95. (Lapsus).
1995. *Exochirus:* Pavlinov, Borissenko, Kruskop and Jahonton, Arch. Zool. Mus., Moscow State Univ., 133: 95. (Lapsus).

? *Loeconoe:* (Alternate Spelling).
? *Myotis sp.:*

TAXONOMY:

Woodman (1993) indicated that the genus name ending on -otis" is female, and therefore the species name should also be female. Benda and Tsytsulina (2000: 335) agree with Woodman (1993), but continue to understand *Myotis* as a masculine name, because it has been used for over 170 years, and hence was conserved in this way. Simmons (2005) follows Pritchard (1994) and retains the masculine names too. Simmons *et al.* (2021: 9) furthermore remarked that both Woodman (1993) and Pritchard (1994)

overlooked a 1958 ruling by the ICZN, which fixed the gender of *Myotis* as masculine and placed the name as such on the Official List of Generic Names in Zoology. See also Gardner (2005: 184) where *Myotis* = My (mouse) + ot (ear[ed]) + is (Latin third declension ending) = masculine (Mammalia).

Bronner *et al.* (2003) state that the genus *Myotis* has been considered to include several subgenera, but the number thereof, and placement of species, varied considerably. Meester *et al.* (1986) listed three subgenera from the Southern African subregion, namely *Cistugo* Thomas, 1912 (for *seabrai* and *lesueuri*), *Chrysopteron* Jentink, 1910 (for *welwitschii*) and *Selysius* Bonaparte, 1841 (for *tricolor* and *bocagei*). Menu (1987) proposed synonymising *Selysius* under the subgenus *Leuconoe* Boie, 1830 on the basis of dental characters. This was endorsed by Koopman (1993a, 1994) who transferred *M. bocagei* to *Leuconoe* but included other *Selysius* and *Chrysopteron* in the subgenus *Myotis*, and also by Godawa-Stormark (1998)'s phenetic analysis of dental variation in the genus. Phylogenetic analysis of mitochondrial DNA sequences, however, do not support the monophyly of the three subgenera (*Selysius, Leuconoe* and *Myotis*) analysed (Ruedi and Mayer, 2001), but *Cistugo* warrants generic separation (N. Simmons in litt.) owing to the distinct wing glands and unique karyotypes (see Rautenbach *et al.*, 1993) found in *seabrai* and *lesueuri* from southern Africa.

Meester *et al.* (1986) state that their synonymy is slightly modified from Ellerman and Morrison-Scott (1951), who include also *Aeorestes* Fitzinger, 1870, a South American group, in the synonymy of *Myotis*, as does Hall (1981). However, J.E. Hill points out (in litt) that of the species included in this genus, the first, *Vespertilio villosissimus* E. Geoffroy, 1806, is a *Lasiurus* Gray, 1831, although the others, *albescens* E. Geoffroy, 1806, *nigricans* Schinz, 1821, and *levis* I. Geoffroy, 1824, belong in *Myotis*. If, as Hill suggests, *villosissimus* can be regarded as the type species of *Aeorestes*, it should instead be included in *Lasiurus*.

Phylogenetic analyses performed by Ruedi *et al.* (2013: 441) confirm that the Ethiopian clade within *Myotis* is highly supported with all methods of reconstruction (see also Stadelmann *et al.*, 2004b). This clade contains all of the sub-Saharan species, the species inhabiting the islands in the Western Indian Ocean, as well as *M. emarginatus* (which occurs circum-Mediterranean) and two Asian forms (*M.* cf. *formosus* and *M. formosus flavus*).

Patterson *et al.* (2019a: "4') made an extensive phylogenetic analysis on the Afrotropical *Myotis* species and found that they were not monophyletic as *M. welwitschii* formed a sister clade with the east Asian *M. rufoniger*, which was separate from all other African species. All African species, together with *M. rufoniger, M. formosus* and *M. emarginatus* appeared to be grouping on a higher level.

Ghazali *et al.* (2016: 475) state that phylogenetic relationships within *Myotis* reflect biogeographic affinities rather than phenotypes. They also suggest that *Myotis* diverged from other bats in the early Miocene, with a subsequent split between Old and New World lineages about 19 MYA, and that ecomorphs ('Leuconoe' [near-water hunters], 'Myotis' [gleaners], 'Selysius' [aerial hawkers]) emerged independently in different lineages of *Myotis*. Their analyses indicate the ancestor of the African (Ethiopian) clade was most likely a *Myotis*, which diverged from the Eurasian clade about 17.0 MYA. Depending on the calibration, Morales *et al.* (2019: 2271) estimated this last split to have occurred at either 27 ± 3.5 mya or at 17.8 ± 3.5 mya.

Bogdanowicz *et al.* (2015: Fig. 2, p. 640) mention Moroccan data for *Myotis nattereri*, but in the supplementary information, these are mentioned as *Myotis* cf. *nattereri*. They also include the Mediterranean coastal areas of Morocco and Algeria in the distribution area of *M. capaccinii*.

Currently (Simmons and Cirranello, 2024a) recognized subgenera and species of the genus *Myotis*:
Subgenus *Pizonyx* Miller, 1906: *albescens* (E. Geoffroy Saint-Hilaire, 1806) – southern Veracruz (Mexico), Guatemala, Honduras, Nicaragua, Panama, Colombia, Venezuela, Guyana, Surinam, Equador, Peru, Brazil, Uruguay, northern Argentina, Paraguay and Bolivia (Simmons, 2005: 501); *arescens* Osgood, 1943 – C Chile; *armiensis* Carrión-Bonilla and Cook, 2020 – Panama; Costa Rica; *atacamensis* (Lataste, 1892) – southern Peru, northern Chile (Simmons, 2005: 502); *attenboroughi* Moratelli, Wilson, Novaes, Helgen and Gutiérrez, 2017 – Tobago Island; *auriculus* Baker and Stains, 1955 – Arizona and New Mexico (USA) to Jalisco and Veracruz (Mexico); Guatemala (Simmons, 2005: 502); auriculus Baker and Stains, 1955: USA (Arizona and New Mexico) to Mexico (Chihuahua, Coahuila, Colima, Durango, Hidalgo, Jalisco, Michoacán, Nayarit, Nuevo Leon, Sinaloa, Sonora, Tamaulipas, Veracruz, Zacatecas); Guatemala; *austroriparius* (Rhoads, 1897) –

southeastern USA including Florida, north to Indiana and North Carolina, west to Texas and southeastern Oklahoma (Simmons, 2005: 502); *bakeri* Moratelli, Novaes, Bonilla and Wilson, 2019 – Known only from two localities in the departments of Lima and Lambayeque, Peru; *barquezi* Novaes, Cláudio, Díaz, Wilson, Weksler and Moratelli, 2022 – Known only from the type locality in Argentina; *brandtii* (Eversmann, 1845) – Britain south to Italy, Greece and Bulgaria, east to Kazakhstan and Mongolia, eastern Siberia, Kamchatka Peninsula and Kurile Islands; Ussuri region (Russia), Korea (Simmons, 2005: 503); *californicus* (Audubon and Bachman, 1842) – southern Alaska Panhandle (USA) to Baja California and higher elevations in the Sonoran and Chihuahuan deserts (Mexico); Guatemala (Simmons, 2005: 504); *carteri* LaVal, 1973 – Mexico (Colima, Jalisco, México, Michoacán, Nayarit); *caucensis* J.A. Allen, 1914 – occurs along the Andes of Colombia, Ecuador, and Peru, including intermontane valleys and adjacent Amazon lowlands of those countries; *chiloensis* (G.R. Waterhouse, 1840) – central and southern Chile; Argentina (Simmons, 2005: 504); *ciliolabrum* (Merriam, 1886) – southern Alberta and Saskatchewan (Canada) south through eastern Colorado and western Kansas (USA) (Simmons, 2005: 505); *clydejonesi* Moratelli, Wilson, Gardner, Fisher and Gutiérrez, 2016 – Only known from the type specimen from Suriname; *cobanensis* Goodwin, 1955 – central Guatemala (Simmons, 2005: 505); *csorbai* Topál, 1997 – Nepal (Simmons, 2005: 505); *diminutus* Moratelli and Wilson, 2010 – Ecuador, Colombia; *dinellii* Thomas, 1902 – Bolivia, Uruguay, Argentina (incl. Entre dos Rios; Patagonia); Brazil; *dominicensis* Miller, 1902 – Dominica, Guadeloupe (Simmons, 2005: 506); *elegans* Hall, 1962 – Mexico to Costa Rica (Simmons, 2005: 506); *evotis* (H. Allen, 1864) – southern British Columbia, southern Alberta, southern Saskatchewan (Canada) to New Mexico (USA) and Baja California (Mexico) (Simmons, 2005: 506); *findleyi* Bogan, 1978 – Trés Marías Isls (Mexico) (Simmons, 2005: 507);*fortidens* Miller and Allen, 1928 – Sonora and Veracruz (Mexico) to Guatemala (Simmons, 2005: 507); *grisescens* A. H. Howell, 1909 – Florida Panhandle to Kentucky, Indiana, Illinois, eastern Kansas and northeastern Oklahoma (USA) (Simmons, 2005: 508); *handleyi* Moratelli, Gardner, de Oliveira and Wilson, 2013 – Known from two cordilleras in northern Venezuela; *izecksohni* Moratelli, Peracchi, Dias and Oliveira, 2011 – Brazil; *keaysi* J. A. Allen, 1914 – Tamaulipas (Mexico) to Bolivia, northern Argentina, Peru, Ecuador, Venezuela and Trinidad (Simmons, 2005: 509); *keenii* (Merriam, 1895) – Alaska Panhandle to W Washington (USA); Mackenzie to Prince Edward Island; British Columbia (Canada), south to Arkansas and Florida Panhandle (USA); *larensis* LaVal, 1973 – mainland South America in northeastern Colombia and northwestern Venezuela; *lavali* Moratelli, Peracchi, Dias and Oliveira, 2011 – Brazil, Paraguay, Argentina; *leibii* (Audubon and Bachman, 1842) – eastern North America from southern Ontario, southern Quebec (Canada) and southern Maine (USA) to southwards to Georgia and western to eastern Oklahoma (USA) (Simmons, 2005: 509); *levis* (I. Geoffroy Saint-Hilaire, 1824) – Bolivia, Argentina, southeastern Brazil, Uruguay (Simmons, 2005: 510); *lucifugus* (Le Conte, 1831) – Alaska (USA) to Labrador and Newfoundland (Canada), south to southern California, northern Arizona, northern New Mexico (USA) (Simmons, 2005: 510); *martiniquensis* LaVal, 1973 – Martinique, Barbados (Lesser Antilles) (Simmons, 2005: 511); *midastactus* Moratelli and Wilson, 2014 – Bolivia, Paraguay; *moratellii* Novaes, Cláudio, Carrión-Bonilla, Abreu, Wilson, Maldonado and Weksler, 2021 – W Ecuador; *nesopolus* Miller, 1900 – northeastern Venezuela; Curaçao and Bonaire (Netherlands Antilles) (Simmons, 2005: 513); *nigricans* (Schinz, 1821) – Nayarit and Tamaulipas (Mexico) to Peru, Bolivia, northern Argentina, Paraguay and southern Brazil; Trinidad and Tobago; St. Martin, Montserrat, Grenada (Lesser Antilles) (Simmons, 2005: 513); *nyctor* LaVal and Schwartz, 1975 – Barbados; Grenada (?); *occultus* Hollister, 1909 – southern California to Arizona, New Mexico and Colorado (USA), south to Distrito Federal (Mexico) (Simmons, 2005: 514); *oxyotus* (Peters, 1867) – Venezuela to Bolivia; Colombia, Ecuador, Panama; Costa Rica; Peru; possibly Guyana; *pampa* Novaes, Wilson and Moratelli, 2021 – Uruguay (Artigas and Tacuarembó provinces); *pilosatibialis* LaVal, 1973 – Colombia; *planiceps* Baker, 1955 – Coahuila, Nuevo León and Zacatecas (Mexico) (Simmons, 2005: 515); *riparius* Handley, 1960 – Honduras south to Uruguay, eastern Brazil, Argentina, Paraguay and Bolivia; Trinidad (Simmons, 2005: 515); *ruber* (E. Geoffroy Saint-Hilaire, 1806) – southeastern Brazil, southeastern Paraguay, northeastern Argentina (Simmons, 2005: 516); *septentrionalis* (Trouessart, 1897) – eastern USA and Canada west to British Columbia, eastern Montana, eastern Wyoming; south to Alabama, Georgia, and Florida Panhandle (Simmons, 2005: 516); *sibiricus* (Kastschenko, 1905) – Southern part of the Russian Far East, S of the Uda river (incl. Sakhalin and Kunashir isls); Korea: Mongolia; *simus* Thomas, 1901 – Colombia, Ecuador, Peru, northern Brazil, Bolivia, northeastern Argentina and Paraguay (Simmons, 2005: 517); *sodalis* Miller and G.M. Allen, 1928 – New Hampshire to Florida Panhandle, west to Wisconsin and

Oklahoma (USA) (Simmons, 2005: 517); *thysanodes* Miller, 1897 – Chiapas (Mexico) to southwestern South Dekota (USA) and south-central British Columbia (Canada) (Simmons, 2005: 517); *velifer* (J. A. Allen, 1890) – Honduras to Kansas and southeastern California (USA) (Simmons, 2005: 517); *vivesi* Menegaux, 1901 – coast of Sonora and Baja California (Mexico), mainly on small islands (Simmons, 2005: 518); *volans* (H. Allen, 1866) – Jalisco to Veracruz (Mexico); Alaska Panhandle (USA) to Baja California (Mexico), east to northern Nuevo León (Mexico), South Dekota (USA) and central Alberta (Canada) (Simmons, 2005: 518); *yumanensis* (H. Allen, 1864) – Hidalgo, Morelos and Baja California (Mexico) north to British Columbia (Canada), east to Montana and western Texas (USA) (Simmons, 2005: 518).

Subgenus *Chrysopteron* Jentink, 1910: ***anjouanensis*** Dorst, 1960; *bartelsi* (Jentink, 1910) – Indonesia (Java and Bali); ***bocagii*** (Peters, 1870); ***dieteri*** M. Happold, 2005; ***emarginatus*** (E. Geoffroy Saint-Hilaire, 1806); *formosus* (Hodgson, 1835) – Afghanistan to northern India, Nepal, Tibet, Kweichow, Kwangsi, Kiangsu and Fukien (China), Taiwan, Korea, Tsushima Isl (Japan), Malaysia, Philippines, Sumatra, Java, Sulawesi and Bali (Simmons, 2005: 507); ***goudotii*** (A.Smith, 1834); *hermani* Thomas, 1923 – Sumatra (Indonesia) (Simmons, 2005: 508); ***morrisi*** Hill, 1971; ***nimbaensis*** Simmons, Flanders, Bakwo Fils, Parker, Suter, Bamba, Douno, Keita, Morales and Frick, 2021; *rufoniger* (Tomes, 1858) – Korea, Japan, China, Taiwan, Laos, Vietnam; *rufopictus* (G.R. Waterhouse, 1845) – Philippines; ***scotti*** Thomas, 1927; ***tricolor*** (Temminck, 1832); *weberi* (Jentink, 1890) – Indonesia (Sulawesi); ***welwitschii*** (Gray, 1866).

Subgenus *Myotis* Kaup, 1829: *adversus* (Horsfield, 1824) – islands in Indonesia, New South Wales, Taiwan, possibly Vietnam and peninsular Malaysia (Simmons, 2005: 500); *alcathoe* von Helversen and Heller, 2001 – Greece, Hungary, France (Simmons, 2005: 501); *altarium* Thomas, 1911 – Szechwan, Kweichow (China), Thailand (Simmons, 2005: 501); *alticraniatus* Osgood, 1932 – Vietnam, Laos; *ancricola* Kruskop, Borisenko, Dudorova and Artyushin, 2018 – Only known from the type locality and the Ngoc Ling mountains in Vietnam; *annatessae* Kruskop and Borisenko, 2013 – Vietnam; Central Laos; *annectans* (Dobson, 1871) – northeastern India to Burma, Thailand, Laos, Cambodia and Vietnam (Simmons, 2005: 502); *ater* (Peters, 1866) – Vietnam, western Sumatra, Peninsular Malaysia, Sulawesi, Togian Isl, northern Borneo, Moluccas, Papua New Guinea (Simmons, 2005: 502); *australis* Dobson, 1878) – New South Wales (Simmons, 2005: 502); *bechsteinii* (Kuhl, 1817) – Europe to Caucasus and Iran; Bulgaria; England; southern Sweden (Simmons, 2005: 503); *blythii* (Tomes, 1857) – Turkey and Israel to Iraq and Iran; northwestern India and the Himalayas; northwestern Altai Mtns; Inner Mongolia and Shensi (China) (Simmons, 2005: 503); *bombinus* Thomas, 1906 – Japan, Korea, southeastern Siberia, northeastern China (Simmons, 2005: 503); *borneoensis* Hill and Francis, 1984 – Sabah (Borneo); *bucharensis* Kuzyakin, 1950 – Uzbekistan, Tajikistan and Afghanistan (Simmons, 2005: 504); ***capaccinii*** (Bonaparte, 1837); *chinensis* (Tomes, 1857) – Szechwan and Yunnan to Kiangsu (China); Hong Kong; northern Thailand; Burma; Vietnam (Simmons, 2005: 505); *crypticus* Ruedi, Ibáñez, Salicini, Juste and Puechmaille, 2019 – Mountain areas of N + C Spain, S France, Italy, SW Austria?, W Switzerland, SE France; *dasycneme* (Boie, 1825) – France and Sweden east to Yenisei River (Russia), south to Ukraine, northwestern Kazakhstan, China (Simmons, 2005: 505); *daubentonii* (Kuhl, 1817) – Europe (including Britain and Ireland; Scandinavia) east to Kamtschatka, Vladivostok, Sakhalin and Kurile Isls (Russia), Japan, Korea, Manchuria, northern and eastern China (including Tibet), Vietnam (Simmons, 2005: 505); *davidii* (Peters, 1869) – northern China (Simmons, 2005: 506); *escalerai* Cabrera, 1904 – France, Spain, Portugal; *federatus* Thomas, 1916 – Peninsular Malaysia; *fimbriatus* (Peters, 1871) – southeastern China (Simmons, 2005: 507); *frater* G. M. Allen, 1923 – eastern Siberia, Ussuri Region, Krasnoyarsk Region (Russia) to Korea, Heilungkiang (China), southeastern China; Japan (Simmons, 2005: 507); *gomantongensis* Francis and Hill, 1998 – Sabah (Borneo, Malaysia) (Simmons, 2005: 508); *hasseltii* (Temminck, 1840) – eastern India, Sri Lanka, Burma, Thailand, Cambodia, Vietnam, western Malaysia, Sumatra, Mentawai Isls, Riau Arch., Java, Borneo (Simmons, 2005: 508); *hayesi* Csorba and Furey, 2022 – Known from the type locality in Cambodja; *horsfieldii* (Temminck, 1840) – India, Andaman Isls, southeastern China, Thailand, Burma, Laos, Vietnam, western Malaysia, Java, Bali, Sulawesi, Borneo, Philippines (Simmons, 2005: 508); *hoveli* Harrison, 1964 – Israel, Lebanon, Syria, Turkey; *hyrcanicus* Benda, Reiter and Vallo, 2012 – Only known from the type locality in Iran; *ikonnikovi* Ognev, 1912 – Ussuri region and North Korea to Lake Baikal (Russia), the Altai Mtns and Mongolia, northeastern China; Sakhalin Isl (Russia) and Honshû and Hokkaido Isls (Japan) (Simmons, 2005: 509); *indochinensis* Son, Görföl, Francis, Motokawa, Estók, Endo, Thong, Dang, Oshida and Csorba, 2013 – Vietnam; *insularum*

(Dobson, 1878) – Samoa (Simmons, 2005: 509); *laniger* (Peters, 1871) – southern China including Tibet, Vietnam, eastern India (Simmons, 2005: 509); *longicaudatus* Ognev, 1927 – E. Siberia, Ussuri region, Korea; Mongolia; *longipes* (Dobson, 1873) – Afghanistan, northeastern India, Nepal (Simmons, 2005: 510); *macrodactylus* (Temminck, 1840) – Japan, Kunashir Isl and Kurile Isls (Russia), southeastern Siberia, Korea (Simmons, 2005: 510); *macropus* (Gould, 1854) – southern Australia (Simmons, 2005: 511); *macrotarsus* (G.R. Waterhouse, 1845) – Philippines, northern Borneo (Simmons, 2005: 511); *moluccarum* (Thomas, 1915) – Ambon and Kai Isls (Moluccas), northern and western Australia, Seram, Waigeo Isl (West Palua, Indonesia), Papua New Guinea, Bismarck Arch., Solomon Isls (Simmons, 2005: 511); *montivagus* (Dobson, 1874) – Yunnan to Fukien and Chihil (China), northeastern India, Burma, Vietnam, Laos, northeastern Thailand, western Malaysia, Borneo (Simmons, 2005: 511); *muricola* (Gray, 1846) – Afghanistan through northern India and Nepal to Taiwan, Vietnam, Malaysia, Indonesia and New Guinea (Simmons, 2005: 512); *myotis* (Borkhausen, 1797) – central and southern Europe, east to Ukraine; southern England, most Mediterranean islands; Asia Minor; Lebanon, Syria and Israel (Simmons, 2005: 512); ***mystacinus*** (Kuhl, 1817); *nattereri* (Kuhl, 1817) – Ireland, Great Britain, Europe (except northern Scandinavia), Morocco, northern Algeria, Turkey, Israel, Jorden, Lebanon, Iraq, Iran, Bulgaria, Crimea and Caucasus to Turkmenistan (Simmons, 2005: 513); *nipalensis* (Dobson, 1871) – Asia from the Caucasus mountains and Caspian Sea to E Turkestan, Tibet, Nepal, Kazakhstan, Mongolia, S Siberia, Turkey, NW Iran. Wiantoro et al. (2012: 272) indicate that *nipalensis* is distributed from Iran, Turkey, and Uzbekistan to Nepal, Mongolia, Tibet, NW China and Siberia. Vietnam?; *nustrale* Ruedi, Beuneux and Puechmaille, 2023 – Endemic to Corsica; *pequinius* Thomas, 1908 – Hong Kong, Hopeh, Shantung, Honan and Kiangsu (China) (Simmons, 2005: 514); *petax* Hollister, 1912 – Kamtschatka, Vladivostok, Sakhalin and Kurile Isls (Russia), Japan, Korea, Manchuria, E and S China Mongolia, Tibet, Vietnam; *peytoni* Wroughton and Ryley, 1913 – S + EC India; *phanluongi* Borisenko, Kruskop and Ivanova, 2009 – Vietnam; *pilosus* (Peters, 1869) – China, Hong Kong, Vietnam, Laos, NE India; *pruinosus* Yoshiyuki, 1971 – Honshu and Shikoku (Japan) (Simmons, 2005: 515); ***punicus*** Felten, Spitzenberger and Storch, 1977; *ridleyi* Thomas, 1898 – western Malaysia, Sumatra, Borneo (Simmons, 2005: 515); *rosseti* (Oey, 1951) – Cambodia, Thailand (Simmons, 2005: 516); *schaubi* Kormos, 1934 – Armenia and western Iran (Simmons, 2005: 516); *secundus* Ruedi, Csorba, Lin and Chou, 2015 – Taiwan; *sicarius* Thomas, 1915 – northeastern India and Nepal (Simmons, 2005: 516); *siligorensis* (Hodgson, 1855) – northern India to southern China, Burma, Vietnam and Laos; south to western Malaysia; Borneo (Simmons, 2005: 516); *soror* Ruedi, Csorba, Lin and Chou, 2015 – Taiwan (only known from the type specimen); *sowerbyi* A.B. Howell, 1926 – China; *stalkeri* Thomas, 1910 – Kai and Gebe Isls (Molucca Isls), Waigeo Isl. (Prov. of Papua, Indonesia) (Simmons, 2005: 517); *tschuliensis* Kusjakin, 1935 – Transcaucasia, Iraq, Turkmenia; *yanbarensis* Maeda and Matsumura, 1998 – Northern Okinawa Isl (Japan) (Simmons, 2005: 518); ***zenatius*** Ibáñez, Juste, Salicini, Puechmaille and Ruedi, 2019.

COMMON NAMES:
Czech: netopýři myší, ouška myší, netopýrcové. English: Mouse-eared Bats, Little Brown Bats, Hairy Bats, Large-footed Bats. French: Murins. German: Mausohr, Mausohren. Polish: nocki. Ukrainian: Нічниця [= Nichnytsya].

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
In Africa *Myotis* sp. have been found deposits of the Plio-Pleistocene, at Bolt's Farm, South Africa (Broom, 1948). Early Pleistocene, at Olduvai (Butler, 1978). Geraads *et al.* (2010: 279) reported the presence of *Myotis* in Late Cenozoic (ca. 2.5 MYA) deposits in Ahl al Oughlam, Morocco.

Molecular dating performed by Ruedi *et al.* (2013: 437-441) suggest an origin of all recent *Myotis* in the early Miocene (about 21 MYA with 95 % highest posterior density interval 23 - 20 MYA).

Shi and Rabosky (2015: 1532) report the approximate fossil date for crown Myotinae to be 27 MYA.

However, a recent study by Gunnell *et al.* (2017) reported on a fossil *Myotis* found in a Belgian Oligocene locality, dating 33 MYA. Morales *et al.* (2019: 2264) find this to be consistent with other fossils of a primitive *Myotis*-like form found in Africa suggest and dating from the late Eocene (37.8 - 33.9 mya), which suggest that the early diversification of the subfamily might have occurred on that continent. However, these authors also indicate that this interpretation depends on the correct identification of the "*Myotis*-like" material. Alternatively, the radiation of *Myotis* could only date from about 18 mya.

The Ethiopian clade (see Taxonomy) would have been separated about 12.33 (15 - 10) MYA.

MOLECULAR BIOLOGY:
Karyotype
Baker *et al.* (1974) recorded the karyotype of *Myotis* as 2*n* = 44, AA = 50, but Dippenaar *et al.* (1983) give it as 2*n* = 50, AA = 48 in both *seabrai* and *lesueuri*.

PREDATORS:
In Algeria, Djilali *et al.* (2016: 159) found the Short-eared owl (*Asio flammeus*) to feed primarily on bats of the genus *Myotis*. They made up 37.8 % of all prey items (195 specimens on 516 prey items). The second one was *Gerbillus nanus* with only 5.4 % of all preys.

PARASITES:
From non-specified *Myotis* specimens, the following nycteribiids were reported by Vermeil (1960) from Tunisia: *Penicillidia conspicua* Speiser, 1900, *Nycteribia vexata vexata* Westwood, 1835, *Nycteribia biarticulata* Hermann, 1804, *Nycteribia latreillii* Leach, 1817, and *Nycteribia schmidlii* Schiner, 1853.

VIRUSES:
Although we cannot find this confirmed, Bonilla-Aldana *et al.* (2020: 5) mention "Multiple studies point at bats of the genus *Myotis* as the main reservoir for Ebola virus given that these bats carry a copy of viral gene VP35, which may hinder human and animal immune responses and thus explaining its high mortality rates."

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Congo (Democratic Republic of the), Egypt, Ethiopia, Gabon, Kenya, Madagascar, Malawi, Tanzania, Tunisia, Uganda.

Subgenus *Myotis (Chrysopteron)* Jentink, 1910

*1910. *Chrysopteron* Jentink, Notes Leyden Mus., 32: 74. Publication date: January 1910 [Goto Description]. - Comments: Type species: *Chryopteron bartelsii* Jentink, 1910 [=*Vespertilio formosa* Hodgson, 1835]. Considered a valid subgenus by Hall and Kelson (1959: 159), Hall (1981: 183), Corbet and Hill (1992: 121) and Pavlinov *et al.* (1995: 95).
1924. *Epetiscus:* Granvik, Lunds Univ. Arss. N.F., (2) 21 (3): 12. (Lapsus).

Myotis (Chrysopteron) anjouanensis Dorst, 1960

*1960. *Myotis Goudoti anjouanensis* Dorst, Bull. Mus. natn. Hist. nat., Paris, sér 2, 31: 476 (for 1959). Type locality: Comoros: Anjouan Island. [Goto Description]. Holotype: MNHN ZM-MO-1886-1536: ad ♀, skull and alcoholic. Collected by: Léon Humblot. - Etymology: The specific name refers to the island where the type specimen was collected.
? *Myotis (Chrysopteron) anjouanensis:* (Current Combination).
? *Myotis anjouanensis;* (Name Combination).

TAXONOMY:
Considered a synonym of *goudotii* by Koopman (1993a: 211), and a subspecies of *goudotii* by Peterson *et al.* (1995: 89), but a valid species by Simmons (2005).

Csorba *et al.* (2014: 667) and Simmons and Cirranello (2023b: 79) include *anjouanensis* in the subgenus *Chrysopteron*.

COMMON NAMES:
Czech: netopýr anžuánský. English: Anjouan Myotis, Anjouan Mouse-eared Bat. French: Murin d'Anjouan, Vespertilion de l'Ile d'Anjouan. German: Anjouan-Mausohr.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) since it has only recently been recognised as a distinct species, and there is still very little information on its extent of occurrence, status, threats and ecological requirements (Jacobs, 2008c; IUCN, 2009; Jacobs, 2019c).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs, 2019c). 2008: DD ver 3.1 (2001) (Jacobs, 2008c; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs, 2004k; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Jacobs, 2008c; IUCN, 2009; Jacobs, 2019c).

CONSERVATION ACTIONS:
Jacobs (2008c) [in IUCN (2009)] and Jacobs (2019c) reports that it is not known if the species is present in any protected areas. Further studies are needed into the natural history and possible threats to this little-known species.

GENERAL DISTRIBUTION:
Myotis anjouanensis is endemic to the island of Anjouan in the Comoros Islands.

Native: Comoros.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 77 minutes, and the digestibility rate about 79.9 %.

POPULATION:
Structure and Density
There is currently little information on the abundance of this species (Jacobs, 2008c; IUCN, 2009; Jacobs, 2019c). Specimens were collected by Goodman, 2007) from Anjouan in 2007.

Trend
2018: Unknown (Jacobs, 2019c).

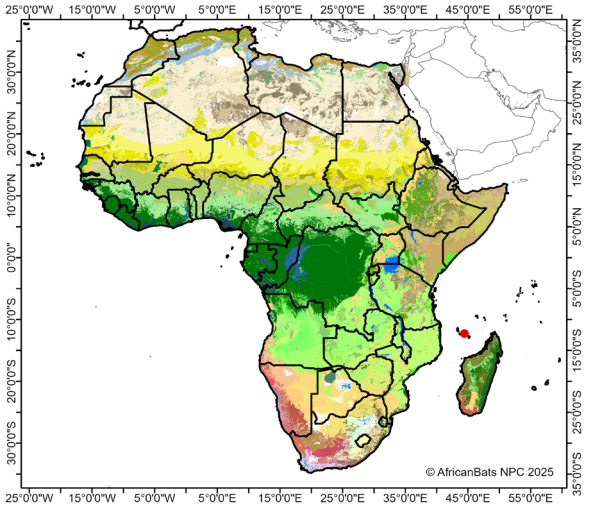

Figure 260. Distribution of *Myotis (Chrysopteron) anjouanensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Comoros.

Myotis (Chrysopteron) bocagii (Peters, 1870)

*1870. *Vespertilio Bocagii* Peters, J. Sci. mat. phys. nat., ser 1, 3 (10): 125. Publication date: December 1870. Type locality: Angola: Duque de Bragança [08 55 S 16 10 E]. Lectotype: ZMB 3973: ad ♂, skull and alcoholic. Presented/Donated by: José Vicente Barboza du Bocage. Lectotype designated by Turni and Kock (2008: 57). - Comments: Turni and Kock (2008: 57) also indicate that Peters did not mention the number of specimens he examined, therefore it might be possible that additional syntypes might have existed in the Lisbon museum, but were destroyed by the fire in 1978. Thorn *et al.* (2009: 51) situate the type locality at 09 23 S 15 53 E. - Etymology: In honour of J.V. Barbosa du Bocage, an eminent Portuguese zoologist, who worked during the nineteenth century, and who named material from the Congo and Angola collected by his Portuguese colleague Snr. M. Jose d'Anchieta (Smithers, 1983: 93).
1976. *Myotis boccagei:* Brosset, Z. Tierpsychol., 42 (1): 50. (Lapsus).
1996. *Myotis bocagi:* Kityo and Kerbis, J. East Afr. Nat. Hist., 85: 63. (Lapsus).
2019. *Myotis bocageii:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).
? *Myotis (Chrysopteron) bocagii:* (Current Combination).
? *Myotis (Selysius) bocagei:* (Name Combination, Alternate Spelling).
? *Myotis bocagei:* (Alternate Spelling).
? *Myotis bocagii:* (Name Combination).

TAXONOMY:
Mentioned as *bocagei* by Corbet (1978: 49), Smithers (1983: 93), Meester *et al.* (1986: 49), Koopman (1993a: 209), Horáček *et al.* (2000: 121) Wilson and Cole (2000: 58), Hutson *et al.* (2001: 28), Fenton and Bogdanowicz (2002: 1008) but as *bocagii* by Ansell and Dowsett (1988: 37), Harrison and Bates (1991: 76), Grubb *et al.* (1998: 82), Stadelmann *et al.* (2004b: 178); and as *bocagi* by Kityo and Kerbis (1996: 63).

Csorba *et al.* (2014: 667) and Simmons and Cirranello (2023b: 79) include *bocagii* in the subgenus *Chrysopteron*, but see Ruedi and Mayer (2001: 436), Ghazali *et al.* (2016: 476) and Patterson *et al.* (2019a: "2") who reject the subgeneric division.

The phylogenetic analyses by Patterson *et al.* (2019a: "5") revealed the presence of two groups within *M. bocagii*: one including a single Senegalese specimen and two all the remainder, including material from Ghana, DRC, Kenya, and Tanzania. These findings do not support the currently accepted division into two subspecies: *bocagii* and *cupreolus*, although the authors stress that no material from Angola (where the type of *bocagii* was collected) was included in the

analyses (p. "9"). As such, it might be possible that two subspecies might still be present, with *bocagii* restricted to Angola. Until this has been resolved, we do retain the two traditionally recognized subspecies. Patterson *et al.* (2019a) also indicated that *M. bocagii* forms a sister group with *M. goudotii* + *M. anjouanensis*, which in turn form a sister group to *M. tricolor* and *M. emarginatus* (based on nuclear genes).

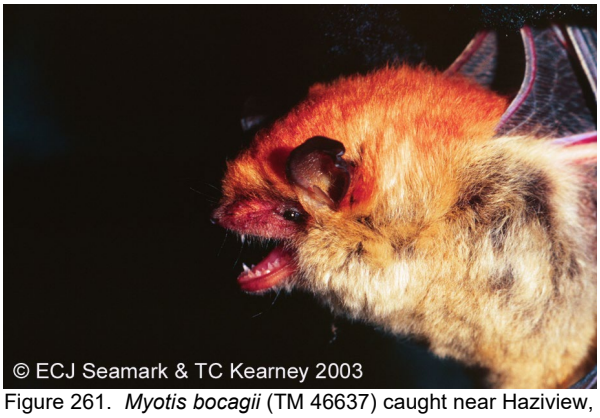

Figure 261. *Myotis bocagii* (TM 46637) caught near Haziview, Mpumalanga, South Africa.

COMMON NAMES:
Afrikaans: Rooi langhaarvlermuis. Castilian (Spain): Murciélago de Orejas de Ratón. Chinese: 棕红鼠耳蝠. Czech: netopýr Bocageův. English: Rufous Mouse-eared bat, Bocage's Mouse-eared Bat, Rufous Mouse-eared Myotis, Rufous Hairy Bat, Bocage Banana Bat, Bocage's Hairy Bat. French: Murin roux, Murin de Du Bocage. German: Kupferfarbenes Mausohr, Bananen-Mausohr. Malawian: Liputiputi, Ndemiya, Namsimsi, Namzeze. Portuguese: Morcego lanudo de Bocage.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs, 2008d; IUCN, 2009; Monadjem and Jacobs, 2017a).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Jacobs, 2017a). 2008: LC ver 3.1 (2001) (Jacobs, 2008d; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs, 2004f; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016j). 2004: DD ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Jacobs, 2008d; IUCN, 2009; Monadjem and Jacobs, 2017a).

CONSERVATION ACTIONS:
Jacobs (2008d) [in IUCN (2009)] and Monadjem and Jacobs (2017a) reports that it has been recorded from Kruger National Park, South Africa (Skinner and Chimimba, 2005), Dzanga-Sangha Special Dense Forest Reserve in the Central African Republic (Lunde *et al.*, 2001), and from the Manga Forest Reserve in Tanzania (Doggart *et al.*, 1999b), and in view of the species wide range it is presumed to be present in many more protected areas. There are no direct conservation measures currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Myotis bocagii is widespread throughout much of sub-Saharan Africa. It occurs from Sierra Leone and Senegal in West Africa, eastwards through Cameroon and Central Africa, to Ethiopia and East Africa, being recorded as far south as northeastern South Africa. Outside of Africa it has been recorded from southern Yemen.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 594,469 km^2.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 564); Benin; Burkina Faso (Kangoyé *et al.*, 2015a: 618); Burundi; Cameroon; Central African Republic; Congo (The Democratic Republic of the) (Allen, 1917; Hayman *et al.*, 1966; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 564); Côte d'Ivoire; Equatorial Guinea; Eswatini (Monadjem *et al.*, 2010d: 564; Shapiro and Monadjem, 2015: 353, Monadjem *et al.*, 2021: 5); Ethiopia; Gabon; Ghana; Guinea (Fahr *et al.*, 2006a: 73); Kenya; Liberia (Monadjem and Fahr, 2007: 50); Malawi (Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 564); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 564; Monadjem *et al.*, 2010c: 383); Nigeria; Rwanda; Senegal; Sierra Leone (Weber *et al.*, 2019: 25); South Africa (Monadjem *et al.*, 2010d: 564); Sudan; Tanzania (Stanley and Goodman, 2011: 43); Togo; Uganda; Yemen; Zambia (Monadjem *et al.*, 2010d: 564); Zimbabwe (Monadjem *et al.*, 2010d: 564).

Bates *et al.* (2013: 339) reject the occurrence of *M. bocagii* in the Republic of Congo as Happold (2013dn: 693) only provided a map without any supporting data.

DETAILED MORPHOLOGY:
Brain
Szubert-Kruszyńska *et al.* (2018: Suppl.) mention a brain mass of 0.21 g for an average body mass of 7.6 g.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 6.4 Pa, aspect ratio 8.5 for a wingspan of 32 cm and a wing area of 123 cm^2 and a body mass of 8 g.

ECHOLOCATION:
Schoeman and Waddington (2011: 291) mention a F_{peak}: 43.2 ± 0.2 kHz and a duration: 2.0 ± 0.1 ms for specimens from Durban, South Africa. Monadjem *et al.* (2017c: 179) reported for one specimen the following parameters from Swaziland: F_{min}: 30.1 kHz, F_{knee}: 41.2 kHz, F_c: 36.6 kHz, and duration: 2.8 ms. They were also to capture the call up to a distance of 5 m.

Moir (2020: 30) and Moir *et al.* (2021a: 371) reported 69 calls of two bats from southern KwaZulu-Natal and Eastern Cape with F_{max}: 64.98 ± 2.71 (58.57 - 69.35) kHz, F_{min}: 35.69 ± 0.16 (35.31 - 35.69) kHz, F_{char}: 39.68 ± 1.08 (38.31 - 46.99) kHz, F_{knee}: 59.01 ± 6.41 (50.35 - 65.79) kHz, and duration: 2.27 ± 0.13 (2.18 - 2.36) ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 99 calls of 8 bats: F_{max}: 56.97 ± 7.52 kHz, F_{min}: 27.67 ± 3.64 kHz, F_{knee}: 43.99 ± 7.41 kHz, F_{char}: 40.53 ± 6.86 kHz, slope: 124.2 ± 3364.36 OPS, duration: 2.76 ± 0.51 ms.

In Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 3 calls: Interpulse interval: 91.6 ± 25.1 (62.6 - 107.0) ms; F_{max}: 47.6 ± 3.4 (44.9 - 51.4) kHz; Start slope: -14.2 ± 2.9 (-10.8 - -16.0) kHz/ms; End slope: -20.2 ± 6.6 (-13.3 - -26.4) kHz/ms; Ledge duration: 0.3 ± 0.0 (0.3 - 0.3) ms.

From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 133 calls of 2 bats: F_{peak}: 40.1 ± 1.0 (39.0 - 42.0) kHz, F_{min}: 31.4 ± 4.2 (28.8 - 42.0) kHz, F_{max}: 67.9 ± 5.6 (61.9 - 76.5) kHz, duration: 3.2 ± 0.7 (2.2 - 4.3) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd (Frequency modulation downward) sonotype.

Sound files are available at the Chirovox website (https://www.chirovox.org/), e.g.: https://chirovox.elte.hu/sounds/A003663_WQKZZOVOSU.WAV, https://chirovox.elte.hu/sounds/A003664_SRAHXRVJTL.WAV, https://chirovox.elte.hu/sounds/A003665_BEMWQOEXAP.WAV, https://chirovox.elte.hu/sounds/A003666_KBLUCEWOVT.WAV

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 44, FN = 50, BA = 8, a submetacentric X chromosome, and an acrocentric Y chromosome, for specimens from South Africa. These results are the same as those obtained for *M. tricolor* specimens from South Africa and Zimbabwe (Rautenbach *et al.*, 1993).

Genetics
See Hoofer and Van Den Bussche (2003).

Morales *et al.* (2024: Suppl.) reported the total length of the genome to consist of 2001.76M base pairs.

HABITAT:
In southern Africa, this species primarily (82 %) occurs in Savanna habitats (Cooper-Bohannon *et al.*, 2016: Table S2).

In the Mount Nimba area, Monadjem *et al.* (2016y: 369) collected one specimen in old growth forest at 420 m.

HABITS:
Brosset (1976) found that harem groups of female *M. bocagii*'s remained very stable over a period of several years. The males in these groups were replaced more often.

ROOST:
Mamba *et al.* (2020: 134) reported on a female, which was captured inside the leaves of a banana plants. Happold and Happold (2023: 143) indicate that they are also found roosting among leaves of other trees (e.g., *Hyphaene* palms). In Gabon, these bats live in harems (one adult male and two to seven adult females and their young)..

DIET:
From the Umbilo River in KwaZulu Natal (RSA), Naidoo *et al.* (2011: 26) reported the following prey volume percentages: during summer: Lepidoptera (1.3 ± 1.9), Coleoptera (0.8 ± 1.0), Hemiptera (8.5 ± 13.1), Diptera (37.8 ± 25.8), and Trichoptera (51.8 ± 29.9); during winter: Lepidoptera (7.5 ± 10.6), Coleoptera (32.5 ±

46.1), Hemiptera (20.0 ± 28.3), Diptera (33.4 ± 33.0), and Trichoptera (6.7 ± 4.7).

Weier *et al.* (2019c: 6) investigated droppings from this species in the Levubu region (Limpopo, RSA) and found DNA sequences of *Bathycoelia distincta* Distant, 1878 (Hemiptera).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 78 minutes, and the digestibility rate about 79.8 %.

Morales *et al.* (2024: Suppl.) assigned this species to the Trawler ecomorph type.

POPULATION:
Structure and Density
Although this species is difficult to catch it is possibly not very rare (Jacobs, 2008d; IUCN, 2009; Monadjem and Jacobs, 2017a).

Trend
2016: Unknown (Monadjem and Jacobs, 2017a).
2008: Unknown (Jacobs, 2008d; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Happold and Happold (1990b: 567) reported that young were born in the middle of the wet season in Malawi.

Stanley and Goodman (2011: 43) report on a male with scrotal testes collected in the East Usambara Mountains (Tanzania) on 30 July 1992.

One female captured on 4 June in Sierra Leone by Weber *et al.* (2019: 25) was pregnant.

PARASITES:
TREMATODA
Urotrematidae
Castiblanco and Vélez (1982: 134) reported the presence of *Urotrema scabridum* in a "*Myotis bocagei*" from Congo.

ARACHNIDA
Psorergatidae
Cierocka *et al.* (2022: 10) mentioned *Psorergatoides kerivoluae* Fain, 1959 being found on the wing membrane of *Myotis bocagii* specimens from Côte d'Ivoire.

Spinturnicidae
Orlova *et al.* (2024: 151) reported the first assocation of this species with *Spinturnix scotophili* Zumpt and Till, 1954

VIRUSES:
Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested between 1986 and 1999, for antibodies to SARS-CoV in serum of one individual from Limpopo Province, South Africa, which tested negative (0/1).

GENERAL DISTRIBUTION:
West Africa, from Senegal to the DRC.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Benin, Cameroon, Central African Republic, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Gabon, Ghana, Guinea, Liberia, Niger, Nigeria, Senegal, Sierra Leone, Togo.

Myotis (Chrysopteron) dieteri M. Happold, 2005

*2005. *Myotis dieteri* M. Happold, Acta Chiropt., 7 (1): 11, figs 1 - 2. Type locality: Congo: Loudima: Grotte du Viaduc [04 15 S 13 00 E]. Holotype: MNHN ZM-MO-1985-1925: ad ♀, skull and alcoholic. Collected by: Jean-Paul Adam; collection date: between 1961 and 1968. - Etymology: In honour of Dr. Dieter Kock of the Senkenberg Museum, Frankfurt, Germany, in recognition of the great contribution he made to the knowledge of African mammals, in recognition of the kindness and generosity with which he has helped so many others with their studies, and in gratitude for our long firendship (see Happold, 2005: 11).
? *Myotis (Chrysopteron) dieteri:* (Current Combination).

TAXONOMY:
Known only from the type specimen (Happold, 2005: 11).

Csorba *et al.* (2014: 668) indicate that *dieteri* is probably the only sub-Saharan *Myotis* that doesn't belong to the subgenus *Chrysopteron*, but molecular data are missing to confirm this. However, Simmons and Cirranello (2023b: 79) assigned it to the subgenus *Chrysopteron* nevertheless.

COMMON NAMES:
Czech: netopýr Kockův. French: Murin de Kock. German: Kocks Mausohr.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) since it has only recently been described, and there is still very little information on its extent of occurrence, status, threats and ecological requirements (Happold, 2008; IUCN, 2009; Happold, 2019).

Assessment History
Global
2018: DD ver 3.1 (2001) (Happold, 2019). 2008: DD ver 3.1 (2001) (Happold, 2008; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
The threats to this species remain unknown (Happold, 2008; IUCN, 2009; Happold, 2019).

CONSERVATION ACTIONS:
Happold (2008) [in IUCN (2009)] and Happold (2019) reports that it is not known if the species is present within any protected areas. Additional studies are needed into the distribution, abundance, breeding biology and general ecology of this species. There is a need to determine if the species is still present at Grotte du Viaduc à Loudima, and to locate additional populations through directed surveys.

GENERAL DISTRIBUTION:
Myotis dieteri has only been recorded from type locality of 'Grotte du Viaduc à Loudima, Republic of Congo (04º15'S, 13º00'E) (Happold, 2005: 11). Despite extensive surveys of other seemingly

suitable localities, it has not been recorded from additional caves in the Loudima-Kimongo region, or from caves in the Mayombe and lower Kouilou regions of Congo, the Haut-Ivindo region of Gabon, or Kikwit in the Democratic Republic of Congo (Happold, 2005).

Native: Congo (Happold, 2005: 11; Bates *et al.*, 2013: 337).

POPULATION:
Structure and Density
It is known only from the holotype collected by Jean-Paul Adam sometime between 1961 and 1968, from a small number of this species present in the cave (Happold, 2005).

Trend
2018: Unknown (Happold, 2019). 2008: Unknown (Happold, 2008; IUCN, 2009).

Myotis (Chrysopteron) emarginatus (E. Geoffroy St.-Hilaire, 1806)

*1806.	*Vespertilio emarginatus* E. Geoffroy Saint-Hilaire, Ann. Mus. Hist. nat. Paris, 8: 198. Type locality: France: Ardennes: Givet: Charlemont. Holotype: MNHN 819-202: ad, mounted skin (skull not removed). Additional skull A6953: see Rode (1941: 244), who mentions Abbeville as locality, and M. Baillon as collector.
?	*Myotis (Chrysopteron) emarginatus:* (Current Combination).
?	*Myotis emarginata:* - Comments: corrected gender for specific name. (Alternate Spelling).
?	*Myotis emarginatus emarginatus:* (Name Combination).
?	*Myotis emarginatus:* (Name Combination).

TAXONOMY:
Assigned to the subgenus *Isotus* by Pavlinov *et al.* (1995: 97), but Csorba *et al.* (2014: 667) and Simmons and Cirranello (2024a: 79) include it in the subgenus *Chrysopteron*.

Dietz and Pir (2023: 258) indicate that *Myotis emarginatus* is probably more related to the Afrotropic species such as *Myotis tricolor* than to any other Palearctic species. Stadelmann *et al.* (2004b: 186) already suggested that this species that this species is derived from two African ancestors that secondarily colonized Eurasia.

Uvizl and Benda (2022: 285) indicate that - based on morphometrics and mitochondrial genes - *Myotis emarginatus* can be divided into two groups: one of small-sized and more variable bats from Europe, the Maghreb and the Levant; and a second covering the large-sized bats of the rest of the Asian range. Each of these was subdivided into two sublineages. For the western group, one of these sublineages occurred in the Holy Land and the other in the rest of the Mediterranean range. The nuclear genes displayed no subdivision, which suggests that this species is monophyletic. Nevertheless, Uvizl and Benda (2022: 285) recognize two subspecies: a small-sized *M. e. emarginatus* from the Mediterranean, western and central Europe and the Levant; and a large-sized *M. e. desertorum* in the eastern Middle East, from Oman to West Turkestan. However, Benda and Uvizl (2021: 25) restricted the latter to the south-eastern Middle East, including southern Iran, Oman, and Afghanistan.

Woodman (1993) notes that many mammalian generic names ending in *-otis* use the wrong gender for specific names therefore this name should be *M. emarginata*. However, see also Benda and Tsytsulina (2000: 335), and Simmons (2005).

COMMON NAMES:
Albanian: Lakuriq nate i Geoffroy-it. Arabian: Khaffash. Armenian: Եռագույն գիշերաչղջիկ. Azerbaijani: Üçrəng gecə şəbpərəsi. Basque: Geoffroy saguzar. Belarusian: Начніца трохкаляровая. Bosnian: Trobojni šišmiš. Breton: Gousperell Geoffroy. Bulgarian: Трицветен нощник. Castilian (Spain): Murciélago orejirroto, Murciélago de Geoffroy, Murciélago ratonero pardo. Catalan (Spain): Ratpenat d'orelles dentades, Ratapinyada d'orella escapçada. Croatian: Riđi šišmiš, Trobojni šišmiš. Conservation status:

Global Justification

The species experienced a significant decline in at least parts of its range from the 1960s to the 1990s, but now it is expanding in central Europe and is stable or not significantly declining elsewhere. The range is still large, and the species is not specialized to restricted habitat, although it has a very specialized diet. Assessed as Least Concern (LC ver 3.1 (2001)) (Hutson *et al.*, 2008m; IUCN, 2009; Piraccini, 2016a).

Assessment History

Global

2016: LC ver 3.1 (2001) (Piraccini, 2016a). 2008: LC ver 3.1 (2001) (Hutson *et al.*, 2008m; IUCN, 2009). 1996: VU A2c ver 2.3 (1994) (Baillie and Groombridge, 1996).

Regional

None known.

Major threats:

In Europe the species is mainly associated with agricultural landscapes, therefore all agricultural activities can affect populations of this species. Loss of and disturbance to roost sites in buildings (including remedial timber treatment in attics) and underground sites are also threats. In the African part of the range, cave habitats, where the species roosts, are being destroyed by fires and vandalism. The species is also collected for traditional medicine practices in North Africa (Hutson *et al.*, 2008m; IUCN, 2009; Piraccini, 2016a).

Conservation actions:

Piraccini (2016a) supports Hutson *et al.* (2008m) [in IUCN (2009)] who report that it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention in the range states where these apply. It is included in Annex IV of EU Habitats and Species Directive, and there is some habitat protection through Natura 2000.

Protection of roosts and promotion of awareness about the lack of medicinal value of the species is required.

General distribution:

Myotis emarginatus occurs in southern Europe from Portugal in the west to the Balkans in the east and southern part of western and central Europe and non-arid parts of southwestern Asia from Asia Minor, Caucasus region and Palestine to Oman, Uzbekistan and Tajikistan; also in north-west Africa (recorded from northern Maghreb (Algeria, Morocco and Tunisia)). In the eastern part of the Mediterranean it occurs in various parts of Turkey, Syria, Lebanon and Israel. It occurs from sea level to 1,800 m, highest records in the Alps are 812 m (maternity colony) and 1,505 m (hibernaculum) (Spitzenberger, 2002).

Native: Afghanistan; Albania; Algeria; Andorra; Armenia; Austria; Azerbaijan; Belgium; Bosnia and Herzegovina; Bulgaria; Croatia; Cyprus; Czech Republic; France [Corse]; Georgia; Germany; Gibraltar; Greece [Kriti] (Benda *et al.*, 2007: 71); Hungary; Iran, Islamic Republic of; Israel; Italy [Sardinia]; Jordan; Kazakhstan; Kyrgyzstan; Lebanon; Luxembourg; Macedonia, the former Yugoslav Republic of; Monaco; Montenegro; Morocco (El Ibrahimi and Rguibi Idrissi, 2015: 360; Dbiba *et al.*, 2025: 8); Netherlands; Oman; Poland; Portugal; Romania; Russian Federation; San Marino; Saudi Arabia; Serbia; Slovakia; Slovenia; Spain [Baleares]; Switzerland; Syrian Arab Republic; Tajikistan; Tunisia (Dalhoumi *et al.*, 2014: 53); Turkey; Turkmenistan; Ukraine; Uzbekistan.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 7.1 Pa, aspect ratio 5.9 and tip shape index of 2.05 for a wingspan of 24 cm and a wing area of 93 cm^2 and a body mass of 7 g.

ECHOLOCATION:
Highly variable depending on activity and habitat; these data refer to cruising calls in the main habitat. Search-phase call-shape (close to foliage): steep linear FM. Start-frequency: 110 kHz; end-frequency: 39 kHz; frequency with maximum energy: 65 kHz; call-duration: 2.6 ms; inter-call interval: 26-32 ms (Barataud, 2005).

The data for 42 animals from Greece were the following: F_{start}: 110.5 ± 10.90 kHz, F_{end}: 42.6 ± 5.57 kHz, F_{peak}: 72.8 ± 7.28 kHz, bandwidth: 43.4 ± 8.29 kHz, duration 3.3 ± 0.73 ms and interpulse interval: 79.4 ± 23.83 ms (Papadatou *et al.*, 2008b: 132).

Walters *et al.* (2012: suppl.) report the following figures for 26 calls (24 sequences) from France and Germany: duration: 2.29 ± 0.70 ms, F_{max}: 93.23 ± 20.18 kHz, F_{min}: 42.00 ± 3.47 kHz, bandwidth: 51.23 ± 17.78 kHz, F_{peak}: 60.23 ± 15.14 kHz.

MOLECULAR BIOLOGY:
Karyotype
Bovey (1949) and Pérez-Suárez *et al.*, 1991) reported 2*n* = 44, aFN = 50, X = submetacentric, Y = acrocentric, while Radjhabli *et al.* (1970) reported aFN = 56 and Zima (1978) aFN = 52 with X = metacentric. The autosomal component consists of three large metacentric, one small metacentric, 15 acrocentric and two dot-like pairs (with one being bi-armed) (Arslan and Zima, 2014: 10). The latter authors also refer to the X chromosome as being a medium-sized metacentric.

Genetics
See García-Mudarra *et al.* (2009).

HABITAT:
In Spain, Goiti *et al.* (2011: 19) found that *M. emarginatus* flew on average 5 km to its foraging areas, with a maximum distance of almost 10 km. The foraging area covered between 120 and 371 ha, and consisted mainly of scrubland (35 % of mean individual foraging time) and pine plantations (34 % of mean individual foraging locations), followed by isolated trees (oak, pine, or eucalyptus - on average 11 %), riparian woods (7 %), oak dehesas (6 %), and eucalyptus plantations (5 %).

DIET:
Goiti *et al.* (2011: 20) found that, in Spain, spiders made up the major part of the diet by both volume (mean 79 %) and frequency (in faeces of all examined bats, and in 95 % of the faeces). The next most important group was formed by moths, with a mean consumption of 7 % of the diet by volume; dipterans (flies and midges - 6.3 %), and lacewings (especially the family Hemerobiidae - 4.4 %). Earwings, harvestmen, wasps, and beetles all made up less than 2 % of the diet.
Benda *et al.* (2012a: 325) summarizes the European food groups as: Araneae, Lepidoptera, brachyceran Diptera, and Lepidoptera larvae. In the Middle East Diptera, Lepidoptera, Coleoptera, and Homoptera are prevailing in Azerbaijan, Araneae and Brachycera in Syria, and Hemiptera, Araneae, and Brachycera in Turkey. In Iran, there was a high proportion of Tipulidae, and in Jordan of scarabaeid beetles. This lead Benda *et al.* (2012a: 325) to conclude that a certain level of flexibility of the trophic niche in *M. emarginatus*.

POPULATION:
Structure and Density
Locally it can be rare or common. The species experienced a significant decline from the 1960s to the 1990s, but in recent time the numbers in several regions have increased and the species has spread into new areas. It lives in large colonies (up to 1,200 individuals in Austria in one maternity colony) (Hutson *et al.*, 2008m; IUCN, 2009; Piraccini, 2016a).

Trend
2016: Stable (Piraccini, 2016a). 2008: Stable (Hutson *et al.*, 2008m; IUCN, 2009).
M. emarginatus populations within the Asia Minor and Levant region are predicted to have a stable population trend, under climate change scenarios (Bilgin *et al.*, 2012: 433).

PARASITES:
Frank *et al.* (2015: 8) mention the following parasites for European *M. emarginatus*:
Arachnida: *Eyndhovenia euryalis* (G. Canestrini, 1885), *Macronyssus rhinolophi* (Oudemans, 1902), *Steatonyssus periblepharus* Kolenati, 1858, *Spinturnix emarginata* (Kolenati, 1856).

Insecta: *Basilia nana* Theodor & Moscona, 1954, *Basilia italica* Theodor, 1954, *Cimex pipistrelli* Jenyns, 1839, *Ischnopsyllus emarginatus*, *Ischnopsyllus simplex* Rothschild, 1906, *Penicillidia dufourii* (Westwood, 1835), *Phthiridium biarcticulatum*, *Rhinolophopsylla unipectinata* (Taschenberg, 1880).

Trematoda - Digenea: *Lecithodendrium linstowi* Dollfus, 1931, *Prosthodendrium aelleni* Dubois, 1956, *Prosthodendrium chilostomum* (Mehlis, 1831).

Cestoda: *Myotolepis grisea* (Beneden, 1873).

Bendjeddou *et al.* (2017: 15) and Khelfaoui *et al.* (2018: 67) mention the following parasites from bats from Algeria: Nycteribiidae: *Nycteribia (Nycteribia) latreillii* (Leach, 1817) and *Penicillidia (Penicillidia) dufourii* Westwood, 1835; Arachnida: *Spinturnix myoti* (Kolenati, 1856) and *Ixodes vespertilionis* Koch, 1844.

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Ixodidae: *Ixodes vespertilionis* Koch, 1844; Nycteribiidae: *Nycteribia latreillii* (Leach, 1817), *Penicillidia dufourii* (Westwood, 1834); Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856).

VIRUSES:
Orthomyxoviridae
Despite sampling and testing of 3 individuals of this species, no evidence of influenza A-like viruses (Orthomyxoviridae) were obtained (Fereidouni *et al.*, 2015).

UTILISATION:
The species is also collected for traditional medicine practices in North Africa (Hutson *et al.*, 2008m; IUCN, 2009).

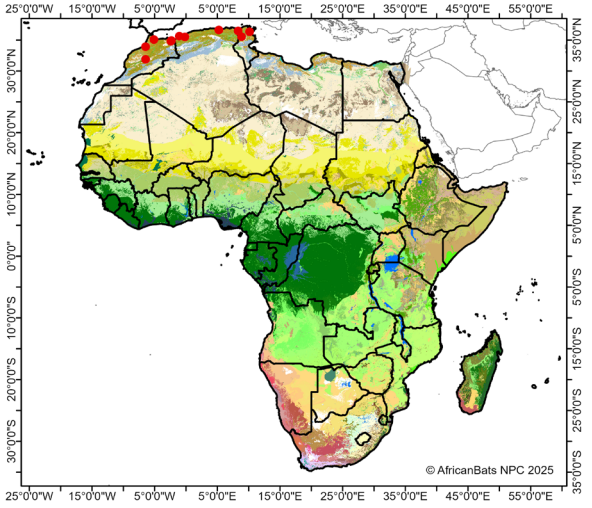

Figure 264. Distribution of *Myotis (Chrysopteron) emarginatus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Algeria, France, Morocco, Tunisia.

Myotis (Chrysopteron) goudotii (A. Smith, 1834)

*1834. *Vespertilio Goudotii* A. Smith, S. Afr. Quart. J., ser 2, 2: 244. Publication date: June 1834. Type locality: Madagascar: "Madagascar". [Goto Description].
1858. *Vespertilio Madagascariensis* Tomes, Proc. zool. Soc. Lond., 1858, XXVI (ccclii): 89. Publication date: 27 April 1858. Type locality: Madagascar: "Madagascar". Holotype: NHMUK 1907.1.1.503.
1870. *Vespertilio sylvicola* A. Grandidier, Rev. Mag. Zool., ser 2, 22: 49. Publication date: February 1870. Type locality: Madagascar: Ambaravantao forest. [Goto Description]. - Comments: The type locality was mentioned as "Forests of Ambaravaranvatou" by Allen (1939a: 91). Dobson (1878: 301, footnote) indicates that the type has been lost and that the description is insufficient. He, therefore, included it with a question mark.
1908. *Myotis goudoti:* G. M. Allen, Bull. Mus. comp. Zool., 52 (3): 43. Publication date: July 1908. (Name Combination).
1939. *Myotis goudotii:* G. M. Allen, Bull. Mus. comp. Zool., 83: 91. Publication date: February 1939. (Name Combination).
? *Myotis (Chrysopteron) goudoti:* (Current Combination).
? *Myotis goudoti goudoti:* (Name Combination).

TAXONOMY:
Simmons (2005) states that it does not appear to include *anjouanensis*; see Peterson *et al.* (1995).

Generally mentioned as *goudoti*, but Andrew Smith (1834: 244) did describe it using a double "i": *Vespertilio Goudotii* (Simmons and Cirranello, 2023a: 79).

Csorba *et al.* (2014: 667) include *goudotii* in the subgenus *Chrysopteron*, but Ruedi and Mayer (2001: 436), Ghazali *et al.* (2016: 476) and Patterson *et al.* (2019a: "2") reject the division in subgenera.

COMMON NAMES:
Czech: netopýr madagaskarský. English: Malagasy Mouse-eared Bat, Malagasy Myotis. French: Murin de Madagascar, Chauve-souris malgache à oreille de souris, Vespertilion de Madagascar. German: Madagaskar-Mausohr.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Samonds (2007: 60) found samples in deposit (SS2), which was collected from the surface near the main cave entrance, dating attempts revealed this sample was contaminated, therefore no date is known for this locality in Anjohibe cave, Madagascar.

Weyeneth (2010) indicated that, during the Pleistocene, populations of this species diverged into a southern and a northern component, with subsequent expansion and adaptation to all biomes.

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) in view of its widespread distribution across Madagascar, and the absence of any major threats. Close monitoring of roosting colonies in areas where the forest is subject to disturbance is needed (Andriafidison *et al.*, 2008h; IUCN, 2009; Monadjem *et al.*, 2017bv).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bv). 2008: LC ver 3.1 (2001) (Andriafidison *et al.*, 2008h; IUCN, 2009). 1996: LR/nt ver 2.3 (1994) (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There are no known threats to this species although additional research is needed to determine the impact of forest degradation on its persistence in cave roosts (IUCN, 2009; IUCN, 2009; Monadjem *et al.*, 2017bv).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008h) [in IUCN (2009)] and Monadjem *et al.* (2017bv) report that this is a widespread species that is found in many of Madagascar's protected areas, including those in the east and west of the island (Goodman, 1999; Russ *et al.*, 2003; Goodman *et al.*, 2005a).

GENERAL DISTRIBUTION:
Myotis goudotii is endemic to the island of Madagascar (Simmons, 2005) where it is widely distributed across a range of different vegetation types (Peterson *et al.*, 1995; Goodman, 1999; Eger and Mitchell, 2003; Russ *et al.*, 2003; Goodman *et al.*, 2005a), including Nosy Be and Nosy Komba (Rakotonandrasana and Goodman, 2007: 6). It occurs on altitudes between 0 and 800 m (with one record from 1,600 m) (Garbutt, 2022: 99)..

Native: Madagascar (Peterson *et al.*, 1995; Goodman, 1999; Eger and Mitchell, 2003; Russ *et al.*, 2003; Goodman *et al.*, 2005a; Rakotonandrasana and Goodman, 2007: 6).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 64) reported the structure as being triangular, and in some cases, with a pronounced proximal indentation; length: 0.87 ± 0.111 (0.68 - 1.02) mm, width: 0.53 ± 0.081 (0.43 - 0.67) mm.

ECHOLOCATION:
Russ *et al.* (2003) describe the echolocation as a single frequency-modulated sweep from 75 kHz to 55 kHz. Kofoky *et al.* (2009: 382) reported the calls of 11 individuals, which were characterized by broadband FM sweeps produced at low duty cycle. The most energy always found in the fundamental at about 64.4 kHz, and the pulses were very short about 3 ms.

Hending *et al.* (2023: 372) reported F_{peak}: 59.0 ± 3.9 kHz, duration: 5 ± 4 ms, and interpulse interval: 66 ± 30 ms.

MOLECULAR BIOLOGY:
Karyotype
Richards *et al.* (2010) examined one female and one male having a 2*n*=44 and a FNa= 50, a submetacentric X and small acrocentric Y chromosome. In addition, Volleth and Eick (2012: 167) mention a segment number of 22.

HABITAT:
Dammhahn and Goodman (2013: 108) mention the lower portion of forest structure and partially open areas as the foraging habitat for this species.

Goodman *et al.* (2023b: 239) [referring to Rafanomezanjanahary (2021)] indicated that 108 individuals captured at Antsahabe were found in *savoka* (regenerating secondary grassland - 53 %), relatively intact forest (23 %), secondary forest (18 %), and the remaining 6 % in a variety of agroforestry habitats and rice fields.

Crowley and Goodman (2025: 4) report this species to be widespread in various habitats between sea level and 1,600 m.

ROOST:
Wilkinson *et al.* (2012: 160) indicate that caves are the typical roosting sites for these bats on Madagascar. Ravelomanantsoa *et al.* (2019: 110) added crevices and possibly tree holes. The colony size is generally small, although in Namoroka a colony of 1,000 animals was recorded (Garbutt, 2022: 99).

DIET:
Razakarivony *et al.* (2005) found Araneae in 27 % of stomachs examined. Rakotoarivelo *et al.*

(2007) in Madagascar found *M. goudotii* to mainly consumed Hymenoptera, Neuroptera, Araneae and fragments of spiders were present in 55 % of the faecal samples.

Rakotondramanana *et al.* (2015: 78) report the following diet items (volume percent, frequency percent): Coleoptera (34.0, 100.00); Hymenoptera (4.0, 60.0); Lepidoptera (62.0, 100.0). Rasoanoro *et al.* (2015: 64) found the following volume percentages for two specimens: Aranea (40.7), Coleoptera (43.7), Hymenoptera (8.4), Isoptera (4.6), Lepidoptera (2.5).

For bats from Kianjavato, Rasoanoro *et al.* (2015: 64) reported Coleoptera (43.7 %), Araneae (40.7 %), and Hymenoptera (8.4 %).

Goodman *et al.* (2023b: 239) [referring to Falimiarintsoa (2022)] indicated that the fecal pellets of 28 bats collected at Sarahandrano contained Coleoptera (55.6 %), Diptera (20.4 %), Lepidoptera (17.7 %), and less than 3 % of Hemiptera and Hymenoptera, and at Antsahabe [referring to Rafanomezanjanahary (2021)]: Coleoptera (44 %), Lepidoptera (22 %), Diptera (14 %), Orthoptera (5 %), and Araneae, Blattoptera, Ephemeroptera, Hemiptera, and Hymenoptera (each less than 4 %).

Kemp *et al.* (2018: Suppl.) used DNA metacarcoding to detect insect pest species in the diet of these bats and found the following prey orders (in descending order): Coleoptera, Hymenoptera, Lepidoptera (*Homona* sp., *Thaumatotibia batrachopa* (Meyrick, 1908)), Diptera (*Simulium lineatum* (Meigen, 1804), *Culex* sp., *Culex annulioris* Theobald, 1901, *Coquillettidia* sp., *Anopheles* sp.), Sarcoptiformes, Ephemeroptera, Hemiptera, Araneae, Blattodea, Trichoptera, Symphypleona, Mesostigmata, Trombidiformes.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 65 minutes, and the digestibility rate about 81.8 %.

Predators:
Goodman *et al.* (2015c: 78) found the remains of one individual in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar.

Population:
Structure and Density
Although widespread, there is a paucity of information on the population status of *M. goudotii*. It is frequently trapped in mist nets during bat surveys and appears to be at least locally abundant in west (Kofoky *et al.*, 2007; Rakotoarivelo and Randrianandrianina, 2007), but is more difficult to net, or is less abundant in the east (Russ *et al.*, 2003; Randrianandriananina *et al.*, 2006). There are few data available on roosting colonies but aggregations of up to 1,000 individuals have been recorded (Monadjem *et al.*, 2017bv).

Trend
2016: Unknown (Monadjem *et al.*, 2017bv).
2008: Unknown (Andriafidison *et al.*, 2008h; IUCN, 2009).

Activity and behaviour:
Rakotoarivelo *et al.* (2007) suggest that *M. goudotii* is better adapted to forage in cluttered areas and may have a closer association with forest vegetation. They also suggest that *M. goudotii* may be a gleaner.

Reproduction and ontogeny:
55 adult females captured at Antsahabe in late September to late November 2019, only three showed signs of breeding activity (no fur around the mammae), and 34 of the 55 males had descended testes. 11 of 21 females collected in Sarahandrano between late March and late April were adults without embryos, whereas the remaining females were subadults. 14 of the 15 males captured in the same timeframe had descended testes (Goodman *et al.*, 2023b: 240).

Of the two males reported by Goodman *et al.* (2025: 215) and collected between mid November and early December, one had abdominal testes and the other only slightly enlarged testes. Two females were pregnant with embryos with crown-rump length of 17 and 20 mm.

Parasites:
BACTERIA
Lagadec *et al.* (2012: 1696), Dietrich *et al.* (2014: Suppl.) and Gomard *et al.* (2016: 5) report the presence of spirochaetes bacteria of the genus *Leptospira*, which are assigned to *L. borghpetersenii* by Dietrich *et al.* (2018a: 3). Lei and Olival (2014: Suppl.) mention "*Myotis goudoti*" as host for *Bartonella* bacteria.

HAEMOSPORIDA
Megali *et al.* (2010: 1042) and Duval *et al.* (2012: 1563) reported Genbank data for *Polychromophilus* sp. from *M. goudotii*. Ramasindrazana *et al.* (2018: Suppl.) identified this parasite as *Polychromophilus murinus* Dionisi, 1899 (see also Chumnandee *et al.*, 2020: Suppl.; Rasoanoro *et al.*, 2021).

Ramasindrazana *et al.* (2016: 6) reported the presence of an unnamed filariod in this bat species.

DIPTERA
Nycteribiidae
Ramasindrazana *et al.* (2017: Suppl.) found the bat flies *Nycteribia stylidiopsis* and *Penicillidia* sp. on specimens from this bat species.

ACARI
Trombiculidae
Stekolnikov (2018a: 116) reported *Trisetica aethiopica* (Hirst, 1926) from this bat species.

VIRUSES:
Astroviridae
Lebarbenchon *et al.* (2017 Suppl.) tested 14 animals and three of them was positive for Astroviruses.

Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 2 individuals from the Madagascar using RT-PCR specific for Respirovirus/Morbillivirus/Henipahvirus (RMH) and Paramyxovirinae (PMV) and found 0 positive results for viral nucleic acids. Wilkinson *et al.* (2014) tested 8 individuals from Anjohikinakia and Bekoaky in Madagascar with an RT-PCR specific for the *Respiro-*, *Morbilli-* and *Henipavirus* genera, two of the 8 individuals tested positive for paramyxovirus RNA.

48 Madagascan *M. goudotii* specimens were tested by Mélade *et al.* (2016b: 4) and five of them were positive for paramyxoviruses.

Rhabdoviridae
Of the 11 bats tested by Mélade *et al.* (2016a: 6), four showed a seroreaction.

UTILISATION:
See Goodman *et al.* (2008d).

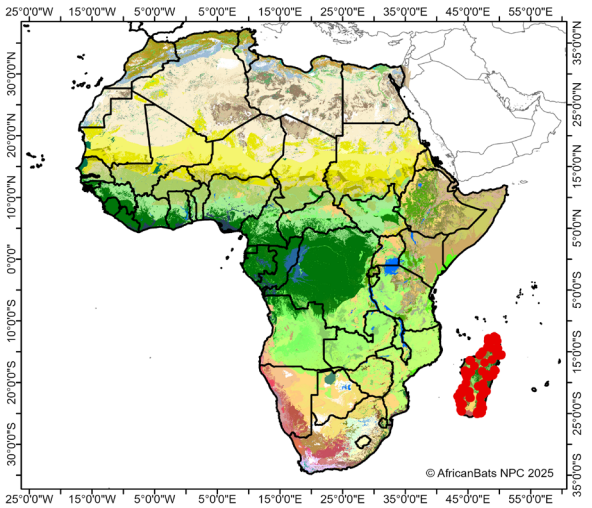

Figure 265. Distribution of *Myotis (Chrysopteron) goudotii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Madagascar.

Myotis (Chrysopteron) morrisi Hill, 1971

*1971. *Myotis morrisi* Hill, in: Hill and Morris, Bull. Br. Mus. (nat. Hist.) Zool., 21 (2): 43, pl 1, 2 (a, b). Publication date: 28 April 1971. Type locality: Ethiopia: Walaga, Blue Nile Gorge: Didessa River mouth: "Forward Base Three" [10 05 N 35 38 E, ca. 1 000 m]. [Goto Description]. Holotype: NHMUK 1970.488: ad ♀, skin and skull. Collected by: The Great Abbai Expedition; collection date: 28 August 1968; original number: A107. (Largen, Yalden & King). Also see Hill and Morris (1971: 43). - Etymology: In honour of Dr. Pat Morris of Royal Holloway College, University of London, in recognition of his many services to the study of the Ethiopian fauna while with the Great Abbai Expedition (Hill in Hill and Morris, 1971: 44).

? *Myotis (Chrysopteron) morrisi:* (Current Combination).

TAXONOMY:
Known only from two specimens (see Stadelmann *et al.*, 2004b: 179).

Simmons and Cirranello (2023b: 79) assigned it to the subgenus *Chrysopteron*.

COMMON NAMES:
Czech: netopýr Morrisův. English: Morris's Mouse-eared Bat, Morris's Bat, Morris's Myotis. French: Murin d'Ethiopie, Vespertilion de Morris. German: Morris' Mausohr.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, threats and conservation status (Jacobs *et al.*, 2008o; IUCN, 2009; Jacobs *et al.*, 2019c).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019c). 2008: DD ver 3.1 (2001) (Jacobs *et al.*, 2008o; IUCN, 2009). 2004: VU D2 ver 3.1 (2001) (Jacobs *et al.*, 2004b; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are unclear. It may be threatened by cave disturbance and subsistence harvesting for food (Jacobs *et al.*, 2008o; IUCN, 2009; Jacobs *et al.*, 2019c).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008o) [in IUCN (2009)] and Jacobs *et al.* (2019c) report that it is not known if the species is present in any protected areas. Further studies are needed into the distribution, abundance, natural history, and threats to this poorly known species.

GENERAL DISTRIBUTION:
Myotis morrisi has only been recorded from two very disjunct sites, the type locality of 'Didessa River mouth, Walaga' in Ethiopia (Hill and Morris, 1971) and from Numan, Adamawa Province, in northeastern Nigeria (Hill *et al.*, 1988).

Native: Ethiopia (Hill and Morris, 1971); Nigeria (Hill *et al.*, 1988).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 84 minutes, and the digestibility rate about 79.1 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Jacobs *et al.*, 2008o; IUCN, 2009; Jacobs *et al.*, 2019c).

Trend
2018: Unknown (Jacobs *et al.*, 2019c). 2008: Unknown (Jacobs *et al.*, 2008o; IUCN, 2009).

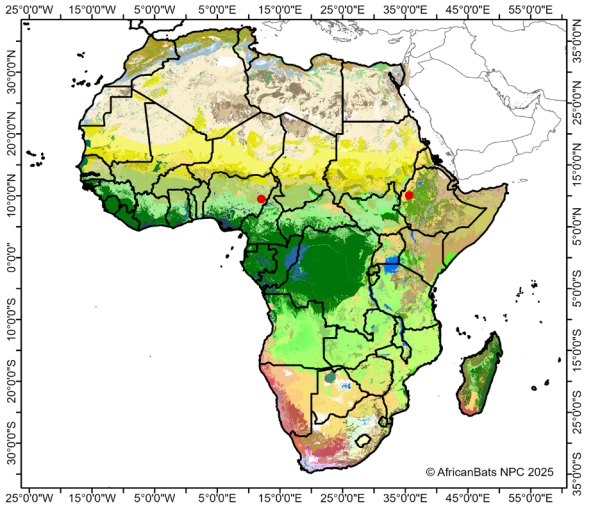

Figure 266. Distribution of *Myotis (Chrysopteron) morrisi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia, Nigeria.

Myotis (Chrysopteron) nimbaensis Simmons, Flanders, Bakwo Fils, Parker, Suter, Bamba, Douno, Keita, Morales and Frick, 2021

*2021. *Myotis nimbaensis* Simmons, Flanders, Bakwo Fils, Parker, Suter, Bamba, Douno, Keita, Morales and Frick, Am. Mus. Novit., 3963: 3, 8, figs 3 - 8. Publication date: 13 January 2021. Type locality: Guinea: N'Zérékoré region: Mount Nimba: Kaiser Adit 1 [07 39 54 N 08 22 20 W]. Holotype: AMNH 279589: ad ♂, skull and alcoholic and tissue. Collected by: Jon Flanders and Eric Moise Bakwo Fils; collection date: 2 February 2018; original number: BCIGU133. Paratype: AMNH 279590: ad ♀, skull and alcoholic and tissue. Collected by: Jon Flanders and Eric Moise Bakwo Fils; collection date: 2 February 2018; original number: BCIGU132. - Etymology: The name refers to Mount Nimba where the type specimen was collected.

? *Myotis (Chrysopteron) nimbaensis:* (Current Combination).

TAXONOMY:
Simmons *et al.* (2021: 8) and Simmons and Cirranello (2023b: 79) assigned this species to the subgenus *Chrysopteron*.

CONSERVATION STATUS:
Simmons *et al.* (2021: 28) suspected, that once assessed by the IUCN, the status would be "Critically Endangered" based on its currently known occurrence area of less than 100 km^2.

GENERAL DISTRIBUTION:
This species is only known from the type locality.

ECHOLOCATION:
Simmons *et al.* (2021: 20) mention a steep frequency-modulated pulse with a bandwidth of 84.1 ± 13.1 kHz; F_{max}: 104 kHz, F_{min}: 20 kHz, F_{peak}: 42.5 ± 4.2 kHz, duration: 3.5 ± 0.3 ms, and an interpulse interval of 113 ± 5.3 ms.

ROOST:
The two specimens collected by Simmons *et al.* (2021: 21) were captured while emerging from a disused mine adit.

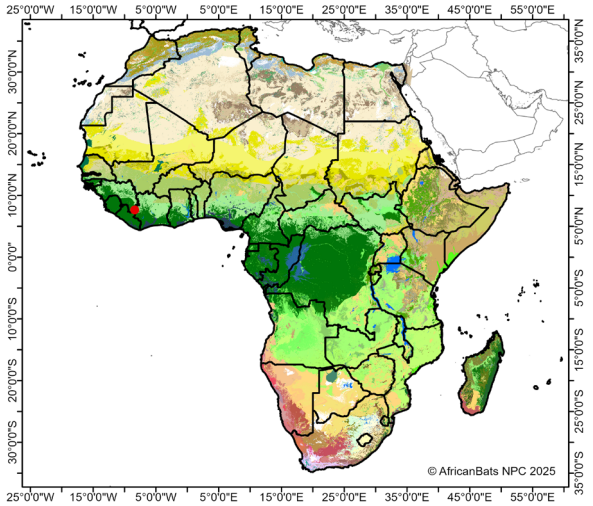

Figure 267. Distribution of *Myotis (Chrysopteron) nimbaensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Guinea.

Myotis (Chrysopteron) scotti Thomas, 1927

*1927. *Myotis scotti* Thomas, Ann. Mag. nat. Hist., ser 9, 19 (113): 554. Publication date: 1 May 1927. Type locality: Ethiopia: Shoa province: ca. 40 mi (64 km) W Addis Ababa: Djem-djem Forest [09 00 N 38 12 E, 8 000 ft]. Holotype: NHMUK 1927.3.4.1. Paratype: NHMUK 1927.3.4.2. Paratype: NHMUK 1927.3.4.3. Paratype: NHMUK 1927.3.4.4. Paratype: NHMUK 1927.3.4.5.

? *Myotis (Chrysopteron) scotti:* (Current Combination).

TAXONOMY:
See Simmons (2005).

Csorba *et al.* (2014: 667) and Simmons and Cirranello (2023b: 79) include *scotti* in the subgenus *Chrysopteron*.

COMMON NAMES:
Czech: netopýr habešský. English: Scott's Mouse-eared Bat, Scott's Mouse-eared Myotis. French: Murin de Scott, Vespertilion de Scott. German: Scotts Mausohr.

CONSERVATION STATUS:
Global Justification
Listed as Vulnerable (VU B2ab(iii) ver 3.1 (2001)) because its area of occupancy (AOO) is possibly less than 2,000 km^2, its distribution is likely to be severely fragmented, and there is continuing decline in the extent and quality of its forest habitat in Ethiopia (Benda and Lavrenchenko, 2008; IUCN, 2009; Benda and Lavrenchenko, 2017).

Assessment History
Global
2016: VU B2ab(iii) ver 3.1 (2001) (Benda and Lavrenchenko, 2017). 2008: VU B2ab(iii) ver 3.1 (2001) (Benda and Lavrenchenko, 2008; IUCN, 2009). 2004: VU B2ab(iii) ver 3.1 (2001) (Benda and Lavrenchenko, 2004; IUCN, 2004). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The forest habitat of this species is being impacted through conversion of land to agricultural use and logging (Benda and Lavrenchenko, 2008; IUCN, 2009; Benda and Lavrenchenko, 2017).

CONSERVATION ACTIONS:
Benda and Lavrenchenko (2008) [in IUCN (2009)] and Benda and Lavrenchenko (2017) report that there appear to be no conservation measures in place, and it is not known if the species is present in any protected areas. There is a need to conserve areas of suitable montane forest habitat for this species. Further studies are needed into the abundance, biology and ecology.

GENERAL DISTRIBUTION:
Myotis scotti is endemic to the highlands of Ethiopia, where it has been recorded from ten localities between 1,300 and 2,500 m asl.

Native: Ethiopia.

MOLECULAR BIOLOGY:
Genetics

Morales *et al.* (2024: Suppl.) reported the total length of the genome to consist of 2002.52M base pairs.

HABITAT:
Chakravarty *et al.* (2024: 7) considers this species to be a "highland dwelling species".

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 73 minutes, and the digestibility rate about 80.6 %.

Morales *et al.* (2024: Suppl.) assigned this species to the Aerial Hawker ecomorph type.

POPULATION:
Structure and Density
It appears to be a rare species that is known from only about 20 specimens (Benda and Lavrenchenko, 2008; IUCN, 2009; Benda and Lavrenchenko, 2017).

Trend
2016: Unknown (Benda and Lavrenchenko, 2017). 2008: Decreasing (Benda and Lavrenchenko, 2008; IUCN, 2009).

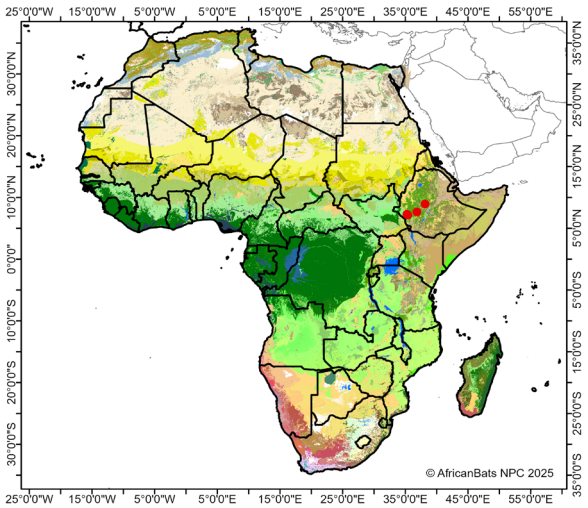

Figure 268. Distribution of *Myotis (Chrysopteron) scotti*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia.

Myotis (Chrysopteron) tricolor (Temminck, 1832)

*1832. *V[espertilio] tricolor* Temminck, in: Smuts, Enumer. Mamm. Capensium, 106. Publication date: 1832. Type locality: South Africa: Cape province: Cape Town [33 56 S 18 28 E]. [Goto Description]. Lectotype: RMNH MAM.35899: ad ♀, skull only. Collected by: Dr. Hubertus Benedictus Van Horstok; collection date: 1828 - 1832. Paralectotype: RMNH MAM.35898: ad ♀, mounted skin and skull. Collected by: Dr. Hubertus Benedictus Van Horstok; collection date: 1828 - 1832. - Comments: Type specimen: RMNH ???.
1901. *Myotis tricolor:* Sclater, The mammals of South Africa, 131. (Name Combination).
*1924. *Epetiscus loveni* Granvik, Acta Univ. Lund, ser 2, 21 (3): 12. Publication date: 1924. Type locality: Kenya: E slopes of Mount Elgon [01 07 N 34 35 E, 8 000 ft]. [Goto Description]. Holotype: NRM 100903:; collection date: 1920.
1939. *Eptesicus loveni:* G. M. Allen, Bull. Mus. comp. Zool., 83: 86. Publication date: February 1939. (Name Combination).
2013. *Myotis tricolor 1:* Ruedi, Stadelmann, Gager, Douzery, Francis, Lin, Guillén-Servent and Cibois, Mol. Phylog. Evol., 69 (3): Suppl. Publication date: 27 August 2013.
2013. *Myotis tricolor 2:* Ruedi, Stadelmann, Gager, Douzery, Francis, Lin, Guillén-Servent and Cibois, Mol. Phylog. Evol., 69 (3): Suppl. Publication date: 27 August 2013.
? *Myotis (Chrysopteron) tricolor:* (Current Combination).
? *Myotis (Selysius) tricolor:* (Name Combination).
? *Myotis tricolor A:*

TAXONOMY:
Includes *Eptesicus loveni*, see Aggundey and Schlitter (1986).

Csorba *et al.* (2014: 667) and Simmons and Cirranello (2023b: 79) include *tricolor* in the subgenus *Chrysopteron*, but see Ruedi and Mayer (2001: 436), Ghazali *et al.* (2016: 476) and Patterson *et al.* (2019a: "2"), who reject the division into subgenera.

The phylogenetic analyses on mitochondrial DNA performed by Patterson *et al.* (2019a: "5", "9"') identified three separate groups, two corresponding to South African samples and a third from Kenya (close to the type locality of *loveni*, which might possibly represent a separate (sub)species. The cyt-*b* sequences of these groups differed by 3.7 - 3.8 %.

COMMON NAMES:
Afrikaans: Temminck se langhaarvlermuis, Temminck-langhaarvlermuis, Kaapse Langhaarvlermuis. Chinese: 南非鼠耳蝠. Czech: netopýr trojbarvý. English: Temminck's Mouse-eared Bat, Cape Myotis, Cape Hairy Bat, Tricoloured Mouse-eared Bat, Cape Hairy Myotis, Temminck's Hairy Bat, Three-coloured bat. French: Murin tricolore, Petit murin brun, Murin

velu du Cap, Vespertilion d'Angola, Murin d'Angola. German: Dreifarb-Mausohr.

Figure 269. *Myotis tricolor* (TM 48188) caught at the Farm Schaapplaats, Free State, South Africa.

ETYMOLOGY OF COMMON NAME:
The colloquial name is after C.J. Temminck, who was the author of *Monographies de Mammalogie* (1827) (Taylor, 2005).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
This species was represented in the very late Holocene at Border Cave, South Africa (Avery, 1991: 6).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs, 2008e; IUCN, 2009; Monadjem and Jacobs, 2017b).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Jacobs, 2017b). 2008: LC ver 3.1 (2001) (Jacobs, 2008e; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs, 2004e; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016k). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Jacobs, 2008e; IUCN, 2009; Monadjem and Jacobs, 2017b).

CONSERVATION ACTIONS:
Jacobs (2008e) [in IUCN (2009)] and Monadjem and Jacobs (2017b) report that it has been recorded from the Virunga National Park in the Democratic Republic of the Congo (Baeten *et al.*, 1984) and in view of its East African range, it seems likely that it is present in additional protected areas. Further studies are needed into the range of this species in West and Central Africa.

GENERAL DISTRIBUTION:
Myotis tricolor has been patchily recorded in sub-Saharan Africa. In West Africa the species has currently only been reported from the northwestern uplands of Liberia (Koopman *et al.*, 1995), while in Central Africa it is known only from a few records in the Democratic Republic of the Congo and Rwanda (Hayman *et al.*, 1966; Baeten *et al.*, 1984). *Myotis tricolor* is much more widely recorded in East Africa, ranging from Ethiopia in the north, through Uganda, Kenya, Tanzania, Malawi, Zambia, Mozambique and Zimbabwe through to southern South Africa.

In the RSA, its distribution is best predicted by geology (Babiker Salata, 2012: 50).

Native: Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 564); Eswatini (Monadjem *et al.*, 2010d: 565 Monadjem *et al.*, 2021: 5); Ethiopia; Kenya; Lesotho (Lynch, 1994: 193; Monadjem *et al.*, 2010d: 564); Liberia (Fahr, 2007a: 104); Malawi (Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 564); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 564; Monadjem *et al.*, 2010c: 384); Nigeria (Tanshi *et al.*, 2022a: 314); Rwanda; Saõ Tomé (Rainho *et al.*, 2010a: 31); South Africa (Monadjem *et al.*, 2010d: 564); Tanzania; Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 565); Zimbabwe (Monadjem *et al.*, 2010d: 565).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Schoeman and Jacobs (2002: 157) mention the following parameters for 1 specimen from the Algeria Forestry Station (RSA): Fa: 46.9 mm, Wing area: 156.6 cm^2, Wing span: 30.6 cm, Wing loading: 6.9 N/m^2, and aspect ratio: 6.0.

Shockney and Rummel (2025: 6) mention the pelage density for this species to be significant on both the dorsal and ventral sides of the proximal arm and the dorsal side of the proximal arm, and moderate on the dorsal side of the plagiopatagium.

DETAILED MORPHOLOGY:
Baculum
Kearney *et al.* (2002).

FUNCTIONAL MORPHOLOGY:
Jordaan and Jacobs (2009: 35) indicate that the wing morphology of *M. tricolor* is intermediate

between that of a typical aerial forager, gleaner (takes insects off a substrate) and trawler (takes prey from the water surface).

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 8.2 Pa, aspect ratio 6.2 for a wingspan of 34 cm and a wing area of 191 cm^2 and a body mass of 16 g.

ECHOLOCATION:
See Taylor (1999b).

Rainho *et al.* (2010a: 21) and Rainho *et al.* (2022: 605) reported the calls of 5 "cf. *tricolor* individuals from São Tomé: F_{min}: 39.3 ± 2.0 (36.6 - 41.6) kHz, F_{max}: 117.3 ± 3.3 (112.0 - 120.8) kHz, F_{maxE}: 78.4 ± 2.1 (76.4 - 81.8) kHz, duration: 1.84 ± 0.1 (1.74 - 1.92) ms and interpulse interval: 82.7 ± 16.2 (58.4 - 102.6) ms.

From Algeria Forest Station (RSA), Schoeman and Jacobs (2002: 157) reported the type of calls to be low duty echolocation dominated by frequency modulated calls, with a F_{peak}: 50.0 kHz.

Jordaan and Jacobs (2009: 35) found that its echolocation call structure is intermediate between that of typical aerial foragers, gleaners and trawlers.

Schoeman and Waddington (2011: 291) mention a F_{peak}: 40.8 kHz and a duration: 4.4 ms for a specimen from Durban, South Africa.

In Waterberg, South Africa and Swaziland, Taylor *et al.* (2013b: 17) recorded 6 calls with the following parameters: F_{max}: 86.1 ± 5.92 (76.6 - 91.9) kHz, F_{min}: 42.7 ± 4.43 (37.1 - 50.0) kHz, F_{knee}: 57.6 ± 7.25 (48.5 - 67.5) kHz, F_{char}: 52.4 ± 6.13 (45.3 - 62.2) kHz, duration: 2.0 ± 0.40 (1.6 - 2.6) ms.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee}: 58 (48 - 68) kHz.

Four calls recorded at Mapungubwe National Park (RSA) by Parker and Bernard (2018: 57) had the following values: F_{char}: 42.68 ± 0.70 kHz, F_{max}: 70.40 ± 3.85 kHz, F_{min}: 40.88 ± 1.98 kHz, F_{knee}: 52.68 ± 3.43 kHz, duration: 3.03 ± 0.70 ms and 11.20 ± 7.85 calls/sec.

Release calls recorded at Telperion Nature Reserve by Kearney *et al.* (2019: 37) had a F_{char}: 37.04 kHz, slope at the start of the call: 372.62, time from start of call to F_{char}: 2.62 ms and duration: 3.13 ms. From the same location, De Jong *et al.* (2025: 322) reported the following parameters for 22 calls from 5 bats: F_{char}: 54.88 ± 10.55 kHz, F_{knee}: 60.73 ± 6.23 kHz, F_{min}: 36.49 ± 1.41 kHz, F_{max}: 80.12 ± 10.13 kHz, Bandwidth: 43.64 ± 10.05 kHz, Duration: 2.49 ± 0.42 ms.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 42.68 ± 0.70 kHz, F_{max}: 70.40 ± 3.85 kHz, F_{min}: 40.88 ± 1.98 kHz.

The 510 calls of 28 bats from southern KwaZulu-Natal and Eastern Cape (RSA), reported by Moir (2020: 30) and Moir *et al.* (2021a: 371), had the following characteristics: F_{max}: 77.20 ± 5.14 (70.53 - 86.49) kHz, F_{min}: 35.59 ± 3.51 (27.35 - 38.95) kHz, F_{char}: 56.38 ± 6.64 (48.32 - 69.75) kHz, F_{knee}: 75.09 ± 5.76 (68.16 - 85.59) kHz, and duration: 2.50 ± 0.47 (2.08 - 3.45) ms.

From Swaziland, Monadjem *et al.* (2017c: 179) reported F_{min}: 38.0 ± 3.78 (34.2 - 41.7) kHz, F_{knee}: 55.4 ± 10.8 (44.6 - 66.2) kHz, F_c: 49.4 ± 11.4 (38.0 - 60.8) kHz, duration: 2.4 ± 0.33 (2.07 - 2.72) ms. The maximum distance over which they were able to detect the calls was 10 m (mean: 4.6 ± 0.73 m).

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 45 calls of 12 bats: F_{max}: 62.29 ± 7.35 kHz, F_{min}: 29.13 ± 3.03 kHz, F_{knee}: 56.04 ± 7.82 kHz, F_{char}: 51.92 ± 7.66 kHz, slope: 468.23 ± 440.5 OPS, duration: 2.75 ± 0.7 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 3 *Myotis tricolor* calls from the Kruger Park (RSA): F_{min}: 40.3 ± 7.5 (31.7 45) kHz, duration: 2.5 ± 0.4 (2.2 3.8) ms, F_{max}: 60.8 ± 24.1 (38.7 86.5) kHz, F_{knee}: 44.9 ± 7.0 (36.8 49.4) kHz, F_{char}: 42.7 ± 4.9 (37.1 46.3) kHz.

Adams and Kwiecinski (2018: 4) reported F_{char}: 41.8 ± 4.3 kHz, F_{max}: 81.5 ± 6.2 kHz, F_{min}: 38.8 ± 2.2 kHz and duration: 2.9 ± 0.9 ms for six calls from the Kalahari Desert.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 47.8 kHz and duration: 3.3 ms.

22 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 31 - 50 kHz, F_{max}: 76 - 91 kHz, F_{char}: 45 - 62 kHz, F_{knee}: 48 - 67 kHz and duration 2 - 3 ms.

Parker (2022: 20) reported 47 passes of these bats in the Mountain Zebra National Park (RSA) with F_{min}: 36.09 ± 9.29 kHz, F_{char}: 39.55 ± 6.93 kHz and F_{max}: 47.24 ± 26.00 kHz.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 42.68 ± 0.70 kHz, F_{max}: 70.40 ± 3.85 kHz and F_{min}: 40.88 ± 1.98 kHz.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 44, FN = 50, BA = 8, a submetacentric X chromosome, and an acrocentric Y chromosome, for specimens from South Africa and Zimbabwe. These results are the same as those obtained for *M. bocagii* specimens from South Africa (Rautenbach *et al.*, 1993).

HABITAT:
Sirami *et al.* (2013: 34) recorded in the Western Cape Province, South Africa that *M. tricolor* activity was not significantly, nor positively influenced by size of wetland, while habitats 100 m surrounding wetlands were also significantly and positively influenced by the water body. *M. tricolor* was observed near trees and in orchards but also in open habitats surrounding wetlands (Sirami *et al.*, 2013: 35).

On São Tomé, Castro-Fernandes *et al.* (2024: 2) reported *Myotis* cf. *tricolor* to be an edge forager.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 820,776 km^2.

HABITS:
In the Long One cave (RSA), Norton and van der Merwe (1978: 219) found that *M. tricolor* was less sensitive to light and relatively higher temperatures than *Miniopterus natalensis*, which resulted in these bats remaining longer in torpid and preferring dimly illuminated places.

ROOST:
In the Durban area, Taylor *et al.* (1999: 69) reported it roosting in the Shongweni Dam tunnel, with a colony size between 100 and 400. A colony consisting of females only, occupied this tunnel from September to the end of January.

In South Africa; these bats can migrate over hundreds of kilometers between the maternity colonies and the hibernation caves (Happold and Happold, 2023: 145).

DIET:
From the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) reported the following prey groups based on 11 faecal pellets from 1 bat (in volume percent): Coleoptera (50), Hemiptera (25), Hymenoptera (25).

Moyo and Jacobs (2020: 1) found that the diet of *M. tricolor* contained high proportions of fatty acids that were only obtainable from aquatic insects such as pond skaters (Gerridae) and whirligig beetles (Gyrinidae), This suggests that this bat probably uses both aerial hawking and trawling (or at least gleaning) to take insects from water surfaces.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 105 minutes, and the digestibility rate about 76.7 %.

PREDATORS:
Avery *et al.* (2005: 1054) found this bat species in pellets from *Tyto alba* (Scopoli, 1769) in South Africa.

Malan *et al.* (2022: 167) reported two individual found in pellets from a bat hawk (*Macheiramphus alcinus* Bonaparte, 1850.

POPULATION:
Structure and Density
This is a common species with colonies often consisting of thousands of animals (Jacobs, 2008e; IUCN, 2009; Monadjem and Jacobs, 2017b).

Trend
2016: Unknown (Monadjem and Jacobs, 2017b).
2008: Unknown (Jacobs, 2008e; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Bernard (1982b) [in Badwaik and Rasweiler (2000: 276) and Racey and Entwistle (2000: 374)] indicate that females exhibit partial regression of the corpus luteum during pregnancy, and that it has a restricted seasonal monoestry reproduction pattern. Bernard (1982b: 83) also indicated that in Natal copulation occurred in April, and that ovulation and fertilization probably occurred in mid-September, suggesting that sperm storage probably occurred during winter and ovulation was delayed until spring.

Jordaan and Jacobs (2009: 35) found that late pregnancy females forage for longer (307.0 ± 173.5 min) than early pregnant females (147.7 ± 154.5 min) to meet the high energy demands associated with the developing foetus.

Females lactate for about six weeks (Happold and Happold, 2023: 146).

PARASITES:
HAEMOSPORIDA
Lutz *et al.* (2016: 9) examined 3 *M. tricolor* specimens from East Africa and found one of

them infected with a haemosporidan parasite of the genus *Polychromophilus*.

DIPTERA
Streblidae
Raymondia hardyi Fiedler, 1954 from South Africa (Shapiro *et al.*, 2016: 254).

Nycteribiidae
Nycteribia capensis Karaman, 1939 which may be the natural parasite for this species (Haeselbarth *et al.*, 1966: 108). *Nycteribia latiterga* Theodor, 1957 from Mt. Menengai, Kenya (Haeselbarth *et al.*, 1966: 108). *Penicillidia fulvida* (Bigot, 1885) (Haeselbarth *et al.*, 1966:114; Verrett *et al.*, 2022: 8; Dick *et al.*, 2023).

SIPHONAPTERA
Ischnopsyllidae
Oxyparius isomalus (Waterston, 1915) locality not stated (Haeselbarth *et al.*, 1966: 188). *Rhinolophopsylla capensis* Jordan and Rothschild.

ACARI
Trombiculidae
Stekolnikov (2018a: 189) reported *Willmannium natalense* (Lawrence, 1949) from bats in South Africa.

VIRUSES:
In their country-wide survey of Kenyan bats, Waruhiu *et al.* (2017) found the following viruses in *Myotis tricolor*: Astroviruses and Polyomaviruses. Kamau *et al.* (2022: 5) reported Astroviridae and Retroviridae

Bunyaviridae
Phlebovirus
Rift Valley Fever Virus (RVFV)
Oelofsen and Van der Ryst (1999) tested two individuals from two localities in the Free State Province, South Africa and Lesotho for RVFV antigen using an enzyme linked immunosorbet assay (ELISA), none tested positive.

Rhabdoviridae
Lyssavirus - Rabies related viruses
Rabies
Oelofsen and Smith (1993) tested 10 individual brains, from four localities by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), none were tested positive.

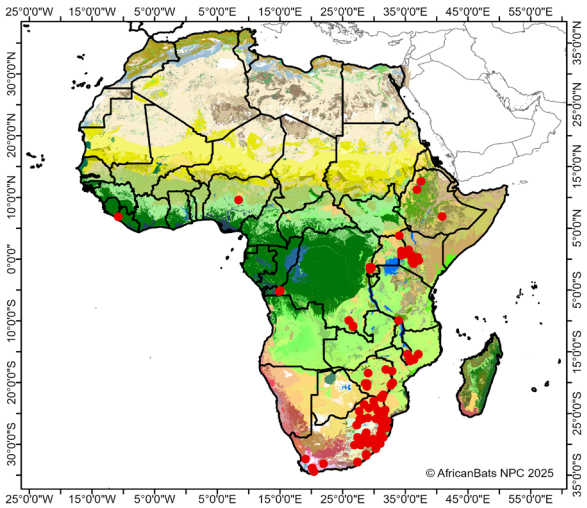

Figure 270. Distribution of *Myotis (Chrysopteron) tricolor*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Congo (Democratic Republic of the), Eswatini, Ethiopia, Kenya, Lesotho, Liberia, Malawi, Mozambique, Nigeria, Rwanda, South Africa, Tanzania, Uganda, Zambia, Zimbabwe.

Myotis (Chrysopteron) welwitschii (J. E. Gray, 1866)

*1866. *Scotophilus welwitschii* J. E. Gray, Proc. zool. Soc. Lond., 1866, II: 211, pl 24. Publication date: September 1866. Type locality: Angola: NE Angola: (probably near Pungo Andongo: see Crawford-Cabral (1989: 17) in Thorn *et al.* (2009: 50)). [Goto Description]. Holotype: NHMUK 1866.4.12.2: ♂. Collected by: Dr. F.M. Welwitsch. - Etymology: Named after Welwitsch, an Austrian botanist who made extensive collections in Angola (Taylor, 2005).
1878. *Vespertilio welwitschii:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 306. Publication date: 15 June 1878. (Name Combination).
1899. *Vespertilio venustus* Matschie, Sber. Ges. naturf. Freunde Berlin, 74. Publication date: 1899. Type locality: Tanzania: Morogoro district: Ukami Mts., [north slope of Uluguru Mountains]: Kinole [06 50 S 37 42]. Holotype: ZMB 54653: ♂, skin and skull. Vendor: Schlüter; see Turni and Kock (2008: 63).
1922. *Myotis welwitschii:* Kershaw, Ann. Mag. nat. Hist., ser 9, 10 (56): 181. Publication date: 1 August 1922. (Name Combination, Current Combination).
1951. *Scotophilus welwetschii:* Roberts, Mammals of South Africa, 80. (Lapsus).
1967. *Myotis venustus:* Kock, Senckenb. biol., 48 (5/6): 319. (Name Combination).
2013. *Myotis welwitschii 1:* Ruedi, Stadelmann, Gager, Douzery, Francis, Lin, Guillèn-Servent and Cibois, Mol. Phylog. Evol., 69 (3): Suppl. Publication date: 27 August 2013.
2013. *Myotis welwitschii 2:* Ruedi, Stadelmann, Gager, Douzery, Francis, Lin, Guillén-Servent and Cibois, Mol. Phylog. Evol., 69 (3): Supp. Publication date: 27 August 2013.
2013. *Myotis welwitschii 3:* Ruedi, Stadelmann, Gager, Douzery, Francis, Lin, Guillèn-Servent and Cibois, Mol. Phylog. Evol., 69 (3): Suppl. Publication date: 27 August 2013.
2014. *Myotis wilwitschii:* Ndara R., IJISR, 12 (1): 254. Publication date: November 2014. (Lapsus).

2016. *Myotis weltwitschii:* Simmons, Seiffert and Gunnell, Am. Mus. Novit., 3857: 43. Publication date: 9 May 2016. (Lapsus).
2022. *Myotis welwitschia:* Mushabati, Eiseb, Benda and Laverty, Afr. J. Ecol., 7. Publication date: 27 February 2022. (Lapsus).
? *Myotis (Chrysopteron) welwitschii:* (Name Combination).

TAXONOMY:

Figure 271. *Myotis welwitschii* (TM 47968) caught at Lapalala Wilderness area, Limpopo Province, South Africa.

Csorba *et al.* (2014: 667) and Simmons and Cirranello (2023b: 79) include *welwitschii* in the subgenus *Chrysopteron*, although Ruedi and Mayer (2001: 436), Ghazali *et al.* (2016: 476) and Patterson *et al.* (2019a: "2") reject the division in subgenera.

Myotis welwitschii is monotypic (Kershaw, 1922b: 181; Hayman and Hill, 1971; Findley, 1972; Kock, 1967; Meester *et al.*, 1986; Simmons, 2005). However, the phylogenetic analyses by Patterson *et al.* (2019a: "5", "9") indicate the existence of two groups within this species: one corresponding to an equatorial group occurring from Guinea to western Kenya and a second group existing in eastern and southern Africa, from Tanzania to South Africa (possibly representing *venustus*). These groups differ by 5 % in their cyt-*b* sequence.

COMMON NAMES:

Afrikaans: Welwitsch se langhaarvlermuis, Welwitsch-langhaarvlermuis. Chinese: 魏氏鼠耳蝠. Czech: netopýr Welwitschův, netopýr Welwitschiův. English: Welwitsch's Mouse-eared Bat, Welwitsch's Hairy Bat, Welwitch's Bat, Welwitsch's Myotis. French: Murin de Welwitsch, Myotis de Welwitsch, Vespertilion de Welwitsch. German: Welwitschs Mausohr. Kiluba (DRC): Mulima. Malawian: Liputiputi, Ndemiya, Namsimsi, Namzeze. Portuguese: Morcego lanudo de weltsch. Tshokwe (Angola): Kafukufuku.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

No fossils are known (Ratcliffe, 2002).

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008p; IUCN, 2009; Monadjem *et al.*, 2017ck).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017ck). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008p; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004d; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016l). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:

There appear to be no major threats to this species as a whole (Jacobs *et al.*, 2008p; IUCN, 2009; Monadjem *et al.*, 2017ck).

CONSERVATION ACTIONS:

Jacobs *et al.* (2008p) [in IUCN (2009)] and Monadjem *et al.* (2017ck) report that this species has been recorded from the Sengwa Wildlife Research Area and Kruger National Park in South Africa, and seem likely to be present in additional East or southern African protected areas. No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:

Myotis welwitschii has been widely, but patchily, recorded over much of East Africa and southern Africa, parts of southern Central Africa, and with a single West African locality in southeastern Guinea. In East and southern Africa, it is distributed from Ethiopia and the Sudan in the north, through Kenya, Tanzania and Malawi, to Zambia, Mozambique, Zimbabwe and northeastern South Africa (where its distribution is linked with land use/land cover (Babiker Salata, 2012: 50)). In Central Africa, it is largely confined to southern Democratic Republic of the Congo, northern Angola, Rwanda and Burundi and western Uganda. It has not been recorded from Namibia or Botswana.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 920,261 km^2.

Native: Angola (Hayman, 1963; Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 565; Taylor *et al.*, 2018b: 63); Burundi (Fahr and Ebigbo, 2003: 128); Congo (The Democratic Republic of the) (Fahr and Ebigbo, 2003; Monadjem *et al.*, 2010d: 565); Eswatini (Monadjem *et al.*, 2021: 5); Ethiopia; Guinea (Fahr and Ebigbo, 2003: 128); Kenya; Malawi (Happold *et al.*, 1988; Happold and Happold, 1997b: 819; Fahr and Ebigbo, 2003; Monadjem *et al.*, 2010d: 565); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 565); Rwanda; South Africa (Fahr and Ebigbo, 2003; Monadjem *et al.*, 2010d: 565); Sudan; Tanzania; Uganda (Kityo and Kerbis, 1996: 61); Zambia (Fahr and Ebigbo, 2003; Monadjem *et al.*, 2010d: 565); Zimbabwe (Fahr and Ebigbo, 2003; Monadjem *et al.*, 2010d: 565).

GEOGRAPHIC VARIATION:

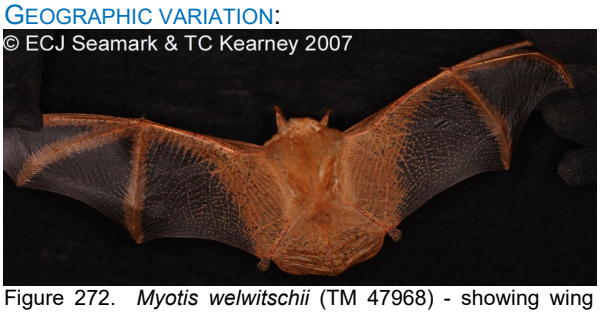

Figure 272. *Myotis welwitschii* (TM 47968) - showing wing reticulations.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Ratcliffe (2002).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Ratcliffe (2002).

DETAILED MORPHOLOGY:
Others
For a description of the skull, teeth, ears and tragus, and wingshape and aspect ratio see Ratcliffe (2002).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 7.5 Pa, aspect ratio 5.7 for a wingspan of 37 cm and a wing area of 235 cm^2 and a body mass of 18 g.

ECHOLOCATION:
In Soutpansberg, South Africa, Taylor *et al.* (2013b: 17) recorded 1 call with the following parameters: F_{max}: 73.8 kHz, F_{min}: 33.8 kHz, F_{knee}: 52.9 kHz, F_{char}: 50.3 kHz, duration: 2.1 ms.

Linden *et al.* (2014: 40) reported the following parameters from the Southpansberg range (RSA): F_{min}: 34 kHz, F_{char}:50 kHz, F_{knee}: 53, slope: 563 OPS, duration: 2.1 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 36 calls of 11 bats: F_{max}: 58.88 ± 4.53 kHz, F_{min}: 30.3 ± 3.49 kHz, F_{knee}: 51.03 ± 4.84 kHz, F_{char}: 47.27 ± 4.98 kHz, slope: 493.64 ± 133.78 OPS, duration: 2.58 ± 0.42 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 4 *Myotis welwitschii* calls from the Kruger Park (RSA): F_{min}: 30.3 ± 3.7 (25.3 - 34.2) kHz, duration: 2.8 ± 0.7 (2.2 - 3.8) ms, F_{max}: 69.1 ± 3.8 (66.2 - 74.7) kHz, F_{knee}: 60.7 ± 11.5 (44.4 - 71.5) kHz, F_{char}: 49.2 ± 7.0 (39.6 - 56.0) kHz.

Thiagavel *et al.* (2017: Suppl.) mention a F_{peak} of 32.66 kHz.

9 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 33 kHz, F_{max}: 73 kHz, F_{char}: 50 kHz, F_{knee}: 52 kHz and duration 2 ms.

From Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 9 calls: Interpulse interval: 71.4 ± 32.3 (32.3 - 120.0) ms; F_{max}: 39.7 ± 5.0 (34.7 - 49.9) kHz; Start slope: -19.2 ± 3.7 (-14.1 - -24.8) kHz/ms; End slope: -18.8 ± 4.5 (-13.6 - -25.9) kHz/ms; Ledge duration: 0.4 ± 0.1 (0.3 - 0.6) ms.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 44, FN = 50, BA = 8, and submetacentric X and Y chromosomes, for specimens from South Africa.

Genetics
See Hoofer and Van Den Bussche (2003).

Morales *et al.* (2024: Suppl.) reported the total length of the genome to consist of 2001.87M base pairs.

HABITAT:
See Ratcliffe (2002).

In southern Africa, it occurs in Savanna (70 %) and Afromontane (20 %) habitats (Cooper-Bohannon *et al.*, 2016: Table S2).

HABITS:
See Ratcliffe (2002).

ROOST:
See Ratcliffe (2002).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 111 minutes, and the digestibility rate about 76.1 %.

Morales *et al.* (2024: Suppl.) assigned this species to the Gleaner ecomorph type.

POPULATION:
Structure
Considered solitary in its roosting habits (Smithers and Wilson, 1979; Ratcliffe, 2002). However; in a single instance two animals were found roosting in the same bush (Smithers and Wilson, 1979).

Density
Unknown, although this species is widespread, it does not appear to be particularly common (Jacobs *et al.*, 2008p; IUCN, 2009; Monadjem *et al.*, 2017ck).

Trend
2016: Unknown (Monadjem *et al.*, 2017ck). 2008: Unknown (Jacobs *et al.*, 2008p; IUCN, 2009).

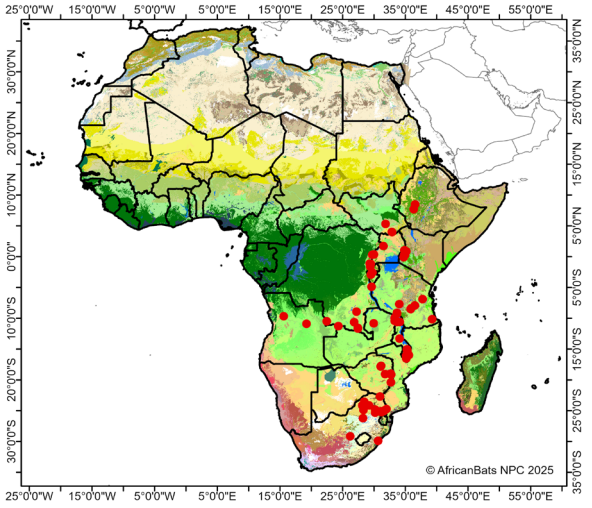

Figure 273. Distribution of *Myotis (Chrysopteron) welwitschii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Burundi, Congo (Democratic Republic of the), Ethiopia, Kenya, Malawi, Rwanda, South Africa, South Sudan, Tanzania, Uganda, Zambia, Zimbabwe.

†***Myotis darelbeidensis*** Gunnell, Eiting and Geraads, 2011

*2011. *Myotis darelbeidensis* Gunnell, Eiting and Geraads, N. Jb. Geol. Paläont. Abh., 260 (1): 59, figs 3C, 5A-C, 8A-C. Publication date: January 2011. Type locality: Morocco: Ahl al Oughlam [ca. 33 35 N 07 30 W]. Holotype: INSAP AaO 4571. Right dentary fragment with p2-m3. Paratype: INSAP AaO 4589. Left maxilla P4-M1. - Etymology: Name taken from Dar el Beida ("white house"), the Arabic name for Casablanca (see Gunnell *et al.*, 2011: 60). (Current Combination).

TAXONOMY:
Gunnell *et al.* (2011: 60) describe it as a large species of *Myotis*, similar in size to *M. blythii* and *M. myotis*, much larger than most other extant Mediterranean *Myotis* species (including *M. capaccinii, M. bechsteinii, M. emarginatus*).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Pliocene (Brown *et al.*, 2019: Suppl.).

Subgenus *Myotis (Myotis)* Kaup, 1829

*1829. *Myotis* Kaup, Skizzierte Entwicklungs-Geschichte Natürliche Systematik der Europäische Thierwelt, 1: 106. Publication date: 1829. - Comments: Type species: *Vespertilio myotis* Borkhausen, 1797, by subsequent designation by Miller (1912: 167). Kaup (1829: 106) mentioned *Vespertilio murinus*, but for a discussion on the type species, see Jackson and Groves (2015: 280). - Etymology: From the Greek "*μύς*" or "*μυός*", meaning mouse and "*οὐς*" or "*ὠτός*" meaning ear (see Palmer, 1904: 442). Gardner (2005:184) considers the name to be masculine (My = mouse + ot = ear(ed) + is (Latin third declension ending)). - Phonetics: mie-oh'-tis.

Myotis (Myotis) capaccinii (Bonaparte, 1837)

*1837. *Vespertilio Capaccinii* Bonaparte, Iconografia Fauna italiana, 1, fasc 20 and pl, fig. Publication date: 1837. Type locality: Italy: Sicily. [Goto Description]. Holotype: NHMUK 1907.1.1.734. - Etymology: In honour of Francesco Capaccini, undersecretary of state of Rome about 1833-34, and a patron of Bonaparte's "Iconografia della Fauna Italica," published in 1832-1841 (Palmer, 1904: 49). (see Palmer, 1904: 49; Kozhurina, 2002: 15).

2022. *Myotis cappaccinii:* Mechouk, Mihalca, Deak and Bouslama, Parasites & Vectors, 15 (302): 8. Publication date: 27 August 2022. (Lapsus).
? *Myotis (Myotis) capaccinii:* (Current Combination).
? *Myotis capaccinii capaccinii:* (Name Combination).
? *Myotis capaccinii:* (Name Combination).

TAXONOMY:
Most recent authors consider *M. capaccinii* as a monotypic species (Spitzenberger and von Helversen, 2001; Simmons, 2005). However, Aihartza and Aizpurua (2023: 162) indicate that based on morphological characters, *Myotis capaccinii capaccinii* is recognized from North-western Africa to the Western Balkans, and *Myotis capaccinii bureschi* from Bulgaria to Iran. In 2019, another subspecies was described from southern Turkey: *Myotis capaccinii abidinbudaki*.

Simmons and Cirranello (2023b: 79) did not assigned it to a subgenus ("unassigned").

COMMON NAMES:
Albanian: Lakuriq nate gishtgjatë. Arabian: Khaffash. Armenian: Միջերկրածովային գիշերաչղջիկ. Azerbaijani: Uzunbarmaq gecə şəbpərəsi. Basque: Saguzar hatz-luze, Saguzar hankahandia. Turkish: Uzunayaklı Yarasa. Ukrainian: Нічниця довгопала. Welsh: Ystlum hirfys.

CONSERVATION STATUS:
Global Justification
The species occupies specialised habitat (caves and associated water systems). In the eastern part of the range it congregates in winter in a few sites which are threatened by human disturbance. It has declined between 30 and 50 % in Spain in the last 10 years, and there are indications of declines in other parts of the range. It only hunts in watercourses and is therefore threatened by water pollution and the development of tourist infrastructure, which is expected to continue in the future. It is suspected that population declines are underway that will exceed 30 % over 18 years (3 generations), and for that reason the species is considered Vulnerable (VU A4bce ver 3.1 (2001)) (Hutson *et al.*, 2008k; IUCN, 2009; Paunović, 2016).

Assessment History
Global
2016: VU A4bce ver 3.1 (2001) (Paunović, 2016). 2008: VU A4bce ver 3.1 (2001) (Hutson *et al.*, 2008k; IUCN, 2009). 1996: VU (Baillie and Groombridge, 1996). 1994: VU (IUCN, 1994). 1990: VU (IUCN, 1990). 1988: VU (IUCN, 1988).

Regional
None known.

MAJOR THREATS:
Threats include changes in water quality through pollution and dam building, and loss of water bodies and watercourses. Damage or disturbance to caves (tourism, fires and vandalism) used as roosts may also be a problem, as the species is very dependent on caves. The species is collected for medicinal purposes in North Africa (Hutson *et al.*, 2008k; IUCN, 2009; Paunović, 2016).

The species' small distribution range, cave or tree roosting, and aerial hawking feeding style are considered to be the most important risk factors related to climatic change (Sherwin *et al.*, 2012: 174). Bilgin *et al.* (2012: 434) predict that the range retraction for *M. capaccinii* as a result of climatic change may pose severe threats to its

survival as this species has the bulk of its range in the Mediterranean region.

CONSERVATION ACTIONS:
Paunović (2016) supports Hutson *et al.* (2008k) [in IUCN (2009)] who report that it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention in the range states where these apply. It is included in Annex II (and IV) of EU Habitats and Species Directive, and hence requires special measures for conservation including designation of Special Areas for Conservation. Some habitat protection through Natura 2000. In Spain, fences are in place to protect several known colonies. Measures needed include protection of colonies (these measures should avoid the blocking of any cave entrances with gates and control of tourist access) and improvement of water quality.

GENERAL DISTRIBUTION:
Myotis capaccinii is sparsely distributed from eastern Iberia, Spain through the northern Mediterranean to coastal Asia Minor and Israel, Lebanon and Jordan, and also in Mesopotamia from Turkey to Iran and in north-west Africa (limited to the Mediterranean fringe of western Maghreb: north Morocco and northwest Algeria). It occurs from sea level to 900 m.

Bilgin *et al.* (2012) examined climate change scenarios within the Asia Minor and Levant region, they predict that *M. capaccinii* will have a range contraction, which may pose severe threats to their survival of this species.

Native: Albania; Algeria (Kowalski and Rzebik-Kowalska, 1991: 91); Andorra; Austria (?); Bosnia and Herzegovina; Bulgaria; Croatia; Cyprus (Benda *et al.*, 2007: 71); France [Corsica]; Greece [Kriti]; Holy See [Vatican City State]; Iran, Islamic Republic of; Iraq; Israel; Italy [Sardinia, Sicily]; Jordan; Lebanon; Macedonia, the former Yugoslav Republic of; Montenegro; Morocco (Aulagnier and Thevenot, 1986: 44; Dbiba *et al.*, 2025: 8); Romania; Russian Federation (?); Serbia; Slovenia; Spain [Baleares]; Syrian Arab Republic; Tunisia (Dalhoumi *et al.*, 2019b: 26); Turkey; Uzbekistan.
Regionally extinct: Switzerland.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Almenar *et al.* (2006: 158) indicate that the large hind feet and pointed wings of this species are well suited for capturing prey while trawling through the water surface.

FUNCTIONAL MORPHOLOGY:
Gardiner and Nudds (2011: 2187), in their study of flight-initiating jumps, found that *M. capaccinii* did not show a reduced jumping performance, which could have been expected due to the large feet, which leads to extra weight at the extremities.

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 10.5 Pa for a wingspan of 25 cm and a wing area of 56 cm^2 and a body mass of 6 g.

In their study on take-off performance, Gardiner *et al.* (2014: 1059) determined a wing beat frequency of 12.96 ± 0.18 Hz.

ECHOLOCATION:
Highly variable depending on activity and habitat; these data refer to cruising calls in the main habitat. Search-phase call-shape (while hunting above water surface): hyperbolic FM. F_{max}: 43 kHz; F_{min}: 22 kHz; F_{peak}: 28 - 35 kHz; call-duration: 6 - 9 ms, inter-call interval: 145 - 165 ms (Barataud, 2002, 2005).

The data for 56 animals from Greece were the following: F_{start}: 89.7 ± 7.35 kHz, F_{end}: 35.1 ± 2.18 kHz, F_{peak}: 48.9 ± 4.76 kHz, bandwidth: 14.2 ± 9.93 kHz, duration 4.6 ± 0.77 ms and interpulse interval: 75.4 ± 22.97 ms (Papadatou *et al.*, 2008b: 132).

Walters *et al.* (2012: suppl.) report the next figures for 30 calls of bats from France and Italy: duration: 3.62 ± 1.40 ms, F_{max}: 73.51 ± 9.28 kHz, F_{min}: 36.6 ± 3.18 kHz, bandwidth: 36.91 ± 10.73 kHz, F_{peak}: 52.2 ± 6.93 kHz.

The following data for 20 calls from Iran were reported by Benda *et al.* (2012a: 182): F_{start}: 66.0 ± 12.3 (53.1 - 87.1) kHz, F_{end}: 48.9 ± 2.0 (46.6 - 52.6) kHz, F_{peak}: 52.9 ± 1.9 (49.9 - 55.3) kHz, duration: 5.3 ± 0.7 (3.9 - 6.3) ms, and interpulse interval: 49.1 ± 20.4 (19.4 - 84.4) ms. Mehdizadeh *et al.* (2018: 1) reported that isolation calls of 1 to 4 day old Iranian *M. capaccinii* were FM shallow calls with longer duration (7.54 ± 1.83 ms) and lower F_{peak} (20.07 ± 0.89 kHz) as compared to adult female calls (2.35 ± 0.75 ms and 54.02 ± 4.34 kHz). Between days 12 and 16, the calls began to sound more like these of the adults.

Luo *et al.* (2019a: Supp.) reported the following data (from two calls): F_{peak}: 50.4, 48.9 kHz, F_{start}: 83.6, 89.7 kHz, F_{end}: 39.7, 35.1 kHz, Band width: 43.9, 54.6 kHz, and duration: 3.8, 4.6 ms.

Ait-Abdesselam *et al.* (2025: 40) mentioned an F_{end} value of 41.2 ± 5.17 kHz for Algerian bats.

Aizpurua *et al.* (2013: 4) indicate that *M. capaccinii* is able to regulate the temporal component of the echolocation call so that they can modify their capturing technique depending on whether they are hunting for aquatic arthropods or fish.

MOLECULAR BIOLOGY:
Karyotype
Capanna *et al.* (1968) and Rushton (1970: 463) reported 2*n* = 44, aFN = 50, X = metacentric, Y = acrocentric for specimens from Italy, while Pérez-Suárez *et al.* (1991) reported 2*n* = 44, aFN = 52, X = submetacentric, Y = acrocentric for specimens from Spain.

From Italy, Capanna and Manfredi Romanini (1971: 474) mention 2*n* = 44, aFN =60, 3 metacentric pairs of chromosomes, 1 submetacentric and 17 acrocentric; with the X chromosome being metacentric and the Y chromosome acrocentric.

Genetics
See Hoofer and Van Den Bussche (2003).

Karaman *et al.* (2017: 119) indicate that the ddRAD and mtDNA structure suggests that three lineages in the Mediterranean area could be considered different species, but this needs to be investigated further.

HABITAT:
In the eastern Iberian Peninsula, Almenar *et al.* (2006: 157) report that *M. capaccinii* only used aquatic habitats as foraging sites, and that most of their foraging activity was on rivers.

In northern Africa, this species occupies a narrow coastal band from Morocco to Tunisia.

M. capaccinii preferentially used river stretches characterised by an open course and smooth water surfaces (Almenar *et al.*, 2012). They shifted foraging stretches seasonally, likely following the spatiotemporal dynamics of prey production over the watershed (Almenar *et al.*, 2012).

HABITS:
Aihartza *et al.* (2008: 287) describe the fishing behaviour of *M. capaccinii* as observed in a flight tent containing an artificial pool. They distinguished two patterns: "A) long series of circular flights, skimming along the water and dipping in softly twice or three times in each roundabout; B) long figure-eight loops with bats flying faster and higher, swooping down on the centre of the pond, where they snapped their hind feet hard into the water." They also suggest (p. 297) that the bats detect the presence of fish by touching them when they dip their feet into the water.

ROOST:
Within the Iberian Peninsula, within the lower basin of the Xúquer River, Almenar *et al.* (2012) reported a main roost within a limestone cave with a variable colony size through the season: 81 *M. capaccinii* during pre-breeding, 219 during lactation and 113 during weaning of 2004. More than 100 individuals inhabit the second roost during lactation, located 8.4 km from the first. Both roosts are shared with other bat species (*Rhinolophus euryale*, *Rhinolophus mehelyi*, *Myotis blythii*, *Myotis myotis*, *Myotis emarginatus*, *Myotis nattereri* and *Miniopterus schreibersii*) (Almenar *et al.*, 2012).

DIET:
Aihartza *et al.* (2008: 288) indicate that in the Mediterranean area aquatic arthropods (e.g., Diptera: Culicidae and Chironomidae) form the main prey of this species, supplemented by Trichoptera, Neuroptera, Lepidoptera, Heteroptera and arachnids. But its diet also contains fish.

Although some *M. capaccinii* populations are known to eat fish in the wild Aihartza *et al.*, 2003; Levin *et al.*, 2006; Biscardi *et al.*, 2007), the diet of the surveyed individuals appeared to be exclusively arthropods (Almenar, 2008).

On the Iberian Peninsula, Aizpurua *et al.* (2011: 48) examined 2600 guano samples and retrieved 97 otoliths, all from the mosquitofish (*Gambusia holbrooki*) which would have been between 1.5 and 3.6 cm in length (maximum size of fishes: 5 cm in males and 8 cm in females, see Aihartza *et al.*, 2003: 196). They also found that one of the bats was able to eat between 8 and 15 fishes in one or two nights.

Piscivory is only reported for three geographically distinct colonies: Dénia (Iberian Peninsula), Hazorea (Levant) and Amaseno Valley (Italy) (Aihartza and Aizpurua, 2023: 176).

Aizpurua *et al.* (2021: 5) compared the gut microbiotas of bats with a piscivorous diet with that of conspecifics which were alleged to be non-piscivorous and found the microbiota composition to be very similar, which led them to believe that consumption of fish in this species is much more widespread than previously thought. Examination of faecal pellets, however, did not reveal the

presence of fish remains in the diet of non-piscivorous bats. Aizpurua *et al.* (2021: 5) hypothesize that the similar gut microbiota might be the result of an ancestral diet with more widespread fishing behavior.

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 76 minutes, and the digestibility rate about 80.2 %.

POPULATION:
Structure and Density
See Hutson *et al.*, 2008k) [in IUCN (2009)] and Paunović (2016).

Trend
2016: Decreasing (Paunović, 2016). 2008: Decreasing (Hutson *et al.*, 2008k; IUCN, 2009). *Myotis capaccinii* populations within the Asia Minor and Levant region are predicted to have a declining population trend, under climate change scenarios (Bilgin *et al.*, 2012: 433).

REPRODUCTION AND ONTOGENY:
In Greece, most females were pregnant by the second half of April and had given birth before the end of May. The first flying young were found by the end of June or the beginning of July (Papadatou *et al.*, 2008a 509).

In Iran, Mehdizadeh *et al.* (2018: 1) found the forearm length of neonates to be 19.59 ± 1.23 mm, with a linear growth of 0.74 mm/day until day 28. The weight at day one was 3.59 ± 0.23 g, and this increased linearly with 0.15 g/day until day 28.

POSTNATAL DEVELOPMENT:
Sharifi and Javanbakht (2018: 30) studied the post-natal growth of three captive bats. At birth the pups weighted 2.6 ± 0.1 g and a forearm length of 18 ± 1.5 mm. On day 54, the weight was increased to 6.7 ± 0.2 g (82.71 % of the adults) and the forearm to 34.56 ± 0.4 mm (80.37 % of the adult). Both increased lineary during the first three weeks (respectively 0.09 g/d and 0.6 mm/d).

PARASITES:
In Italy, Voyron *et al.* (2011: 193) reported the following fungal entities from carcasses: *Alternaria* sp., *Candida palmioleophila*, *Chrysosporium/Gymnoascus*, *Cladosporium cladosporioides*, Gimnoascacea, *Verticillium lecanii*, *Trichosporon chiropterorum*, *Mucor hiemalis f. hiemalis*, *Mucor racemosus*.

Ševčík *et al.* (2012: 35) report on the presence of the bat flies *Nycteribia pedicularia* Latreille, 1805, *Nycteribia schmidlii schmidlii* Schiner, 1853, and *Penicillidia dufourii* Westwood, 1835 on bats from Crete and Cyprus. *Nycteribia kolenati* Theodor & Moscona, 1954 and *Phthiridium biarticulatum* Hermann, 1804 were reported for the first time by Haelewaters *et al.* (2017: 1) from bats from Hungary.

From a non-specified area, Haelewaters *et al.* (2018: 794) added *Penicillidia conspicua* Speiser, 1901.

In Algeria, Bendjeddou *et al.* (2013: 325) reported two ectoparasites: *Cimex lectularius* (Linnaeus, 1758) (Hemiptera: Cimicidae) and *Rhipicephalus sanguineus* (Latreille, 1806) (Arachnidae: Ixodida: Ixodidae). Bendjeddou *et al.* (2017: 15) and Khelfaoui *et al.* (2018: 67) added the following species: *Nycteribia (Nycteribia) latreillii* (Leach, 1817) and *Phthiridium biarticulatum* Hermann, 1804 (Nycteribiidae); *Brachytarsina (Brachytarsina) flavipennis* Macquart, 1851 (Streblidae) and *Spinturnix myoti* (Kolenati, 1856) and *Ixodes vespertilionis* Koch, 1844 (Arachnida).

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Ixodidae: *Ixodes vespertilionis* Koch, 1844; Macronyssidae: *Rhipicephalus sanguineus* s.l.; Nycteribiidae: *Nycteribia latreillii* (Leach, 1817), *Nycteribia pedicularia* Latreille, 1805, *Nycteribia schmidlii schmidlii* Schiner, 1853, *Phthiridium biarticulatum* (Hermann, 1804); Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856); Streblidae: *Brachytarsina flavipennis* Masquart, 1851.

Júnior *et al.* (2020: Suppl.) reported the presence of additional Nycteribiid flies (not specifically for Africa): *Basilia italica* Theodor, 1954, *Basilia nana* Theodor, 1954, *Basilia nattereri* (Kolenati, 1857), *Nycteribia schmidlii* Schiner, 1853, *Nycteribia kolenati* Theodor and Moscona, 1954, *Nycteribia latreillii* (Leach, 1817), *Nycteribia vexata* Westwood, 1835, *Penicillidia dufourii* (Westwood, 1834), *Phthiridium biarticulatum* Hermann, 1804.

VIRUSES:
Paramyxoviridae
Morbillivirus
This virus was reported from Bulgaria, Germany and Romania by Kohl and Kurth (2014: 3113).

UTILISATION:
The species is collected for medicinal purposes in North Africa (Hutson *et al.*, 2008k; IUCN, 2009).

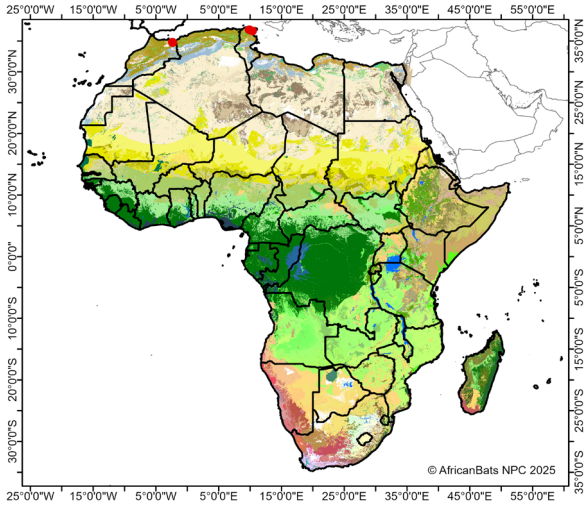

Figure 274. Distribution of *Myotis (Myotis) capaccinii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Morocco, Tunisia.

Myotis (Myotis) mystacinus (Kuhl, 1817)

*1817. *Vespertilio mystacinus* Kuhl, Die Deutsche Fledermäuse, 7, 58. Type locality: Germany. Syntype: ZMB 461: ♂, skin and skull. Unknown locality, presumably coll. Kuhl, purchased from Kuhl, 09.1818.: see Turni and Kock (2008: 60).
? *Myotis (Myotis) mystacinus:* (Current Combination).
? *Myotis mystacinus:* (Name Combination).

TAXONOMY:
Simmons and Cirranello (2023b: 79) did not assign this species to a subgenus ("unassigned").

Despite the fact that numerous species have been recently recognized within this complex, the whiskered bats from Morocco are still included in the nominal form (von Helversen *et al.*, 2001; Mayer *et al.*, 2007; García-Mudarra *et al.*, 2009).

At present, this species includes three forms differing in morphological traits: *M. mystacinus mystacinus* (most of European range), *M. mystacinus occidentalis* (Iberia and Morocco) and *M. mystacinus caucasicus* (Caucasus region).

COMMON NAMES:
Albanian: Lakuriq nate me mustaqe. Armenian: Բեղավոր գիշերաչղջիկ. Azerbaijani: Bığlı gecə şəbpərəsi. Basque: Saguzar biboteduna. Belarusian: Начніца вусатая. Bosnian: Mali brkati šišmiš. Breton: Gousperell varvek. Bulgarian: Мустакат нощник. Castilian (Spain): Murciélago bigotudo, Murciélago ratonero bigotudo. Catalan (Spain): Ratpenat de bigotis, Rat penat de bigotis. Croatian: Brkati šišmiš, Mali brkati šišmiš. Czech: Netopýr vousatý, nedopír walausatý, netopýrec vousatý. Danish: Skægflagermus. Dutch: Baardvleermuis, Gewone pisang blad vleermuis. English: Whiskered Mouse-eared Bat, Whiskered Bat, Whiskered Myotis, Mouse-eared bat. Estonian: Habelendlane. Finnish: Viiksisiippa. French: Murin à moustaches, Vespertilion à moustaches. Frisian: Burdflearmûs. Galician (Spain): Morcego bigotudo, Morcego de bigotes. Georgian: ულვაშა მღამიობი. German: Bartfledermaus, Kleine Bartfledermaus, Schnauzbärtige Fledermaus. Greek: Μουστακονυχτερίδα. Hungarian: Bajuszos denevér, Nycteris i mystakophoros. Indonesian: Kelelewar myotis pucuk. Irish Gaelic: Ialtóg ghiobach. Italian: Vespertilio mustacchino. Montenegrin: Brkati večernjak. Norwegian: Skjeggflaggermus. Polish: Nocek wąsatek. Portuguese: Morcego-de-bigodes. Rhaeto-Romance: Vespertil dal barbis, Vespertil pitschen dal barbis. Romanian: Liliacul mustăcio, Liliac-cu-mustăți. Russian: Ночница усатая, Усатая ночница [= Usataya nochnitsa]. Serbian: Тамнолики бркати вечерњак [= Tamnoliki brkati večernjak]. Scottish Gaelic: Ialtag ghibeach. Slovak: Netopier fúzatý. Slovenian: Brkati netopir, Skupina brkatih netopirjev. Swedish: Mustaschfladdermus. Turkish: Bıyıklı Siyah Yarasa. Ukrainian: Нічниця вусата [= Nichnytsya vusata]. Welsh: Ystlum barfog.

CONSERVATION STATUS:
Global Justification
Myotis mystacinus has a large population size and a wide distribution. No declines in population size have been detected, and there are no known widespread major threats. Assessed as Least

Concern (LC ver 3.1 (2001)) (Hutson *et al.*, 2008r; IUCN, 2009; Coroiu, 2016).

Assessment History
Global
2016: LC ver 3.1 (2001) (Coroiu, 2016). 2008: LC ver 3.1 (2001) (Hutson *et al.*, 2008r; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
There are no major threats to this species overall, but the species is affected by loss of woodland and other aspects of land management and development. It is also affected by loss of and damage to roost sites in trees, buildings and underground habitats. In the African part of the species' range, cave habitats where the species roosts are being destroyed by fires and vandalism. This species is also collected for medicine, but not at a level that constitutes a threat to the species (Hutson *et al.*, 2008r; IUCN, 2009; Coroiu, 2016).

CONSERVATION ACTIONS:
Coroiu (2016) supports Hutson *et al.* (2008r) [in IUCN (2009)] who report that it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention. It is included in Annex IV of EU Habitats and Species Directive, and there is some habitat protection through Natura 2000. It occurs in protected areas throughout its range. Protection of cave roost sites is required.

GENERAL DISTRIBUTION:
Myotis mystacinus is a western Palaearctic species, occurring in western and central Europe, southern parts of Scandinavia, the British Isles, Morocco, northern parts of eastern Europe, western parts of the Caucasus and the Urals. The occurrence in southeast Europe is questionable but likely. It is marginal in Africa, restricted to Moroccan mountains from the Rif in the north to the southern slope of High Atlas in the south. It has been recorded from sea level up to 1,920 m asl (Gerell, 1999).

Native: Andorra; Armenia; Austria; Azerbaijan; Belgium; Bosnia and Herzegovina; Bulgaria; China; Croatia; Czech Republic; Denmark; Estonia; Finland; France [Corse]; Georgia; Germany; Greece [Kriti]; Hungary; Ireland; Italy; Latvia; Liechtenstein; Lithuania; Luxembourg; Macedonia, the former Yugoslav Republic of; Montenegro; Morocco (Benda *et al.*, 2004d; El Ibrahimi and Rguibi Idrissi, 2015: 360; Dbiba *et al.*, 2025: 8); Netherlands; Norway; Poland; Romania; Russian Federation; Serbia; Slovakia; Slovenia; Spain; Sweden; Switzerland; Turkey; Ukraine; United Kingdom.
Regionally extinct: Portugal.
Presence uncertain: Albania; Lebanon.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 7.1 Pa, aspect ratio 6.0 and tip shape index of 2.26 for a wingspan of 21 cm and a wing area of 75 cm^2 and a body mass of 5 g.

ECHOLOCATION:
Papadatou *et al.* (2008b: 132) report the following data for 1 Greek specimen belonging to *M. mustacinus bulgaricus*: F_{start}: 104.0 kHz, F_{end}: 33.6 kHz, F_{peak}: 47.7 kHz, bandwidth: 9.1 kHz, duration 3.8 ms and interpulse interval: 72.7 ms.
Data for 51 calls from France, Greece, Switzerland, and the UK, presented by Walters *et al.* (2012: suppl.) include: duration: 2.36 ± 0.59 ms, F_{max}: 84.76 ± 14.10 kHz, F_{min}: 37.04 ± 3.24 kHz, bandwidth: 47.72 ± 14.14 kHz, F_{peak}: 51.55 ± 7.70 kHz.

MOLECULAR BIOLOGY:
Karyotype
Bovey (1949) reported a $2n$ = 44, aFN = 50, X = metacentric, Y = acrocentric, while Zima (1978) found aFN = 52. Arslan and Zima (2014: 9) added an FN of 54 and that the autosomal component consists of three large metacentric, one small metacentric, 15 acrocentric and two dot-like pairs.

Genetics
See von Helversen *et al.* (2001), Mayer *et al.* (2007), García-Mudarra *et al.* (2009).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 61 minutes, and the digestibility rate about 82.4 %.

POPULATION:
Structure and Density
In Europe, it is one of the more common species within the regular distribution area. It is very rare in North Africa, with only 25 specimens in 4 locations (Hutson *et al.*, 2008r; IUCN, 2009; Coroiu, 2016).

Trend
2016: Unknown (Coroiu, 2016). 2008: Unknown (Hutson *et al.*, 2008r; IUCN, 2009).

PARASITES:
In Europe, Genov *et al.* (1992) reported the presence of the following Nematodes: *Molinostrongylus alatus* (Ortlepp, 1932), *M. skrjabini* Skarbilovitch, 1934, *M. spasskii* Andrejko, Pinchuk and Skvorzov, 1968, and *M. vespertilionis* Morosov and Spassky, 1961.

Frank *et al.* (2015: 8) provide the following overview for parasites in European *M. mystacinus*:
Arachnida: *Argas vespertilionis* (Latreille, 1796, *Ixodes* sp., *Ixodes vespertilionis* Koch, 1844, *Macronyssus ellipticus* (Kolenati, 1857), *Macronyssus flavus* (Kolenati, 1856), *Spinturnix kolenatii* Oudemans, 1910, *Spinturnix myoti* (Kolenati, 1856), *Spinturnix mystacinus* (Kolenati, 1857), *Steatonyssus periblepharus* Kolenati, 1858, *Steatonyssus spinosus* Wilmann, 1936.

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following tick: Argasidae: *Secretargas transgariepinus* (White, 1846).

Insecta: *Basilia nana* Theodor & Moscona, 1954, *Basilia nattereri* Kolenati, 1857, *Basilia italica* Theodor, 1954, *Cimex pipistrelli* (Jenyns, 1839), *Ischnopsyllus hexactenus* (Kolenati, 1856), *Ischnopsyllus mysticus* Jordan, 1942, *Ischnopsyllus octactenus* (Kolenati, 1856), *Ischnopsyllus simplex* Rotschild, 1906, *Ischnopsyllus variabilis* (Wagner, 1898), *Myodopsylla trisellis* Jorda, 1929, *Nycteribia kolenatii* Theodor and Moscona, 1954, *Nycteribia pedicularia* Latreille, 1805, *Nycteridopsylla longiceps* Rotschild, 1908, *Nycteridopsylla pentactena* (Kolenati, 1856).

Trematoda - Digenea: *Lecithodendrium linstowi* Dollfus, 1931, *Plagiorchis vespertilionis* (Muller, 1784), *Prosthodendrium chilostomum* (Mehlis, 1831).

Nematoda: *Molinostrongylus alatus* (Ortlepp, 1932), *Molinostrongylus spasskii* Andrejko, Pintschuk and Skvorzov, 1968, *Molinostrongylus vespertilionis* Morosov and Spassky, 1961.

Cestoda: *Vampirolepis balsaci* (Joyeux and Baer, 1934).

VIRUSES:
Orthomyxoviridae
Despite sampling and testing of 44 individuals of this species, no evidence of influenza A-like viruses (*Orthomyxoviridae*) were obtained (Fereidouni *et al.*, 2015).

UTILISATION:
In Northern Africa, this species is collected for traditional medicine, but not at a level that constitutes a threat to the species (Hutson *et al.*, 2008r; IUCN, 2009; Coroiu, 2016; Budinski and López-Baucells, 2023: 332).

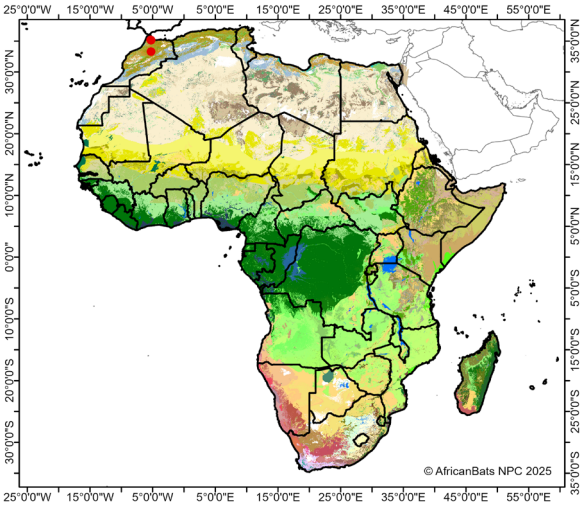

Figure 275. Distribution of *Myotis (Myotis) mystacinus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Morocco.

Myotis (Myotis) punicus Felten, 1977

1875. *Vespertilio [(Vespertilio)] africanus* Dobson, Ann. Mag. nat. Hist., ser 4, 16 (94): 260. Publication date: 1 October 1875. Type locality: Gabon: "Gaboon". Holotype: NHMUK 1873.4.16.5. . - Comments: The type locality was originally mentioned as 'Gaboon', but the specimen is more probably from Kashmir, see Blanford (1888-91) and Hayman and Hill (1971: 35) (in Corbet and Hill, 1992: 120). However, see also Grubb (2004: 92); who indicates that Gabon might not be rejected.

*1977. *Myotis blythii punicus* Felten, in: Felten, Spitzenberger and Storch, Senckenb. biol., 58 (1/2): 39. Publication date: 22 August 1977. Type locality: Tunisia: Cap Bon: El Haouaria cave [37 03 N 11 01 E]. [Goto Description]. Holotype: SMF 44104: ad ♂, skull and alcoholic. Collected by: Nagel, Schubert and Indulis Evalds Vesmanis; collection date: 25 March 1971. See Felten *et al.* (1977: 39). Paratype: SMF 18946: ♂, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18947: ♂, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18948: ♂, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18949: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18950: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18951: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18952: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18955: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18956: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18957: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18958: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18959: ♀, skull and alcoholic.

Collection date: 15 May 1960. Paratype: SMF 18960: ♀, skull and alcoholic. Collection date: 15 May 1960. Paratype: SMF 18961: ♀, skull and alcoholic. Collection date: 15 May 1960. 2000. *Myotis cf. punicus* Castella, Ruedi, Excoffier, Ibanez, Arlettaz and Hausser, Mol. Ecol., 9: 1761.

? *Myotis (Myotis) punicus:* (Current Combination).

? *Myotis blythii oxygnathus:*

? *Myotis blythii:*

? *Myotis myotis myotis:*

? *Myotis myotis:*

? *Myotis oxygnathus:*

? *Myotis punicus:* (Name Combination).

General Comments:

In the literature, a lot of information on this species has been published as pertaining to *Myotis blythii*.

Taxonomy:

Originally described as a subspecies of *M. blythii*, but recently shown to lie outside a clade including *blythii*, *myotis* and *oxygnathus* (Ruedi and Mayer, 2001). Considered a valid species by Castella *et al.* (2000), Dietz and von Helversen (2004: 71), Benda *et al.* (2004d) and Evin *et al.* (2008).

Biollaz *et al.* (2010) suggest that the Corsican and Sardinian populations are currently isolated from the continental gene pool and therefore should be considered as different evolutionary significant units. Baron (2012: 5) found that the population on Malta is a single panmitic unit with an tendency towards becoming isolated mating systems.

Simmons and Cirranello (2023b: 79) assigned it to the subgenus *Chrysopteron*.

Common Names:

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Ruedi (2020: 4) indicated that fossils from Morocco, attributed to *Myotis blythii* by Ouahbi *et al.* (2003: 281, 284) and Aouraghe *et al.* (2010: 322) should be assigned to *M. punicus*.

CONSERVATION STATUS:
Global Justification
Juste and Paunović (2016a) reports that insufficient information about population dimension and demographic trends to make an assessment. It is probably declining but needs further research.

Assessment History
Global
2016: DD ver 3.1 (2001) (Juste and Paunović, 2016a). 2008: NT ver 3.1 (2001) (Aulagnier *et al.*, 2008c; IUCN, 2009). 2004: DD ver 3.1 (2001) (Aulagnier and Juste, 2004; IUCN, 2004).

Regional
In the Maltese Island *Myotis punicus* is listed as Vulnerable (VU) (Baron and Vella, 2010).

Legal Status
Aulagnier *et al.* (2008c) [in IUCN (2009)] report that it is protected by national legislation in its European range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention, in parts of its range where these apply. It is included in Annex IV of the EU Habitats and Species Directive, and some habitat protection may be provided through Natura 2000.

MAJOR THREATS:
Human disturbance is a major threat, as colonies are located in tourist areas, in caves that are well known and popular. Changes in land management and agricultural pollution are also threats (Aulagnier *et al.*, 2008c; IUCN, 2009).

Juste and Paunović (2016a) report that in the African part of the range, the cave habitat where the species roosts is being destroyed by fires and vandalism. In North Africa the species is collected for traditional medicinal use (Aulagnier *et al.*, 2008c; IUCN, 2009; Juste and Paunović, 2016a).

The species is a cave or tree rooster, its water stress and long-distance dispersal were found to be the major risk factors related to climatic change (Sherwin *et al.*, 2012: 174).

CONSERVATION ACTIONS:
Juste and Paunović (2016a) reports that no conservation actions are in place and further research into population trends, establishment and management of protected areas, education, and implementation of national-scale legislation are needed.

While Aulagnier *et al.* (2008c) [in IUCN (2009)] report that there are ongoing project for the conservation of this species. Appropriate conservation measures include fencing cave entrances (but not gating) and obtaining legal protection for the species.

In North Africa further research into population trends, establishment and management of protected areas, education, and implementation of national-scale legislation are needed (Aulagnier *et al.* (2008c) [in IUCN (2009)).

Biollaz *et al.* (2010) suggest that special care is needed for the Sardinian population as an important source of genetic diversity.

GENERAL DISTRIBUTION:
Myotis punicus occurs in North-west Africa (Morocco, Algeria, Tunisia, and to extreme northwestern Libya) and on the Mediterranean islands of Corsica (France), Sardinia (Italy), and Malta (including Gozo [Baron and Borg, 2013: 407]; Ruedi, 2023: 399).

Native: Algeria; Libyan Arab Jamahiriya; Malta; Morocco (Benda *et al.*, 2004d; 2010a: 157; El Ibrahimi and Rguibi Idrissi, 2015: 361; Dbiba *et al.*, 2025: 8); Tunisia (Dalhoumi *et al.*, 2014: 53; 2016b: 867, 2019b: 26; Ruedi, 2023: 400).

BIOGEOGRAPHY:
Biollaz *et al.* (2010: 8)'s study suggests that the islands (Corsica and Sardinia) were colonized by *M. punicus* in a stepping-stone manner and predates human colonization. Mitochondrial analysis revealed that the insular populations were well differentiated from the mainland, with mean haplotypes and nucleotide diversities decreasing from Tunisia to Sardinia, and from Sardinia to Corsica. While a Baysian and ML trees showed that the Corsican haplotypes are nested within the Sardinian ones, suggesting that the Corsica might have been colonized from Sardinia (Biollaz *et al.*, 2010: 8). Compared with the North African populations, the two islands harbour significant lower allelic richness as well as observed and expected heterozygosities, which could reflect recent population crashes or a bottleneck during the colonization of the islands (Biollaz *et al.*, 2010). The Sardinian and Corsican populations were estimated to date back to the

early and mid-Pleistocene, respectively (Biollaz *et al.*, 2010). During the glacial episodes that punctuated this period, low sea levels exposed land that was previously underwater. Geographical distances between the islands and the mainland were thus reduced with the emergence of land bridges between some of the islands, favouring island colonization, with the first the colonization of Sardinia from North Africa and then the colonization of Corsica from Sardinia. As the Ice Age ended, sea levels rose and isolated the two islands, explaining the strong reduction of gene flow currently observed (Biollaz *et al.*, 2010).

The large divergence between the Moroccan and Tunisian populations suggest that both populations had been isolated since the Pleistocene (Biollaz *et al.*, 2010), despite current nuclear gene flow, no female exchange seems to have occurred since then. The confinement of Moroccan populations in the High Atlas Range and the philopatric behaviour of females could have enhanced the isolation of these populations, explaining the low haplotype diversity (Biollaz *et al.*, 2010). In North Africa, poor nuclear differentiation between colonies associated with a strong mitochondrial differentiation suggested current male-biased dispersal on the continental area.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Dietz and von Helversen (2004) and Baron (2012: 1) mention the following external characters: large size (comparable to *M. myotis*), the wing membrane starting at the base of the toes, a lancet shaped tragus and distinct dorsal (light brown) and ventral (white) fur coloration.

DENTAL FORMULA:
The permanent dental formula is as follows: $I^2/_3$, $C^1/_1$, $PM^3/_3$, $C^3/_3$ = 38 teeth and all the lower molars are myotodont (Ruedi, 2020: 7).

ECHOLOCATION:
For this species, Disca *et al.* (2014: 226) report two call types: A - FM APMF, with the following parameters: F_{start}: 79.2 ± 16.4 kHz, F_{end}: 25.0 ± 2.1 kHz, F_{peak}: 37 ± 7.9 kHz, bandwidth: 54.2 ± 15.5 kHz, duration: 5.5 ± 0.6 ms; B - FM APBF, with the following parameters: F_{start}: 77.3 ± 6.6 kHz, F_{end}: 20.2 ± 1.2 kHz, F_{peak}: 32.0 ± 5.2 kHz, bandwidth: 57.1 ± 7.1 kHz, duration: 8.6 ± 0.6 ms.

Ruedi (2023: 410) mention a F_{start}: 60.42 ± 15.65 (60 - 75) kHz, F_{end}: 27.07 ± 2.26 (20 - 30) kHz, F_{max}: 35.82 ± 4.21 (30 - 40) kHz, duration: 3.62 ± 0.96 (5 - 10) ms.

Ait-Abdesselam *et al.* (2025: 40) reported an F_{end} value of 25.3 kHz for Algerian bats.

MOLECULAR BIOLOGY:
Karyotype
Baker *et al.* (1974: 706) mentioned 2N = 44 and FN = 50 with a medium-sized submetacentric X and an acrocentric Y for "*Myotis blythii*" from Tunisia, whereas Ruedi (2023: 405), referring to the same publication, mentioned a FN value of 54. The latter divided the autosomes into three pairs of large and one pair of small metacentrics, and 17 pairs of submetacentric or acrocentric chromosomes.

Genetics
See Castella *et al.* (2000) and Biollaz *et al.* (2010).

Ruedi (2020: 10) refers to Biollaz *et al.* (2010), who found clear differences in the mitochondrial control region (HVII) of bats from the Mediterranean islands and those from northern Africa, where the latter differed by nine to ten mutations from the insular haplotypes.

ROOST:
Benda *et al.* (2014c: 38-39) reported that, in Libya, these bats are only found in ruins, which might serve as temporary roosts or perhaps as maternity roost.
Kowalski *et al.* (1986) [in Ruedi (2023: 407)] reported this species to occupy the same cave in northern Algeria throughout the year, although with in much smaller numbers during winter. In September-October the bats leave their summer roosts and move to alternative, colder roosts.

DIET:
Ahmim and Moali (2011: 45, 48) found that the diet of *M. punicus* in Algeria consisted of 96.06 % of insects, 2.82 % of chilopods, and 1.12 % of spiders. Among the insects, Diptera (46.32 %), Lepidoptera (20.33 %), and Hemiptera (10.16 %) were found most frequently in the bat's guano.

On Malta, Baron and Borg (2013: 415) report that the major food sources are Orthoptera (65 %), Lepidoptera (20 %), and Coleoptera (15 %), whereas on Corsica, the Orthoptera only account for 36 %.

In Libya, Benda *et al.* (2014c: 44) analyses two groups of pellets. One set (from one individual) contained only large spiders (Aranea), while the other consisted primarily of Coleoptera (Scarabaeidae: Melolonthinae), which were supplemented by solifuges (Solpugida), cockroaches (Blattodea) and small scorpions (Scorpionida).

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 77 minutes, and the digestibility rate about 79.9 %.

PREDATORS:
Ruedi (2023: 408) mentioned that skulls of *M. punicus* were found in owl pellets of *Bubo ascalaphus* Savigny, 1809, *Strix aluco* Linnaeus, 1758, *Tyto alba* (Scopoli, 1769), and *Athene noctua* (Scopoli, 1769). Other predators include the horseshoe whip snake *Hemorrhois hippocrepis* (Linnaeus, 1758), and possibly martens (*Martes* spp.), genets (*Genetta genetta*) and cats (*Felis* spp.).

Rihane *et al.* (2024: 224) counted three *Myotis punicus* prey items in pellets of a Magreb Owl (*Strix mauritanica* (Witherby, 1905)).

POPULATION:
Structure and Density
Over 10,000 individuals, found in large colonies (300 - 500 individuals) (Juste and Paunović, 2016a). On Corsica, there are around 4,000 individuals in four colonies. The total population size on Corsica, Sardinia and Malta is estimated at between 7,000 and 9,000 individuals. This is a cave dwelling species, therefore there are few colonies. On Malta, over 50 % of the population was lost between the latter half of the 1980s and the early 1990s. Numbers appear to have stabilised at 400 - 450 individuals (Borg, 2002, J.J. Borg *unpubl. data* [in Aulagnier *et al.* (2008c) in IUCN (2009)]).

Trend
2016: Unknown (Juste and Paunović, 2016a).
2008: Decreasing (Aulagnier *et al.*, 2008c; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
At Sabratha (Libya), Benda *et al.* (2014c: 40) collected a pregnant female on 2 April and a juvenile female on 14 April. Dalhoumi *et al.* (2019a: 158) reported about 50 neonates in a cave in Tunisia on 19 May. Ruedi (2023: 407) mentioned births between April and early June.

In the Maghreb, *M. punicus* can form maternity colonies of a few thousands' specimens (Ruedi, 2020: 14).

MATING:
Ruedi (2020: 11) mentioned that adult males hold small territories near nurseries and start to attrack females starting in August.

PARASITES:
Aellen (1955b) mentioned the following nycteribid and streblid flies occurring on "*Myotis oxygnathus*" from Morocco and Algeria: *Nycteribia (Nycteribia) latreillei* (Leach, 1817), *Nycteribia (Nycteribia) schmidli* Schiner, 1853, *Nycteribia (Acrocholidia) vexata* Westwood, 1835, *Penicillidia dufouri* (Westwood, 1835), *Penicillidia conspicua* Speiser, 1901, and *Nycteribosca kollari* (Frauenfeld, 1855).

Bruyndonckx *et al.* (2010) collected *Spinturnix myoti* (Kolenati, 1856) in 11 colonies in North Africa, Corsica and Sardinia. These mites were also collected by Thiévent *et al.* (2020: 2) from bats from Morocco and Tunisia. Three of the seven Moroccan and two of the three Tunisian mites they examined were infected by Chlamydiae bacteria.

From Libya, Benda *et al.* (2014c: 44) reported the following ectoparasites: Nycteribiidae: *Nycteribia vexata* Westwood, 1835, *Nycteribia latreillii* (Leach, 1817); Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856); Macronyssidae: *Steatonyssus occidentalis* (Ewing, 1933); Ischnopsyllidae: *Rhinolophopsylla unipectinata* (Taschenberg, 1880).

From Algeria, Bendjeddou *et al.* (2013: 325) reported the following ectoparasites:
Nycteribiidae: *Penicillidia dufouri* (Westwood, 1825), *Phthiridium biarticulatum* Hermann, 1804; Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856); Ixodidae: *Rhipicephalus sanguineus* (Latreille, 1806).

Bendjeddou *et al.* (2016a: 109) added *Ixodes vespertilionis* Koch, 1844.

Bendjeddou *et al.* (2017: 15) mentioned the following species from Algeria: Nycteribiidae: *Nycteribia (Nycteribia) latreillii* (Leach, 1817) and *Phthiridium biarticulatum* Hermann, 1804; Streblidae: *Brachytarsina (Brachytarsina) flavipennis* Macquart, 1851 and Arachnida: *Spinturnix myoti* (Kolenati, 1856) and *Ixodes vespertilionis* Koch, 1844.

Bendjoudi *et al.* (2019: 71) furthermore reported the nycteriibid *Nycteribia pedicularia* Latreille, 1805.

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Ischnopsyllidae: *Rhinolophopsylla unipectinata arabs* Jordan and Rothschild, 1921; Ixodidae: *Ixodes vespertilionis* Koch, 1844; Macronyssidae: *Rhipicephalus sanguineus* s.l., *Steatonyssus occidentalis*

(Ewing, 1933); Nycteribiidae: *Nycteribia latreillii* (Leach, 1817), *Nycteribia pedicularia* Latreille, 1805, *Nycteribia schmidlii schmidlii* Schiner, 1853, *Nycteribia vexata* Westwood, 1835, *Penicillidia conspicua* Speiser, 1901, *Penicillidia dufourii* (Westwood, 1834), *Phthiridium biarticulatum* (Hermann, 1804); Spinturnicidae: *Spinturnix myoti* (Kolenati, 1856); and Streblidae: *Brachytarsina flavipennis* Masquart, 1851;

Blackwell (1980: 145) and Haelewaters *et al.* (2017: Suppl.) mention the presence of the Nycteribiid bat-fly *Nycteribia vexata* Westwood, 1835 on "*M. oxygnathus*" in Tunisia, which in turn was infected by the fungus *Arthrorhynchus nycteribiae* (Peyritsch) Thaxter (see also de Groot *et al.*, 2020: Suppl.)..

VIRUSES:
Coronaviridae - Coronaviruses
Alphacoronavirus
Ar Gouilh *et al.* (2018: 92) reported the EPI 9 virus from Tunisia (3 infected out of 8 bats).

Rhabdoviridae
Lyssavirus
Serra-Cobo *et al.* (2018: 2) tested 63 Algerian bats for European bat lyssavirus type 1 and found one being seropositive. This was also the case for 15 out of 262 Moroccan bats.

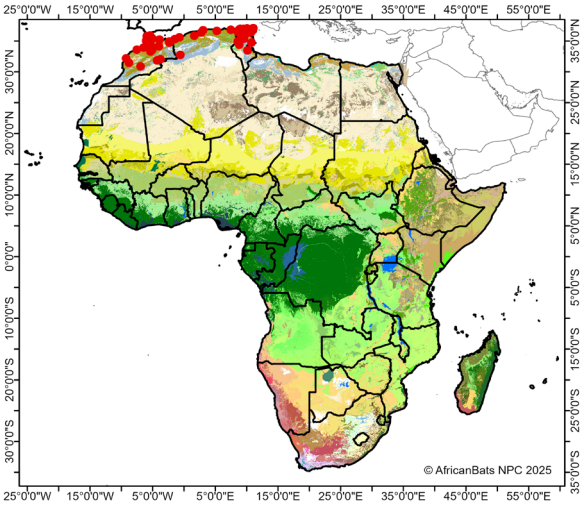

Figure 276. Distribution of *Myotis (Myotis) punicus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Algeria, Libya, Morocco, Tunisia.

Myotis (Myotis) zenatius Ibáñez, Juste, Salicini, Puechmaille and Ruedi, 2019

2019. *Myotis escalerai cabrerae* Çoraman, Mayer and Dietz, in: Çoraman et al., J. Biogeogr., 46 (2): 350. Publication date: 28 January 2019. Type locality: Morocco: Sous_Massa region: Wim Timdouine cave: near Agadir [30 40 49 N 09 20 42 W, 1340 M]. Holotype: ZMB 107229: ♀, tissue. - Etymology: In honour of Angel Cabrera, who described *M. escalerai* from Spain.

*2019. *Myotis zenatius* Ibáñez, Juste, Salicini, Puechmaille and Ruedi, in: Juste et al., Acta Chiropt., 20 (2): 293, 295, figs 3C, 5D (for 2018). Publication date: 30 January 2019. Type locality: Morocco: Tanger-Tétouan-Al Hoceima region: Mizou Cave [c. 35 30 42 N 05 19 53 W, 330 m]. Holotype: EBD 29831M: ad ♂, skull and alcoholic. Collected by: Irene Salicini, Carlos J. Ibáñez Uargui and Javier Juste; collection date: 18 July 2011; original number: 110718MspB12. Paratype: EBD 26020M: ♀, skull and alcoholic. Collection date: 10 June 2002; original number: MNA-56. Paratype: EBD 26023M: ♂, skull and alcoholic. Collection date: 11 July 2002; original number: MNA-15. Paratype: EBD 29826M: ad ♀, skin and skull. Collected by: Irene Salicini, Carlos J. Ibáñez Uargui and Javier Juste; collection date: 18 July 2011; original number: MspB6. Paratype: EBD 29829M: ad ♂, skull and alcoholic. Collected by: Irene Salicini, Carlos J. Ibáñez Uargui and Javier Juste; collection date: 18 July 2011; original number: Msp7. Paratype: EBD 29830M: ad ♀, skull and alcoholic. Collected by: Irene Salicini, Carlos J. Ibáñez Uargui and Javier Juste; collection date: 18 July 2011; original number: Msp11. - Etymology: "*zenatius*" refers to "Zanatah", a little known Berber tribe that lived in the Maghreb region in the Middle Ages (see Juste *et al.*, 2019: 297).

? *Myotis (Myotis) zenatius:* (Current Combination).

TAXONOMY:
Simmons and Cirranello (2023b: 79) did not assign this species to a subgenus ("unassigned").

The specimens forming this taxon were formerly included in *Myotis nattereri* (e.g., Brosset, 1963: 440; Gaisler, 1983: 362; Gaisler, 1984: 89; Kowalski *et al.*, 1986: 185; Aulagnier and Thevenot, 1986: 44; Benda *et al.*, 2004d: 19; Dieuleveut, 2010: 37). Various authors (e.g., García-Mudarra *et al.*, 2009: 442; Puechmaille *et al.*, 2011a: 225; Salicini *et al.*, 2011: 890; 2012: 1185), however, found differences between the European representatives of *M. nattereri* and the animals from northern Africa and assigned the latter tentatively to "*Myotis* sp. B".

Based on DNA, Çoraman *et al.* (2019: 350) indicated that "*Myotis* sp. B" is clearly distinct, both in mitochondrial and nuclear markers from *M. nattereri*, and suggests that this taxon should be considered as a subspecies of *Myotis escalerai*, for which they propose the name *Myotis escalerai cabrerae* Çoraman, Mayer and Dietz 2018. The paper only contains a short paragraph on the proposed name, where as the

"description" itself is in the online supplement and is also restricted to a single sentence. The description is not supported by the designation of a physical museum specimen, but rather a DNA (tissue) sample, which according to the ICZN (http://iczn.org/content/can-dna-be-type-specimen) should nevertheless be acceptable.

Juste *et al.* (2019) compared physical specimens of "*Myotis* sp. B" with *M. escalerai* from the Iberian Peninsula and found a number of differences (including a much darker dorsal fur), which led them to describe a new species: *Myotis zenatius*.

As these two publications suggest a name for the populations previously assigned to "*Myotis* sp. B" (see Salicini *et al.*, 2011; 2012) the priority principle comes into play. Both papers were published in early 2019:

1) "*Myotis zenatius* Ibáñez, Juste, Salicini, Puechmaille and Ruedi, 2019" was published in "Acta Chiropterologica, 20 (2): 225 - 300, 2018", the front page of which indicates "December 2018", but the BioOne website (https://bioone.org/journals/Acta-Chiropterologica/volume-20/issue-2/15081109ACC2018.20.2.001/Two-New-Cryptic-Bat-Species-within-the-Myotis-nattereri-Species/10.3161/15081109ACC2018.20.2.001.full) mentions 14 February 2019 as date. Furthermore, the paper header mentions: "Version of Record, published online January 30, 2019 with fixed content and layout in compliance with Art.8.1.3.2.ICZN and registered in Zoobank with LSID urn:lsid:zoobank.org:pub:2348ACBD-2ECC-4A80-8EA4-E3DF05C878E3". This suggest that 30 January is to be considered as date of publication.

2) "*Myotis escalerai cabrerae* Çoraman, Mayer and Dietz, 2018" was published in "Journal of Biogeography, 46 (2): 343 - 354, 2019". Here the Wiley Online Library website (https://onlinelibrary.wiley.com/loi/13652699) mentions "February 2019" as publication date for the issue and for the paper itself (https://onlinelibrary.wiley.com/doi/10.1111/jbi.13509), it mentions "First published: 28 January 2019". The fact that the authors mention "2018" in the header of their description should be ignored.

ICZN article 21.9. mentions "Works issued on paper and electronically. A name or nomenclatural act published in a work issued in both print and electronic editions takes its date of publication from the edition that first fulfilled the criteria of publication of Article 8 and is not excluded by Article 9."

The members of our "Taxonomic Advisory Committee" [Petr Benda, Gábor Csorba, Peter Taylor, Stéphane Aulagnier] indicated that a description published in an online (part of the) paper without a ZooBank number (a requirement since 2012; IUCN, 2012: 1) is invalid for taxonomic purposes [="*nomen nudum*"]. ZooBank currently contains urn:lsid:zoobank.org:pub:A4A8BF4B-D592-485C-9E02-DC2A0B7C94F8 for the paper by Çoraman et al. and mentions publication date "February 2019". This agrees with the remark made in IUCN (2012: 3): "The following are examples of inadmissible errors: An author, in preparing a manuscript for publication, states that day's date for the registration date, intending to register it later that day but forgetting to do so. The author discovers the omission after the work is published and immediately registers it; because registration occurred after publication, the work is not available."

The problem was also signalled by Ruedi *et al.* (2019), who indicated that the new names proposed by Çoraman *et al.* (2019) (besides *M. escalerai cabrerae*, they also introduced *M. nattereri helverseni*) do not follow several mandatory rules imposed by the Code, they are declared unavailable and are not to be used for further taxonomy studies.

As such, we accept the name *Myotis zenatius* proposed in Juste *et al.* (2019) for this taxon.

COMMON NAMES:
Castilian (Spain): Murcielago ratonero Zenate. English: Zenati myotis. French: Murin Zenati. German: Zenati Mausohr.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Probably endemic to the Mediterranean region of Morocco and Algeria, and possibly Tunisia (Juste *et al.*, 2019: 296; Dbiba *et al.*, 2025: 8).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

PARASITES:
In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Ischnopsyllidae: *Ischnopsyllus hispanicus* Jordan, 1942; and Spinturnicidae: *Spinturnix mystacina* (Kolenati, 1857).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Morocco.

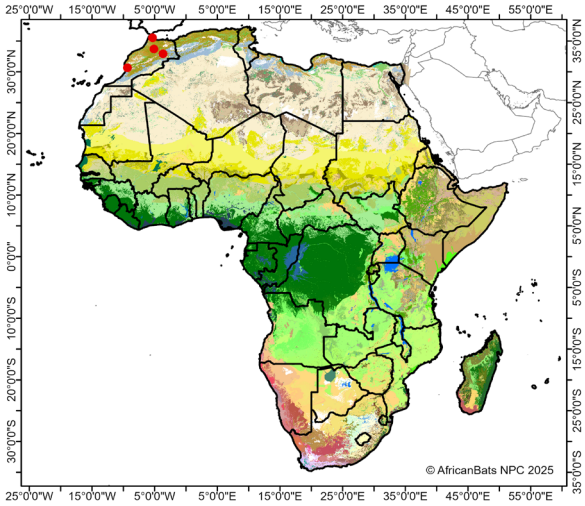

Figure 277. Distribution of *Myotis (Myotis) zenatius*.

Subfamily Scotophilinae Van Cakenberghe and Seamark, 2008

1866. *Scotophili* A. Murray, The geographical distribution of mammals, 238. - Comments: Type genus: *Scotophilus* Leach, 1821. Introduced as "section". Synonymized with the Nycticeiini tribe by McKenna and Bell (1997: 320) (see Jackson and Groves, 2015: 276).
1866. *Scotophilina* J. E. Gray, Ann. Mag. nat. Hist., er 3, 17 (98): 90.
1987. *Scotophilini* Hill and Harrison, Bull. Br. Mus. (nat. Hist.) Zool., 52 (7): 278. Publication date: 30 July 1987. - Comments: Type genus: *Scotophilus* Leach, 1821. Introduced as tribe, and originally included the genera *Scotomanes* Dobson, 1875 [including *Scoteinus* Dobson, 1875] and *Scotophilus* Leach, 1821. The rank was recognized by Hoofer and Van Den Bussche (2003: 38), but synonimized with the Nycticeiini tribe by McKenna and Bell (1997: 320) (see Jackson and Groves, 2015: 276).
2006. *Philisinae* Horáček, Fejfar and Hulva, Lynx, 37: 145. - Comments: Type genus: *Philisis* Sigé, 1985.
*2008. *Scotophilinae* Van Cakenberghe and Seamark, African Chiroptera Report, 238. Publication date: 1 July 2008. - Comments: Type genus: *Scotophilus* Leach, 1821. Following the principle of typification. (Current Combination).

TAXONOMY:
Known genera of the subfamily Scotophilinae: †***Scotophilisis*** Horácek, Fejfar and Hulva 2006; †***Vampyravus*** Schlosser, 1910; ***Scotophilus*** Leach 1821.

COMMON NAMES:
Czech: mračníkové.

†Genus ***Scotophilisis*** Horácek, Fejfar and Hulva, 2006

*2006. *Scotophilisis* Horáček, Fejfar and Hulva, Lynx, ns37: 131, 140. - Comments: Type species - *Scotophilisis libycus* Horácek, Fejfar and Hulva, 2006. The publication might date from 2007, since the paper was only received on 8 December 2006. - Etymology: Combination of the extant genus *Scotophilus* Leach, 1821 and a Palaeogene genus *Phylisis* Sigé, 1985, as this new genus is supposedly related to the stem line (Horáček *et al.*, 2006). (Current Combination).
2014. *Scotiphilisis:* Ravel, Adaci, Bensalah, Mahboubi, Mebrouk, Essid, Marzougui, Ammar, Charruault, Lebrun, Tabuce, Vianey-Liaud and Marivaux, J. Syst. Palaeontol., 13 (8): 694. Publication date: 21 August 2014. (Lapsus).

TAXONOMY:
Currently recognized species of the genus *Scotophilisis*: †***libycus*** Horácek, Fejfar and Hulva, 2006.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Time frame - Early Miocene (Burdigalian).

†***Scotophilisis libycus*** Horácek, Fejfar and Hulva, 2006

*2006. *Scotophilisis libycus* Horáček, Fejfar and Hulva, Lynx, ns 37: 131, 140, figs 1 - 3. Type locality: Libya: MS2: Jebel Zelten [28 28 N 20 00 E]. Holotype: NMP NMPC/OF.J.Zel./Chil.. Right mandible with M_1 and M_2 and alveoli of I_1 to P_4 and M_3. - Comments: Early Miocene, MN4-5. (Current Combination).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS: Timeframe: Middle Miocene (Langhian - Brown *et al.*, 2019: Suppl.).

Genus ***Scotophilus*** Leach, 1821

*1821. *Scotophilus* Leach, Trans. Linn. Soc. Lond., 13 (1): 69, 71. Publication date: 23 May - 21 June 1821 [Goto Description]. - Comments: Type species: *Scotophilus kuhlii* Leach, 1821 (According to Meester *et al.*, 1986: 59 "=juvenile *Vespertilio temmincki* Horsfield"). Not *Scotophilus* Swainson, 1836 (Aves, Strigiformes, Strigidae). Not *Scotophilus* Meinert, 1870 (Arthropoda, Chilopoda, Geophilomorpha, Dignathodontidae). Not *Scotophilus* Hesse, 1881 (Crustacea, Maxillopoda, Cyclopodea, Family incertae sedis) (see Jackson and Groves, 2015: 272). - Etymology: From the Greek "*σκόοτος*", meaning "darkness" and "*φίλος*", meaning "loving" (see Palmer, 1904: 627). - ZooBank: EE74E9E4-260A-48A5-9CD7-C690F661AF90. (Current Combination).
1831. *Pachyotus* J. E. Gray, Zool. Misc., 1: 38. Publication date: 1831 [Goto Description]. - Comments: Type species: *Scotophilus kuhlii* Leach, 1821. - Etymology: From the Greek "*παχύς*" meaning thick and "*ούς*" or "*ώτός*", meaning ear (see Palmer, 1904: 495).
1842. *Nicticejus* Rüppell, Mus. Senckenberg., 3 (2): 157, 188. - Comments: Type species: *Nycticejus leucogaster* Cretzschmar, 1826.
1981. *Scotophilous:* Demeter, Vertebr. Hung., 20: 135. (Lapsus).
2013. *Scatphalous:* McCulloch, Barcoding of South African bat species and evaluation of their natural exposure to lyssaviruses, 159. Publication date: July 2013. (Lapsus).
2018. *Schotophilus:* Leopardi, Holmes, Gastaldelli, Tassoni, Priori, Scaravelli, Zamperin and De Benedictis, Infec. Gen. Evol., 58: 284. Publication date: 30 January 2018. (Lapsus).
2018. *Scotophilis:* Adams and Kwiecinski, Diversity, 10 (3) 103: 4. Publication date: 18 September 2018. (Lapsus).
2019. *Scroptophilus:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).
? *Scotophilus sp. B156*

? *Scotophilus sp. DMR-2017*
? *Scotophilus sp. IVK-2011*

TAXONOMY:

Bronner *et al.* (2003) states that the taxonomy of African *Scotophilus* remains problematic. Three species, differing mainly in body size, probably occur in the [southern African] subregion, but species limits and phylogenetic inter-relationships are unclear (Meester *et al.*, 1986). Ellerman *et al.* (1953) referred to the largest species as *gigas*, but Robbins (1978a) showed that in describing *gigas*, Dobson (1875a) had in fact re-described *nigrita*, the name used by Ellerman *et al.* (1953) for the medium-sized species. Koopman (1982) accepted *nigrita* as a senior synonym of *gigas*, but argued that *nigrita* is a *nomen dubium* and should therefore not be used; a position later recanted (Koopman, 1993a, 1994). Since *nigrita* was no longer available for the medium-sized species, Robbins (1978a) used *dinganii* as the next valid name. Koopman (1975, 1978), however, regarded *leucogaster* as a senior synonym of *dinganii*, but later revised this opinion and recognised these as discrete species (Koopman, 1993a). Shortly thereafter he reverted to his earlier treatment and again listed *dinganii* under *leucogaster* (Koopman, 1994).

Ellerman *et al.* (1953) referred to the smallest of the three species in the [southern African] subregion as *viridis*, containing two subspecies (*S. v. viridis* and *S. v. damarensis*), which they recognised as distinct from *borbonicus* on Reunion Island. Hill (1980) regarded these taxa as conspecific and, therefore, used *borbonicus* as the prior name for this taxon. Corbet and Hill (1980) followed Koopman (1975) in confining *borbonicus* to Madagascar and Reunion, and thus once again recognised *viridis* as a mainland species, a treatment followed by Swanepoel *et al.* (1980) and Koopman (1982). Robbins *et al.* (1985) followed suit, but also listed *leucogaster* to accommodate *damarensis*, which they considered distinct from *viridis*, a treatment endorsed by Corbet and Hill (1992). Koopman (1993a) considered *damarensis* synonymous with *viridis*, but subsequently recognised both of these as only subspecies of *borbonicus* (Koopman, 1994).

Vallo *et al.* (2010: 303) indicate that several unrelated mitochondrial lineages occur within *S. dinganii*, but also that the African *Scotophilus* as a whole is in need of more detailed investigation and formal revision of systematics.

For a discussion on the names introduced by Brooks and Bickham, see Vallo and Van Cakenberghe (2017: 6).

Demos *et al.* (2018: 10) used multi-locus coalescent delimitation methods and concluded that 15 different species may occur in continental Africa, keeping in mind that large parts of the continent are seriously undersampled.

Prié *et al.* (2016) report on the echolocation characteristics of a "Chiroptera sp. 1" from Réunion, which they believe to be a *Scotophilus*. However, due to the terrible physical status and the taxonomic uncertainty of the *S. borbonicus* specimen(s) collected on the island, they feel it impossible to use the name *borbonicus* for these "Chiroptera sp. 1" specimens. Additional acoustic and distributional information on this species is provided by Augros (2017).

Currently (Simmons and Cirranello, 2023b) recognized species of the genus *Scotophilus*: ***altilis*** G.M. Allen, 1914; ***andrewreborii*** Brooks and Bickham, 2014; ***borbonicus*** (E. Geoffroy Saint-Hilaire, 1803); ***colias*** Thomas, 1904; *collinus* Sody, 1936 – Sabah, western Java, Bali, Lombok, Flores, Lembata, Timor, Semanu and Roti Isls (Indonesia) (Simmons, 2005: 466); ***dinganii*** (A. Smith, 1833); ***ejetai*** Brooks and Bickham, 2014; *heathii* (Horsfield, 1831) – Afghanistan to southern China, including Hainan Isl, south to Sri Lanka, Vietnam, Cambodia, Thailand and Burma (Simmons, 2005: 466); *kuhlii* Leach, 1821 – Bangladesh, Pakistan to Taiwan, south to Sri Lanka, Burma, Cambodia, western Malaysia, Java, Bali, Nusa Tenggara (Indonesia), southeast to Philippines and Aru Isls (Indonesia) (Simmons, 2005: 466); ***leucogaster*** (Cretzschmar, 1830); ***livingstonii*** Brooks and Bickham, 2014; ***marovaza*** Goodman, Ratrimomanarivo and Randrianandrianina, 2006; ***nigrita*** (Schreber, 1774); ***nigritellus*** de Winton, 1899; ***nucella*** Robbins, 1983; ***nux*** Thomas, 1904; ***robustus*** A. Milne-Edwards, 1881; ***tandrefana*** Goodman, Jenkins and Ratrimomanarivo, 2005; ***trujilloi*** Brooks and Bickham, 2014; ***viridis*** (Peters, 1852).

Common Names:

Czech: mračníkové, mrakolibové. English: Yellow bats, House bats, Brown bats. French: Scotophiles. German: Hausfledermäuse. Italian: Scotòfili.

Detailed morphology:

Baculum

Hill and Harrison (1987).

Molecular Biology:

Karyotype

Volleth *et al.* (2006) reported 2*n* = 36, FN = 50, BA = 18, a submetacentric X and a submetacentric Y chromosome for a male *S. leucogaster* from Burkina Faso. Recently, Eick *et al.* (2007) reported 2*n* = 36, FN = 50, BA = 16, a metacentric X chromosome and an acrocentric Y chromosome for South African specimens of *S. dinganii*.

For an Ethiopian bat (either *S. dinganii* or *S. viridis*); Tolera *et al.* (2021: 127) reported 2n = 36 and FN = 56. The autosomal chromosomes included three pairs of large metacentrics, two pairs of medium metacentrics and 11 (5 + 6?) pairs of acrocentrics. The X and Y chromosomes consist of a medium sized metacentric and a small sized acrocentric, but it was not possible to determine which was the X and the Y.

Genetics

See Hoofer and Van Den Bussche (2003) for a *S. borbonicus* from Kenya.

Habits:

Foord *et al.* (2018: 5) indicate that clutter-edge bats such as *Scotophilus* spp. may commute up to 3 km between roosts and feeding areas, but generally use a smaller core area.

Rainho *et al.* (2023: 7) assigned the *Scotophilus* bats in Meru county (Kenya) to a medium-to-high flying bats guild occurring at altitudes between 3 and 15 m.

Diet:

Jacobs (2000: 201) reported the following proportions of prey categories for 32 "*Scotophilus borbonicus*" specimens: Lepidoptera (13.8 ± 23.0), Coleoptera (37.4 ± 38.1), Isoptera (15.8 ± 28.7), Hymenoptera (11.5 ± 26.0), Diptera (7.5 ± 23.1), Hemiptera (13.4 ± 29.8), and unknown (0.6 ± 2.0).

Reproduction and ontogeny:

van der Merwe and Rautenbach (1988: 321) described the placenta of the lesser yellow house bat ("*S. borbonicus*") as antimesometrial discoidal, deciduate and hemodichorial. van der Merwe and Rautenbach (1990: 540) reported that this bat commonly gives birth to twins and occasionally even triplets. van der Merwe *et al.* (1988: 551) found that insemination, ovulation and fertilization take place in autumn. The embryonic growth is soon retarded, but not arrested and the embryo remains in the morula stage for 6 to 8 weeks, followed by a blastocyst stage of about two months.

In the same species, van der Merwe and Rautenbach (1989: 83) found that spermatogenesis was prolonged and extended over 8 months, coinciding with spring, summer and autumn.

The above information might pertain to either *S. leucogaster* or *S. viridis*.

PARASITES:
PROTOZOA
Espinosa-Álvarez *et al.* (2018: 572, Suppl.) reported new trypanosomes (*Trypanosoma vespertilionis*-like G1 and *Trypanosoma* sp. HochG3) from *Scotophilus* bats collected in Guinea-Bissau.

DIPTERA
Nycteribiidae
Basilia ansifera Theodor, 1956 mainly a West African species, reaching Lake Victoria in the east and Lake Nyasa in the south, nearly all localities lie between 15° latitude north and south (Haeselbarth *et al.*, 1966: 110).

Dick *et al.* (2023) mentioned the following nycteribiid flies have been found on *Scotophilus* sp.: *Basilia (Basilia) ansifera* Theodor, 1956 and *Basilia (Paracyclopodia) bouvieri* (Falcoz, 1924), *Basilia (Basilia) robusta* Theodor, 1956 has been found on *Scotophilus* clade 4 (although this might have been erroneous). *Basilia (Paracyclopodia) bouvieri* (Falcoz, 1924) has been reported from a "*Scotophilus nigrita*", which might be either a true *nigrita* or a *S. dinganii*.

SIPHONAPTERA
Ischnopsyllidae
The genus *Scotophilus* was reported by Beaucournu and Kock (1996) as the first African host (in Eritrea) for *C. brockmani* Rothschild, 1915.

VIRUSES:
Togaviridae
Alphavirus
Chikungunya virus
Isolates from Senegal in 1962, from the salivary glands of *Scotophilus* sp. were reported by Bres and Chambon (1963).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Burundi, Cameroon, Central African Republic, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Ethiopia, Ghana, Guinea, Kenya, Madagascar, Malawi, Mali, Mozambique, Namibia, Nigeria, Rwanda, Senegal, South Africa, South Sudan, Sudan, Tanzania, Uganda, Zambia, Zimbabwe.

Scotophilus 'incertae-sedis'

Scotophilus altilis G.M. Allen, 1914

*1914. *Scotophilus altilis* G.M. Allen, Bull. Mus. comp. Zool., 58 (7): 350. Publication date: July 1914. Type locality: Sudan: Blue Nile province: north of [Er] Roseires: Aradeiba [12 25 N 34 20 E]. Holotype: MCZ 14463: ad ♂, skin and skull. Collected by: Glover Morrill Allen and The Phillips Sudan Expedition; collection date: 22 January 1913; original number: 73. See Helgen and McFadden (2001: 147). Paratype: FMNH 34161: ad ♂, skin and skull. Collected by: Glover Morrill Allen; collection date: 6 January 1913; original number: 22. Formely MCZ 14462. Paratype: MCZ 14610: ad ♂, alcoholic (skull not removed). Paratype: MCZ 14611: ad ♂, alcoholic (skull not removed). See Helgen and McFadden (2001: 147).

TAXONOMY:
Traditionally considered a synonym of *Scotophilus leucogaster*, but see Vallo *et al.* (2019: 148) who found that there is a 10% genetic difference for *cytb* between *S. leucogaster* and specimens from southwestern Ethiopia and southern South Sudan. These latter specimens were also slightly smaller and had a slightly different ventral colour. Additionally, two nuclear markers (*zfy* and *fgb7* also showed similar differences.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Native: Democratic Republic of the Congo, Ethiopia, Kenya, South Sudan, Sudan (Vallo *et al.*, 2019: 151).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

Scotophilus andrewreborii Brooks and Bickham, 2014

*2014. *Scotophilus andrewreborii* Brooks and Bickham, Occ. Pap. Mus. Texas Tech Univ., 326: 1, 8, fig 2. Publication date: 26 June 2014. Type locality: Kenya: Nakuru district, 12 km S, 4 km E Nakuru [00 24 S 36 07 E]. Holotype: CM 98049: ad ♂, skin and skull. Collected by: Dr. Kimberlyn ("Kim") Nelson; collection date: 7 October 1985; original number: 217. Muscle tissue sample TK 33143. Paratype: CM 98048: ad ♀, skin and skull. Collected by: Dr. Kimberlyn ("Kim") Nelson; collection date: 7 October 1985; original number: 214. Muscle tissue sample TK 33140. Demos *et al.* (2018) identified this specimen as *Scotophilus livingstonii* and Goodman *et al.* (2020: Suppl.) considered it a paratype of *S. livingstonii*. As it doesn't represent the first species and was not designated as a paratype of the second, its status as "paratype" should be ignored. Paratype: CM 98050: ad ♂, skin and skull. Collected by: Dr. Kimberlyn ("Kim") Nelson; collection date: 8 October 1985; original number: 219. Muscle tissue sample TK 33149. - Etymology: In honor of Andrew N. Rebori (1948 - 2011), who unknowingly touched the lives and inspired many individuals, including many museum professionals. He always maintained a keen interest in animals, especially bats, which exemplified his spirit and attitude toward life, 'Take flight every new day!' (see Brooks and Bickham, 2014: 8).

TAXONOMY:
Brooks and Bickham (2014) described four new species in the genus *Scotophilus*. However, they did not compare them with a number of already described taxa such as *colias* Thomas, 1904 or *flavigaster* Heuglin, 1861, which make the validity of (some of) these names doubtful.

The analyses performed by Demos *et al.* (2018: 2) confirmed the validity of the taxon, but these authors also indicate that they cannot vouch for the validity of the name with respect to older taxa that would have nomenclatural priority. Benda *et al.* (2025: 32) consider *andrewreborii* to be a synonym of *Scotophilus colias*.

COMMON NAMES:
Chinese: 安氏黄蝠. English: Andrew Rebori's House Bat. German: Andrews Hausfledermaus

CONSERVATION STATUS:
Global Justification
This species is known from at least six widely distributed localities in Kenya including several protected areas (Brooks and Bickham, 2014) and occurs in close association with human altered landscapes, roosting in buildings (Monadjem, 2017a).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem, 2017a).

Regional
None known.

MAJOR THREATS:
Brooks and Bickham (2014) report that the major threat is persecution of roosting sites.

CONSERVATION ACTIONS:
This species is known to occur in Tsavo National Park and may occur in other protected areas in Kenya (Monadjem, 2017a).

GENERAL DISTRIBUTION:
Brooks and Bickham (2014: 8) indicate that the type series was collected in two localities in Kenya, and that there are at least five other Kenyan localities where this species occurs.

ROOST:
Jackson *et al.* (2023: 5) reported three roosts in buildings in Kenya, of which two were shared with another bat species.

POPULATION:
Structure and Density
Population size is not known but is presumably large since it occurs in anthropomorphic environments (Monadjem, 2017a).

Trend
2016: Unknown (Monadjem, 2017a).

PARASITES:
DIPTERA
Nycteribiidae
Dick *et al.* (2023: 75) reported *Basilia (Paracyclopodia) bouvieri* (Falcoz, 1924) on bats from the Marsabit National Park (Kenya).

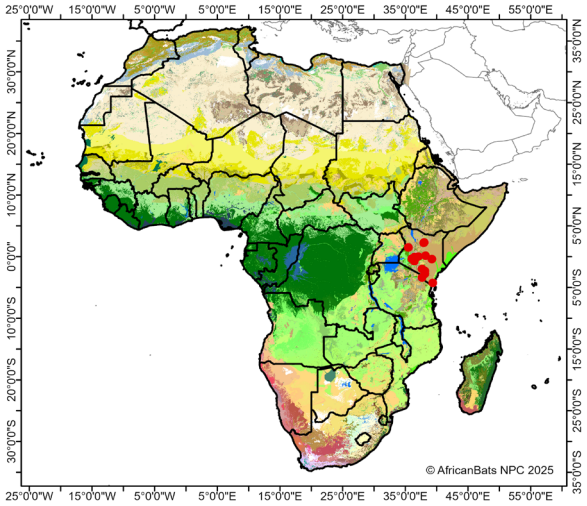

Figure 279. Distribution of *Scotophilus andrewreborii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya.

Scotophilus borbonicus (E. Geoffroy St.-Hilaire, 1803)

*1803. *Vespertilio borbonicus* E. Geoffroy Saint-Hilaire, Catalogue des Mammifères du Muséum national d'Histoire naturelle, Paris, 55. Type locality: Réunion: Ile Bourbon [=Réunion Island]. [Goto Description]. Lectotype: RMNH MAM.28508: ad ♂, mounted skin (skull not removed). "Individu adulte monté, figuré dans la Mammalogie de Temminck, T.H. Pl. XLVII, fig. 6. Bourbon. Du voyage de M. Macé": see Goodman *et al.* (2005b: 871).
. - Etymology: Refering to "Ile Bourbon" where the type specimen was collected.
1855. *N[ycticejus] borbonicus:* Giebel, Die Säugethiere, 928. (Name Combination).
? *Scotophilus borbonicus:* (Name Combination, Current Combination).
? *Scotophilus cf. borbonicus:*

TAXONOMY:
The authorship and date of this name was fixed to E. Geoffroy St.-Hilaire (1803) by Opinion 2005 (Case 3022) (see Anonymus, 2002b: 154).

Included equivocally in *leucogaster* by Hayman and Hill (1971: 50 - 51), but see Koopman (1975: 414 - 416). Hill (1980) considered African *viridis* and *damarensis*, and possibly *leucogaster* to be conspecific with *borbonicus*; but Robbins *et al.* (1985) rejected any affinity with African mainland species. Also see comment under *leucogaster* and genus. Koopman (1986) included *viridis*, *damarensis*, and *nigritellus* (but not *leucogaster*) in this species.

As the lectotype (RMNH MAM.28508) is collected on the east coast of Africa, rather than on La Réunion and its mitochondrial sequence is similar to *S. trujilloi* captured in Kenya, this might lead to priority issues and taxonomic ambiguity. To resolve potential taxonomic problems, Goodman *et al.* (2020: 41) propose to consider the name *S. borbonicus* a nomen dubium. Recent inventories on La Réunion failed to find any *Scotophilus*, which led Goodman *et al.* (2020: 46) to conclude that if specimens are captured on the island, they might potentially represent a (new) separate species.

COMMON NAMES:
Czech: mračník réunionský, netopýr zelený. English: Lesser Yellow Bat, Lesser Yellow House Bat, Madagascar Yellow House Bat, Bourbon Bat. French: Scotophile de Bourbon, Scotophile de Madagascar, Petite Chauve-souris jaune des maisons, chauve-souris des Hauts, Scotophile de la Réunion. German: Réunion-Hausfledermaus, Bourbonische Schwirrfledermaus. Portuguese: Morcego amarelo pequeno.

CONSERVATION STATUS:
Global Justification
There have been exhaustive surveys of Réunion (e.g., Moutou, 1982) and this species has not been recorded for nearly 140 years. Abhaya and Probst (1999: 54) refer to Coquerel (1864) as one of the last to report on this species on Réunion ("Autrefois très commun sur l'île; très rare aujourd'hui.").

There is, however, not enough information to determine its taxonomic status, as the holotype is badly damaged and other possible specimens cannot be reliably assigned to this species. If the taxonomic status of this species is confirmed, then the species may qualify for a higher threat category and may well be extinct (Andriafidison *et al.*, 2008j; IUCN, 2009; Andriafidison *et al.*, 2019).

Assessment History
Global
2018: DD ver 3.1 (2001) (Andriafidison *et al.*, 2019). 2008: DD ver 3.1 (2001) (Andriafidison *et al.*, 2008j; IUCN, 2009). 2004: CR A1c ver 2.3 (1994) (IUCN, 2004). 2002: CR: A1c (Mickleburgh *et al.*, 2002a: 22).

Jones *et al.* (2009b: 507) assessed its status as Critically endangered - A1c. Conenna *et al.* (2017: Suppl.) assessed it as Data Deficient (DD).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Andriafidison *et al.*, 2008j; IUCN, 2009).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008j) [in IUCN (2009)] and Andriafidison *et al.* (2019) report that there are no conservation measures in place.

GENERAL DISTRIBUTION:
This holotype was described from two specimens from La Réunion and one of these was designated as the lectotype but is now in very poor condition (Goodman *et al.*, 2005a). In Madagascar, it is known only from a single specimen collected in 1868, at Sarodrano, near Toliara in the south (Goodman *et al.*, 2005a). The identity of the Madagascar specimen cannot be confirmed due to absence of reliable material from La Réunion. The area near Sarodrano has been relatively well surveyed recently, but no new specimens were obtained (Goodman *et al.*, 2005a).

Records from Mauritius (Mascarene Islands) are erroneous, see Cheke and Dahl, 1981: 217, Moutou, 1982: 44).

Native: Madagascar (?); Réunion.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 10.4 Pa, aspect ratio 7.5 for a wingspan of 34 cm and a wing area of 151 cm^2 and a body mass of 16 g, although this is probably not for "*borbonicus*" as recognized here.

ECHOLOCATION:
During their field work on Réunion, Barataud and Giosa (2013) captured some echolocation calls of two unidentified bats, which were neither *Mormopterus francoismoutoui* nor *Taphozous mauritianus*. The signals for one of these ("Chiroptera sp1" - QFC = 60 kHz, FM = 61 kHz) were very similar to those of Madagascan and African continental *Scotophilus*, which lead them to hypothesize that "Chiroptera sp1" might possibly be *S. borbonicus*.

MOLECULAR BIOLOGY:
Genetics
See Hoofer and Van Den Bussche (2003) for the results of a specimen from Kenya (which most probably represents a different species).

HABITAT:
Maillard (1862: 158) indicated that this species usually lived in forests and also near the coast of Réunion.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 120 minutes, and a digestibility rate of about 75.4 %.

POPULATION:
Structure and Density
This species was considered to be relatively common in the early 19th Century on La Réunion; however, it was not recorded in the 20th century or 21st century (Cheke and Dahl, 1981).

Trend
2018: Unknown (Andriafidison *et al.*, 2019). 2008: Unknown (Andriafidison *et al.*, 2008j; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) report this species as being polytocous (more than one young per litter).

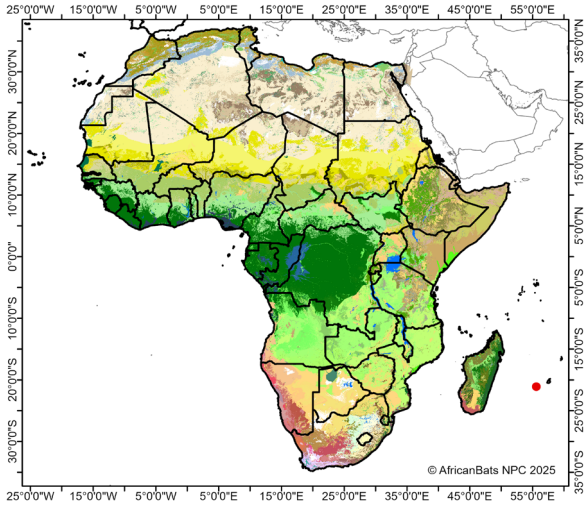

Figure 280. Distribution of *Scotophilus borbonicus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Réunion.

Scotophilus colias Thomas, 1904

*1904. *Scotophilus nigrita colias* Thomas, Ann. Mag. nat. Hist., ser 7, 13 (75): 207. Publication date: 1 March 1904. Type locality: Kenya: Fort Hall [=Muranga] [00 43 S 37 09 E]. [Goto Description]. Holotype: NHMUK 1902.7.6.11: ad ♂. Collected by: Mrs. Hildegarde Beatrice Hinde; collection date: 25 January 1902; original number: 107. Presented/Donated by: Mrs. Hildegarde Beatrice Hinde.

1958. *Scotophilus nigrita coreas:* Eisentraut, Veröff. Überseemus. Bremen, (A) 3: 23. - Comments: Lapsus for *colias* (see Kock, 1969a: 193). (Lapsus).

2014. *S[cotophilus] colias:* Vallo, Benda, Červený and Koubek, Mammalia, 79 (2): 225. Publication date: 19 June 2014. (Name Combination).

2015. *Scotophilus colias:* Kassahun, Sadlova, Benda, Kostalova, Warburg, Hailu, Baneth, Volf, Votypka, Acta Trop., 150: 168. Publication date: 29 July 2015. (Current Combination).

TAXONOMY:
In their study on Arabian *Scotophilus*, Vallo *et al.* (2011c: 359) tentatively suggested to use the name *S. colias* for the East African yellow-bellied house bat as these bats clearly differ from the typical *S.dinganii* from southern Africa. This view was confirmed by Vallo and Van Cakenberghe (2017: 7) and Cosentino *et al.* (2023b: Suppl.), and followed by Wilson and Mittermeier (2019), Azami-Conesa *et al.* (2021) and Marsh *et al.* (2022).

Two other names were recently introduced by Brooks and Bickham (2014) for eastern African forms: *andrewreborii* and *ejetai*. However, they omitted any of the other *Scotophilus* names previously proposed from that area. Benda *et al.* (2025: 103) tentatively reject these names until further data confirm they represent different taxa.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Native: Eritrea, Ethiopia, Kenya, Somalia (?), South Sudan (?), Northern Tanzania (?), Uganda (?), Yemen. (see Benda *et al.*, 2025: 102).

PARASITES:
PROTOZOA
Kassahun *et al.* (2015: 168) examined 12 Ethiopian *S. colias* specimens and found one (out of 11 from Metu) infected with *Leishmania* parasites (see also Azami-Conesa *et al.*, 2021: Suppl.; de Souza *et al.*, 2023: 5).

ARACHNIDA
Spinturnicidae
Orlova *et al.* (2024: 151) referred to Zumpt and Till (1954), who described *Spinturnix scotophili* from a "*Scotophilus murinoflavus*".

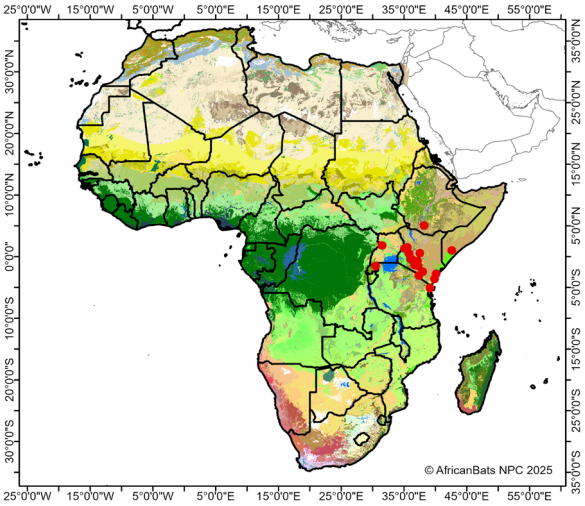

Figure 281. Distribution of *Scotophilus colias*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Ethiopia, Kenya, Rwanda, Somalia, Tanzania, Uganda.

Scotophilus dinganii (A. Smith, 1833)

1832. *Vespertilio epichrysus* Temminck, in: Smuts, Enumer. Mamm. Capensium, 106. Type locality: South Africa: Cape Town [33 56 S 18 28 E]. - Comments: Allen (1939a) and Ellerman *et al.* (1953) regard this taxon as unidentifiable, besides which it appears to fall outside the known range of the species as a whole (see Roberts, 1951: 90); Meester *et al.*, 1986: 60), who include it with a question mark). However, if valid, this is the senior name for the species. Dobson (1878: 303) mentions *Vespertilio epichrysus* (Temminck, Monogr. Mamm., 2: 208) with a question mark in the synonymy of *Vespertilio* [=*Myotis*] *emarginatus*.

*1833. *Vespertilio Dinganii* A. Smith, S. Afr. Quart. J., ser 2, 1 (2): 59. Publication date: November 1833. Type locality: South Africa: Port Natal [=Durban] & Delagoa Bay [=Maputo], btwn. [Goto Description]. - Etymology: In honour of Dingane (or Dingan / Dingaan), king of the Zulus (1795 - 1840) (see Lanza *et al.*, 2015: 487).

*1846. *Vesperugo Dinganii* Sundevall, Öfvers. kongl. Sv. Vet.-Akad. Förhandl., 3 (4): 119. Type locality: South Africa: Gauteng: Magaliesberg [25 46 00 S 27 40 00 E, 1350 m]. [Goto Description]. Neotype: NRM 651065: ad, skin only. Collected by: Johan August Wahlberg; collection date: 18 April 1841. Robbins *et al.* (1985: 65) mention that "The second specimen, NHRM 1065, is a mounted skin only. Based on the locality given by Sundevall (1846), the specimen from Caffer could be considered as the holotype of *Scotophilus dinganii* (Sundevall). To clarify the problem, we designate the Caffer specimen as the lectotype of *Scotophilus dinganii* (Sundevall)." However, as the name *Scotophilus dinganii* is based on *Vespertilio dinganii* A. Smith, 1833, this specimen can not be a lectotype as it wasn't part of the original material. It therefore should be considered a neotype as suggested by Kearney *et al.* (2010: 22). The latter authors, however, selected the wrong specimen [NRM 1064]. - Comments: Sundevall (1846: 119) mentioned the locality as "interior of Caffraria", but the type specimen in the NRM .

1852. *Nycticejus planirostris* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 65, pl; 17, fig 1, a-e. Publication date: 1852. Type locality: Mozambique: Lower Zambesi River: Tete [16 10 S 33 35 E, 230 m]. [Goto Description]. Holotype: ZMB 527: ad ♂, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: March 1845. See Turni and Kock (2008) [=An 16363].

1855. *N[ycticejus] Dingani:* Giebel, Die Säugethiere, 927. (Name Combination).

1906. *Scotophilus nigrita herero* Thomas, Ann. Mag. nat. Hist., ser 7, 17 (98): 174. Publication date: 1 February 1906. Type locality: Namibia: Ovamboland: Olifants Vlei [18 00 S 17 30 E]. [Goto Description]. Holotype: NHMUK 1907.1.1.449: ad ♀, skin and skull. Collected by: Mr. Charles John Andersson; collection date: 8 August 1859; original number: 260. Formerly in Tomes collection. - Comments: Ellerman *et al.* (1953) point out that the type locality is not in Damaraland, as claimed by Thomas for both *herero* and *damarensis*: see Meester *et al.* (1986: 60).

1914. *Vespertilio dinyani:* Rothschild, Bull. Entom. Res., 5 (1): 41. Publication date: April 1914. (Lapsus).

1921. *Scotophilus nigrita dingani:* Kershaw, Durban Mus. Novit., 3 (1): 29. (Name Combination, Alternate Spelling).

1946. *Scotophilus nigrita pondoensis* Roberts, Ann. Transv. Mus., 20 (4): 304. Type locality: South Africa: Transkei, Western Pondoland: Port St.Johns [31 27 S 29 33 E]. [Goto Description]. Holotype: SAMC 6858: Collected by: Captain Guy Chester Shortridge; collection date: 22 August 1902.

1951. *Vespertilio epichrysurus:* Roberts, Mammals of South Africa, 90. (Lapsus).

1953. *Scotophilus nigrita dingaanii:* Lawrence and Loveridge, Bull. Mus. comp. Zool., 110 (1): 6. (Lapsus).

2001. *scotophilus nigrata:* Lameed, Biodiversity, 8 (4): 8. - Comments: We can not exclude that this might be a synonym for *S. nigrita*. (Lapsus).

2019. *Scroptophilus dinganii:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).

2025. *Scotophilus diaganii:* Ngene, Okwuonu, Ogbonna, Ukwueze and Ejere, Caryologia, 78 (1): 3. Publication date: 1 October 2025. (Lapsus).

? *Scotophilus dingani:* (Alternate Spelling).

? *Scotophilus dinganii colias:* (Name Combination).

? *Scotophilus dinganii dinganii:* (Name Combination).

? *Scotophilus dinganii herero:* (Name Combination).

? *Scotophilus dinganii:* (Name Combination, Current Combination).
? *Scotophilus nigrita dinganii:* (Name Combination).
? *Scotophilus nigrita nigrita:* (Name Combination).
? *Scotophilus nigrita:*

TAXONOMY:

Figure 282. *Scotophilus dinganii*.

Placed in *leucogaster* by Koopman (1975: 414 - 416, as *nigrita*; 2004ah: 11) and Koopman *et al.* (1978: 4 - 5); but see also Schlitter *et al.* (1980).

See also the discussion under the genus and under *nigrita* and *leucogaster*.

In their study on Arabian *Scotophilus*, Vallo *et al.* (2011c: 359) tentatively suggest to use the name *S. colias* for the East African yellow-bellied house bat as these bats clearly differ from the typical *S. dinganii* from southern Africa.

Trujillo *et al.* (2009: 554) found several divergent cytochrome *b* lineages in *S. dinganii*, suggesting that cryptic species might be present in different geographic areas southern Africa, eastern Africa, Ghana to Kakamega Forest (Kenya).

Decher *et al.* (2021: 271) suggest that the West African specimens probably represent *S. livingstonii* rather than *S. dinganii* as one of the paratypes of the former was collected in Legon (Ghana). However, we believe that further examination of additional specimens is needed to evaluate the status of the West African specimens.

COMMON NAMES:
Afrikaans: Geel Dakvlermuis. English: Yellow House Bat, Dingan's Bat, Dingaan's House Bat, Yellow-bellied House Bat, Dingaan's Yellow Bat, African Yellow Bat, African Yellow House Bat. French: Scotophile africain, Chauve-souris jaune des maisons, Scotophile à ventre jaune. German: Gelbbäuchige Hausfledermaus, Natalischen Schwirrfledermaus, Flachschnauzigen Schwirrfledermaus. Italian: Scotòfilo di Dìngan. Malawian: Liputiputi, Ndemiya, Namzeze. Portuguese: Morcego caseiro amarelo. Tshokwe (Angola): Kafukufuku.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
This species has been recovered from the upper Pleistocene in South Africa, at Border Cave (Avery, 1991: 6), and Wonderwerk (Avery and Avery, 2011: 19).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Griffin, 2008a; IUCN, 2009; Monadjem and Griffin, 2017a).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Griffin, 2017a). 2008: LC ver 3.1 (2001) (Griffin, 2008a; IUCN, 2009). 2004: LC ver 3.1 (2001) (Griffin, 2004b; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016s). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Griffin, 2008a; IUCN, 2009; Monadjem and Griffin, 2017a).

CONSERVATION ACTIONS:
Griffin (2008a) [in IUCN (2009)] and Monadjem and Griffin (2017a) report that in view of the species wide range it is believed to be present in many protected areas. No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Scotophilus dinganii is widely distributed in sub-Saharan Africa. It ranges from Senegal and the Gambia in the west, through West Africa and parts of Central Africa, to Sudan, Eritrea, Djibouti and Ethiopia in the east, from here it ranges south through much of East Africa and southern Africa, being recorded as far south as eastern South Africa, Lesotho and Swaziland. For South Africa, Babiker Salata (2012: 49) found that its

distribution is strongly associated with the mean temperature of the coldest quarter.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,251,825 km^2.

Native: Angola (Crawford-Cabral, 1989; Cotterill, 2004a: 262; Monadjem *et al.*, 2010d: 573; Taylor *et al.*, 2018b: 63); Benin (Capo-Chichi *et al.*, 2004: 163); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 573); Burkina Faso (Kangoyé *et al.*, 2012: 6026; 2015a: 626); Burundi; Cameroon; Central African Republic; Congo (Bates *et al.*, 2013: 337); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Dowsett *et al.*, 1991: 259; Van Cakenberghe *et al.*, 1999; Monadjem *et al.*, 2010d: 573); Côte d'Ivoire; Djibouti (Pearch *et al.*, 2001: 398); Eritrea; Eswatini (Monadjem *et al.*, 2010d: 574, Monadjem *et al.*, 2021: 5); Ethiopia (Lavrenchenko *et al.*, 2004b: 131); Gambia; Ghana; Guinea; Guinea-Bissau (Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 71); Kenya; Lesotho; Liberia; Malawi (Ansell and Dowsett, 1988: 38; Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 573); Mali; Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 573; Monadjem *et al.*, 2010c: 384); Namibia (Monadjem *et al.*, 2010d: 573); Nigeria; Rwanda; Saudi Arabia; Senegal; Sierra Leone; Somalia; South Africa (De Graaf, 1960; Monadjem *et al.*, 2010d: 573); Sudan; Tanzania (Stanley and Goodman, 2011: 45); Togo; Uganda; Yemen (Benda *et al.*, 2011b: 42); Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 574); Zimbabwe (Monadjem *et al.*, 2010d: 574).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987) and Kearney *et al.* (2002).

Vomeronasal complex
In this species, the VNC is bar-shaped in cross section (Smith *et al.*, 2024: 9).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 12.4 Pa, aspect ratio 7.3 and tip shape index of 7.71 for a wingspan of 37 cm and a wing area of 190 cm^2 and a body mass of 24 g.

In their study on rewarming along an altitudinal gradient in the RSA, Marsden *et al.* (2022: 5) found that the rewarming rate of these bats decreased with increasing altitude.

ECHOLOCATION:
See Taylor (1999b) and Taylor *et al.* (2005).

Jacobs *et al.* (2007a) recorded the peak echolocation frequency (33.4 ± 1.4 kHz) for individuals from St. Lucia, KwaZulu Natal, South Africa. Schoeman and Waddington (2011: 291) mention a peak frequency of 33.9 ± 1.1 kHz and a duration of 4.1 ± 0.7 ms for specimens from Durban, South Africa.

Taylor *et al.* (2013b: 17) recorded the following parameters for 7 calls from Soutpansberg, South Africa: F_{max}: 51.6 ± 8.19 (42.1 - 65.2) kHz, F_{min}: 33.1 ± 0.79 (31.6 - 34.1) kHz, F_{knee}: 36.4 ± 1.10 (34.4 - 37.4) kHz, F_{char}: 33.8 ± 1.03 (31.9 - 35.3) kHz, duration: 3.4 ± 0.66 (2.7 - 4.6) ms.

Linden *et al.* (2014: 40) reported the following parameters from the Soutpansberg range (RSA): F_{min}: 32 - 34 kHz, F_{char}: 32 - 35 kHz, F_{knee}: 34 - 37 kHz, slope: 287 - 588 OPS, duration: 3 - 5 ms.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 36 (34 - 37) kHz. From Maroua, Cameroon, Manga Mongombe (2012: 79) and Bakwo Fils *et al.* (2018: 4) reported for 19 calls a call type of FM/QCF and the following parameters: F_{max}: 58.5 ± 8.9 (49.4 - 84.8) kHz, F_{min}: 52.6 ± 6.2 (46.7 - 69.5) kHz, F_{mean}: 55.6 ± 7.5 (48.1 - 77.0) kHz, F_{knee}: 58.5 ± 8.9 (49.4 - 84.0) kHZ, F_{char}: 52.7 ± 6.2 (46.8 - 69.5) kHz, and duration: 0.88 ± 0.92 (0.73 - 1.02) ms.

132 calls of 5 bats from KwaZulu-Natal and Eastern Cape (RSA) reported by Moir (2020: 30) and Moir *et al.* (2021a: 371) had the following parameters: F_{max}: 53.63 ± 8.39 (51.57 - 74.49) kHz, F_{min}: 34.68 ± 1.58 (33.15 - 36.94) kHz, F_{char}: 34.68 ± 1.58 (33.15 - 36.94) kHz, F_{knee}: 35.33 ± 1.72 (33.57 - 37.95) kHz, and duration: 2.65 ± 0.52 (2.30 - 3.55) ms.

Eisenring *et al.* (2016: SI 2) report on two calls from *S. nigrita* from the Aberdares Range in Kenya with the following characteristics: PF: 36.8 ± 3.3 (34.5 - 39.2), HF: 57.3 ± 12.4 (48.5 - 66.1), LF: 29.8 ± 0.4 (29.5 - 30.1), DT: 0.1 ± 0.0 (0.1 - 0.1) DF: 27.5 ± 12.9 (18.4 - 36.6), IPI: 1.1 ± 0.4 (0.9 - 1.4). As they compare their values with those presented by Fenton (1975), Fenton and Bell (1981) and O'Shea and Vaughan (1980), these values are probably also for *S. dinganii*.

From Swaziland, the following parameters were reported by Monadjem *et al.* (2017c: 179): F_{min}: 33.2 ± 1.26 (30.3 - 34.7) kHz, F_{knee}: 36.4 ± 1.61 (32.1 - 38.6) kHz, F_c: 33.7 ± 1.44 (30.3 - 35.6)

kHz, and duration: 3.8 ± 0.94 (2.6 - 6.1) ms. The calls were detectable up to a distance of 20 m.

Adams and Kwiecinski (2018: 4) recorded the following characteristics for four calls of bats from the Kalahari Desert: F_{char}: 33.9 ± 2.4 kHz, F_{max}: 40.9 ± 2.1 kHz, F_{min}: 33.4 ± 2.0 kHz, duration: 3.3 ± 0.9 ms.

Four calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 41.28 ± 5.17 kHz, F_{min}: 33.95 ± 1.18 kHz, F_{knee}: 35.71 ± 1.49 kHz, F_{char}: 34.39 ± 1.46 kHz, slope: 39.62 ± 32.49 OPS, duration: 3.77 ± 1.67 ms.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 33.6 kHz and duration: 4.9 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 99 calls of 10 bats: F_{max}: 47.09 ± 7.53 kHz, F_{min}: 31.86 ± 6.25 kHz, F_{knee}: 36.27 ± 1.63 kHz, F_{char}: 33.43 ± 1.26 kHz, slope: 363.33 ± 166.43 OPS, duration: 3.52 ± 2.09 ms. 11 calls recorded by Cory-Toussaint and Taylor (2022: Table S1) at the Venatia mine had a duration of 4.24 ± 1.06 ms, F_{min}: 32.23 ± 1.78 kHz, F_{max}: 38.28 ± 3.11 kHz, F_{knee}: 35.03 ± 0.80 kHz and F_{char}: 33.30 ± 0.82 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 26 *Scotophilus dinganii* calls from the Kruger Park (RSA): F_{min}: 32.3 ± 1.1 (30.1 34.7) kHz, Duration: 3.7 ± 0.9 (2.2 5.8) ms, F_{max}: 53.6 ± 8.1 (40.2 64.8) kHz, F_{knee}: 35.0 ± 2.3 (31.6 42.1) kHz, F_{char}: 33.0 ± 1.2 (30.4 35.9) kHz.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 33.00 ± 1.20 kHz, F_{max}: 53.60 ± 8.10 kHz, F_{min}: 32.30 ± 1.10 kHz.

86 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 32 - 34 kHz, F_{max}: 42 - 65 kHz, F_{char}: 32 - 35 kHz, F_{knee}: 34 - 37 kHz and duration 3 - 5 ms.

Parker (2022: 20) reported F_{min}: 31.72 ± 2.70 kHz, F_{char}: 35.05 ± 1.42 kHz and F_{max}: 41.34 ± 3.48 kHz for 15 passes at Mountain Zebra National Park (RSA).

For 40 calls from 2 *Scotophilus dinganii* females from Telperion Nature Reserve (RSA), De Jong *et al.* (2025: 322) reported the following parameters: F_{char}: 33.06 ± 1.34 kHz, F_{knee}: 37.53 ± 3.30 kHz, F_{min}: 32.55 ± 1.31 kHz, F_{max}: 57.44 ± 9.68 kHz, Bandwidth: 24.89 ± 9.23 kHz, Duration: 2.96 ± 0.55 ms. 38 calls from 4 males showed the following values: F_{char}: 32.71 ± 1.48 kHz, F_{knee}: 36.87 ± 2.92 kHz, F_{min}: 32.20 ± 1.40 kHz, F_{max}: 63.03 ± 10.10 kHz, Bandwidth: 30.84 ± 9.61 kHz, Duration: 3.06 ± 0.66 ms.

In Benin, Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 55) reported F_{char}: 33.00 ± 1.20 kHz, F_{max}: 53.60 ± 8.10 kHz and F_{min}: 32.30 ± 1.10 kHz.

Taylor-Boyd *et al.* (2025: 116) report the following values for 16 calls for Zambian *Scotophilus dinganii*: Interpulse interval: 73.8 ± 20.4 (43.1 - 112.0) ms; F_{max}: 37.7 ± 2.6 (32.2 - 43.3) kHz; Start slope: -15.1 ± 2.8 (-10.4 - -21.0) kHz/ms; End slope: -6.7 ± 3.2 (-10.5 - -9.8) kHz/ms; Ledge duration: 0.4 ± 0.1 (0.3 - 0.5) ms.

Molecular Biology:

Karyotype

Peterson and Nagorsen (1975), Schlitter *et al.* (1980) and Ruedas *et al.* (1990) all reported 2*n* = 36. However, while Schlitter *et al.* (1980) reported FN = 52, BA = 18, an acrocentric X chromosome, and a metacentric Y chromosome, Ruedas *et al.* (1990) reported FN = 50, BA = 16, a submetacentric X chromosome, and a telocentric Y chromosome. Eick *et al.* (2007) reported the following autosomal pairs: seven meta- to submetacentric, nine acrocentric, and one subtelocentric. One homologue of the smallest acrocentric pairs showed a small heterochromatic short arm in one specimen, resulting in a subtelocentric state (Eick *et al.*, 2007). The diploid chromosome number (2*n*) is 36, the fundamental number of autosomal arms (Fna) is 50 (Eick *et al.*, 2007). The X chromosome is a medium-sized metacentric and the Y chromosome a small, probably acrocentric, partly heterochromatic chromosome (Eick *et al.*, 2007).

Ngene *et al.* (2025: 6) reported *2n* = 36 and FN = 45 for Nigerian bats.

Genetics

See Hoofer and Van Den Bussche (2003) for the results of a specimen from Tanzania.

Habitat:

In southern Africa, this species is found in Savanna habitats (80 %; Cooper-Bohannon *et al.*, 2016: Table S2).

HABITS:
Scotophilus dinganii is gregarious, roosting in small groups of up to 12 individuals (Skinner and Smithers, 1990).
Thermoregulation - See Jacobs *et al.*, 2007b).

ROOST:
Type - Buildings (Skinner and Smithers, 1990). In KwaZulu Natal, South Africa, Jacobs *et al.* (2007b), found *S. dinganii* roosted in the roofs of buildings in the crevices between the roof (either made of asbestos, clay tiles, or corrugated metal sheets) and the brickwork of the walls. Jacobs *et al.* (2007b) did not find any relationship between aspect and roost selection, or any relationship that the bats preferred roosts which received the direct rays of the afternoon sun. Monadjem *et al.* (2010b: 74) found that they roosted in *Combretum imberbe* trees.

Microclimate - Jacobs *et al.* (2007b) found that the temperature of building roosts appeared to track ambient temperature with a slight lag (see also Marroquin and Muñoz-Garcia, 2023: 9)..

Happold and Happold (2023: 172) mention that these bats sometimes roost singly, but more often they are found in groups of up to 20 animals, and more than one group can occupy the same roof, but at different places.

DIET:
On the Umbilo River (KwaZulu Natal, RSA), Naidoo *et al.* (2011: 26) found the diet to contain the following volume percentages during summer: Lepidoptera (17.5 ± 15.9), Coleoptera (81.9 ± 16.6), and Diptera (0.6 ± 1.3). And during winter: Lepidoptera (24.9 ± 12.9), Coleoptera (66.4 ± 21.7), and Diptera (8.9 ± 8.7).

Taylor *et al.* (2017b: 245, 252 - 254) reported the following 23 food items in the Limpopo province (RSA): five insect orders: Lepidoptera (*Toxocampinae tathorhynchus* + *Achrosis* sp. + *Isturgia roraria* + *Sena* sp. + *Sena prompta* + *Cortyta canescens* + *Pandesma robusta* + *Pericyma atrifusa* + *Argyrogrammatini*sp. + *Spodoptera exigua* + *Maurilia arcuata* + unmatched), Orthoptera (Tettigoninae + unmatched), Hemiptera (*Nezera viridula* + *Macrorhaphis acuta* + unmatched), Coleoptera (unmatched) and Blattodea (unmatched).

Weier *et al.* (2019c: 6) investigated droppings from this species in the Levubu region (Limpopo, RSA) and found DNA sequences of: Lepidoptera: *Cryptophlebia peltastica* (Meyrick, 1921) and *Thaumatotibia batrachopa* (Meyrick, 1908); Hemiptera: *Bathycoelia distincta* Distant, 1878 and *Nezara viridula* (Linnaeus, 1758).

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 143 minutes, and a digestibility rate of about 73.6 %.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) and the African harrier-hawk (*Polyboroides typus* Smith, 1829) as diurnal avian predators. Malan *et al.* (2022: 167) also mentioned 41 individuals found in pellets of South African Bat hawks.

Mumford (1980: 11) observed a *Scotophilus dinganii* being caught by an African goshawk (*Accipiter tachiro* (Daudin, 1800)) in Kenya.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Griffin, 2008a; IUCN, 2009; Monadjem and Griffin, 2017a).

Trend
2016: Unknown (Monadjem and Griffin, 2017a).
2008: Unknown (Griffin, 2008a; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Jacobs *et al.* (2007b) found that bats roost exit times were variable, but most left their roost for the first time on a particular day between 17h15 and 18h00 and returned between 18h45 and 19h15 (remaining out of the roost on average for about 1hr).

REPRODUCTION AND ONTOGENY:
van der Merwe *et al.* (2006) reported, from examination of serially sectioned reproductive tracts of females, that *S. dinganii* is monoestrous species and that insemination, ovulation and fertilization take place during mid to late autumn (April to May), Kruger-NP., South Africa. Early embryonic development of normally two embryos (one in each uterine horn) was retarded and implantation delayed until mid-winter (July), when the blastocysts implanted (van der Merwe *et al.*, 2006). van der Merwe (2006) found *S. dinganii* in the Kruger-N.P., South Africa to be seasonally monestrus, carrying a single foetus in each of the two uterine horns of the bicornute uterus. The amnion in *S. dinganii* was a schizamnion, and van der Merwe (2006) deduced that its formation was preceded by cavitation of the inner cell mass, with formation of the definitive amniotic cavity, where the floor of the cavity eventually formed the

embryonic disc and its roof the ectodermal part of the true or definitive amnion.

van der Merwe and Rautenbach (1990: 540) reported that *S. dinganii* commonly gives birth to twins and occasionally even triplets (= polytocy, see Garbino *et al.*, 2021: Suppl.).

In Malawi, births occurred early in the wet season (Happold and Happold, 1990b: 568).

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births taking place between November and December.

Two pregnant females were reported from Sierra Leone on 7 April and 29 May by Weber *et al.* (2019: 27).

PARASITES:

BACTERIA

Dietrich *et al.* (2016b: 3) found one out of 12 bats from Rocktail Bay (RSA) to be positive for *Rickettsia*. Also from the RSA, Dietrich *et al.* (2018a: 4) reported the presence of *Leptospira borgpetersenii*.

PROTOZOA

Clément *et al.* (2019a: 5) reported on two southern African bats, which were both infected by *Trypanosoma vespertilionis*_likeG1_AF3.

HEMIPTERA

Cimicidae

Cacodmus sparsilis Rothschild, 1914 was described from one female specimen taken from a "*Vespertilio dinyani*" at Durban, South Africa (Haeselbarth *et al.*, 1966: 10, referred to as *Scotophilus nigrita*). *Stricticimex transverses* Ferris and Usinger, 1957 recorded from Windhoek, Namibia (Haeselbarth *et al.*, 1966: 14). Kock *et al.* (1998b: 237) reported *Cacodmus sparsilis* Rothschild, 1914 too, but also *Aphrania* cf. *barys* Jordan and Rothschild, 1912.

DIPTERA

Nycteribiidae

Basilia bouvieri (Falcoz, 1924) from Tanzania, Sudan, Senegal and Sierra Leone (Haeselbarth *et al.*, 1966: 111), referred to as *Scotophilus nigrita*).

SIPHONAPTERA

Ischnopsyllidae

(*Chiropteropsylla brockmani* Rothschild, 1915 was reported on *Scotophilus dinganii flavigaster* from Eritrea by Beaucournu and Kock (1996).

ARACHNIDAI

Spinturnicidae

Orlova *et al.* (2024: 151) mentioned this species (as *Scotophilus nigrita*) as host for *Spinturnix scotophili* Zumpt and Till, 1954.

Trombiculidae

Stekolnikov (2018a: 134) reported the presence of *Ericotrombidium scotophilum* (Vercammen-Grandjean and Langston, 1976) from "*Scotophilus nigrita*" from Pietermaritzburg, RSA. Zajkowska *et al.* (2018: 199) [referring to Anciaux de Faveaux (1971)] mentioned *Microtrombicula scotophili* Vercammen-Grandjean, 1965 and *Schoutedenichia trombiculoides* Vercammen-Grandjean, 1958 from a "*Scotophilus dinganii colias*" from Sudan.

VIRUSES:

Coronaviridae - Coronaviruses

SARS-CoV

Müller *et al.* (2007b) tested between 1986 to 1999, for antibody to SARS-CoV in sera in five individuals from Limpopo Province, South Africa, none were tested positive (0/5). One out of 14 (7.1 %) Kenyan bats tested by Tao *et al.* (2017: Suppl.) was positive for CoV. Only one of the 29 Congolese bats examined by Kumakamba *et al.* (2021: 7) tested positive for coronaviruses.

Montecino-Latorre *et al.* (2022: 5) mention the CoV as Eidolon bat coronavirus/Kenya/KY24/2006.

Flaviviridae

Pegivirus (BPgV)

1 of 2 Kenyan specimens examined by Quan *et al.* (2013: Table S5) (50.0 %) was infected by clade G type *Pegivirus*.

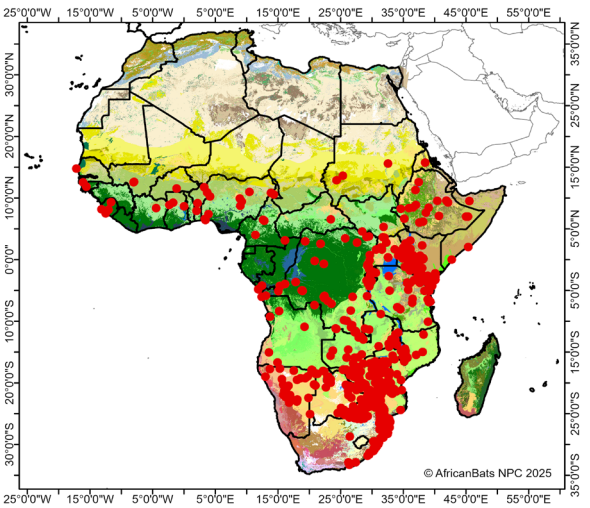

Figure 283. Distribution of *Scotophilus dinganii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Central African Republic, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Eritrea, Eswatini, Ethiopia, Ghana, Guinea-Bissau, Kenya, Malawi, Mali, Mozambique, Namibia, Nigeria, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Uganda, Zambia, Zimbabwe.

Scotophilus ejetai Brooks and Bickham, 2014

*2014. *Scotophilus ejetai* Brooks and Bickham, Occ. Pap. Mus. Texas Tech Univ., 326: 1, 14, fig 5. Publication date: 26 Jun 2014. Type locality: Ethiopia: Orimaya region: Dogy River Bridge [08 21 43 N 35 53 02 E, 1390 m]. Holotype: BRTC 57950: ad ♂, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 23 February 2001; original number: 10310. Muscle tissue sample AK 21235. Paratype: BRTC 57954: ad ♀, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 21 February 2001; original number: 10292. Tissue sample AK 21213. Paratype: CM 114043: ad ♀, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 2 April 1995; original number: 9986. Tissue sample SP 13027. - Etymology: In honour of Dr. Gebisa Ejeta, distinguished professor of plant breeding & genetics and international agriculture at Purdue University (see Brooks and Bickham, 2014: 14).

TAXONOMY:
Brooks and Bickham (2014) described four new species in the genus *Scotophilus*. However, they did not compare them with a number of already described taxa such as *colias* Thomas, 1904 or *flavigaster* Heuglin, 1861, which make the validity of (some of) these names doubtful. Benda *et al.* (2025: 32) consider *ejetai* to be a synonym of *Scotophilus colias*.

COMMON NAMES:
English: Ejeta's House Bat. German: Äthiopische Hausfledermaus.

CONSERVATION STATUS:
Global Justification
Assessed as Least Concern as this species is known from at three widely distributed localities in Ethiopia (Brooks and Bickham, 2014), and possibly occurs widely throughout the country (Largen *et al.*, 1974) and may occur in protected areas (Monadjem, 2017b).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem, 2017b).

Regional
None known.

MAJOR THREATS:
The major threat is persecution at roosting sites (Monadjem, 2017b).

CONSERVATION ACTIONS:
Monadjem (2017b) report that this species is not currently known to occur in any protected areas. However, other medium-sized *Scotophilus* species in eastern and southern Africa occur in close association with human-altered landscapes and if this is the case with *S. ejetai*, then it is unlikely to need specific protection.

GENERAL DISTRIBUTION:
Known from three localities in Ethiopia.

Native: Ethiopia.

POPULATION:
Trend: 2016: Unknown (Monadjem, 2017b).

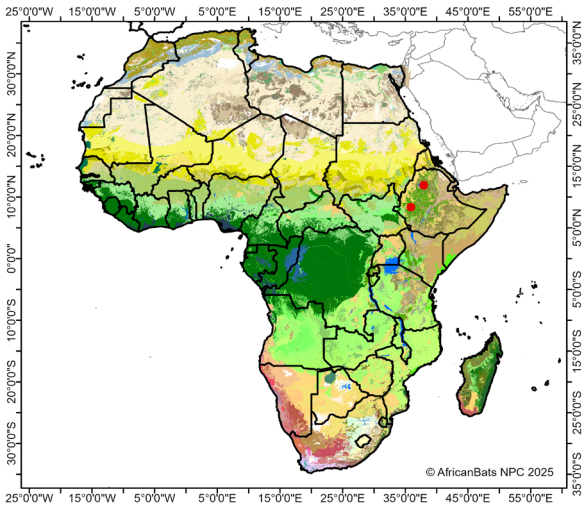

Figure 284. Distribution of *Scotophilus ejetai*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia.

Scotophilus leucogaster (Cretzschmar, 1826)

*1826. *Nycticejus leucogaster* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 71, pl 28a, 1, 2. Publication date: 1826. Type locality: Sudan: Kordofan province: Brunnen Nedger [=Nedger Wel; Bir Nedger]:. [Goto Description]. Lectotype: SMF 4309: Collected by: Wilhem Peter Edward Simon Rüppell. Mertens (1925: 22) old catalog II.O.1.b. Paralectotype: RMNH MAM.27432: ad, skin and skull. Collected by:

Wilhem Peter Edward Simon Rüppell. Mertens (1925: 22) mentions SMF 4309 (old catalog II.O.1.b, coll. E. Rüppell, 1825) as lectotype).
The RMNH catalog mentions two numbers: 27432.a (skull + loose bones) and 27432.b (mounted skin). - Comments: The publication date of Cretzschmar's work is sometimes indicated as "1826" (as mentioned on the title page), but also as "1827", "1828", "1830-1831". - Etymology: From the masculine Greek adjective "*λευκος*" (leukós), meaning "white" and the feminine Greek substantive "*γαστήρ*" (gastér), meaning "stomach", referring to the relatively light belly colour of the type specimen (see Lanza *et al.*, 2015: 487).

1861. *Nycticejus flavigaster* Heuglin, Nov. Act. Acad. Cæs. Leop.-Carol., 29 (8): 5, 14. Publication date: 1861. Type locality: Eritrea: Kérén [ca. 15 45 N 38 20 E]. [Goto Description]. Syntype: SMNS 983: ad ♂, skull and alcoholic. Collected by: Martin Theodor von Heuglin; collection date: 1861. See Dieterlen *et al.* (2013: 294). Syntype: SMNS 983a: ad ♀, skull and alcoholic. Collected by: Martin Theodor von Heuglin; collection date: 1861. See Dieterlen *et al.* (2013: 294).

1861. *Nycticejus murino-flavus* Heuglin, Nov. Act. Acad. Cæs. Leop.-Carol., 29 (8): 5, 15. Publication date: 1861. Type locality: Eritrea: near Massaua [=Massawa]: M'kullu [15 38 N 39 24 E]. [Goto Description]. Holotype: [Unknown] |TS294|: ad ♂.

1878. *Scotophilus borbonicus:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 260. Publication date: 15 June 1878. - Comments: .

1906. *Scotophilus damarensis* Thomas, Ann. Mag. nat. Hist., ser 7, 17 (98): 175. Publication date: 1 February 1906. Type locality: Namibia: Ovamboland: Olifants Vlei [18 00 S 17 30 E]. [Goto Description]. Holotype: NHMUK 1907.1.1.463: ad ♂, skin and skull. Collected by: Mr. Charles John Andersson; collection date: 10 August 1859; original number: 276. Received in the Tomes collection. - Comments: Included in *borbonicus* by Meester *et al.* (1986: 61), in *viridis* by Koopman (1993a: 228), but in *leucogaster* by Simmons (2005).

1938. *[Pachyotus] altilis:* Frechkop, Exploration du Parc National Albert, 53.

2019. *Scroptophilus leucigaster:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).

? *Scotophilus borbonicus damarensis:* (Name Combination).

? *Scotophilus cf. leucogaster:*

? *Scotophilus leucogaster damarensis:* (Name Combination).

? *Scotophilus leucogaster leucogaster:* (Name Combination).

? *Scotophilus leucogaster:* (Name Combination, Current Combination).

? *Scotophilus nigrita leucogaster:* (Name Combination).

? *Scotophilus viridis damarensis:*

TAXONOMY:

Figure 285. *Scotophilus leucogaster*

Does not include *damarensis*, see Koopman (1986); but see Robbins *et al.* (1985). Herkt *et al.* (2017: Appendix S9) found that *damarenis* occupies a noticeably different ecological niche as compared with the northern populations of *leucogaster*.

Included *nucella*; but see Robbins *et al.* (1985).

For scope of this species see Koopman (1975: 414 - 416); as *nigrita*) and Koopman *et al.* (1978: 4 - 5). However Robbins (1978a: 212 - 213) has shown that the name *nigrita* was misapplied to another species, for which the next available name was *dinganii*, and which would be included in *leucogaster* if Koopman (1975)'s reasoning were followed. However Schlitter *et al.* (1980) listed *dinganii* as distinct from *leucogaster*, as did Robbins *et al.* (1985). See Koopman (1986).

COMMON NAMES:

Chinese: 白腹黄⚲ . Czech: mračník bělobřichý, netopýr bělobřichý. English: Lesser Yellow House Bat, White-bellied House Bat, White-bellied Yellow Bat, Cretzschmar's Brown Bat. French: Scotophile à ventre blanc. German: Weißbäuchige Hausfledermaus, Weissbauchige Schwirrfledermaus, Gelbbauchige Schwirrfledermaus, Olivenbraune Schwirrfledermaus. Italian: Scotòfilo panciabianca.

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Griffin, 2008b; IUCN, 2009; Monadjem and Griffin, 2017b).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem and Griffin, 2017b). 2008: LC ver 3.1 (2001) (Griffin, 2008b; IUCN, 2009). 2004: LC ver 3.1 (2001) (Griffin, 2004a; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Taylor *et al.*, 2016e).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Griffin, 2008b; IUCN, 2009; Monadjem and Griffin, 2017b).

CONSERVATION ACTIONS:
Griffin (2008b) [in IUCN (2009)] and Monadjem and Griffin (2017b) reports that in view of the species wide range it is presumably present in many protected areas. No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Scotophilus leucogaster has been recorded in much of West Africa (including northern parts of Cameroon, Nigeria, Benin, Togo, Ghana, Côte d'Ivoire, Sierra Leone, and Guinea, much of Senegal, Gambia, and Burkina Faso, and southern parts of Mali and Niger). There are isolated records from southwestern Mauritania, as well as western parts of the Central African Republic. The eastern parts of the distribution include records from Sudan, and the northern parts of Uganda and Kenya. Further south this species is found in Mozambique, Angola and Namibia, Zambia, northern Botswana, and northern South Africa.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 426,596 km^2.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 575; Taylor *et al.*, 2018b: 60); Benin (Capo-Chichi *et al.*, 2004: 163); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 575); Burkina Faso (Kangoyé *et al.*, 2015a: 626); Cameroon; Central African Republic; Chad; Côte d'Ivoire; Ethiopia (Benda *et al.*, 2020: 2587); Gambia; Ghana; Guinea (Ziegler *et al.*, 2002: 78); Guinea-Bissau (Vaughan *et al.*, 1997b; Robbins *et al.*, 1985; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001: 70); Kenya; Mali (Meinig, 2000: 105); Mauritania; Mozambique (Monadjem *et al.*, 2010d: 575; Monadjem *et al.*, 2010c: 385); Namibia (Monadjem *et al.*, 2010d: 575); Niger; Nigeria; Senegal; Saudi Arabia; Sierra Leone; South Africa (Monadjem *et al.*, 2010d: 575); Sudan; Togo; Uganda (Kityo and Kerbis, 1996: 62); Yemen; Zambia (Monadjem *et al.*, 2010d: 575); Zimbabwe (Monadjem *et al.*, 2010d: 575).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Leblanc and Taupin (2004: 26) refers to Fahr (2001), who reported an albino specimen found in the Nuba mountains of Sudan.

DETAILED MORPHOLOGY:
Brain
Amrein *et al.* (2007), from specimens collected from Bénin, reported that proliferating cells, detected with Ki-67 and MCM2, in the subgranular layer of the dentate gyrus was found to be absent. Amrein *et al.* (2007) also reported moderate to ample proliferating cells (Ki-67 positive cells) and migrating young neurons (DCX positive cells) in the rostral migratory stream. Amrein *et al.* (2007) furthermore detected few DCX positive cells in the rostral migratory stream and the olfactory bulb. Hippocampal granule cells were homogeneously positive for NeuroD (Bigalke, 1968).

SEXUAL DIMORPHISM:
In Burkina Faso, Kangoyé *et al.* (2015a: 626) found the averages of the body measurements (except 3ph2) to be larger in females than in males, but the averages of the cranial measurements were larger in males.

ECHOLOCATION:
12 FM/QCF type calls from Maroua (Cameroon) were reported by Manga Mongombe (2012: 79) and Bakwo Fils *et al.* (2018: 4) with the following parameters: F_{max}: 55.7 ± 4.3 (48.5 - 64.1) kHz, F_{min}: 50.6 ± 3.0 (46.1 - 56.3) kHz, F_{mean}: 53.2 ± 3.6 (47.3 - 59.3) kHz, F_{knee}: 55.7 ± 4.3 (48.5 - 64.1) kHz, F_{char}: 50.7 ± 3.0 (46.1 - 55.0) kHZ, and duration: 0.81 ± 0.23 (0.44 - 1.00) ms.

Thiagavel *et al.* (2017: Suppl.) mention a F_{peak} of 46.27 kHz.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

MOLECULAR BIOLOGY:
Karyotype
Ngene *et al.* (2025: 6) reported 2n = 36 and FN = 54 for Nigerian bats.

See also discussion in generic account.

Genetics
See Hoofer and Van Den Bussche (2003) for the results of a specimen from Kenya.

HABITAT:
In southern Africa, it occurs in Savanna (89 %) and SW arid (10 %) habitats (Cooper-Bohannon *et al.*, 2016: Table S2).

ROOST:
Happold and Happold (2023: 173) indicate that these bats roosted in groups of up to nine individuals.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 127 minutes, and a digestibility rate of about 74.7 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Griffin, 2008b; IUCN, 2009; Monadjem and Griffin, 2017b).

Trend
2016: Unknown (Monadjem and Griffin, 2017b).
2008: Unknown (Griffin, 2008b; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) mention that this species has more than one young per litter.

PARASITES:
PROTOZOA
From Burkina Faso, Thiombiano *et al.* (2023: 4) reported that five out of 29 Scotophilus leucogaster bats was carrying *Trypanosoma* cf. *vespertilionis* parasites.

ACARI
Dermanyssidae
Zumpt and Till (1954: 50) reported the presence of *Steatonyssus nyassae* (Hirst, 1922) on a "*Scolophilus murinoflavus*" from near Torit, South Sudan.

Spinturnicidae
Orlova *et al.* (2024: 151) mentioned this species as host for *Spinturnix scotophili* Zumpt and Till, 1954.

Trombiculidae
Stekolnikov (2018a: 114) reported *Schoutedenichia (Schoutedenichia) trombiculoides* Vercammen-Grandjean, 1958 and *Microtrombicula scotophili* Vercammen-Grandjean, 1965 from *S. leucogaster leucogaster* from South Sudan.

HEMIPTERA
Cimicidae
Szentiványi *et al.* (2022 12) reported *Aphrania elongata* Usinger, 1966 from a Mauritanian bat.

DIPTERA
Nycteribiidae
Dick *et al.* (2023: 75) mentioned that *Basilia (Paracyclopodia) bouvieri* (Falcoz, 1924) had been reported from Senegal and Uganda.

VIRUSES:
Coronaviridae - Coronaviruses
SARS-CoV
In Nigeria during June 2008, Quan *et al.* (2010) screened the gastrointestinal tissue for the presence of coronaviruses by PCRs, none tested positive.
The viruses found in bats from Cameroon were assigned to the subgenus *Nobecovirus* by Motayo *et al.* (2020: 4).

Rhabdoviridae
Lyssavirus - Rabies related viruses
In Nigeria during June 2008, Quan *et al.* (2010) did not detect any lyssavirus-specific antigens from the brains by use of direct fluorescent antibody testing.

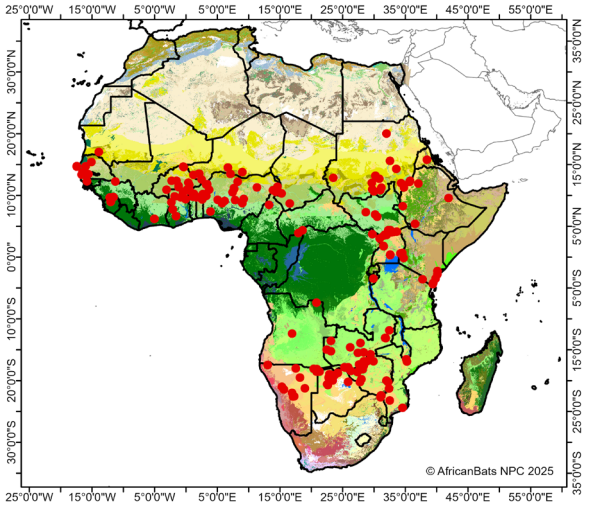

Figure 286. Distribution of *Scotophilus leucogaster*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Central African Republic, Chad, Congo (Democratic Republic of the), Côte d'Ivoire, Eritrea, Ethiopia, Ghana, Guinea-Bissau, Kenya, Malawi, Mali, Mauritania, Mozambique, Namibia, Niger, Nigeria, Senegal, Sierra Leone, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

Scotophilus livingstonii Brooks and Bickham, 2014

2011. *S[cotophilus] aff. dinganii:* Vallo, Benda and Reiter, Afr. Zool., 48 (2): 350. Publication date: October 2011. (Name Combination).

*2014. *Scotophilus livingstonii* Brooks and Bickham, Occ. Pap. Mus. Texas Tech Univ., 326: 1, 11, fig 4. Publication date: 26 June 2014. Type locality: Kenya: Western province: Kakamega district: Ikuywa River Bridge, 6.5 km S, 19 km E Kakamega [00 13 N 34 55 E]. Holotype: CM 98051: ad ♂, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 8 November 1985; original number: 7394. Muscle tissue sample TK 33534. Paratype: CM 98053: ad ♀, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 8 November 1985; original number: 7396. Muscle tissue sample TK 33536. Paratype: USNM 412150: ad ♀, skin and skull. Collected by: Bruce Joliffe Hayward; collection date: 22 July 1967; original number: 4135. Collected at University of Ghana Botanical Garden (5º40'N, 10º12'W [sic]), Legon, Eastern (Greater Accra) Region, Ghana (Brooks and Bickham, 2014: 13). - Etymology: In honour of David Livingstone (1813 - 1873) (see Brooks and Bickham (2014: 13).

? *Scotophilus dinganii:* (Name Combination).

TAXONOMY:

Brooks and Bickham (2014) described four new species in the genus *Scotophilus*. However, they did not compare them with a number of already described taxa such as *colias* Thomas, 1904 or *flavigaster* Heuglin, 1861, which make the validity of (some of) these names doubtful.

The analyses performed by Demos *et al.* (2018: 2) confirmed the validity of the taxon, but these authors also indicate that they cannot vouch for the validity of the name with respect to older taxa that would have nomenclatural priority.

COMMON NAMES:

Chinese: 利文斯顿黄蝠. English: Livingstone's House Bat. German: Livingstone-Hausfledermaus.

CONSERVATION STATUS:

Global Justification

This species is assessed as Least Concern (LC ver 3.1 (2000)) as it is known from two extremely widely distributed localities in Kenya and Ghana (Brooks and Bickham, 2014), and the species is likely to occur in between. More research is needed across its region and requires examination of existing museum material to determine its full distribution (Monadjem, 2017c).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem, 2017c).

Regional

None known.

MAJOR THREATS:

The major threat is persecution of roosting sites (Monadjem, 2017c).

CONSERVATION ACTIONS:

Monadjem (2017c) report that this species is not currently known to occur in any protected area, but specimens of *Scotophilus* within the range of this species have been recorded from several protected areas.

GENERAL DISTRIBUTION:

This species is known from SW Kenya and SE Ghana, with a gap of about 4,000 km between them. Benda *et al.* (2023a: 27) report this species from Benin.

POPULATION:

There is no information about population size, but it is presumably large since it occurs over a large area and in anthropogenic environments (Monadjem, 2017c).

Trend:- 2016: Unknown (Monadjem, 2017c).

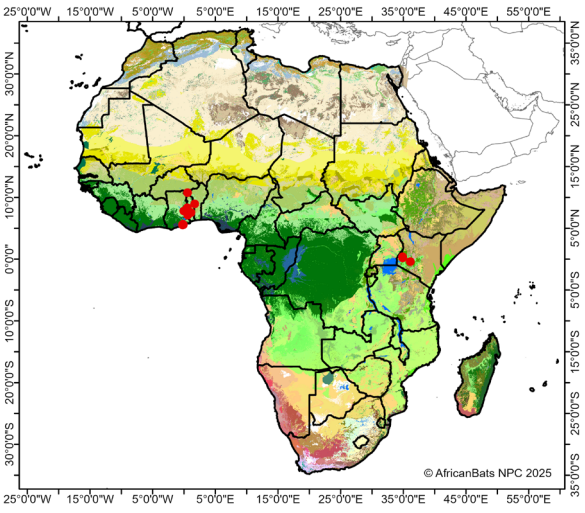

Figure 287. Distribution of *Scotophilus livingstonii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

Benin, Ghana, Kenya, Togo.

Scotophilus marovaza Goodman, Ratrimomanarivo and Randrianandrianina, 2006

2005. *Scotophilus nov. sp.:* Ratrimamanarivo and Goodman, ABCN, 6: 4.

*2006. *Scotophilus marovaza* Goodman, Ratrimomanarivo and Randrianandrianina, Acta Chiropt., 8 (1): 23, figs 2 - 5. Type locality: Madagascar: Mahajanga province: Marovaza [14 56 S 47 16 E, 5 m]. Holotype: FMNH 184050: ad ♂, skull and alcoholic. Collected by: Steven M. Goodman and Fania H. Ratrimomanarivo; collection date: 11 December 2004. Paratype: FMNH 184051: Collected by: Steven M. Goodman and Fania H. Ratrimomanarivo; collection date: 21 - 22 April 2005. locality: Madagascar: Province de Mahajanga - Marovaza [14 56 S 47 16 E, 5 m asl]. Paratype: FMNH 184052: Collected by: Steven M. Goodman and Fania H. Ratrimomanarivo; collection date: 21 - 22 April 2005. Locality: Madagascar: Province de Mahajanga - Marovaza [14 56 S 47 16 E, 5 m asl]. Paratype: FMNH 184085: Collected by: Steven M. Goodman and Fania H. Ratrimomanarivo; collection date: 21 - 22 April 2005. Locality: Madagascar: Province de Mahajanga - Marovaza [14 56 S 47 16 E, 5 m asl]. Paratype: FMNH 184086: Collected by: Steven M. Goodman and Fania H. Ratrimomanarivo; collection date: 21 - 22 April 2005. Locality: Madagascar: Province de Mahajanga - Marovaza [14 56 S 47 16 E, 5 m asl]. Paratype: MNHN ZM-MO-1984-433: Collected by: Steven M. Goodman and Fania H. Ratrimomanarivo; collection date: 29 April 1869. Paratype: UADBA 46965: Collected by: Richard K.B. Jenkins; collection date: 24 November 2004; original number: RBJ 215. Locality: Madagascar: Antafinimihakatra, Parc National d' Ankarafantsika [16 16 S 46 48 E). - Comments: Publication date: prior to 15 May 2006. - Etymology: The name of the type locality (Marovaza) is placed in apposition to the generic name (Goodman *et al.*, 2006b). (Current Combination).

TAXONOMY:
See Goodman *et al.* (2006b).

COMMON NAMES:
Czech: mračník Goodmanův. English: Marovaza House Bat, Marovaza Yellow Bat. French: Scotophile de Marovaza. German: Marovaza-Hausfledermaus.

ETYMOLOGY OF COMMON NAME:
Refers to the name of the type locality (Marovaza).

CONSERVATION STATUS:
Global Justification
This species is listed as Least Concern (LC ver 3.1 (2001)) because it is widely distributed in lowland areas of western Madagascar, there are no major threats, and its survival is not dependent on the conservation of intact forests (Jenkins *et al.*, 2008b; IUCN, 2009; Monadjem *et al.*, 2017o).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017o). 2008: LC ver 3.1 (2001) (Jenkins *et al.*, 2008b; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
Jenkins *et al.* (2008b) [in IUCN (2009)] and Monadjem *et al.* (2017o) report that there are no major threats known. It is a widely distributed species and is tolerant of habitat disturbance (Goodman *et al.*, 2006b; Rakotoarivelo and Randrianandrianina, 2007).

CONSERVATION ACTIONS:
Jenkins *et al.* (2008b) [in IUCN (2009)] and Monadjem *et al.* (2017o) report that given the wide distribution of this species and occurrence in heavily disturbed habitats there are no pressing conservation measures. However, it should be noted that prevalence for synanthropic roosts does not automatically indicate a bat species is not of conservation concern. Furthermore, it should be noted that *S. marovaza* was not found in many of the sites surveyed for bats in western Madagascar (Goodman *et al.*, 2005a) which included areas from where it is suspected of being present (Goodman *et al.*, 2006b). Additional field studies are therefore needed to define its range, local abundance and habitat needs, but this is not a conservation priority (Goodman *et al.*, 2006b).

GENERAL DISTRIBUTION:
Scotophilus marovaza is known from a wide area of western Madagascar from near Morondava in the south, to the holotype locality at Marovaza in the north near Mahajanga (Goodman *et al.*, 2006b; Rakotoarivelo and Randrianandrianina, 2007). Goodman *et al.* (2006b) suspect that *S. marovaza* is distributed across much of western lowland Madagascar although specimen evidence for this is still lacking (Goodman *et al.*, 2005a). Current records are from below 200 m.

Native: Madagascar (Goodman *et al.*, 2006b).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Goodman *et al.* (2006b).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Goodman *et al.* (2006b).

DETAILED MORPHOLOGY:
Baculum
Rakotondramanana and Goodman (2017: 64) mention that the baculum is a flat triangular structure, with a rounded, expanded proximal portion and which gradually tapers to a rounded distal tip; length: 1.60 ± 0.155 (1.47 - 1.77) mm, width: 0.99 ± 0.071 (0.93 - 1.07) mm.

Other

For a description of the crania, teeth, ears and tragus see Goodman *et al.* (2006b).

ECHOLOCATION:
Kofoky *et al.* (2009: 384) reported the calls of nine individuals, characterized by broadband steep FM followed by QCF, and emitted low duty cycle calls with a maximum energy at about 45.9 kHz.

HABITAT:
It is known from dry forests, fragmented forests and anthropogenic savannas in proximity of forests (Goodman *et al.* (2006b; Garbutt, 2022: 103).

Ravelomanantsoa *et al.* (2019: 110) caught it over a pool surrounded by banana trees.

ROOST:
The type specimen was collected day roosting in dry palm leaves (*Bismarckia nobilis*) forming the roof of a building (Goodman *et al.*, 2006b).

DIET:
Diet primarily consisting of beetles (Coleoptera - 73.8 %), although bugs (Hemiptera - 15.0 %), moths (Lepidoptera - 9.8 %) and ants (Hymenoptera - 8.7 %) are also consumed in smaller numbers (Ravelojaona, 2017 [in Garbutt (2022: 103); Goodman *et al.* (2022: 1906].

PREDATORS:
Goodman *et al.* (2015c: 78) found the remains of one individual in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar.

POPULATION:
Structure and Density
There is very little information on this species. Only singletons are known from two of the four sites from which it has been recorded (Goodman *et al.*, 2006b). It has been found in small roosting colonies (< 5 individuals) in huts made from palm leaves (Ratrimomanarivo and Goodman, 2005).

Trend
2016: Unknown (Monadjem *et al.*, 2017o). 2008: Unknown (Jenkins *et al.*, 2008b; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
See Goodman *et al.* (2006b).

PARASITES:
BACTERIA
Gomard *et al.* (2016: 5) found the single specimen they tested to be positive for *Leptospira*.

DIPTERA
Nycteribiidae
Wilkinson *et al.* (2016) reported the presence of *Basilia (Paracyclopodia)* sp. Ramasindrazana *et al.* (2017: Suppl.) refer to this bat fly as "*Basilia* sp. 2". Szentiványi *et al.* (2019a: Suppl.) indicated that these flies were, in turn, infected by bacteria belonging to: Enterobacteriales, *Wolbachia* sp., *Bartonella* sp.

ANTHROPOPHILOUS:
Known to roost in the palm roofs of houses (Goodman *et al.*, 2006b).

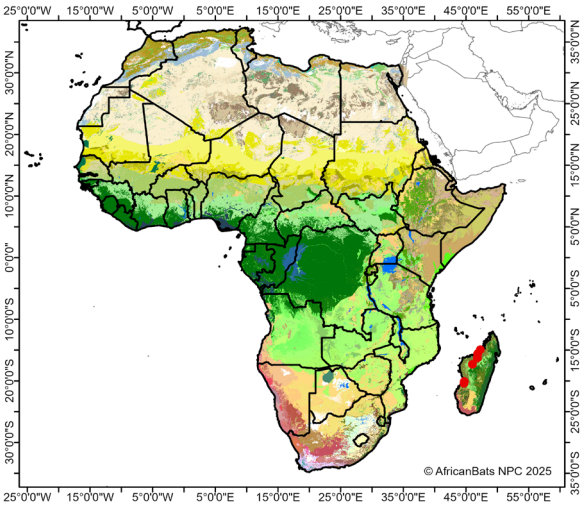

Figure 288. Distribution of *Scotophilus marovaza*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Scotophilus nigrita (Schreber, 1774)

*1774. *Vespertilio Nigrita* Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, 1 (8): pl 58 + 1 (9): 171. Publication date: 1774. Type locality: Senegal: "Senegal". [Goto Description]. - Etymology: Lanza *et al.* (2015: 493) state: "From the scientific Latin *nigritus*, diminutive of the masculin Latin adjective *niger* (nìger) 'black', (masculine *nigrìtus*; feminin *nigrita*, neuter *nigrìtum*), referring to the blackish uropatagial colour of the type specimen: 'Die Schwanzhaut ist schwärzlich' (Schreber 1774). Note that Schreber erroneously used a feminine adjective with the masculine gender noun *Vespertilio*, unless he did not consider *nigrita* as a noun in apposition (noun seemingly non-existent even in the post-classic Latin; instead, there exists in classic Latin the noun *nigritia*, meaning 'black or blackish colour').
.

1855. *N[ycticejus] nigrita:* Giebel, Die Säugethiere, 928. (Name Combination).

1875. *Scotophilus gigas* Dobson, Ann. Mag. nat. Hist., ser 4, 16 (92): 122. Publication date: 1 August 1875. Type locality: Nigeria: Western region: Lagos [06 27 N 03 23 E]. [Goto Description]. Holotype: NHMUK 1872.10.24.5: ad ♀, skull and alcoholic.

1965. *Scotophilus alvenslebeni* Dalquest, J. Mamm., 46 (2): 254, 258. Publication date: May 1965. Type locality: Mozambique: S bank Save River: Zinave National Park [ca. 21 26 S 33 52 E]. [Goto Description]. Holotype: KU 105222: ad ♂, skin and skull. Collected by: Prof. Dr. Walter Woelber Dalquest; collection date: 9 October 1963; original number: MWUC 18767. See Jones and Genoways (1969: 132). - Comments: Type locality originally as "S Bank Save River, bei Zinave, 212 km SSW Beira": see Kock (1969a: 204). - Etymology: In honour of Baron Werner von Alvensleben, in partial recognition of his labors in behalf of our work in Mozambique (see Dalquest, 1965: 258).

2016. *Scotophilus nigritta:* Mikula, Morelli, Lučan, Jones and Tryjanowski, Mammal Rev., Suppl Data. Publication date: 20 January 2016. (Lapsus).

? *Scotophilus nigrita alvenslebeni:* (Name Combination).

? *Scotophilus nigrita nigrita:* (Name Combination).

? *Scotophilus nigrita:* - Comments: . (Name Combination, Current Combination).

TAXONOMY:

For a review of this species see Robbins (1978a). The identity of this species is clear and *nigrita* is the senior synonym of *gigas* (although the latter name still persists in recent literature, e.g., Ospina-Garcés *et al.* (2018: 1615)). Most specimens called *nigrita* prior to 1978 should be called *dinganii* (see Robbins, 1978a: 212 - 213).

Based on cytochrome *b*, Vallo *et al.* (2014: 225) found *N. nigrita* to be paraphyletic with respect to the other continental African species *S. colias, S. dinganii, S. nigritellus* and *S. viridis*. They also found that cytochrome *b* from West and Southern African *S. nigrita* specimens differed between 7.6 and 8.1 %, which suggest that *S. nigrita* might differ on specific level from *alvenslebeni*. However, they (p. 229) find it too preliminary to officialize this split, and suggest further, more extensive genetic sampling and morphological analyses.

See Lanza *et al.* (2015: 493)'s remark on the taxon's suffix in the synonymy list above.

COMMON NAMES:

Afrikaans: Groot geel dakvlermuis. Castilian (Spain): Murciélago Amarillo. Chinese: 非洲大黄蝠. Czech: mračník olbřímí. English: Giant House Bat, Giant Brown House Bat, Brown House Bat, Great Brown House Bat, Giant Yellow House Bat, Schreber's Yellow Bat, Geat Brown Bat, Giant Brown Bat, Senegal Bat, Schreber's Brown Bat. French: Grand scotophile africain. German: Riesen-Hausfledermaus, Hundkopf-Schwirrfledermaus. Italian: Scotòfilo scùro. Portuguese: Morcego gigante amarelo das casas.

ETYMOLOGY OF COMMON NAME:

Most of the colloquial names refer to its colour (yellow) and being a House bat. The colloquial name Schreber's Yellow bat refers to J. von Schreber, who originally described the species (Taylor, 2005).

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Cotterill, 2008d; IUCN, 2009; Monadjem and Cotterill, 2017a).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem and Cotterill, 2017a). 2008: LC ver 3.1 (2001) (Cotterill, 2008d; IUCN, 2009). 2004: NT ver 3.1 (2001) (Cotterill, 2004d; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: NT D2 ver 3.1 (2001) (Fernsby *et al.*, 2016). 2004: considered a vagrant not assessed, not recorded in SA (Friedmann and Daly, 2004).

MAJOR THREATS:

This species is threatened by the conversion of its habitat to agricultural use in parts of its range (Cotterill, 2008d; IUCN, 2009; Monadjem and Cotterill, 2017a).

CONSERVATION ACTIONS:

Cotterill (2008d) [in IUCN (2009)] and Monadjem and Cotterill (2017a) reports that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Management of protected areas is necessary.

GENERAL DISTRIBUTION:

Scotophilus nigrita has been recorded as scattered records from West, East, and south-east Africa. It has been reported from Senegal, Côte d'Ivoire, Ghana, Togo, Nigeria and Cameroon in West Africa, from central Sudan, and from western Democratic Republic of the Congo, western Kenya and Tanzania, south to

Mozambique, Malawi, eastern Zimbabwe and north-eastern South Africa.

Native: Benin (Benda *et al.*, 2023a: 27); Cameroon (Bakwo Fils *et al.*, 2012: 55); Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 575); Côte d'Ivoire; Ghana; Kenya; Malawi (Ansell and Dowsett, 1988: 37; Monadjem *et al.*, 2010d: 575); Mozambique (Dalquest, 1965; Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 575); Nigeria; Senegal; South Africa (Monadjem *et al.*, 2010d: 575); Sudan; Tanzania; Togo; Uganda (Kityo and Kerbis, 1996: 63); Zimbabwe (Cotterill, 1996a; Monadjem *et al.*, 2010d: 575).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to O'Shea and Vaughan (1980), Amador *et al.* (2019), Mendes (2011)] mention a wing loading value of 5.2 Pa, aspect ratio 6.7 for a wingspan of 58 cm and a wing area of 507 cm^2 and a body mass of 27 g.

ECHOLOCATION:
Thiagavel *et al.* (2017: Suppl.) mention a peak frequency of 32.85 kHz.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 294 minutes, and a digestibility rate of about 66.8 %.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the African goshawk (*Accipiter tachiro* (Daudin, 1800)) preying upon *S. nigrita*. They also mention this bat to be a possible prey of the Lanner falcon (*Falco biarmicus* Temminck, 1825), Peregrine falcon (*Falco peregrinus* Tunstall, 1771), and Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850).

POPULATION:
Structure and Density
It appears to be a rare, or rarely recorded, species (Cotterill, 2008d; IUCN, 2009; Monadjem and Cotterill, 2017a).

Trend
2016: Decreasing (Monadjem and Cotterill, 2017a). 2008: Decreasing (Cotterill, 2008d; IUCN, 2009).

PARASITES:
PROTOZOA
Baleela *et al.* (2020: 360) reported *Leishmania donovani* from a *S. nigrita* specimen from Sudan.

ARACHNIDA
Spinturnicidae
Orlova *et al.* (2024: 151) reported this species (as *Scotophilus gigas)* as host for *Spinturnix scotophili* Zumpt and Till, 1954.

HEMIPTERA
Cimicidae
Kock *et al.* (1998b: 236) reported the presence of *Cacodmus villosus* (Stål, 1855), explicitly confirming the bat's identity.

VIRUSES:
Nairoviridae (formerly included in Bunyaviridae)
Nairovirus
Qalyub virus was reported by Luis *et al.* (2013: suppl.).

Coronaviridae - Coronaviruses
SARS-CoV
In Nigeria during June 2008, Quan *et al.* (2010) screened the gastrointestinal tissue for the presence of coronaviruses by PCRs, none tested positive.

Flaviviridae
Flavivirus
The presence of Dakar bat virus was mentioned by Luis *et al.* (2013: Suppl.), Blitvich and Firth (2017: 3), Willoughby *et al.* (2017: Suppl.).

Rhabdoviridae
Lyssavirus - Rabies related viruses
In Nigeria during June 2008, Quan *et al.* (2010) did not detect any lyssavirus-specific antigens from the brains by use of direct fluorescent antibody testing.

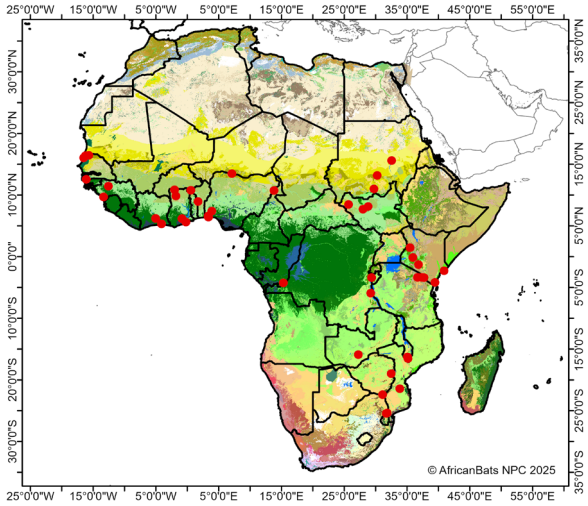

Figure 289. Distribution of *Scotophilus nigrita*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Benin, Burundi, Cameroon, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Guinea, Kenya, Malawi, Mozambique, Niger, Nigeria, Senegal, South Africa, South Sudan, Sudan, Tanzania, Togo, Zambia, Zimbabwe.

Scotophilus nigritellus de Winton, 1899

1899. *Scotophilus nigritellus* de Winton, Ann. Mag. nat. Hist., ser 7, 4 (23): 355. Publication date: 1 November 1899. Type locality: Ghana: Gambaga [10 32 N 00 26 W]. [Goto Description]. Holotype: NHMUK 1899.6.15.9: ad ♂. Collected by: Captain W. Giffard; collection date: 9 January 1899.
2014. *Scotophilus cf. nigritellus/sp. n.* Vallo, Benda, Červený and Koubek, Mammalia, 79 (2): 227. Publication date: 19 June 2014. (Name Combination).
? *Scotophilus leucogaster nigritellus:*
? *Scotophilus viridis nigritellus:* (Name Combination).

TAXONOMY:
This small sized *Scotophilus* has been included in *leucogaster* (Robbins *et al.*, 1985) or *viridis*, but see Vallo and Van Cakenberghe (2017) and Demos *et al.* (2018)

Vallo *et al.* (2011a: 45) showed that their cytochrome *b* analyses indicated that *S. viridis* contains two paraphyletic lineages, differing by about 12 %. They indicated that the greenish-yellow specimens from West Africa could be reliably identified with *S. nigritellus*. mtDNA analyses performed by Trujillo *et al.* (2009: 553) confirm that *S. viridis* is distinct from *S. nigritellus*, as suggested by Grubb *et al.* (1998).

Vallo *et al.* (2012: 5), who analyses the cytochrome *b* gene of West African "*S. nigritellus*" specimens, found that two paraphyletic lineages were present (agreeing with the belly colour of the specimens), with a genetic divergence ranging between 12.3 and 13.5 %. The white bellied lineage differed only 2.6 to 2.8 % from *S. leucogaster*. Their analysis of the *zfy* gene (zinc finger protein on the Y-chromosome) indicated that the white bellied lineage differed by 10 substitutions from the yellow bellied lineage, and that the white bellied lineage furthermore differed by 9 substitutions from *S. leucogaster*. Vallo *et al.* (2012: 10) concluded that the yellow bellied form agrees with the form *S. nigritellus* described by de Winton in 1899 but were unable to provide a name for the white bellied form.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Scotophilus nigritellus is widespread in West Africa, ranging from Senegal and Gambia to northern Cameroon and the Central African Republic.

Native: Benin (Capo-Chichi *et al.*, 2004: 163); Burkina Faso (Kangoyé *et al.*, 2015a: 626); Cameroon; Central African Republic; Chad; Côte d'Ivoire; Gambia; Ghana; Guinea-Bissau (Peters, 1870; Seabra, 1900a; Rainho and Ranco, 2001: 72); Mali; Niger; Nigeria; Senegal; Togo.

ECHOLOCATION:
In Benin, the bat's call was categorized as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype by Roemer *et al.* (2021: Suppl.) [as "*Scotophilus viridis*"].

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Benin, Burkina Faso, Cameroon, Côte d'Ivoire, Ghana, Mali, Niger, Nigeria, Senegal, Sierra Leone, The Gambia, Togo, Uganda.

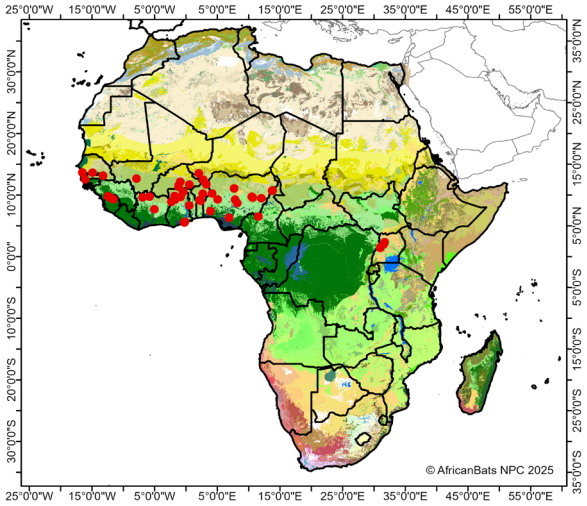

Figure 290. Distribution of *Scotophilus nigritellus*.

Scotophilus nucella Robbins, 1983

*1983. *Scotophilus nucella* Robbins, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., 273: 19. Type locality: Ghana: Eastern region: Nkawkaw, 1 mi N [06 33 N 00 44 W]. Holotype: USNM 412141: ad ♂, skin and skull. Collected by: Bruce Joliffe Hayward; collection date: 5 August 1967. - Etymology: *nucella* is a diminutive of *nux*. Following the rules for construction of a diminutive, the latin root of *nux* is used (=*nuc*). Although *Scotophilus* is masculine in gener, formation of a diminutive of a noun in apposition (*nux*) must retain the same gender as its root (*nuc*) which is feminine. The only ending then possible are *-ula* or *-ella*. (Current Combination).

TAXONOMY:
Included in *leucogaster* by Koopman (1993a: 227), Grubb *et al.* (1998: 91).

Vallo *et al.* (2016: 302) showed that cytochrome *b* sequences separated *S. nucella* 7.8 - 9.4 % from *S. nux* and puts both in a sister position. This was corroborated by the nuclear zinc finger protein gene on the Y-chromosome. Both species were separated from one another at the Pliocene-Pleistocene transition, some 2.5 MYA.

COMMON NAMES:
Czech: mračník guinejský. English: Lesser Nut-coloured House Bat, Rainforest House Bat, Robbins's House Bat, Robbin's House Bat, Nucella House Bat, Little Nut-coloured House Bat, Robbins's Yellow Bat. French: Scotophile de Robbins, Scotophile des hauteurs. German: Robbins Hausfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status. The range is very poorly known, and it is unclear if the species is declining (Fahr, 2008o; IUCN, 2009; Fahr, 2019b).

Assessment History
Global
2018: DD ver 3.1 (2001) (Fahr, 2019b). 2008: DD ver 3.1 (2001) (Fahr, 2008o; IUCN, 2009). 2004: VU A2a; B2ab(iii) ver 3.1 (2001) (Fahr, 2004b; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Fahr, 2008o; IUCN, 2009; Fahr, 2019b).

CONSERVATION ACTIONS:
Fahr (2008o) [in IUCN (2009)] and Fahr (2019b) reports that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed.

GENERAL DISTRIBUTION:
Scotophilus nucella has only been recorded from southeastern Côte d'Ivoire, southern Ghana, and western Uganda close to the border with the Democratic Republic of the Congo, and Kambai Forest Reserve in the East Usambara Mountains of Tanzania (Cunneyworth, 1996b). Known from the high forest vegetation zone in Ghana (Decher and Fahr, 2007: 20) and Uganda, but it may occur in the high forest areas of West, Central and East Africa (Robbins, 1983a).

Native: Côte d'Ivoire; Ghana (Decher and Fahr, 2007: 20); Tanzania Cunneyworth, 1996b); Uganda.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 152 minutes, and a digestibility rate of about 73.0 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species. It is suspected to be declining as it appears that the species has not been collected since 1984 (Fahr, 2008o; IUCN, 2009; Fahr, 2019b).

Trend
2018: Unknown (Fahr, 2019b). 2008: Unknown (Fahr, 2008o; IUCN, 2009).

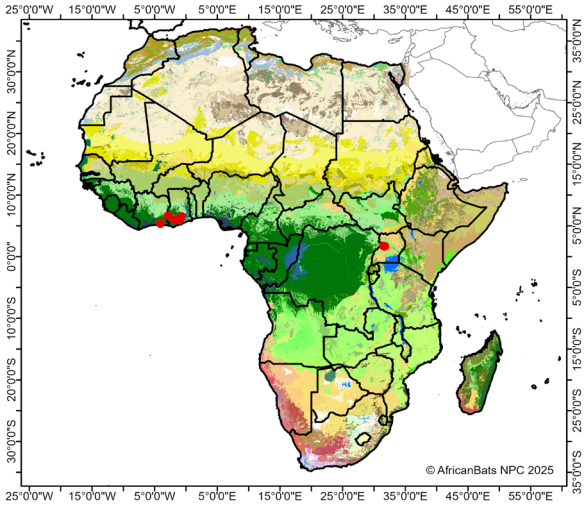

Figure 291. Distribution of *Scotophilus nucella*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Côte d'Ivoire, Ghana, Tanzania, Uganda.

Scotophilus nux Thomas, 1904

*1904. *Scotophilus nigrita nux* Thomas, Ann. Mag. nat. Hist., ser 7, 13 (75): 208. Publication date: 1 March 1904. Type locality: Cameroon: Efulen [02 46 N 10 42 E]. [Goto Description]. Holotype: NHMUK 1903.2.4.5: ad ♂. Collected by: George Latimer Bates Esq. - Etymology: From the Latin "*nux*" meaning nut.
1915. *Scotophilus nux:* Thomas, Ann. Mag. nat. Hist., ser 8, 16 (96): 468. Publication date: 1 December 1915. (Name Combination, Current Combination).
1938. *[Pachyotus] nux:* Frechkop, Exploration du Parc National Albert, 53. (Name Combination).
1938. *Pachyotus mux:* Frechkop, Exploration du Parc National Albert, 59. (Lapsus).
1938. *Pachyotus nigrita mux:* Frechkop, Exploration du Parc National Albert, 59. - Comments: Mentioned in the synonymy of *Pachyotus mux* (sic). (Lapsus).
1938. *Scotophilus nigrita mux:* Frechkop, Exploration du Parc National Albert, 59. - Comments: Mentioned in the synonymy of *Pachyotus mux* (sic). (Lapsus).
? *Scotophilus dinganii nux:* (Name Combination).
? *Scotophilus leucogaster nux:* (Name Combination).

TAXONOMY:
S. nux has been most often recognized as a subspecies of *nigrita*, when *nigrita* was used for the species now called *dinganii*; see Allen (1939a), Rosevear (1965), and Hayman and Hill (1971: 50). Koopman (1965: 4 - 5) listed it as a subspecies of *leucogaster*. Grubb *et al.* (1998: 90) include *nux* as a subspecies of *dinganii*.

Vallo *et al.* (2016: 306) found that the cyt-*b* of specimens from Guinea differs 3.4 - 4.5 % from that of conspecifics from other parts of Africa and therefore these specimens might probably be assigned to a separate subspecies.

COMMON NAMES:
Chinese: 喀麦隆黄蝠. Czech: mračník ořechový. English: Nut-coloured House Bat, Dark House Bat, Nut-colored Yellow Bat, Nux Yellow House Bat. French: Scotophile noisette, Scotophile nux. German: Nußfarbene Hausfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Fahr, 2008p; IUCN, 2009; Monadjem and Fahr, 2017c).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Fahr, 2017c). 2008: LC ver 3.1 (2001) (Fahr, 2008p; IUCN, 2009). 2004: LC ver 3.1 (2001) (Fahr, 2004q; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this species. Some populations may be impacted by general deforestation, however, this needs to be confirmed (Fahr, 2008p; IUCN, 2009; Monadjem and Fahr, 2017c).

CONSERVATION ACTIONS:
Fahr (2008p) [in IUCN (2009)] and Monadjem and Fahr (2017c) reports that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas.

GENERAL DISTRIBUTION:
Scotophilus nux has been patchily recorded from West Africa (Sierra Leone, Guinea, Liberia Côte d'Ivoire, Ghana and Nigeria), Central Africa (Cameroon and Democratic Republic of the Congo) and East Africa (Uganda and Kenya), and is believed to likely occur more widely than is currently known. It is possibly present in Equatorial Guinea; however, this needs to be confirmed.

Native: Cameroon; Congo (Bates *et al.*, 2013: 337); Congo (The Democratic Republic of the); Côte d'Ivoire; Ghana (Decher and Fahr, 2007: 21); Guinea (Fahr *et al.*, 2006a: 74; Decher *et al.*, 2016: 274); Kenya; Liberia (Fahr, 2007a: 104); Nigeria; Rwanda; Sierra Leone; Uganda.

Presence uncertain: Equatorial Guinea.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
From western Uganda, Monadjem *et al.* (2011: 30) reported the following data: Fa: 55.6 mm, mass: 30 g, wing loading: 6.4 N/m^2, aspect ratio: 5.5.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Monadjem *et al.* (2011)] mention a wing loading value of 13.7 Pa, aspect ratio 5.5 for a wingspan of 34 cm and a wing area of 215 cm^2 and a body mass of 30 g.

ECHOLOCATION:
From western Uganda, Monadjem *et al.* (2011: 32) reported the following values: F_{min}: 40.71 kHz, F_{max}: 54.05 kHz, F_{char}: 43.01 kHz, F_{knee}: 45.07 kHz, and duration: 2.0 ms.

For a *S.* cf. *nux* specimen from Gabon, Peereboom and van Lieshout (2015: 6) mention F_{min}: 38.49 ± 0.83 (37.82 - 40.04) kHz, F_{max}: 59.45 ± 7.23 (52.54 - 75.79) kHz, $F_{min\ dom}$: 44.54 ± 1.91 (41.11 - 47.37) kHz, duration: 1.87 ± 0.30 (1.60 - 2.50) ms, interpulse interval: 57.08 ± 33.44 (16.20 - 108.60) ms.

From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 23 calls of 1 bat: F_{peak}: 43.7 ± 1.0 (42.7 - 44.9) kHz, F_{min}: 41.2 ± 2.8 (38.1 - 44.1) kHz, F_{max}: 75.1 ± 5.8 (71.5 - 83.8) kHz, duration: 2.0 ± 0.2 (1.7 - 2.2) ms.

Thiagavel *et al.* (2017: Suppl.) mention a peak frequency of 26.09 kHz.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

Figure 292. Clockwise from top lateral, ventral and dorsal skull images of NHMUK 1903.2.4.5, holotype of *Scotophilus nigrita nux* Thomas, 1904.

MOLECULAR BIOLOGY:
Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
Monadjem *et al.* (2016y: 371) collected two specimens over water in a disturbed forest habitat on the Liberian side of Mount Nimba at 520 m.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 156 minutes, and a digestibility rate of about 72.7 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Fahr, 2008p; IUCN, 2009; Monadjem and Fahr, 2017c).

Trend
2016: Unknown (Monadjem and Fahr, 2017c).
2008: Unknown (Fahr, 2008p; IUCN, 2009).

VIRUSES:
Coronaviridae
Anthony *et al.* (2017b: Suppl.) mention the alphacoronavirus Predict_CoV_33.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Guinea, Kenya, Liberia, Nigeria, Sierra Leone, Uganda.

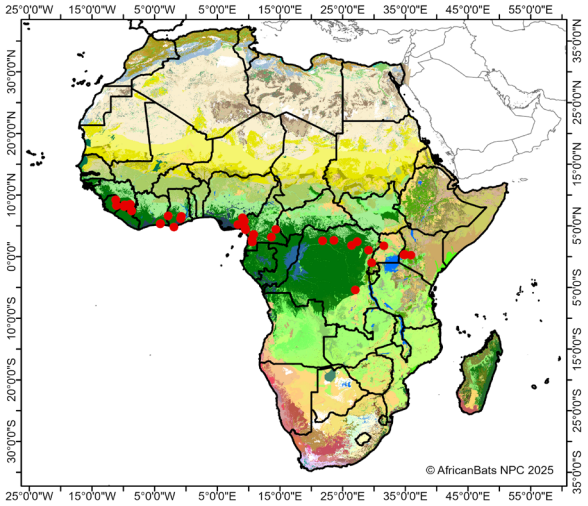

Figure 293. Distribution of *Scotophilus nux*.

Scotophilus robustus A. Milne-Edwards, 1881

*1881. *Scotophilus robustus* A. Milne-Edwards, C. R. séances Acad. Sci., Paris, 91: 1035. Publication date: 1881. Type locality: Madagascar: "Madagascar". [Goto Description]. Holotype: MNHN 218: ♀. Holotype: MNHN ZM-MO-1997-1833a: ad ♀, alcoholic (skull not removed). Collected by: Léon Humblot. Number 218 in Rode (1941: 248). See also Peterson *et al.* (1995: 112), Goodman *et al.* (2005b: 873). Paratype: MNHN ZM-MO-1997-1833b: ad ♀, alcoholic (skull not removed). Collected by: Léon Humblot. Number 218a in Rode (1941: 248). Goodman *et al.* (2005b: 873) additionally mention that the jar with the type specimen contains two specimens (1997-1883a and 1997-1883b), but that not can be determined which of the two is the holotype. - Comments: Goodman *et al.* (2005b: 873) mention "entre Foulpointe et le lac d'Alaoutre" in the central portion of het eastern humid forest as type locality. Goodman *et al.* (2005b: 873) also mention that the jar with the type specimen contains two specimens (1997.1883a and 1997.1883b), but that not can be determined which of the two is the holotype. (Current Combination).
? *Scotophilus nigrita robustus:* (Name Combination).

TAXONOMY:
Recognized as a subspecies of *nigrita* (when *nigrita* was used for the species now called *dinganii*) by Hayman and Hill (1971: 50). However, Robbins *et al.* (1985) considered it specifically distinct from *dinganii* and *borbonicus*.

COMMON NAMES:
Czech: mračník statný. English: Malagasy Large House Bat, Robust House Bat, Robust Yellow Bat. French: Scotophile de Madagascar, Chauve-souris domestique malgache, Grande scotophile de Madagascar, Scotophile robuste. German: Madagaskar-Hausfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) as although the species is not thought to be abundant and has not often been recorded, the available information indicates that the species is widespread across Madagascar occurring in a wide variety of habitats, including in human habitations. While the threats affecting the species are imperfectly known, there is no reason to expect that the species is currently undergoing a decline that would warrant listing in a threatened category (Andriafidison *et al.*, 2008k; IUCN, 2009; Monadjem *et al.*, 2017bx).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017bx). 2008: LC ver 3.1 (2001) (Andriafidison *et al.*, 2008k; IUCN, 2009). 1996: LR/nt ver 2.3 (1994).

Regional
None known.

MAJOR THREATS:
Andriafidison *et al.* (2008k) [in IUCN (2009)] and Monadjem *et al.* (2017bx) report that the major threats to this species are not well known. This species uses forest habitat, but it also occurs outside of forested areas. There is one reported occurrence of this species being hunted by food by local people, but there is no evidence that this constitutes a major threat (Goodman *et al.*, 2008d).

CONSERVATION ACTIONS:
Andriafidison *et al.* (2008k) [in IUCN (2009)] and Monadjem *et al.* (2017bx) report that this species

is known from a number of protected areas across Madagascar and does not appear to require specific conservation measures but, like many other Malagasy bats that are not considered to be threatened, there is a lack of basic natural history data.

GENERAL DISTRIBUTION:
Scotophilus robustus is endemic to the island of Madagascar, where it is broadly distributed from the coast to the highland plateau up to 1,400 m in Tsinjoarivo (Goodman *et al.*, 2005a). This species is rarely recorded, but as more surveys are conducted it is likely that this species will be found to have a wider distribution.

Native: Madagascar (Russ *et al.*, 2001).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
S. robustus is the largest vespertilionid bat occurring on Madagascar (Garbutt, 2022: 103).

DETAILED MORPHOLOGY:
Baculum
This bone has a flat triangular structure, with a distinct indentation to the proximal margin (Rakotondramanana and Goodman, 2017: 64); length: 2.02 ± 0.048 (.94 - 2.09) mm, width: 1.18 ± 0.096 (0.98 - 1.29) mm.

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls which were characterized by a broadband steep FM followed by a QCF calls at low duty cycle. The fundamental was always the most intense with peak energy at about 38.1 kHz.

Hending *et al.* (2023: 372) mention the following values: F_{peak}: 38.6 ± 3.0 kHz, duration: 12 ± 5 ms, and interpulse interva: 115 ± 40 ms.

HABITAT:
Ravelomanantsoa *et al.* (2019: 110) indicated that this large species occurs in wet and dry deciduous forests. It is known for inhabiting human constructions. They also caught it near the base of a *Ficus cocculifolia* and near a *Mangifera indica* plantation.

ROOST:
Roosts are found around habitation and in natural sites (Garbutt, 2022: 103).

DIET:
The following prey volume percentages were reported from the faeces of 2 *S. robustus* specimens by Rakotondramanana *et al.* (2015: 74): Coleoptera: 14.5 ± 20.51; Lepidoptera: 50.0 ± 70.71; Homoptera: 8.0 ± 11.31; Blattoidea: 27.5 ± 38.90. Expressed as frequency percentages, the values are: Coleoptera: 50.0 ± 70.71; Lepidoptera: 50.0 ± 70.71; Homoptera: 60.0 ± 42.43; Blattoidea: 50.0 ± 70.71.

Rasoanoro *et al.* (2015: 63) found that Coleoptera formed about 68 % of the diet, whereas sampling in the feeding area revealed that only 3 % of the available prey consisted of Coleoptera. They indicated that - at least in the hot season - *S. robustus* is a Coleopteran specialist. The droppings of three bats contained the following volume percentages of prey types: Aranea: 5.7 ± 0.33, Coleoptera: 68.0 ± 10.08, Diptera: 1.9 ± 1.88, Homoptera: 2.1 ± 2.06, Hymenoptera: 8.7 ± 3.87, Lepidoptera: 9.1 ± 4.50, and Orthoptera: 4.3 ± 2.15.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 145 minutes, and a digestibility rate of about 73.4 %.

PREDATORS:
Razakaratrimo *et al.* (2019: 114) mention the bat hawk (*Macheiramphus alcinus anderssoni* (Gurney, 1866)).

POPULATION:
Structure and Density
A number of bat surveys have failed to locate this species (Goodman *et al.*, 2005b; Robinson *et al.*, 2006; Rakotoarivelo and Randrianandrianina, 2007) and it appears not to be locally abundant (Andriafidison *et al.*, 2008k; IUCN, 2009; Monadjem *et al.*, 2017bx).

Trend
2016: Unknown (Monadjem *et al.*, 2017bx).
2008: Unknown (Andriafidison *et al.*, 2008k; IUCN, 2009).

PARASITES:
HAEMOSPORIDA
Rasoanoro *et al.* (2021: 4) report the presence of a new, unidentified *Polychromophilus* in a single representative of this bat species.

DIPTERA
Nycteribiidae
Duron *et al.* (2014: 2108) refer to a *Basilia* nov. sp. collected from this bat species.

Wilkinson *et al.* (2016) reported the presence of *Basilia (Paracyclopodia)* sp., which was carrying *Bartonella* bacteria, as well as Enterobacteriales. Ramasindrazana *et al.* (2017: Suppl.) refer to the bat fly as "*Basalia* sp. 1". They also mention (p. 6) a *Basilia (Paracyclopodia) madagascarensis*, which was collected from a "*Scotophilus borbonicus*" from Nosy Be, but this bat most

probably should be assigned to *S. robustus*. Szentiványi *et al.* (2019a: Suppl.) furthermore indicated that a new bat fly (Basilia nov. spec.) found on a *S. robustus* bats, was parasitized by an *Arsenophonus* sp. Bacteria.

VIRUSES:
Flaviviridae
Flavivirus
Dakar Bat Virus (DBV)
Isolated from salivary glands (Coulanges *et al.*, 1974; Rousset and Andrianarivelo, 2003).

UTILISATION:
See Goodman *et al.* (2008d).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

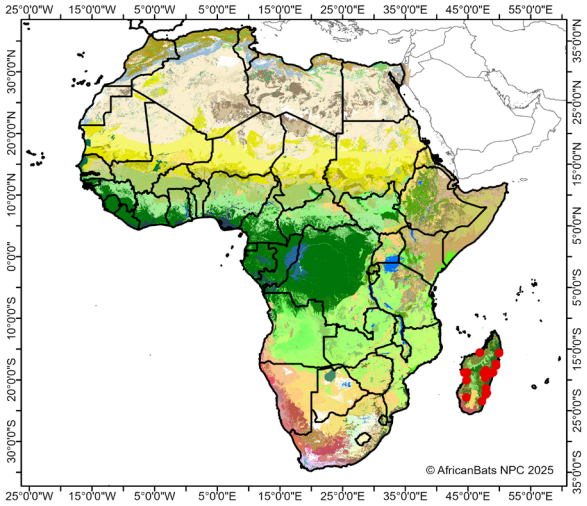

Figure 294. Distribution of *Scotophilus robustus*.

Scotophilus tandrefana Goodman, Jenkins and Ratrimomanarivo, 2005

*2005. *Scotophilus tandrefana* Goodman, Jenkins and Ratrimomanarivo, Zoosystema, 27 (4): 867, 875, figs 3 - 5. Type locality: Madagascar: Mahajanga province: just outside the Parc national de Bemaraha: 1.8 km SE Bekopake and 0.6 km NE Andadoany [19 08 S 44 49 E, 50 m]. Holotype: UADBA 46923: ad ♂, skull and alcoholic. Collected by: Richard K.B. Jenkins and Fania H. Ratrimomanarivo; collection date: 27 July 2003; original number: RBJ 161. - Etymology: From the Malagasy meaning "from the west" (see Goodman *et al.*, 2005b: 875). (Current Combination).

TAXONOMY:
Goodman *et al.* (2005b) described this species based on three specimens which were collected in 1868, 1869 and 2003 (the latter being designated as the holotype). One of these (the specimen collected in 1869) was later reassessed as *S. marovaza* (Goodman *et al.*, 2006b).

Trujillo *et al.* (2009: 553) indicate that inferred phylogenies do not support the separation of *S. tandrefana* and *S. marovaza* as the cytochrome *b* phylogeny only reveals a genetic divergence of 0.6 %, a level indicative of within-species divergence. This might indicate that cytochrome *b* is not representative or that the separation between the two taxa occurred too recent to be already reflected in that gene.

COMMON NAMES:
Czech: mračník madagaskarský. English: Malagasy Western house bat, Western Yellow Bat, Malagasy Yellow Bat, Western House Bat. French: Scotophile d'Andadoany, Scotophile de l'ouest de Madagascar. German: Westliche Hausfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) as the species is known from only two specimens (one collected as recently as 2003) and there is no information on its population status or threats (Jenkins *et al.*, 2008c; IUCN, 2009; Jenkins *et al.*, 2019b).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jenkins *et al.*, 2019b).
2008: DD ver 3.1 (2001) (Jenkins *et al.*, 2008c; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
The major threats to this species are not known (Jenkins *et al.*, 2008c; IUCN, 2009; Jenkins *et al.*, 2019b).

CONSERVATION ACTIONS:
Jenkins *et al.* (2008c) [in IUCN (2009)] and Jenkins *et al.* (2019b) report that this species has been recorded from near Parc National Tsingy de Bemaraha and the managed forest of Kirindy CFPF (Goodman *et al.*, 2005a), but evidence is lacking that it actually roosts or feeds in these forests.

GENERAL DISTRIBUTION:
Scotophilus tandrefana is endemic to Madagascar where it is known from two localities below 100 m: near Parc National Tsingy de Bemaraha in the west and Sarodrano in the south (Goodman *et al.*, 2005a). Photographs and

forearm measurements of an individual from Kirindy (CFPF) forest in the west represents the third known locality for this species (Goodman *et al.*, 2005a).

Native: Madagascar.

ECHOLOCATION:
Kofoky *et al.* (2009: 382) reported the calls from a single individual in a flight cage, which emitted broadband FM/QCF calls at low duty cycle with frequency containing most energy at about 48.2 kHz.

HABITAT:
This species occurs In dry forests and forest edges including grassland (Garbutt, 2022: 103).

POPULATION:
Structure and Density
There are no data on the population of this species and all existing information is based on two specimens that were collected in 1868 and 2003 (Goodman *et al.*, 2005b; 2006b).

Trend
2018: Unknown (Jenkins *et al.*, 2019b). 2008: Unknown (Jenkins *et al.*, 2008c; IUCN, 2009).

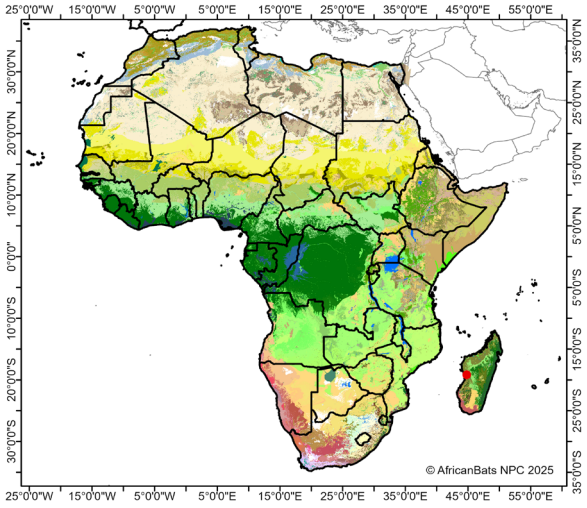

Figure 295. Distribution of *Scotophilus tandrefana*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Madagascar.

Scotophilus trujilloi Brooks and Bickham, 2014

*2014. *Scotophilus trujilloi* Brooks and Bickham, Occ. Pap. Mus. Texas Tech Univ., 326: 1, 16, fig 6. Publication date: 26 Jun 2014. Type locality: Kenya: Coastal province: Kwale district: Moana Marine Station, 1 km S, 2 km E Ukunda [04 18 S 39 35 E]. Holotype: CM 98038: ad ♂, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 18 October 1985; original number: 7086. Muscle tissue sample TK 33263. Paratype: CM 98040: ad ♀, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 18 October 1985; original number: 7087. Tissue sample TK 33266. Paratype: CM 98041: ad ♀, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 18 October 1985; original number: 7090. - Etymology: In honour of Dr. Robert Trujillo (b. 1975), who's ground-breaking doctoral dissertation on the molecular systematics of *Scotophilus* paved the way for the description of the four cryptic species described in this paper (Trujillo 2005; Trujillo *et al.* 2009) (see Brooks and Bickham (2014 18).

TAXONOMY:
Brooks and Bickham (2014) described four new species in the genus *Scotophilus*. However, they did not compare them with a number of already described taxa such as *colias* Thomas, 1904 or *flavigaster* Heuglin, 1861, which make the validity of (some of) these names doubtful.

The analyses performed by Demos *et al.* (2018: 2) confirmed the validity of the taxon, but these authors also indicate that they cannot vouch for the validity of the name with respect to older taxa that would have nomenclatural priority. Benda *et al.* (2025: 104) consider this name tentatively as valid, at least for the series of NMW and NMP specimens from Kenya.

Musila *et al.* (2018a: 29) indicate that *trujilloi* should be used for the Kenyan animals formerly included in *S. viridis*.

COMMON NAMES:
Chinese: 特鲁黄蝠. English: Trujillo's House Bat. German: Trujillos Hausfledermaus.

CONSERVATION STATUS:
Global Justification
Assessed as Least Concerned (LC ver 3.1 (2001) as this species is from five samples from coastal Kenya (Brooks and Bickham, 2014). Further research is required to verify the taxonomy of this taxon (Monadjem, 2017d).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem, 2017d).

Regional
None known.

MAJOR THREATS:
The major threat is persecution of roosting sites (Monadjem, 2017d).

CONSERVATION ACTIONS:
Monadjem (2017d) reported that this species is known to occur in the Shimba Hills National Park and may occur in the other protected areas in Kenya.

ECHOLOCATION:
Musila *et al.* (2018c: 43) [referring to Monadjem *et al.* (2010d)] mention a shallow frequency modulated call, with a peak frequency of 40 kHz and a bandwidth of 25 kHz, but Monadjem *et al.* (2010d: 528) had these parameters assigned to *S. viridis*.

POPULATION:
There is no information about population size and trend (Monadjem, 2017d).

Trend:- 2016: Unknown (Monadjem, 2017d).

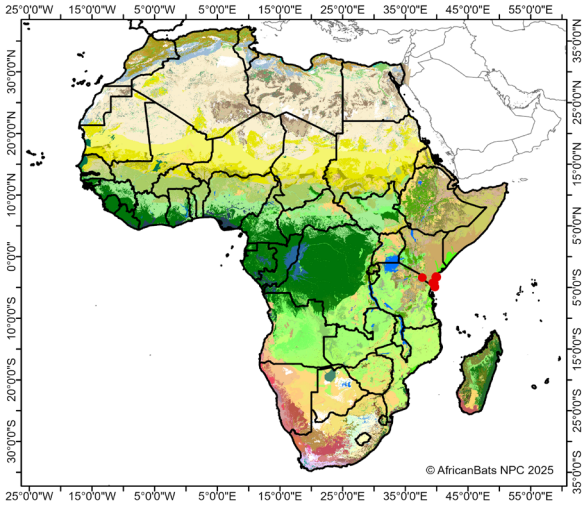

Figure 296. Distribution of *Scotophilus trujilloi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya, Tanzania.

Scotophilus viridis (Peters, 1852)

*1852. *Nycticejus viridis* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 67, pl 17, fig 2, a-e. Publication date: 1852. Type locality: Mozambique: Mozambique Island [15 S 40 42 E]. [Goto Description]. Holotype: ZMB 73610: ad ♂, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: March 1845. Formerly ZMB 526 [=An 16362]; see Turni and Kock (2008: 53). - Etymology: From the masculine Latin adjective *viridis*, meaning "green", referring to the body colour: "Die Farbe der Rückseite ist ein schönes dunkles Olivengrün, die Haare der Bauchseite sind grünlichgelb" (Peters (1852: 68) (see Lanza *et al.*, 2015: 498).

1984. *Scotophilus borbonicus viridis:* Aggundey and Schlitter, Ann. Carnegie Mus., 53 (5): 121, 138. Publication date: 19 April 1984. (Name Combination).

2018. *Scotophilus viridus:* Adams and Kwiecinski, Diversity, 10 (3) 103: 1. Publication date: 18 September 2018. (Lapsus).

2019. *Scroptophilus borbonicus:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).

2019. *Scroptophilus vividis:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).

? *Scotophilus cf. viridis*

? *Scotophilus leucogaster viridis:* (Name Combination).

? *Scotophilus viridis viridis:* (Name Combination).

? *Scotophilus viridis:* (Name Combination, Current Combination).

TAXONOMY:
Included in *leucogaster* by Hayman and Hill (1971: 50) but see Koopman (1975: 414 - 416) and Schlitter *et al.* (1980). Included *damarensis* but see Robbins *et al.* (1985).

Vallo *et al.* (2011a: 45) showed that their cytochrome *b* analyses indicate that *S. viridis* contained two paraphyletic lineages, differing by about 12 %. They indicated that the greenish-yellow specimens from West Africa could be reliably identified with *S. nigritellus*. mtDNA analyses performed by Trujillo *et al.* (2009: 553) confirm that *S. viridis* is distinct from *S. nigritellus*, as suggested by Grubb *et al.* (1998). They also found that *S. viridis* s.s. is not monophyletic because it is found in 2 divergent clades; specimens from Kenya group with *S. dinganii* from South Africa, and specimens of *S. viridis* from South Africa group with *S. robustus* from Madagascar.

COMMON NAMES:
Afrikaans: Klein geel dakvlermuis. Czech: mračník zelený. English: Green House Bat, Greenish Yellow Bat, Lesser Yellow House Bat. French: Petit scotophile africain, Scotophile verdâtre. German: Grünliche Hausfledermaus, Olivengrüne Schwirrfledermaus. Italian: Scotòfilo vérde. Malawian: Liputiputi, Ndemiya, Namzeze.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a

more threatened category (Griffin, 2008c; IUCN, 2009; Monadjem and Griffin, 2017c).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem and Griffin, 2017c). 2008: LC ver 3.1 (2001) (Griffin, 2008c; IUCN, 2009). 2004: LC ver 3.1 (2001) (Griffin, 2004c; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Richards *et al.*, 2016a). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this species (Griffin, 2008c; IUCN, 2009; Monadjem and Griffin, 2017c).

CONSERVATION ACTIONS:
Griffin (2008c) [in IUCN (2009)] and Monadjem and Griffin (2017c) reports that there appear to be no direct conservation measures in place. It has been recorded from the Matusadona National Park in Zimbabwe, and likely is present in several other protected areas.

GENERAL DISTRIBUTION:
Scotophilus viridis is widespread in sub-Saharan Africa, ranging from Sudan and Ethiopia southwards through much of East Africa and southeastern Africa, being reported as far south as eastern South Africa and Swaziland. For South Africa, Babiker Salata (2012: 49) found that its distribution is strongly associated with the mean temperature of the coldest quarter.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 895,732 km^2.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 575); Botswana; Eswatini (Monadjem *et al.*, 2010d: 575, Monadjem *et al.*, 2021: 5); Ethiopia; Kenya; Malawi (Ansell and Dowsett, 1988: 38; Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 575); Mozambique (Monadjem *et al.*, 2010d: 575; Monadjem *et al.*, 2010c: 385 as *S.* cf. *viridis*); Namibia; South Africa (De Graaf, 1960; Monadjem *et al.*, 2010d: 575); Sudan; Tanzania (Stanley and Goodman, 2011: 45) (including the islands of Pemba and Mafia [O'Brien, 2011: 290]); Zambia (Monadjem *et al.*, 2010d: 575); Zimbabwe (Cotterill, 2004a: 262; Monadjem *et al.*, 2010d: 575).

ECHOLOCATION:
See Taylor (1999b).

Schoeman and Waddington (2011: 291) mention a F_{peak} 46.9 ± 1.1 kHz and a duration of 2.9 ± 1.2 ms for *S.* cf. *viridis* specimens from St. Lucia Wetland Park, South Africa.

From Swaziland, Monadjem *et al.* (2017c: 179) reported F_{min}: 39.8 ± 1.33 (38.5 - 41.2) kHz, F_{knee}: 42.7 ± 1.05 (41.6 - 43.7) kHz, F_c: 40.1 ± 1.31 (38.8 - 42.4) kHz and duration: 3.5 ± 1.55 (2.0 - 5.0) ms. The calls could be detected up to a distance of 15 m.

Thiagavel *et al.* (2017: Suppl.) mention a peak frequency of 40.1 kHz.

In the Kalahari Desert, Adams and Kwiecinski (2018: 4) recorded three calls with the following parameters: F_{char}: 37.5 ± 1.6 kHz, F_{max}: 70.6 ± 6.6 kHz, F_{min}: 36.7 ± 1.8 kHz, duration: 4.3 ± 0.3 ms.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 40 kHz and duration: 10 ms.

4 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 41 kHz, F_{max}: 57 kHz, F_{char}: 43 kHz, F_{knee}: 46 kHz and duration 4 ms.

From Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 10 calls: Interpulse interval: 58.3 ± 12.0 (39.3 - 77.3) ms; F_{max}: 48.3 ± 4.8 (42.2 - 58.3) kHz; Start slope: -16.7 ± 6.7 (-13.5 - -9.7) kHz/ms; End slope: -6.4 ± 3.0 (-1.2 - -9.6) kHz/ms; Ledge duration: 0.4 ± 0.0 (0.4 - 0.5) ms.

MOLECULAR BIOLOGY:
Karyotype
See discussion in generic account.

Genetics
See Hoofer and Van Den Bussche (2003) for the results of a specimen from Tanzania.

HABITAT:
In southern Africa, the species primarily occurs in Savanna (77 %) and Coastal mosaic (13 %) habitats (Cooper-Bohannon *et al.*, 2016: Table S2).

HABITS:
Cotterill and Giddings (1987: 175) studied the activity patterns of *S. viridis* in Zimbabwe and found that most of the females were active between 7 and 9 p.m. (when there is a peak in

insect abundance)., whereas most of the males were active between 9 and 10 p.m.

ROOST:
Monadjem *et al.* (2010b: 74) found that they roosted in *Combretum imberbe* and *Acacia nigrescens* trees in Swaziland, where they found that 4 of the 5 radio tracked individuals roosted simultaneously in the same *Combretum imberbe* on a single night, and then one individual switched roosts to a different *Combretum imberbe* for two nights.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 125 minutes, and a digestibility rate of about 74.9 %.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the following diurnal avian predators: Red-necked falcon (*Falco ruficollis* Daudin, 1800), Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) [although the prey might have been a *S. nigrita*]; Grey-headed bushshrike (*Malaconotus blanchoti* Stephens, 1826).

POPULATION:
Structure and Density
This is a common species (Griffin, 2008c; IUCN, 2009; Monadjem and Griffin, 2017c).

Trend
2016: Unknown (Monadjem and Griffin, 2017c).
2008: Unknown (Griffin, 2008c; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) report this species as being polytocous (more than one young per litter).

Delayed development (van der Merwe *et al.*, 1988).

VIRUSES:
Astroviridae
Neither of the two bats from Mozambique tested by Hoarau *et al.* (2018: 2) was positive for these viruses.

Coronaviridae - Coronaviruses
SARS-CoV
Müller *et al.* (2007b) tested [as *S. borbonicus*] between 1986 to 1999, for antibody to SARS-CoV in sera in one individual from Limpopo Province, South Africa, which turned out to be negative.

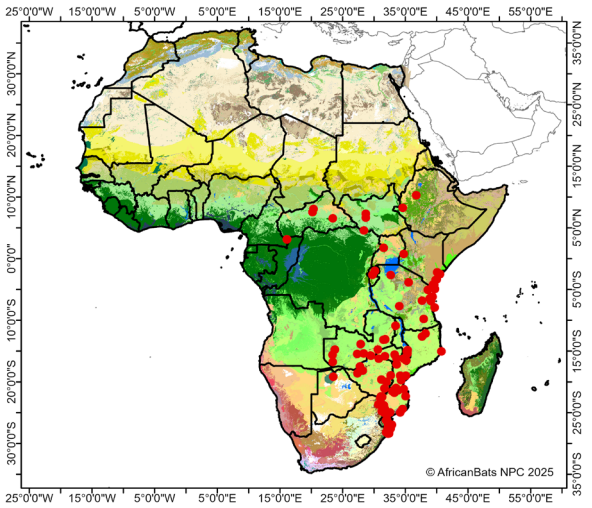

Figure 297. Distribution of *Scotophilus viridis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Botswana, Central African Republic, Eswatini, Ethiopia, Kenya, Malawi, Mozambique, Rwanda, South Africa, South Sudan, Tanzania, Uganda, Zambia, Zimbabwe.

†Genus ***Vampyravus*** Schlosser, 1910

*1910. *Vampyravus* Schlosser, Zool. Anz., 35: xxx. (Current Combination).
1911. *Provampyrus* Schlosser, Beitr. Paläont. Geol. Öst.-Ung., 24: xxx. - Comments: This is possibly a synonym of *Vampyravus* Schlosser, 1910.

TAXONOMY:
The position of this genus is still uncertain.

Sigé (1985) [in Ravel *et al.* (2014: 696)] found some similarities between the humerus (the only known specimen of this species) and the Natalidae, but Gunnell *et al.* (2009) indicated that the morphology of this bone was more compatible with that of the Emballonuridae and Rhinopomatidae.

Currently recognized species of the genus *Vampyravus*: †***orientalis*** Schlosser, 1910.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Time frame - Late Eocene, Early Oligocene (Rupelian).

†*Vampyravus orientalis* Schlosser, 1910

*1910. *Vampyravus orientalis* Schlosser, Zool. Anz., 35: xxx. Type locality: Egypt: Fayum: Jebel Qatrani Formation. Holotype: SMNS unnumbered |TS1092|. - Comments: This is a fossil form from Egypt's Lower Oligocene, of which the type (the right humerus) is in the collection of the SMNS. (Current Combination).

1911. *Provampyrus orientalis* Schlosser, Beitr. Paläont. Geol. Öst.-Ung. (Name Combination).

TAXONOMY:
Gunnell *et al.* (2008: 5) indicate that the holotype is from an unknown horizon in the Jebel Qatrani Formation. The humerus resembles in size to *Rousettus aegyptiacus* (49 mm) and could possible represent the same taxon as *Philisis sphingis*, only known from teeth.

Bown *et al.* (1982: 624) include this taxon in the "*Phyllostomatidae*?".

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Early Oligocene (Rupelian - 32.46 - 29 mya - Brown *et al.*, 2019: Suppl.).

Subfamily Vespertilioninae J. E. Gray, 1821

*1821. *Vespertilioninae* J. E. Gray, London Med. Repos., 15: 299. Publication date: 1 April 1821. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. (Current Combination).

1821. *Vespertilionini* J. E. Gray, London Med. Repos., 15: 299. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Originally included the genera *Megadermes* [sic = *Megaderma*] É. Geoffroy, 1810; *Rhynolophus* [sic = *Rhinolophus*] Lacépède, 1799; *Nycterus* [sic = *Nycteris*] É. Geoffroy and G. Cuvier, 1795; *Rhynopoma* [sic = *Rhinopoma*] É. Geoffroy, 1818; *Thaphosores* [sic = *Taphozous*] É. Geoffroy, 1818; *Vespertilio* Linnaeus, 1758; *Pecotus* [sic = *Plecotus* É. Geoffroy, 1818; and Barbastella *J. Gray*, 1821 (see Jackson and Groves, 2015: 271). Accepted as tribe by Koopman and Jones (1970: 27), McKenna and Bell (1997: 318), Hoofer and Van Den Bussche (2003: 38) and Simmons (2005: 484) (see Jackson and Groves, 2015: 271).

1865. *Nyctophilinae* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 1865: 524. - Comments: Type genus: *Nyctophilus* Leach, 1821. Considered a valid subfamily by Hall and Kelson (1959: 201) [including *Antrozous*], Corbet and Hill (1992: 156), but see Hoofer and Van Den Bussche (2003: 1), who reject this (actually Peters uses "Nyctophili").

1878. *Vespertiliones* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 168. Publication date: 15 June 1878. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Dobson (1878: 168) introduced the name Vespertiliones in his key as "Group II" including the bats of the Vespertilioninae subfamily (see Jackson and Groves, 2015: 227). Originally included the genera *Vesperugo* Keyserling and Blasius, 1839 [= *Vespertilio* Linnaeus, 1758]; *Chalinolobus* Peters, 1865; *Scotophilus* Tomes, 1857; *Nycticejus* [sic = *Nycticeius*] Rafinesque, 1819; *Atalapha* Rafinesque, 1814 [= *Nyctalus* Bowdich, 1825]; *Harpiocephalus* J. Gray, 1842; *Vespertilio* Linnaeus, 1758; and *Kerivoula* J. Gray, 1842. Not Vespertiliones Pallas, 1767, nor Vespertiliones Peters, 1865.

1897. *Vespertilioninæ* Miller, N. Am. Fauna, 13: 41, 54. Publication date: 16 October 1897. - Comments: Type genus: *Vespertilio* Linnaeus, 1758. Originally included the genera *Dasypterus* Peters, 1870 [= *Lasiurus* J. Gray, 1831]; *Rhogeëssa* H. Allen, 1866; *Nycticeius* Rafinesque, 1819; *Lasiurus* J. Gray, 1831; *Vespertilio* Linnaeus, 1758; *Pipistrellus* Kaup, 1829; *Lasionycteris* Peters, 1865; and *Myotis* Kaup, 1829 (see Jackson and Groves, 2015: 270).

1942. *Nycticeini* Tate, Bull. Am. Mus. Nat. Hist., 80 (7): 280. Publication date: 27 November 1942. - Comments: type genus: *Nycticeius* Rafinesque, 1819. Introducted as tribe and originally included the genera *Scoteinus* Dobson, 1875 [= *Scotomanes* Dobson, 1875]; *Nycticeius* Rafinesque, 1819; *Rhogeëssa* H. Allen, 1866; *Baeodon* Miller, 1906 [= *Rhogeëssa* H. Allen, 1866]; *Scotoecus* Thomas, 1901; *Scotophilus* Leach, 1821; *Scotomanes* Dobson, 1875; and *Otonycteris* Peters, 1859 (see Jackson and Groves, 2015: 276).

1987. *Eptésiformes* Menu, Palaeovert., 17 (3): 78, 104, 134. Publication date: 31 March 1987. - Comments: Type genus: *Eptesicus* Rafinesque, 1820. Originally included the genera *Eptesicus* Rafinesque, 1820 and *Nycterikaupius* Menu, 1987. Emended by McKenna and Bell (1997: 318) as published as 'les eptésiformes' as it seems to meet the requirements of Article 11 of the Code (ICZN, 1985a: 19) (see Jackson and Groves, 2015: 271).. Jackson and Groves (2015: 271) erroneously mentioned the genus *Nyctalus* Bowdich, 1825 as type genus.

1987. *Leuconoïdes* Menu, Palaeovert., 17 (3): 77, 82. Publication date: 31 March 1987. - Comments: Type genus: *Leuconoe* Boie, 1830. Introduced without formal rank, and originally including the genera *Leuconöe* Boie, 1830 [= *Myotis* Kaup, 1829]; *Pizonyx* Miller, 1906 [= *Myotis* Kaup , 1829]; and *Perimyotis* Menu, 1984 [= *Pipistrellus* Kaup, 1829] (see Jackson and Groves, 2015: 271). Emended by McKenna and Bell (1997: 316) to 'les leuconoïdes" as it apparently meets the requirements of Article 11 of the Code (ICZN, 1985a: 19) (see Jackson and Groves, 2015: 271).

1987. *Néoeptésiformes* Menu, Palaeovert., 17 (3): 77, 123, 134. Publication date: 31 March 1987. - Comments: Type genus: *Nyctalus* Bowdich, 1825. Originally included the genera *Hypsugo* Kolenati, 1856; *Tylonycteris* Peters, 1872; and *Mimetillus* Thomas, 1904. Emended by McKenna and Bell (1997: 318) as published as 'les néoeptésiformes' as it seems to meet the requirements of Article 11 of the Code (ICZN, 1985a: 19) (see Jackson and Groves, 2015: 271)..

1987. *Nyctaliformes* Menu, Palaeovert., 17 (3): 77, 95, 133. Publication date: 31 March 1987. - Comments: Type genus: *Nyctalus* Bowdich, 1825. Its original rank was unclear, but it was ranked in the "Les Nyctaloïdes" and included the genera *Pipistrellus* Kaup, 1829; *Glischropus* Dobson, 1875; *Philetor* Thomas, 1902; *Scotoecus* Thomas, 1901; and *Nyctalus* Bowdich, 1825 (see Jackson and Groves, 2015: 274). Synonymized with

Vespertilioninae by McKenna and Bell (1997: 318), but with the tribe Pipistrellini by Jackson and Groves (2015: 274).

1987. *Nyctaloïdes* Menu, Palaeovert., 17 (3): 77, 94. Publication date: 31 March 1987. - Comments: Type genus: *Nyctalus* Bowdich, 1825. Originally, the rank was unclear, and it included the Nyctaliformes Menu, 1987, Eptésiformes Menu, 1987 and Néoeptésiformes Menu, 1987 (see Jackson and Groves, 2015: 274). McKenna and Bell (1997: 318) synonymized it with the subfamily Vespertilioninae, whereas Jackson and Groves (2015: 274) synonymized it with the tribe Pipistrellini.

2018. *Vespertilininae:* Foord, Swanepoel, Evans, Schoeman, Erasmus, Schoeman, Keith, Smith, Mauda, Maree, Nembudani, Dippenaar-Schoeman, Munyai and Taylor, PLoS ONE, 13(5): e0194336: 6. Publication date: 8 May 2018. (Lapsus).

2025. *Vespertilionae:* Guan, Huang, Huang, Zhou, Yang, Yu, Guo, Feng, Wu, Hu and Wei, Sci. China Life Sci., xxx: 1. Publication date: 18 July 2025. (Lapsus).

TAXONOMY:

Bronner *et al.* (2003) state that the classification of the subfamily Vespertilioninae was historically based on facial shortening and dental reduction characters (Miller, 1907), and augmented by bacula morphology (Hill and Harrison, 1987). Interrelationships among *Eptesicus* and *Pipistrellus* species have long been contentious and have for the most part remained unresolved. The principal character used to diagnose these genera was the presence (*Pipistrellus*) or absence (*Eptesicus*) of the anterior upper premolar. However, this character is variable in both genera Wallin, 1969; Koopman, 1975; Heller and Volleth, 1984). Baculum morphology (Heller and Volleth, 1984; Hill and Harrison, 1987) and karyological properties (Heller and Volleth, 1984; Zima and Horáček, 1985) also vary markedly among species assigned to *Pipistrellus* using dental characters. Heller and Volleth (1984) concluded that the genus *Eptesicus* is characterised by a distinct karyotype of 2*n* = 50, and removed those taxa with 2*n* = >44 (*E. capensis* and some Australian species) from *Eptesicus* to *Pipistrellus*, a treatment they considered consistent with patterns of variation in baculum morphology.

After extensively reviewing variation in baculum morphology, Hill and Harrison (1987) divived *Pipistrellus* into seven subgenera. They transferred *anchietae* (see Kock (2001c: 246) for justification of spelling) to the subgenus *Hypsugo* and four African species of *Eptesicus* (*capensis, melckorum, zuluensis* and *rendalli*) to the subgenus *Neoromicia* within *Pipistrellus*. *Hypsugo* was subsequently raised to generic rank on the basis of detailed morphological and biochemical analyses (Horáček and Hanák, 1986; Ruedi and Arlettaz, 1991), a treatment supported also by cytogenetic evidence showing radical reorganization of the genome and karyotypic evolution in *H. anchietae* (Kearney *et al.*, 2002). Most of the other (extralimital) subgenera were subsequently also awarded full genus status, with the exception of *Pipistrellus* and *Neoromicia*. McBee *et al.* (1987) and Morales *et al.* (1991) provided further cytogenetic and electrophoretic evidence supporting the findings of Heller and Volleth (1984), but argued that further studies were needed to justify the inclusion of these species in *Pipistrellus*. Koopman (1993a), therefore, recognised *Neoromicia*, but retained it as a subgenus of *Eptesicus*.

Volleth and Heller (1994) subsequently published more karyotypic evidence supporting the inclusion of *Neoromicia* within *Pipistrellus*, a treatment formalised by Koopman (1994). Most recently, Volleth *et al.* (2001) showed that the four African species included in *Neoromicia* (*capensis, nanus, rendalli* and *zuluensis*) display karyotypic synapomorphies typical of the Vespertilionini, in contrast to the other African *Pipistrellus* that show cytogenetic traits characteristic of the Pipistrellini. *Neoromicia* should thus be elevated to full generic rank to avoid recognising a paraphyletic *Pipistrellus*. Cladistic analysis of chromosomal data (showing that the four *Neoromicia* species also share three Robertsonian fusions), and of baculum characters in southern African species, provide additional support for recognising *Neoromicia* as a distinct genus (Kearney *et al.*, 2002). Consequently, the genus *Eptesicus* in southern Africa is represented by only one species, namely *E. hottentotus*.

Using digenomic DNA, Roehrs *et al.* (2010: 1073) were able to distinguish 6 tribes in the Vespertilioninae: Antrozoini, Lasiurini, Scotophilini, Vespertilionini, and 2 new unnamed tribal clades, the perimyotine group and the hypsugine group. They were unable to confirm a Nycticeiini-Eptesicini group, nor were they able to separate the Plecotini.

Guan *et al.* (2025: 3) also recovered six tribes, with Scotophilini and Lasiurini forming the basal clade and Plecotini being sister to Vespertilionini, Pipistrellini and Eptesicini, whereby Vespertilionini is closer to Pipstrellini than to Eptesicini.

COMMON NAMES:

Czech: praví netopýři. Ukrainian: Лилики [= Lylyky]

HABITS:
Rainho *et al.* (2023: 7) assigned the *Pipistrellus, Afronycteris, Neoromicia* and *Nycticeinops* bats in Meru county (Kenya) to a medium-to-high-flying guild flying at altitudes between 2 and 10 m.

PARASITES:
DIPTERA
Nycteribiidae
Nycteribia tecta Theodor, 1957 (Haeselbarth *et al.*, 1966: 110 as *Eptesicus sp.*).

SIPHONAPTERA
Ischnopsyllidae
Dampfia grahami (Waterston, 1915) collected in the Free State and KwaZulu Natal, South Africa where the host is assumed to belong to the genus *Eptesicus* now possibly referring to *Neoromicia* (Haeselbarth *et al.*, 1966: 187).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Algeria, Angola, Cameroon, Congo, Congo (Democratic Republic of the), Djibouti, Ghana, Kenya, Madagascar, Mali, Namibia, Rwanda, Senegal, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

TRIBE Nycticeiini Gervais, 1855

1855. *Nycticeiini* Gervais, in: F. Comte de Castelnau, Exped. Partes Cen. Am. Sud.Zool, Zool (Sec 7), Vol 1, pt 2: 71, footnote. Publication date: 23 July 1855. - Comments: Type genus: *Nycticeius* Rafinesque, 1819. Introduced as tribe (Nycticéins) and originally included the genera *Atalapha* Rafinesque, 1814 [= *Nyctalus* Bowdich, 1825] and *Nycticejus* [sic = *Nycticeius*] Rafinesque, 1819 (see Jackson and Groves, 2015: 275, who also recognized it as a valid tribe). (Current Spelling).

*1855. *Nycticeina* Gervais, in: F. Comte de Castelnau, Exped. Partes Cen. Am. Sud, Zool (Sec 7), Vol 1, pt 2: 71, footnote. Publication date: 23 July 1855. - Comments: Type genus: *Nycticeius* Rafinesque, 1819. Introduced as tribe (Nycticéins) and originally included the genera *Atalapha* Rafinesque, 1814 [= *Nyctalus* Bowdich, 1825] and *Nycticejus* [sic = *Nycticeius*] Rafinesque, 1819 (see Jackson and Groves, 2015: 275).

1872. *Nycticejinae* Gill, Smiths. Misc. Coll., 11 (1): 17. Publication date: November 1872. - Comments: Type genus: *Nycticeius* Rafinesque, 1819. Introduced as subfamily but considered a synonym of the tribe Nycticeiini by Jackson and Groves (2015: 276).

Genus ***Cnephaeus*** Kaup, 1829

*1829. *Cnephæus* Kaup, Skizzierte Entwicklungs-Geschichte Natürliche Systematik der Europäische Thierwelt, 1: 103. Publication date: 1829. - Comments: Type species: *Vespertilio serotinus* Schreber, 1774. Considered a valid subgenus by Hoofer and Van Den Bussche (2003: 38), including *serotinus* and *hottentotus*.

TAXONOMY:
Artyushin *et al.* (2018: 475) indicated that the previously proposed inclusion of the Old World representatives of the subgenus *Cnephaeus* into the genus *Eptesicus* could not be confirmed by their analyses of five nuclear and one mitochondrial (cyt-*b*) genes.

Subsequently, Cláudio *et al.* (2023: 1) restricted the genus name *Eptesicus* to *E. fuscus* (Palisot de Beauvois, 1796) and *E. guadeloupensis* Genoways and Baker, 1975, both of them New World species. The next available generic name for the Old World taxa is *Cnephaeus* Kaup, 1829.

Currently, Simmons and Cirranello (2024a) do not recognize subgenera, but they recognize the following species in the genus *Cnephaeus*:
Subgenus *Cnephaeus* Kaup, 1829: *anatolicus* Felten, 1971 – Anatolia (Turkey), Cyprus, Lebanon to SW Iran; Kurdistan; ***bottae*** (Peters, 1869); *gobiensis* Bobrinskii, 1926 – Iran, northern Afghanistan, Kashmir, Pakistan and Nepal, southern Russia, Mongolia (Simmons, 2005: 454); ***hottentotus*** (A. Smith, 1833); ***isabellinus*** (Temminck, 1840); *japonensis* Imaizumi, 1953 – Honshû Isl (Japan) (Simmons, 2005: 455); *kobayashii* Mori, 1928 – Korea (Simmons, 2005: 455); *nilssonii* (Keyserling and Blasius, 1839) – western and eastern Europe to eastern Siberia and northwestern China, north beyond Artic Circle in Scandinavia, south to Bulgaria, Iraq, the Elburz Mtns (northern Iran), The Pamirs and western China (not Tibet), Korea, Hokkaido (Japan), Sakhalin Isl (Russia) (Simmons, 2005: 456); *ognevi* Bobrinskii, 1918 – Transcaucasia to Pakistan, Afghanistan and NW China; *pachyomus* (Tomes, 1857) – Afghanistan, Pakistan and NW India (Rajasthan, Kashmir); *pachyotis* (Dobson, 1871) – Bangladesh, northeastern India, Tibet (China), northern Burma, northern Thailand (Simmons, 2005: 456);

platyops (Thomas, 1901); *serotinus* (Schreber, 1774) – western Europe through Turkey and southern Asiatic Russia to Himalayas, Thailand and China, north to Korea, Taiwan, south England, most islands in Mediterranean, possibility north Africa (Simmons, 2005: 456); *tatei* Ellerman and Morrison-Scott, 1951 – northeastern India (Simmons, 2005: 456).
Subgenus *Rhinopterus* Miller, 1906: ***floweri*** (de Winton, 1901).

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Avery (2007: 619) reported on the presence of "*Eptesicus*" sp. in Pleistocene deposits at Wonderwerk Cave, South Africa.

PARASITES:
DIPTERA
Nycteribiidae
Dick *et al.* (2023) mentioned the following nycteribiid flies have been found on African "*Eptesicus*" sp.: *Basilia (Basilia) robusta* Theodor, 1956 and *Nycteribia schmidlii scotti* Falcoz, 1923. However, it is not clear whether these reports refer to what is currently considered *Cnephaeus*, *Neoromicia* or *Pseudoromicia* (or perhaps any other "little brown bat").

Cnephaeus bottae (Peters, 1869)

*1869. *Vesperus Bottae* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 406. Type locality: Yemen: "Yemen": Restricted to W Yemen, between Al Hudayda, Ta'izz and Al Mukha, according to Karami *et al.* (2009: 70). Holotype: MNHN ZM-MO-1987-297: ad, skull and alcoholic. Collected by: Dr. Paolo Emilio Botta; collection date: 1837. Number 212 in Rode (1941: 247). Rode (1941) mentions a male specimen, whereas Peters (1869a: 406) mentions a female. - Etymology: In honour of Paul-Emile Botta (1802 - 1870), who collected the type specimen (see Kozhurina, 2002: 14).
1887. *Vesperugo (Vesperus) Innesi* Lataste, Ann. Mus. civ. Stor. nat. Genova, ser 2, 4 (OS 24): 625, 2 text-figs. Publication date: 25 July 1887. Type locality: Egypt: Cairo [30 03 N 31 15 E]. [Goto Description]. Lectotype: NHMUK 1919.7.7.3528: sad ♀, skull and alcoholic. Collected by: Dr. Walter F. Innes Bey; collection date: 1885. See Qumsiyeh (1985). Paralectotype: MSNG unknown |1|: ♂. . - Etymology: In honour of M. Walter Innes, curator of the Medical Museum, who collected the type specimens (see Lataste, 1887b: 628).
1891. *Vesperugo innesi:* Noack, Jb. Hamb. Wiss. Anst., 9: 139. (Name Combination).
1902. *Vespertilio innesi:* Anderson and de Winton, Zoology of Egypt: Mammalia, 121. (Name Combination).
1919. *E[ptesicus] innesi:* Thomas, J. Bomb. nat. Hist. Soc., 26: 746.
1932. *Eptesicus innesi:* Flower, Proc. zool. Soc. Lond., 101: 382. (Name Combination).
1942. *Eptesicus [(Eptesicus)] bottae:* Tate, Bull. Am. Mus. Nat. Hist., 80: 275, 277. (Name Combination).
1955. *Eptesicus isabellinus innesi:* Sanborn and Hoogstraal, J. Egypt. Publ. Health Ass., 30 (4): xxx.
1956. *Eptesicus isabellinus bottae:* Harrison, Proc. zool. Soc. Lond., 127: ???. (Name Combination).
1963. *E[ptesicus] bottae:* Harrison, Z. Säugetierk., 28 (1): 109. (Name Combination).
1964. *Eptesicus bottae bottae:* Harrison, Mammals of Arabia, 140. (Name Combination).
1964. *Eptesicus bottae innesi:* Harrison, Mammals of Arabia, 140. (Name Combination).
1964. *Eptesicus bottae:* Harrison, Mammals of Arabia, 140. (Name Combination).
1971. *Eptesicus [(Eptesicus)] bottae innesi:* Hayman and Hill, Mammals of Africa: Chiroptera, 45. (Name Combination).
1990. *Eptesicus (Eptesicus) bottae bottae:* Nader and Kock, Senckenb. biol., 79 (1/3): 2 (for 1989). (Name Combination).
1994. *E[ptesicus (Eptesicus)] b[ottae] bottae:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 120. (Name Combination).
1994. *E[ptesicus (Eptesicus)] b[ottae] innesi:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 120. (Name Combination).
2023. *Cnephaeus bottae:* Cláudio, Novaes, Gardner, Nogueira, Wilson, Maldonado, Oliveira and Moratelli, Zoologia, 40 (e22029): 13, 21. Publication date: 17 July 2023. (Current Combination).

TAXONOMY:
Revised by Nader and Kock (1990a).

Cláudio *et al.* (2023: 11) transferred this species from the genus *Eptesicus* to *Cnephaeus*.

Populations in Turkey and northern Syria (and possibly other areas) are considered by Felten (1971) and Benda *et al.* (2006) to be a separate species: *Cnephaeus anatolicus* Felten 1971.

Based on mtDNA analyses, Artyushin *et al.* (2018: 473) distinguished two clusters in "*E. bottae*": one including "*E. b. ognevi*" and the second including "*E. b. hingstoni*", "*E. b. innesi*" and "*E. b. taftanimontis*", and the differences between them are almost large enough to distinguish them as separate species. The relation of these taxa to "*E. b. bottae*" still needs to be determined.

COMMON NAMES:
Albanian: Serotinë e Botta's. Arabian: Khaffash. Armenian: Ամպպատային մաշկեղ. Azerbaijani: Səhra gönlücəsi. Basque: Botta serotino. Belarusian: Кажан Бота. Bosnian: Botin šišmiš. Breton: Serotin Botta. Bulgarian: Полунощен прилеп на Бот. Castilian (Spain): Murciélago hortelano de Botta, La serotina de Botta. Catalan (Spain): Ratpenat dels graners de Botta.

Croatian: Bottin noćnjak. Czech: Netopýr Bottův, Netopýr Ogněvův. Danish: Bottas sydflagermus. Dutch: Botta's vleermuis. English: Botta's Serotine, Botta's Serotine Bat. Estonian: Kõrbe-nahkhiir. Finnish: Turkinserotiini. French: Sérotine de Botta. Frisian: Botta's lette flearmûs. Galician (Spain): Morcego das hortas de Botta. Georgian: უდაბნოს მეგვიანე. German: Bottas Breitflügelfledermaus, Bottas Fledermaus. Greek: Ασιατική τρανονυχτερίδα. Hebrew: אפלול מצוי, Aflul Matzuy, Aflul Matsui. Hungarian: Botta-késeidenevér. Irish Gaelic: Ialtóg Botta. Italian: Serotino di Botta. Latvian: Botas sikspārnis. Lithuanian: Uolinis šikšnys. Luxembourgish: Botta-Fliedermaus. Macedonian: Ботев лилјак. Maltese: Serotin ta' Botta. Montenegrin: Svijetlotrbušasti slijepi miš. Norwegian: Blekflaggermus. Polish: Mroczek Botty. Portuguese: Morcego-hortelão de Botta. Rhaeto-Romance: Serotin da Botta. Romanian: Liliacul lui Botta. Russian: Кожан пустынный. Serbian: Блискоисточни поноћњак [= Bliskoistočni ponoćnjak]. Scottish Gaelic: Ialtag Botta. Slovak: Večernica Bottova. Slovenian: Svetlotrebušni poznik. Swedish: Blek sydfladdermus. Turkish: Bottae'nin Genişkanatlı Yarasası. Ukrainian: илик (Пергач) пустельний. Welsh: Ystlum adain-lydan Botta.

Conservation status:

Global Justification

The species as described has a relatively wide range. Although generally considered uncommon it is described as locally common in at least part of the range (Egypt). No major threats are known. Hence it is listed as Least Concern (LC ver 3.1 (2001)) (Aulagnier *et al.*, 2008d; IUCN, 2009).

Assessment History

Global

2008: LC ver 3.1 (2001) (Aulagnier *et al.*, 2008d; IUCN, 2009). 2004: LC ver 3.1 (2001) (Benda and Juste, 2004; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

None known.

Legal Status

Protected through Eurobats (Bonn Convention) and Bern Convention, and included in Annex IV of EU Habitats and Species Directive in the very small part of the range where these apply.

Major threats:

The species requires ruins which are decreasing in number and can be disturbed by tourists (A. Karatas *pers. comm.,* 2007), however, this is not thought to be a major threat to the species as a whole at present (Aulagnier *et al.*, 2008d; IUCN, 2009). Bilgin *et al.* (2012: 434) predict that climatic change will result in a major range contraction for this species.

Holderied *et al.* (2005: 6) indicated that this species is vulnerable for light pollution.

Conservation actions:

Aulagnier *et al.* (2008d) [in IUCN (2009)] suggest that taxonomic work is required to determine if more than one species is involved here and what the ranges of these are, and what their population status is.

General distribution:

Cnephaeus bottae is a Palaearctic species, occurring from the eastern Mediterranean around margins of Arabian peninsula to Iraq, Iran and southern Caucasus states; also central Asia to India, northwestern China and possibly Mongolia.

Native: Afghanistan; Armenia; Azerbaijan; Egypt (Sinai); Georgia; Greece (East Aegean Is.); India; Iran, Islamic Republic of; Iraq; Israel; Jordan; Kazakhstan; Kyrgyzstan; Lebanon; Oman; Pakistan; Palestinian Territory, Occupied; Saudi Arabia; Syrian Arab Republic; Tajikistan; Turkey; Turkmenistan; United Arab Emirates; Uzbekistan; Yemen.

Presence uncertain: Djibouti; Eritrea; Mongolia; Russian Federation; Somalia; Sudan.

Dental Formula:

The permanent dental formula is as follows: $I^{2}/_{3}$, $C^{1}/_{1}$, $PM^{1}/_{2}$, $M^{3}/_{3}$ = 32.

Detailed morphology:

Baculum

Hill and Harrison (1987).

Sexual dimorphism:

Korine (2021: 3) mentions that a weak sexual dimorphism exists, but does not provide any details.

Echolocation:

Walters *et al.* (2012: suppl.) report the following figures for 26 calls (21 sequences) from bats from Egypt and Israel: duration: 8.35 ± 2.16 ms, F_{max}: 44.18 ± 6.90 kHz, F_{min}: 30.44 ± 1.10 kHz, bandwidth: 13.73 ± 6.25 kHz, F_{peak}: 33.47 ± 1.80 kHz.

In Jordan, the following parameters were reported by Benda *et al.* (2010b: 204) for 146 calls: F_{start} 53.6 ± 9.3 (37.9 - 83.0) kHz, F_{end}: 30.4 ± 1.5 (27.0 - 33.7) kHz, F_{peak}: 34.3 ± 1.8 (29.6 - 39.5) kHz,

Pulse duration: 5.5 ± 1.3 (2.7 - 9.4) ms, and Inter-pulse interval: 123.6 ± 39.7 (52.0 - 241.0) ms.

Hackett *et al.* (2016: 223) reported on 147 calls from Israel: Pulse duration: 6.19 ± 1.51 ms, F_{start}: 42.63 ± 4.05 (38 - 51) kHz, F_{end}: 30.51 ± 1.21 (28.8 - 35.0) kHz, F_{peak}: 32.08 ± 1.29 (29.2 - 37.1) kHz.

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats): F_{peak}: 32.08 kHz, F_{start}: 42.63 kHz, F_{end}: 30.51 kHz, Band width: 12.12 kHz, and duration: 6.19 ms.

The loudest *C. bottae* call registered by Holderied *et al.* (2005: 1321) was at 133·dB·peSPL. They also determined that the maximum detection distance for large flying prey or conspecifics was 21 m.

Molecular Biology:

Karyotype

Volleth *et al.* (2001) reported 2*n* = 50, FN = 48, BA = 0, a metacentric X chromosome and a metacentric Y chromosome for a male from Greece.

Roost:

Korine (2021: 7) mentioned that many roosts are in ruins.

Diet:

Hackett *et al.* (2013: 7) classify *Cnephaeus bottae* as a background cluttered space aerial insectivore.

In the Dead Sea area of Israel Hymenoptera, Lepidoptera and Coleoptera form the most important groups of food items, whereas in Syria, Coleoptera were the prime food category, followed by Heteroptera and Auchenorrhyncha, and in Iran Hymenoptera (Formicoidea) (89 % volume) and Coleoptera (Scarabaeidae) were the most important food items, indicating that *C. bottae* is a flexible species feeding opportunistically especially on ants and beetles. (Benda *et al.*, 2012a: 387).

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 106 minutes, and a digestibility rate of 76.6 %.

Population:

Structure and Density

Reported to be locally common in Egypt, with colonies of up to 200 females being reported (African Mammal Assessment Workshop, 2004).

Trend

2008: Unknown (Aulagnier *et al.*, 2008d; IUCN, 2009). *Cnephaeus bottae* populations within the Asia Minor and Levant region are unknown population trend, under predictive climate change scenarios (Bilgin *et al.*, 2012: 433).

Activity and Behaviour:

In the Negev desert, Polak *et al.* (2011: 25) found that this species only passed through areas lighted by street lamps (flight speed: 9.25 ± 1.19 m/s), and never foraged there (contrary to *Pipistrellus kuhlii*. The flight speed during foraging in dark areas was 5.7 ± 1.3 m/s.

Reproduction and Ontogeny:

Garbino *et al.* (2021: Suppl.) report this species as being polytocous (more than one young per litter).

Postnatal Development:

Korine (2021: 3) mentions that age classification based on the ossification of the epiphyses becomes difficult once the young start to fly independently.

Parasites:

DIPTERA

Nycteribiidae

In bats from a non-specified country, Júnior *et al.* (2020: Suppl.) mention the presence of *Phthiridium integrum* (Theodor and Moscona, 1954).

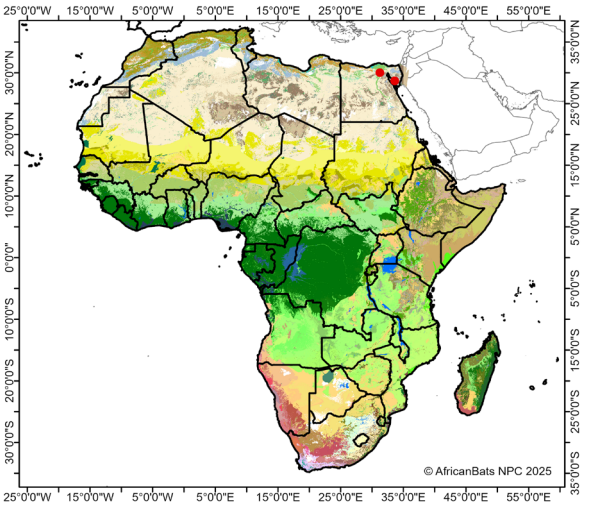

Figure 298. Distribution of *Cnephaeus bottae*.

Distribution based on voucher specimens:

Egypt, Yemen.

Cnephaeus hottentotus (A. Smith, 1833)

*1833. *Vespertilio Hottentota* A. Smith, S. Afr. Quart. J., ser 2, 1 (2): 59. Publication date: November 1833. Type locality: South Africa: Cape province: Uitenhage [ca. 33 45 S 25 25 E]. [Goto Description]. - Comments: Type locality restricted to Uitenhage (from Uitenhage and Albany) by Ellerman *et al.* (1953): see Meester *et al.* (1986: 57).

1840. *Vespertilio megalurus* Temminck, Monographies de mammalogie ou description de quelques genres de mammifères, dont les espèces ont été observées dans les différens musées de l'Europe. Tome Seconde, 2 (13): 206. Publication date: 1840. Type locality: South Africa: "Interior of South Africa". [Goto Description]. Syntype: RMNH MAM.35893: ad, mounted skin and skull. Collected by: Dr. Hubertus Benedictus Van Horstok. The RMNH catalog mentions two numbers: 35893.a (skull + loose bones) and 35893.b (mounted skin). - Comments: Type specimen: RMNH. (Name Combination).

1849. *Vespertilio minutus* A. Smith, Illustrated Zoology of South African Mammals, pl 51 and text. - Comments: Preoccupied by *Vespertilio minutus* Montagu, 1808 and *Vespertilio minuta* Temminck, 1840. (Name Combination).

1855. *V[espertilio] Smithii* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 5: 747, footnote. Publication date: 28 September 1855. Type locality: South Africa: "South Africa". - Comments: . (Name Combination).

1855. *Vespertilio (Vesperus) megalurus:* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 5: 747. (Name Combination).

1855. *Vespertilio smithii* Wagner, Supplementband 5. In: Schreber, J.C.D. von: Die Säugethiere in Abbildungen nach der Natur, mit Beschreibungen, 747 [Goto Description]. (Name Combination).

1860. *Cateorus megalurus:* Kolenati, Monographie der Europäischen Chiroptern, 20. (Name Combination).

1878. *Vesperugo (Vesperus) megalurus:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 199. Publication date: 15 June 1878. (Name Combination).

1878. *Vesperugo (Vesperus) smithii:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 198. Publication date: 15 June 1878. - Comments: Dobson (1878) considered it to be a synonym of *Vesperugo (Vesperus) capensis*. (Name Combination).

1887. *Vesperus megalurus:* Jentink, Mus. Hist. nat. Pays-Bas, Leyden, 275. (Name Combination).

1897. *Vesperugo (Eptesicus) megalurus:* Thomas, Proc. zool. Soc. Lond., 1896, IV: 791. (Name Combination).

1901. *Vespertilio (Eptesicus) megalurus:* Sclater, Mammals of South Africa, 123. (Name Combination).

1924. *E[ptesicus] smithi:* Roberts, Ann. Transv. Mus., 10 (2): 60. (Name Combination).

1931. *Eptesicus megalurus:* Hewitt, A guide to the Vertebrate fauna of the Eastern Cape Province, 23. (Name Combination).

1938. *Scotophilus angusticeps* Shortridge and Carter, Ann. S. Afr. Mus., 32 (4): 282. Publication date: July 1938. Type locality: South Africa: Western Cape province: 10 mi (16 km) N Citrusdal: Hex River Estate [33 30 S 19 35 E, 100 m]. [Goto Description]. Holotype: KM 1984: ad ♀. Collected by: Captain Guy Chester Shortridge and Thomas Donald Carter; collection date: 28 December 1937; original number: 1937. Cotype: KM 1985: ad ♀. Collected by: Captain Guy Chester Shortridge and Thomas Donald Carter; collection date: 3 January 1938; original number: 3308. (Name Combination).

1939. *Eptesicus smithii:* G.M. Allen, Bull. Mus. comp. Zool., 83: 87. (Name Combination).

1942. *Eptesicus megalurus pallidior* Shortridge, Ann. S. Afr. Mus., 36: 37. Type locality: South Africa: NW Cape province: Klein Namaqualand, Orange River: Goodhouse [ca. 28 54 S 18 15 E, 300 ft]. [Goto Description]. Holotype: KM 1986: ad ♀. Collected by: Captain Guy Chester Shortridge; collection date: 29 December 1936; original number: 1157. - Comments: Holotype (ad F, orig nr. 1157) possibly in the collection of the NHMUK or KM. (Name Combination).

1946. *E[ptesicus] h[ottentotus] hottentotus:* Roberts, Ann. Transv. Mus., 20 (4): 305. (Name Combination).

1946. *Eptesicus hottentotus bensoni* Roberts, Ann. Transv. Mus., 20 (4): 305. Type locality: Malawi: Ncheu [=Ntcheu] [14 49 S 34 38 E, 1 100 m]. [Goto Description]. Holotype: TM 9167: ad ♂, skin and skull. Collected by: Constantine ("Con") Walter Benson; collection date: 31 October 1939; original number: 94. (Name Combination).

1951. *Eptesicus hottentotus angusticeps:* Roberts, Mammals of South Africa, 551. (Name Combination).

1951. *Eptesicus hottentotus hottentotus:* Roberts, Mammals of South Africa, 86. (Name Combination).

1951. *Eptesicus hottentotus pallidior:* Roberts, Mammals of South Africa, 86. (Name Combination).

1953. *Eptesicus (Eptesicus) hottentotus bensoni:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 76. (Name Combination).

1953. *Eptesicus (Eptesicus) hottentotus hottentotus:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 76. (Name Combination).

1953. *Eptesicus (Eptesicus) hottentotus pallidior:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 76. (Name Combination).

1953. *Eptesicus (Eptesicus) hottentotus:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 76. (Name Combination).

1954. *Eptesicus hottentotus:* Ellerman, Ann. Univ. Stellenbosch, 30 A (1): 32. (Name Combination).

1969. *Eptesicus serotinus hottentotus:* Kock, Abh. Senckenberg. naturforsch. Ges., 521: 214. (Name Combination).

1986. *Eptesicus hottentotus portavernus* Schlitter and Aggundey, Cimbebasia, (A) 8 (20): 172, fig 5. Publication date: 14 February 1986. Type locality: Kenya: Rift Valley province: Naivasha district: 20 km S, 14 km W Naivasha: Hell's Gate Canyon (=Njorowa Gorge) [00 54 S 36 19 E]. [Goto Description]. Holotype: CM 89000: ad ♂, skin and skull. Collected by: Dr. Duane Albert Schlitter; collection date: 30 September 1985; original number: 6906. See Schlitter and Aggundey (1986: 172). (Name Combination).

1986. *Eptesicus hottentotus protavernus:* Schlitter and Aggundey, Cimbebasia, (A) 8 (20): 174. (Lapsus).

1994. *E[ptesicus (Eptesicus)] h[ottentotus] portavernus:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 120. (Name Combination).

2003. *Eptesicus (Cnephaeus) hottentotus:* Hoofer and Van Den Bussche, Acta Chiropt., 5 (Suppl): 38. (Name Combination).

? *Cnephaeus hottentotus:* (Current Combination).

TAXONOMY:

Figure 299. *Cnephaeu) hottentotus* (TM 48193) caught at Farm Schaapplaats, Free State, South Africa.

Revised by Schlitter and Aggundey (1986), who described a new subspecies from Kenya - "*Eptesicus hottentotus portavernus*". Besides the nominate form and the newly described subspecies, their work recognised one other subspecies "*E. h. bensoni*" (Roberts, 1946), but not "*E. h. pallidior*" (Shortridge, 1942), which they synonymised with the nominate subspecies (Schlitter and Aggundey, 1986). Simmons (2005: 455) recognised the same subspecies. An analysis of specimens from southern Africa showed support for the synonymization of "*E. h. pallidior*", but also indicated that either the subspecies delineation between "*E. h. hottentotus*" and "*E. h. bensoni*" is also not as distinct, or the distribution of "*E. h. bensoni*", described from Malawi, requires revision (Kearney, 2005). Although the distribution of "*E. h. bensoni*" in Meester *et al.* (1986: 57) included parts of South Africa, as well as Mozambique, Zimbabwe and Malawi, Hayman and Hill (1971) listed only Malawi and Zambia, and the subspecies was not included in the list of mammals from South Africa by Roberts (1951, 1954). Included in the subgenus *Cnephaeus* by Hoofer and Van Den Bussche (2003: 38), which was raised to full genus status by Cláudio *et al.* (2023).

Based on mitochondrial and nuclear DNA analyses, Juste *et al.* (2013: 449) retain two subspecies: *R. h. hottentotus* and *R. h. pallidior*, but they only included material from South Africa.

COMMON NAMES:

Afrikaans: Langstert-dakvlermuis. Chinese: 长尾棕蝠. Czech: netopýr hotentotský. English: Long-tailed Serotine Bat, Hottentot Serotine Bat, Long-tailed Greater Serotine Bat, Long-tailed House Bat, Hottentot bat. French: Sérotine hottentote, Sérotine des maisons à longue queue, Sérotine hottentote. German: Hottentotten-Breitflügelfledermaus, Capische Trugfledermaus. Malawian: Liputiputi, Ndemiya, Namzeze. Portuguese: Morcego caseiro Hottentot.

ETYMOLOGY OF COMMON NAME:

The colloquial name is derived from the fact that the tail of this species is much longer than in its sister taxa (see Smithers, 1983; Skinner and Smithers, 1990: 108; Taylor, 2005).

SIMILAR SPECIES:

Has been confused with *Scotophilus* (Roberts, 1946; 1951: 86; 1954: 86; Kearney and Seamark, 2004), although *E. hottentotus* has bicoloured hair and two upper incisors, while *Scotophilus* has single coloured hair and one upper incisor.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:

Butler (1978) reported as *Eptesicus* cf. *hottentotus* (Smith) from the early Pleistocene deposits at Olduvai. *E. hottentotus* was found from the upper Pleistocene at Border Cave and possibly the late Holocene at Nkupe, South Africa (Avery, 1991: 6). Further South African Pleistocene (Wonderwerk) and Holocene (Blinkklipkop) findings were reported by Avery and Avery (2011: 19).

CONSERVATION STATUS:

Global Justification

Listed [as *Eptesicus hottentotus*] as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, it occurs in a number of protected areas, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs and Cotterill, 2008a; IUCN, 2009; Monadjem *et al.*, 2017ac).

Assessment History

Global

2016: LC ver 3.1 (2001) [assessed as *Eptesicus hottentotus*] (Monadjem *et al.*, 2017ac). 2008: LC ver 3.1 (2001) [assessed as *Eptesicus hottentotus*] (Jacobs and Cotterill, 2008a; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessed as *Eptesicus hottentotus*] (Jacobs and Cotterill, 2004a; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: LC ver 3.1 (2001) (Watson *et al.*, 2016). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this species (Jacobs and Cotterill, 2008a; IUCN, 2009; Monadjem *et al.*, 2017ac).

CONSERVATION ACTIONS:
Jacobs and Cotterill (2008a) [in IUCN (2009)] and Monadjem *et al.* (2017ac) indicate that *C. hottentotus* has been recorded from several protected areas in South Africa, and presumably is present in protected areas within other parts of the species range. Further studies are needed into the distribution of this species.

GENERAL DISTRIBUTION:
Cnephaeus hottentotus is largely a Southern African species ranging from southern Angola in west, through parts of Namibia, South Africa, southern Lesotho, Botswana, Zimbabwe, Mozambique, Malawi and Zambia, with a single record as far north as southwestern Kenya.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 813,384 km^2. In the RSA, its distribution is best predicted by geology (Babiker Salata, 2012: 50).

Native: Angola (Crawford-Cabral, 1966: 137; 1989; Feiler, 1990; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562; Taylor *et al.*, 2018b: 63); Eswatini (Monadjem *et al.*, 2021: 5): Kenya (Schlitter and Aggundey, 1986; Kearney *et al.*, 2008b); Lesotho (Lynch, 1994: 196; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562); Malawi (Kershaw, 1922b: 182; Roberts, 1946: 305;Happold *et al.*, 1988; Ansell and Dowsett, 1988: 38; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562); Mozambique (Smithers and Lobão Tello, 1976: 60; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562; Monadjem *et al.*, 2010c: 382); Namibia (Griffin, 1999: 30; Rautenbach *et al.*, 1993: 93; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562); South Africa (Shortridge and Carter, 1938: 282; Shortridge, 1942: 38; Roberts, 1951: 86; 1954; Rautenbach *et al.*, 1981b; Rautenbach and Espie, 1982; Herselman and Norton, 1985: 100; Rautenbach *et al.*, 1993: 93; Lynch, 1994; Taylor, 1998; Watson, 1998; Avery, 1991: 6; Kearney and Seamark, 2004; Seamark and Brand, 2005: 8; Seamark and Kearney, 2007: 4; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562); Zambia (Ansell, 1960a: 20; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562); Zimbabwe (Peterson and Nagorsen, 1975; Cotterill, 1996a: 78; Kearney *et al.*, 2008b; Monadjem *et al.*, 2010d: 562).

GEOGRAPHIC VARIATION:
See also the section on "Taxonomy". *C. h. bensoni* is smaller than either *C. h. hottentotus* or *C. h. portavernus* (Schlitter and Aggundey, 1986). *C. h. bensoni* is darker in colour, "tawny olive" (Roberts, 1946), than *C. h. portavernus* (Schlitter and Aggundey, 1986), and *C. h. hottentotus* (Roberts, 1946: 305). Morphometric analysis of cranial size supported synonymising *C. h. pallidior* with the nominate species (Schlitter and Aggundey, 1986; Kearney, 2005), which had been described on the basis of the paler colour, "rufous-buff" (Shortridge, 1942), that is found in specimens from the Northern Cape and Namibia. Although, colour is darker in specimens from Taung in the North West Province of South Africa (Herselman and Norton, 1985: 100), and in specimens from Angola - "gold brownish" (Crawford-Cabral, 1966; 1989: 19). Relative to *C. h. hottentotus*, *C. h. portavernus* has a deeper braincase and shorter palatal length (Schlitter and Aggundey, 1986).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
For a general description of overall size, and pelage and membrane colour see Temminck (1840), Sclater (1901: 126), Shortridge and Carter (1938: 282), Shortridge (1942), Roberts (1946), Smithers (1983), Skinner and Smithers (1990: 108), Taylor (2000), Taylor (2005: 318). For a general description of the ear and tragus see Temminck (1840), Sclater (1901: 126), Smithers (1983), Skinner and Smithers (1990: 108), Taylor (2000), Taylor (2005: 318).

Schoeman and Jacobs (2002: 157) reported the following parameters for 6 specimens from the Algeria Forestry Station (RSA): Fa: 48.9 ± 1.4 mm, Wing area: 173.7 ± 14.1 cm^2, Wing span: 33.0 ± 0.5 cm, Wing loading: 10.3 ± 1.6 N/m^2, and aspect ratio: 6.3 ± 0.6.

DENTAL FORMULA:
See Menu (1985; 1987).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
For a general description of the skull, see Shortridge and Carter (1938: 282), Roberts (1946). For a general description of the teeth, see Sclater (1901: 126).

DETAILED MORPHOLOGY:
Baculum
See Hill and Harrison (1987) and Kearney *et al.* (2002).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value

of 14.0 Pa, aspect ratio 7.2 for a wingspan of 39 cm and a wing area of 210 cm^2 and a body mass of 30 g.

SEXUAL DIMORPHISM:
An analysis of specimens from southern Africa showed no significant difference between the sexes in 12 cranial and dental, and eight external measurements, but females were significantly larger than males by 5.21 and 6.78 percent respectively for forearm and third metatarsal lengths (Kearney, 2005).

ECHOLOCATION:
Based on a single room-flown individual the call was recorded as a short duration (2 - 4 ms), broad-band (20 - 54 kHz) call with a dominant frequency of 28 - 32 kHz, and harmonic components (Taylor, 2000: 89). The call frequency, outside the sensitivity range of moths, is suggested to have evolved in response to moth hearing (Schoeman and Jacobs, 2002). These authors (p. 157) also reported the call type to be a low duty echolocation dominated by frequency modulated calls, with a F_{peak}: 31.8 ± 1.0 kHz.

Taylor *et al.* (2013b: 17) recorded the following parameters for 3 *C. hottentotus* calls from Soutpansberg, South Africa: F_{max}: 60.6 ± 8.23 (54.0 - 69.8) kHz, F_{min}: 30.1 ± 1.74 (28.2 - 31.6) kHz, F_{knee}: 35.2 ± 1.48 (34.2 - 36.9) kHz, F_{char}: 32.2 ± 1.75 (30.4 - 33.8) kHz, duration: 3.1 ± 0.86 (2.6 - 4.1) ms.

Linden *et al.* (2014: 40) reported the following parameters from the Soutpansberg area (RSA): F_{min}: 28 - 32 khz, F_{char}: 30 - 34 kHz, F_{knee}: 34 - 37 kHz, slope: 367 - 773 OPS, duration: 3 - 4 ms.

Three calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 39.66 ± 9.59 kHz, F_{min}: 31.83 ± 2.30 kHz, F_{knee}: 33.54 ± 1.37 kHz, F_{char}: 32.38 ± 1.14 kHz, slope: 33.69 ± 35.48 OPS, duration: 3.64 ± 1.91 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 99 calls of 9 bats: F_{max}: 53.81 ± 10.93 kHz, F_{min}: 30.93 ± 5.14 kHz, F_{knee}: 34.73 ± 2.32 kHz, F_{char}: 31.1 ± 1.83 kHz, slope: 326.44 ± 1214.91 OPS, duration: 4.46 ± 1.75 ms. 15 calls from the Venatia mine recorded by Cory-Toussaint and Taylor (2022: Table S1) had a duration of 4.01 ± 1.01 ms, F_{min}: 30.84 ± 0.70 kHz, F_{max}: 40.77 ± 4.95 kHz, F_{knee}: 33.87 ± 0.86 kHz and F_{char}: 31.23 ± 0.65 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 13 "*Eptesicus hottentotus*" calls from the Kruger Park (RSA): F_{min}: 30.4 ± 1.8 (26.9 33.8) kHz, Duration: 3.3 ± 0.7 (2.2 4.5) ms, F_{max}: 55.9 ± 9.0 (40.1 70.2) kHz, F_{knee}: 36.9 ± 2.2 (32.3 41.1) kHz, F_{char}: 33.5 ± 2.5 (31.5 40.1) kHz.

88 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 28 - 32 kHz, F_{max}: 54 - 70 kHz, F_{char}: 30 - 34 kHz, F_{knee}: 34 - 37 kHz and duration 3 - 4 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 33.50 ± 2.50 kHz, F_{max}: 55.90 ± 9.00 kHz and F_{min}: 30.40 ± 1.80 kHz.

MOLECULAR BIOLOGY:
Karyotype
Results of all analyses, based on specimens from Zimbabwe (Peterson and Nagorsen, 1975), Namibia and Limpopo Province in South Africa (Rautenbach *et al.*, 1993: 93), and the Western Cape Province in South Africa (Kearney *et al.*, 2002: 59), agreed the diploid number is $2n$ = 50, with 24 pairs of acrocentric autosomes, hence a fundamental number of FN = 48. The X chromosome is a medium-sized submetacentric, and the Y a small acrocentric (Peterson and Nagorsen, 1975; Rautenbach *et al.*, 1993: 93; Kearney *et al.*, 2002: 59).

Protein / allozyme
See Morales *et al.* (1991) for results from ten specimens from Namibia.

Genetics
See Hoofer and Van Den Bussche (2003), Stadelmann *et al.* (2004b), Eick *et al.* (2005) and Matthee *et al.* (2006).

HABITAT:
Often associated with mountainous country, in close proximity to water (see references under "Habits"). Sirami *et al.* (2013: 34) recorded in the Western Cape Province, South Africa that *C. hottentotus* activity was not significantly, nor positively influenced by size of wetland, while habitats 100 m surrounding wetlands were also significantly and positively influenced by the water body.

HABITS:
In Angola specimens collected from Capolopopo were "performing sweeping flights over a water tank, apparently catching insects" (Crawford-Cabral, 1989: 19), as was also noted by Roberts, 1951: 87) for individuals observed at Eronga Mountain in Namibia. In Mozambique a single specimen was mistnetted in the Zambezi Valley

northwest of Tete (Smithers and Lobão Tello, 1976: 60). Specimens collected at Goodhouse in the Northern Cape Province of South Africa were shot "whilst 'planing' very slowly in wide circles around a cattle kraal, to which they were attracted by a swarm of flies" (Shortridge, 1942: 38). Shortridge (1942: 38) also observed them to be weak fliers, coming out at late dusk after *Cistugo* and *Sauromys*. In 1985, near Buxton in the North West Province of South Africa, some 11 years after this species had been taken from a roost at the entrance to an old mine tunnel (see below under "Roost"), three females were netted flying out of the tunnel, two at 20h45, and another at 21h40, while a male was caught returning at 23h30 (James, 1986: 219). The first specimen of this bat caught in the northern part of the Kruger National Park in South Africa was mistnetted after sunset in a figtree forest on the banks of the Luvuvhu River (Rautenbach and Espie, 1982: 112). In the Free State Province of South Africa a specimen was netted at Sterkfontein Dam in "well-wooded, broken country with patches of marshy open grassland" (Watson, 1998). A specimen from Ithala Game Reserve in northern KwaZulu-Natal Province of South Africa was netted over a river with well-wooded banks (Rautenbach *et al.*, 1981b: 24). At Rocherpan in the Western Cape Province of South Africa specimens were netted flying low over a marsh (Herselman and Norton, 1985: 100). In the Cederberg region of the Western Cape Province of South Africa specimens were netted, in January and February between 20h45-21h52, at the edges of water bodies (Seamark and Brand, 2005: 8). In Lesotho specimens were netted over grassy banks adjacent to rivers in mountainous terrain, at Malealea the species was caught in October at 20h30 (Lynch, 1994: 197).

ROOST:
In Zimbabwe a specimen was found "clinging to a wall in an open building with a corrugated iron roof" (Smithers and Lobão Tello, 1976: 60), and at Marandellas "hanging on the wall of a squash court" (Smithers and Wilson, 1979: 45). Specimens from Taung in the North West Province of South Africa were taken (between 1976 - 1979) from a hollow in rocks at the entrance to an old mine tunnel inhabited by *Miniopterus schreibersii* (Herselman and Norton, 1985: 100).

Happold and Happold (2023: 133) mention that these bats roost singly or in small sized groups (no groups larger than five have been reported).

DIET:
Insectivorous (Smithers, 1983; Skinner and Smithers, 1990: 108; Taylor, 2005: 318). Schoeman and Jacobs (2002) identified tympanate moths in the diet of individuals from the Western Cape Province of South Africa.

From the Algeria Forestry Station (RSA) Schoeman and Jacobs (2002: 157) reported the following prey groups based on 67 faecal pellets from 6 bats (in volume percent): Coleoptera (88.3 ± 9.0), Diptera (4.5 ± 9.0), Hemiptera (1.5 ± 3.0), and unknown (1 ± 2).

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 156 minutes, and a digestibility rate of about 72.7 %.

PREDATORS:
Avery *et al.* (2005: 1054) found this species to be present in pellets from *Tyto alba* (Scopoli, 1769) in South Africa.

Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

POPULATION:
Structure and Density
Shortridge (1942:38) indicated this bat was not plentiful around Goodhouse in the Northern Cape of South Africa and only observed half a dozen individuals. In other instances specimens have either been found singly or in groups of two to five (Smithers and Wilson, 1979; Herselman and Norton, 1985: 100; Smithers, 1983; Watson, 1998). Monadjem *et al.* (2017ac) report that although the species is considered to be sparsely distributed, it is locally common in part of the ranges, such as Zimbabwe but is thought to be rarer elsewhere (e.g., South Africa).

Trend
2016: Unknown (Monadjem *et al.*, 2017ac).
2008: Unknown (Jacobs and Cotterill, 2008a; IUCN, 2009).

PARASITES:
Ectoparasite - *Pteracarus pusillus* (Fain, 1978: 78).

ACARI
Spinturnicidae
Orlova *et al.* (2020a: 1) reported the first occurrence of *Spinturnix kolenatii* Oudemans, 1910 from a bat in Africa (Namibia). This mite was considered to have a Palearctic distribution, where it exclusively occurs on bats from the genus *Eptesicus*.

Argasidae

Reeves *et al.* (2020b: 663) collected larvae of *Argas transgariepinus* White, 1846 from three Namibian *Cnephaeus hottentotus* bats.

VIRUSES:

Paramyxoviridae

Mortlock *et al.* (2015: 1841) reported that one of two examined South African *C. hottentotus* specimens tested positive for *Paramyxovirus* sequences.

Rhabdoviridae

Lyssavirus - Rabies related viruses

Rabies

Oelofsen and Smith (1993) tested one individual brain, by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), which did not tested positive.

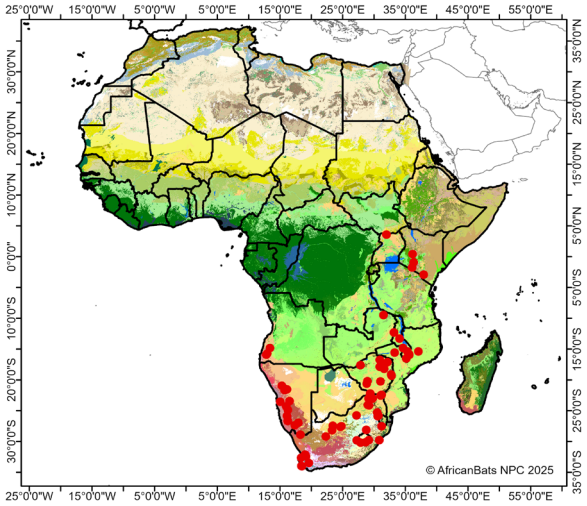

Figure 300. Distribution of *Cnephaeus hottentotus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Kenya, Lesotho, Malawi, Mozambique, Namibia, South Africa, Uganda, Zambia, Zimbabwe.

Cnephaeus isabellinus (Temminck, 1840)

*1840. *Vespertilio isabellinus* Temminck, Monographies de mammalogie ou description de quelques genres de mammifères, dont les espèces ont été observées dans les différens musées de l'Europe, 2 (13): 205, pl 52, fig 1, 2. Publication date: 1840. Type locality: Libya: near Tripoli [ca. 32 58 N 13 12 E]. [Goto Description]. Lectotype: RMNH MAM.17648: ad, mounted skin and skull. Collected by: J.F.H. Clifford Cocq van Breugel; collection date: 1829 - 1835. Paralectotype: RMNH MAM.17649: ad, mounted skin (skull not removed). Collected by: J.F.H. Clifford Cocq van Breugel; collection date: 1829 - 1835. Paralectotype: RMNH MAM.17650: ad. Collected by: J.F.H. Clifford Cocq van Breugel; collection date: 1829 - 1835. Paralectotype: RMNH MAM.17651: ad, mounted skin (skull not removed). Collected by: J.F.H. Clifford Cocq van Breugel; collection date: 1829 - 1835. Paralectotype: RMNH MAM.17652: ad ♀, skin and skull. Collected by: J.F.H. Clifford Cocq van Breugel; collection date: 1829 - 1835. Paralectotype: RMNH MAM.17653: ad, mounted skin (skull not removed). Collected by: J.F.H. Clifford Cocq van Breugel; collection date: 1829 - 1835. - Comments: Considered a valid subspecies by Horáček *et al.* (2000: 124). Considered a valid species of *serotinus* by Benda *et al.* (2004b: xx), and Mayer *et al.* (2007: Additional file 1) based on mitochondrial DNA analyses. Dalhoumi *et al.* (2017b: 142) indicate that the original specimens were collected by J. F. H. Clifford Cocq van Breugel.

1855. *Vespertilio (Vesperus) isabellinus:* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 5: 746. (Name Combination).

1860. *Meteorus isabellinus:* Kolenati, Monographie der Europäischen Chiroptern, 20. (Name Combination).

? *Eptesicus serotinus boscai:* (Name Combination).

TAXONOMY:
Recent genetic studies (Ibañez *et al.*, 2006; Mayer *et al.*, 2007; García-Mudarra *et al.*, 2009) support the specific status of this serotine which occurs sympatrically with *C. serotinus* in the Iberian Peninsula.

Le Berre (1990: 102) considers "*Eptesicus isabellinus*" to be a synonym of "*Eptesicus bottae*" (see also comments under that species).

The study of five nuclear genes and the mitochondrial cytochrome *b* gene led Artyushin *et al.* (2018: 471) to the conclusion that *C. serotinus* and *C. isabellinus* form a monophyletic clade, but with significant genetic differences, which confirm the species status of the later taxon. Ibañez *et al.* (2006: 288) indicate that the genetic differences between the two species correspond to a Late Miocene - Early Pliocene divergence.

The status of *gabonensis* still remains unclear. Although originally described by Trouessart (1897: 108) from Gabon, Hayman and Hill (1971: 44) and Ibáñez and Valverde (1985: 242) suggest it almost certainly originated from Kashmir or Northern India. Kock (1969a: 162) considered it to be senior synonym of "*Eptesicus platyops*", which is supported by Grubb (2004: 92), who discussed this in detail (and who indicates that Gabon might not be rejected as country of origin). Pending further analyses, we retain *gabonensis* in the synonymy of *Cnephaeus isabellinus*.

COMMON NAMES:
Albanian: Serotinë Isabeline. Armenian: Իզաբելլայի մաշկեղ. Azerbaijani:İzabel gönlücə. Basque: Baratze-saguzar isabeldar. Belarusian: Кажан ізабэлавы. Bosnian: Izabelin šišmiš. Slovenian: Kraljičin poznik. Swedish: Isabellfladdermus. Turkish: İzabel Genişkanatlı Yarasası. Ukrainian: Лилик ізабеліновий. Welsh: Ystlum adain-lydan llwydfelyn.

SIMILAR SPECIES:
Santos *et al.* (2014: 158) indicate that *C. isabellinus* and *C. serotinus* have an extensive niche overlap, indicating that they explore very similar conditions. Each species thrives in a specific biogeographical zone, *C. serotinus* in Atlantic climates and *C. isabellinus* in Mediterranean areas, but considering the large niche overlap it is quite possible that competition may occur if prey resources are limited in contact zones.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Gunnell *et al.* (2015a: 13) report on a right distal humerus from the Olduvai Gorge (Tanzania), which they assigned to cf. "*E. isabellinus*".

CONSERVATION STATUS:
Global Justification
The species is locally abundant and widespread. Regional trends are difficult to determine due to the lack of reliable data but it seems that there are no reasons to consider the population to be declining globally (Juste, 2016a).

Assessment History
Global
2016: LC ver 3.1 (2001) [as *Eptesicus isabellinus* (Juste, 2016a). 2008: LC ver 3.1 (2001) [as part of *Eptesicus serotinus*] (Hutson *et al.*, 2008h; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
Sherwin *et al.* (2012: 174) report the aerial hawking feeding style and the long-distance dispersal of *E. serotinus* in Europe and NW Africa to be important risk factors related to climatic change.

No specific threats are known for the species although it can accumulate biocides due its feeding habits in agricultural areas (Guillén et al. 1991).

CONSERVATION ACTIONS:
No specific conservation actions known (Hutson *et al.*, 2008h; IUCN, 2009). No specific actions seem to be required to guarantee the species' future. *C. isabellinus* is profiting from most of the man-made constructions that are being used more and more often as roosting places making the species quite common in urban areas (Juste, 2016a).

GENERAL DISTRIBUTION:
Eptesicus isabellinus has been recorded from North Africa and the Iberian Peninsula.

Martinoli and Spada (2023: 70) [referring to Trujillo (1992: 65) as "*Eptesicus serotinus*"] mention this species from Lanzarote (Canary Islands).

Native: Algeria; Libya; Morocco (Benda *et al.*, 2010a: 157; El Ibrahimi and Rguibi Idrissi, 2015: 363 [as "*Eptesicus serotinus (= E. isabellinus)*"]; Dbiba *et al.*, 2025: 7); Portugal; Spain; Tunisia (Dalhoumi *et al.*, 2014: 53; 2016b: 867; 2019b: 26; 2023: 4).

GEOGRAPHIC VARIATION:
The populations from the Iberian Peninsula, Morocco and western Algeria are assigned to *E. isabellinus boscai* by Juste *et al.* (2013: 443), whereas those from the remaining part of Algeria, Tunisia and western Libya are assigned to "*E. i. isabellinus*". However, they do indicate (p. 450) that the specimens from western Libya seem to form a supported, separate clade.

SEXUAL DIMORPHISM:
In a year-round study in Tunisia, Dalhoumi *et al.* (2016a: 157) found adult females to be significantly heavier than males. Both sexes reach their maximum weight in October (♀♀: 22.68 ± 3.61 g; ♂♂: 21.45 ± 3.34 g) and their minimum weight in January-February (♀♀: 16.75 ± 0.35 g; ♂♂: 14.69 ± 1.13 g) (see also Martinoli and Spada, 2023: 72).

ECHOLOCATION:
Benda *et al.* (2010a: 163) report for 23 Moroccan specimens a start frequency of 35.1 ± 1.0 (33.7 - 36.3) kHz, a maximum energy frequency of 26.9 ± 0.7 (25.8 - 28.3) kHz, an end frequency of 23.3 ± 0.8 (22.4 - 24.2), with a duration of 9.7 ± 2.8 (5.6 - 16.3) ms, and an inter-pulse interval of 244.2 ± 66.7 (128.5 - 362.7) ms.

Also from Morocco, Disca *et al.* (2014: 226) indicate that the type of call is FM-QFC, with the following parameters: F_{start}: 42.3 ± 13.0 kHz, F_{end}: 25.3 ± 1.5 kHz, F_{peak}: 27.4 ± 2.2 kHz, bandwidth: 17.0 ± 11.6 kHz, duration: 11.5 ± 3.0 ms.

In Tunisia, Dalhoumi *et al.* (2016b: 867; 2017b: 143) reported FM/QCF calls with a short constant frequency at 18.5 - 27.1 kHz and maximum energy at 21.7 - 30.3 kHz (25.3 ± 2.0 kHz). Dalhoumi *et al.* (2023: 5) reported F_{start}: 38.74 ± 8.21 (25.8 - 61.8) kHz, F_{end}: 24.28 ± 1.01 (21.8 - 26.4) kHz, F_{max}: 25.76 ± 1.03 (23.3 - 27.9) kHz, duration: 12.44 ± 2.63 (7.2 - 18.5) ms and Interpulse interval: 241.01 ± 74.08 (104.5 - 483.2) ms.

Ait-Abdesselam *et al.* (2025: 40) reported an F_{max} value of 25.97 ± 1.50 kHz for Algerian bats.

MOLECULAR BIOLOGY:
Karyotype
Baker *et al.* (1974) reported 2n = 50, aFN = 48, X = submetacentric for specimens from Tunisia.

Genetics
See Ibañez *et al.* (2006), Mayer *et al.* (2007), García-Mudarra *et al.* (2009), Juste *et al.* (2009).

Extralimitally, in the Iberian contact area between *C. isabellinus* and *C. serotinus*, Centeno-Cuadros *et al.* (2019: "1") examined nuclear markers and found a male-mediated ongoing asymmetric hybridization from *C. isabellinus* to *C. serotinus* (28 % hybrids in *C. serotinus* and 5 % in *C. isabellinus*).

HABITAT:
In the Iberian Peninsula, Lisón *et al.* (2014: 59) found that *E. isabellinus* is primarily found near water courses, scrublands, and zones with high primary productivity. Non-irrigated croplands are avoided, and no preferences were found for human settlements or irrigated croplands. The preference for water bodies was also confirmed in Tunisia by Dalhoumi *et al.* (2017b: 149).

HABITS:
In Spain, Lisón and Calvo (2014: 99) found that the activity of this species increases with high

temperatures, showing the highest activity in June.

ROOST:
Benda *et al.* (2014c: 46) reported solitary males to roost in the ruined Roman town of Leptis Magna (Libya), and additional specimens were found in fissures in ceilings and walls of other ruins. Kelm *et al.* (2015: 27) indicate that this species' roosts are mostly found in anthropogenic structures. Dalhoumi *et al.* (2017b: 142) also mentions rock crevices, tree holes and bridges.

DIET:
Benda *et al.* (2014c: 51) examined four sets of faecal pellets and three digestive tracts from Libya *E. isabellinus* and found primarily ants (Hymenoptera: Formicoidea) and beetles (Coleoptera: mostly Scarabaeidae and Cerambycidae, but also Carabidae, Curculionidae, Staphylinidae, and Tenebrionidae). A set of five pellets from one animal was dominated by moths (Lepidoptera).

Edwards *et al.* (2022: 8) [referring to Kelm *et al.* (2015)] indicate that it takes about 2 hours for the food to pass through the digestive system.

PREDATORS:
Martinoli and Spada (2020: 4) mention that "*Eptesicus isabellinus*" is a frequent prey for the barn owl (*Tyto alba* (Scopoli, 1769), tawny owl (*Strix aluco* Linnaeus, 1758), long-eared owl (*Asio otus* (Linnaeus, 1758)), and the Eurasian eagle-owl (*Bubo bubo* (Linnaeus, 1758)). Diurnal predators include peregrine falcon (*Falco peregrinus* Tunstall, 1771), the common kestrel (*Falco tinnunculus* Linnaeus, 1758) and the Eurasian sparrowhawk (*Accipiter nisus* (Linnaeus, 1758)). Additionally; the horseshoe whip snake (*Hemorrhois hippocrepis* (Linnaeus, 1758)) was found to be an occasional predator.

POPULATION:
Structure and Density
Cnephaeus isabellinus is the most common bat species in northwest Algeria and Libya (Hutson *et al.*, 2008h; IUCN, 2009). While Juste (2016a) reports that there are no estimates of the population figures for the species. Nevertheless, it is reported to be very abundant locally and in some areas of Southern Spain is considered one of the commonest species with density values up to 7.5 individuals per km^2 (Ibáñez 2007). Lifespan is not well known but annual survival rate of adults was found to vary across colonies with an average value around 0.70 (Papadatou *et al.*, 2011). This species is the main host of a differentiated strand of rabies virus in Iberia (Vázquez-Morón *et al.*, 2011).

Trend
2016: Unknown (Juste, 2016a). 2008: Unknown [as part of *C. serotinus* (Hutson *et al.*, 2008h; IUCN, 2009)].

LIFESPAN:
In southern Spain, Papadatou *et al.* (2010: 925) followed six colonies over a period varying between 8 and 26 years and found a mean annual survival probability of 0.71. The mean longevity of the species is 5 to 10 years.

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) mention that this species has more than one young per litter.

Baker *et al.* (1974: 701) mentions four lactating females collected on 5 June 1973. In Tunisia, Dalhoumi *et al.* (2017b: 141) captured pregnant females from April to June (one even in August) and lactating females from May to June. All of the females captured by Dalhoumi *et al.* (2015: 265) in May were pregnant, whereas other bats were found to be pregnant in May and June, but they also captured one pregnant female in August. Two juveniles were captured in June and October.

Benda *et al.* (2014c: 48) refer to a record of two juvenile females made by Hanák and Elgadi (1984) in the spring of 1978 from Janzur (Libya), and to a non-volant juvenile they observed at Sabratha on 28 May 2002.

PARASITES:
Benda *et al.* (2014c: 52) reported the following parasites from Libya: Argasidae: *Argas vespertilionis* (Latreille, 1802), Ischnopsyllidae: *Ischnopsyllus intermedius* (Rothschild, 1898).

From Algeria, Bendjeddou *et al.* (2013: 325) reported the Nycteribiid *Phthiridium biarticulatum* Hermann, 1804 from "*E. serotinus*": Bendjeddou *et al.* (2017: 15) added the following species: Siphonaptera:*Nycteridopsylla longiceps* Rothschild, 1908, *Ischnopsyllus intermedius* (Rothschild, 1898); Heteroptera: *Cimex pipistrelli* Jenyns, 1839, *Cacodmus vicinus* Horváth, 1934; Arachnida: *Argas transgariepinus* White, 1846. Bendjoudi *et al.* (2019: 71) and Khelfaoui *et al.* (2018: 68) furthermore found *Ixodes ricinus* (Linnaeus, 1758), *Steatonyssus occidentalis* (Ewing, 1933), *Ischnopsyllus octactenus* (Kolenati, 1856)

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Argasidae: *Carios vespertilionis* Latreille, 1802, *Secretargas*

transgariepinus (White, 1846); Cicimidae: *Cacodmus vicinus* Horváth, 1934, *Cimex pipistrelli* Jenyns, 1839; Ischnopsyllidae: *Ischnopsyllus hispanicus* (Rothschild, 1898), *Nycteridopsylla longiceps* Rothschild, 1908; Ixodidae: *Ixodes ricinus* (Linnaeus, 1758); and Macronyssidae: *Steatonyssus occidentalis* (Ewing, 1933).

Sándor *et al.* (2021a: 4) reported the presence of the Argasid ticks *Secretargas transgariepinus* (White, 1846) and *Carios vespertilionis* Latreille, 1802. A larval specimen of *Secretargas transgariepinus* was also reported from Libya by Ševčík *et al.* (2024: 3), However, the tick was retrieved from a jar containing ticks from four "*Eptesicus isabellinus*", one *Myotis punicus* and four *Pipistrellus kuhlli*. Sándor *et al.* (2025: Suppl.) also mentioned the presence of the Ixodid tick Rhipicephalus sanguineus (Latreille, 1806) on bats from Algeria.

Martinoli and Spada (2020: 5) mentioned the following parasites: Acarina: *Spinturnix kolenatii* Oudemans, 1910, *Spinturnix psi* (Kolenati, 1856), *Spinturnix plecotinus* (Koch, 1839), *Steatonyssus occidentalis* (Ewing, 1933), *Macronyssus cyclaspi* (Oudemans, 1906), *Argas vespertilionis* (Latreille, 1796) - Diptera: *Basilia nattereri* (Kolenati, 1857) - Siphonaptera: *Ischnopsyllus intermedius* (Rothschild, 1898), *Nycteridopsylla pentactena* (Kolenati, 1856).

VIRUSES:
Coronaviridae - Coronaviruses
Betacoronavirus
Kohl and Kurth (2014: 3112) reported this virus from Spain.

Papillomaviridae – Papillomaviruses
García-Pérez *et al.* (2014: 100) pointed out that there is no strict species specificity in papillomaviruses as they found DNA from EserPV2 and EserPV3 in pharyngeal swaps of both *Cnephaeus serotinus* and *C. isabellinus*.

Rhabdoviridae
"Various European bat lyssaviruses" were reported from various European countries by Kohl and Kurth (2014: 3114).

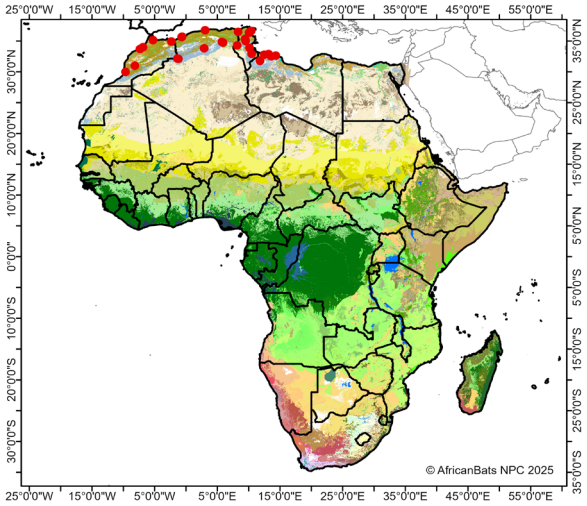

Figure 301. Distribution of *Cnephaeus isabellinus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Algeria, Libya, Morocco, Tunisia.

Cnephaeus platyops (Thomas, 1901)

*1901. *Vespertilio platyops* Thomas, Ann. Mag. nat. Hist., ser 7, 8 (43): 31. Publication date: 1 July 1901. Type locality: Nigeria: Western region: Lagos [06 27 N 03 23 E]. [Goto Description]. Holotype: NHMUK 1888.5.17.3: ad ♀, skull and alcoholic. Presented/Donated by: George Edward Dobson. - Etymology: From the Greek "*platyops*" for broad-faced or flat-faced.
1939. *Eptesicus platyops:* G.M. Allen, Bull. Mus. comp. Zool., 83: 86. (Name Combination).
1969. *Eptesicus serotinus platyops:* Kock, Abh. Senckenberg. naturforsch. Ges., 521: 214. (Name Combination).
1980. *Eptesicus (Eptesicus) platyops:* Corbet and Hill, A world list of mammalian species, 69. (Name Combination).
1994. *E[ptesicus (Eptesicus)] s[erotinus] platyops:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 120. (Name Combination).
? *Cnephaeus platyops:* (Current Combination).

TAXONOMY:
Considered a subspecies of *C. serotinus* by Ibáñez and Valverde (1985) and Koopman (1994: 120), but no comparison with *C. bottae* was made.

COMMON NAMES:
Czech: netopýr nigerijský. English: Lagos Serotine Bat, Flat-faced Serotine Bat, Lagos Serotine. French: Sérotine à grands yeux, Sérotine de Lagos. German: Lagos-Breitflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements,

threats and conservation status (Schlitter, 2008a; IUCN, 2009; Schlitter, 2019b).

Assessment History
Global
2018: DD ver 3.1 (2001) as *Eptesicus platyops* (Schlitter, 2019b). 2008: DD ver 3.1 (2001) (Schlitter, 2008a; IUCN, 2009). 2004: DD ver 3.1 (2001) (IUCN, 2004; Schlitter, 2004e). 1996: VU (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Schlitter, 2008a; IUCN, 2009; Schlitter, 2019b).

CONSERVATION ACTIONS:
Schlitter (2008a) [in IUCN (2009)] and Schlitter (2019b) reports that it is not known if the species is present in any protected areas and additional surveys are needed to try to locate and study a population of this species.

GENERAL DISTRIBUTION:
Cnephaeus platyops is a poorly known West African species known only from a few specimens. It is known from the type locality at Lagos in Nigeria, from specimens from the island of Bioko (Equatorial Guinea) (although these specimens may not have originated on Bioko) and from an unspecified locality in Senegal (Schlitter, 2008a). Senegal specimens were collected around 1900 (Happold, 1987).

Native: Nigeria (Happold, 1987).

Presence uncertain: Equatorial Guinea [= Bioko]; Senegal (Happold, 1987).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 94.6 minutes, and a digestibility rate of about 77.8 %.

POPULATION:
Structure and Density
There is no good information on the population abundance or size of this bat (Schlitter, 2008a; IUCN, 2009; Schlitter, 2019b).

Trend
2018: Unknown (Schlitter, 2019b). 2008: Unknown (Schlitter, 2008a; IUCN, 2009).

1974. *Eptesicus floweri:* Seal and Makey, ISIS Mammalian Taxonomic Director, ???. (Name Combination).
? *Cnephaeus (Rhinopterus) floweri:* (Current Combination).
? *Eptesicus (Rhinopterus) floweri lowei:* (Name Combination).

TAXONOMY:
Includes *lowei*; see Bræstrup (1935b: 92); but also see Hayman and Hill (1971).

COMMON NAMES:
Czech: netopýr Flowerův. English: Horn-skinned Pipistrelle Bat, Flower's Pipistrelle Bat, Horn-skinned Bat, Sudan Horn-skinned Bat, Lesser Sudan Horn-skinned Bat, Sudan Serotine, Horn-skinned Serotine. French: Sérotine de Flower, Sérotine du Soudan. German: Chagrin Fledermaus, Warzen-Breitflügelfledermaus.

CONSERVATION STATUS:
Global Justification
Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, tolerance of a broad range of non-threatened habitats, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008ah; IUCN, 2009; Monadjem *et al.*, 2017am).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Eptesicus floweri*] (Monadjem *et al.*, 2017am). 2008: LC ver 3.1 (2001) [assessed as *Eptesicus floweri*] (Jacobs *et al.*, 2008ah; IUCN, 2009). 2004: VU D2 ver 3.1 (2001) [assessed as *Eptesicus floweri*] (Jacobs *et al.*, 2004at; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this species (Jacobs *et al.*, 2008ah; IUCN, 2009; Monadjem *et al.*, 2017am). However, Siddig (2014: 548) mentions that the conflicts between Sudan and South Sudan, in combination with droughts form an important threat.

CONSERVATION ACTIONS:
Jacobs *et al.* (2008ah) [in IUCN (2009)] and Monadjem *et al.* (2017am) report that there appear to be no direct conservation measures in place, and it is not known if the species is present within any protected areas. Further studies are needed into the distribution and natural history of this poorly known species.

GENERAL DISTRIBUTION:
Cnephaeus (Rhinopterus) floweri has been recorded from Mali (Timbuktu) and Sudan (all records within a 200-mile radius of Ed Dueim) and Mahmûdé Lake, Wilaya Hodh Ech Chargui in Mauritania.

The identification of the two specimens from Mauritania (EBD 26179M and EBD 26180M) was confirmed by Padial and Ibáñez (2005: 240).

Native: Mali (Koopman, 1975); Mauritania (Padial and Ibáñez, 2005: 240); Sudan (Bræstrup, 1935b; Koopman, 1975).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

Figure 303. Clockwise from top lateral, ventral and dorsal skull images of NHMUK 1903.2.7.14, holotype of *Glauconycteris floweri* de Winton, 1901.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 89 minutes, and a digestibility rate of about 78.4 %.

POPULATION:
Structure and Density
It is known from very few specimens (Jacobs *et al.*, 2008ah; IUCN, 2009; Monadjem *et al.*, 2017am).

Trend
2016: Stable (Monadjem *et al.*, 2017am). 2008: Stable (Jacobs *et al.*, 2008ah; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Mauritania, Sudan.

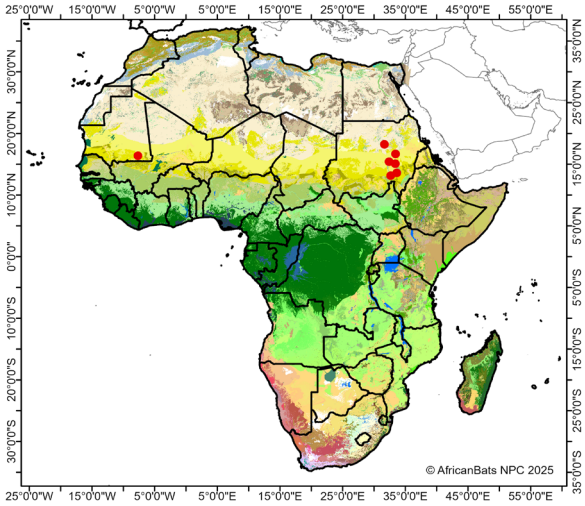

Figure 304. Distribution of *Cnephaeus (Rhinopterus) floweri*.

Genus ***Glauconycteris*** Dobson, 1875

1867. *Chalinolobus* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 1866: 680. - Comments: in part. Type species: *Vespertilio tuberculatus* Forster, 1844 [= *Chalinolobus tuberculatus* (Forster, 1844: 62)], by monotypy (see Jackson and Groves, 2015: 271). - Phonetics: kal-in-oh-loh′-bus.

*1875. *Glauconycteris* Dobson, Proc. zool. Soc. Lond., 1875, III: 383. Publication date: October 1875. - Comments: Type species: *Kerivoula poensis* Gray, 1842. - Etymology: From the Greek "*γλαυκός*", meaning gray and "*γλαυκός*", meaning bat, referring to the fur, which is light gray or cream-colored at the tips (see Palmer, 1904: 295). Rambaldini (2010: 252) indicates that the Greek "glaucos" means bluish gray. Lanza *et al.* (2015: 349) indicate that the first part of the name is a feminine Latin adjective *glàuca*, meaning "glaucous, blue-green".

2013. *Niumbaha* Reeder, Helgen, Vodzak, Lunde and Ejotre. - ZooBank: EDF16BEE-0749-41BC-AE19-BAE130BE58F8.

2014. *Glauconycteries:* Rahoum, SJS, 6 (1): 45. Publication date: February 2014. (Lapsus).

2014. *Glauconyctris:* Rahoum, SJS, 6 (1): 45. Publication date: February 2014. (Lapsus).

2014. *Scotophyllus:* Rahoum, SJS, 6 (1): 45. Publication date: February 2014. (Lapsus).

2021. *Glauconysteris:* Atagana, Bakwo Fils and Kekeunou, Trop. Cons. Sci., 14: 5. Publication date: 14 May 2021. (Lapsus).

TAXONOMY:
Bronner *et al.* (2003) state that although occasionally treated as a subgenus of *Chalinolobus* (Koopman, 1971; Swanepoel *et al.*, 1980; Koopman, 1982; Meester *et al.*, 1986; Koopman, 1993a; Taylor, 1998: 49; Wilson and Cole, 2000), *Glauconycteris* has often been considered as a distinct genus (Allen, 1939a; Roberts, 1951; Ellerman *et al.*, 1953; Hayman and Hill, 1971; Corbet and Hill, 1980, 1992). Despite some superficial cranial resemblance, the marked difference in baculum morphology (Hill and Harrison, 1987) and karyotypic properties (Rautenbach *et al.*, 1993). Ansell and Dowsett (1988), Volleth and Heller (1994) and Eger and Schlitter (2001: 1) support the recognition of these taxa as discrete genera (N. Simmons in litt.). *Glauconycteris* is thus represented in the southern African subregion by a single species, *G. variegata* (butterfly bat), while *Chalinolobus* is extralimital (Australia).

Hassanin *et al.* (2017: 1) analysed the *Cytb* and RAG2 data of the various members of this genus and distinguished three lineage in the small sized species: the "*poensis*" (*G. poensis, G. alboguttata, G. argentata* and *G. egeria*); the "*beatrix*" group (*G. beatrix* and *G. curryae*); and the "*humeralis*" group (*G. humeralis* and *G. atra*).

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Glauconycteris*: ***alboguttata*** J. A. Allen, 1917; ***argentata*** (Dobson, 1875); ***atra*** Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, 2017; ***beatrix*** Thomas, 1901; ***curryae*** Eger and Schlitter, 2001; ***egeria*** Thomas, 1913; ***gleni*** Peterson and Smith, 1973; ***humeralis*** J. A. Allen, 1917; ***kenyacola*** Peterson, 1982; ***machadoi*** Hayman, 1963; ***poensis*** (Gray, 1842); ***superba*** Hayman, 1939; ***variegata*** (Tomes, 1861).

COMMON NAMES:
Czech: motýlí netopýři. English: Butterfly Bats, Lobe-lipped Bats, Silvered Bats, Blue-grey Bats, Dobson's Bats, Glauconycterids. French: Glauconyctères, Murins à bajoues. German: Schmetterlingsfledermäuse. Italian: Glauconittèridi. Glauconictèridi.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo (Democratic Republic of the), Gabon, Guinea, Kenya, Liberia, South Africa, South Sudan, Tanzania.

Glauconycteris alboguttata J.A. Allen, 1917

*1917. *Glauconycteris alboguttatus* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 449, text-fig 7 B. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Medje [02 25 N 27 18 E, 800 m]. [Goto Description]. Holotype: AMNH 49317: ad ♀, skull and alcoholic. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 14 March 1914; original number: 2351. - Etymology: From the Latin "*alboguttata*" meaning white spotted.
2021. *Glauconysteris albogutata:* Atagana, Bakwo Fils and Kekeunou, Trop. Cons. Sci., 14: 5. Publication date: 14 May 2021. (Lapsus).
? *Chalinolobus alboguttatus:* (Name Combination).
? *Glauconycteris alboguttata:* (Current Combination, Current Spelling).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: netopýr pruhovaný. English: Allen's Butterfly Bat, Striped Butterfly Bat, White-spotted Butterfly Bat, Allen's Striped Bat. French: Glauconyctère à gorge blanche, Murin à bajoues d'Allen, Barbastelle d'Allen. German: Gestreifte Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution (that is likely to be even wider than is currently known), extensive available habitat, presumed large overall population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008c; IUCN, 2009; Monadjem *et al.*, 2017cn).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cn). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008c; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004e; IUCN, 2004). 1996: VU [assessed as *Chalinolobus alboguttatus*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known (Jacobs *et al.*, 2008c; IUCN, 2009; Monadjem *et al.*, 2017cn).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008c) [in IUCN (2009)] and Monadjem *et al.* (2017cn) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed into the species distribution, natural history and threats.

GENERAL DISTRIBUTION:
Glauconycteris alboguttata is distributed in Central Africa where it has been recorded from Cameroon and the Democratic Republic of the Congo. The range is poorly known, and it may be distributed more widely (Jacobs *et al.*, 2008c).

Native: Cameroon; Congo (Bates *et al.*, 2013: 323 - 1st record); Congo (The Democratic Republic of the).

HABITAT:
This species is associated with lowland tropical moist forest (Jacobs *et al.*, 2008c).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 81 minutes, and the digestibility rate about 79.5 %.

POPULATION:
Structure and Density
It is generally considered to be rare, however, there have been few recent surveys within the species range (Jacobs *et al.*, 2008c; IUCN, 2009; Monadjem *et al.*, 2017cn).

Trend
2016: Unknown (Monadjem *et al.*, 2017cn). 2008: Unknown (Jacobs *et al.*, 2008c; IUCN, 2009).

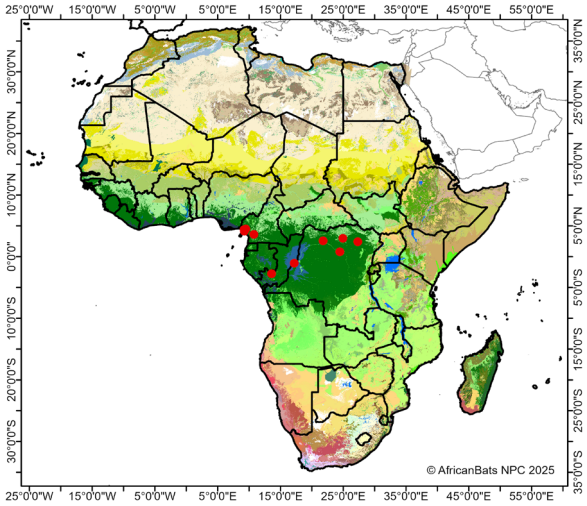

Figure 305. Distribution of *Glauconycteris alboguttata*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Congo, Congo (Democratic Republic of the).

Glauconycteris argentata (Dobson, 1875)

*1875. *Chalinolobus argentatus* Dobson, Proc. zool. Soc. Lond., 1875, III: 385. Publication date: October 1875. Type locality: Cameroon: Western province: Mount Cameroon [04 13 N 09 11 E]. [Goto Description]. Holotype: NHMUK 1871.7.10.5: ad ♀, alcoholic (skull not removed). Purchased (see Dobson (1878: 254). - Etymology: From the feminine Latin adjective *argentàta*, meaning "silvery", referring to the "beautiful dark silvery gray" (Dobson, 1875c: 386) of the terminal third of the dorsal hairs (see Lanza *et al.*, 2015: 351).

1889. *Chalinolobus congicus* Noack, Zool. Jb. Syst., 4: 223, pl 2, fig 1; pl 5, fig 66 - 68. Publication date: 28 February 1889. Type locality: Congo (Democratic Republic of the): Bas Congo province: near mouth of Congo River, Banana Creek: Netonna [05 58 S 12 27 E]. [Goto Description]. Lectotype: SMF 2516: ad ♂, skull only. Collected by: P. Hesse. Mertens (1925: 22) considers this specimen to be a lectotype rather than "the" type. Paralectotype: SMF 11850: Collected by: P. Hesse. Paralectotype: SMF 11851: Collected by: P. Hesse. Paralectotype: SMF 11852: Collected by: P. Hesse. Paralectotype: SMF 11853: Collected by: P. Hesse. Paralectotype: SMF 11854: Collected by: P. Hesse. Paralectotype: SMF 11855: Collected by: P. Hesse. Paralectotype: SMF 2517: Collected by: P. Hesse. Paralectotype: SMF 2518: Collected by: P. Hesse. Paralectotype: SMF 2519: Collected by: P. Hesse. Paralectotype: SMF 2520: Collected by: P. Hesse. Paralectotype: SMF 2521: Collected by: P. Hesse. Paralectotype: SMF 2522: Collected by: P. Hesse. - Comments: Noack (1889: 22) refers to 8 specimens in alcohol 4 ♂♂ and 4 ♀♀, collected in April - May, by P. Hesse).

? *Glauconycteris argentata:* (Current Combination).

? *Glauconycteris argentatus:* (Name Combination, Alternate Spelling).

TAXONOMY:
See Simmons (2005).

Monadjem *et al.* (2016y: 368) collected a *Glauconycteris* specimen in the Mount Nimba area, which looked very similar to this species in measurements and colouration but differed from it by the colouration of its wings (not pale). They also indicated that as *G. argentata* has not been found west of Cameroon, their specimen might represent an undescribed species. Tentatively, they assigned their specimen to *G.* cf. *argentata*.

COMMON NAMES:
Chinese: 银蝶蝠. Czech: netopýr stříbrný. English: Common Butterfly Bat, Silvery Butterfly Bat, Silvered Butterfly Bat, Silvered Bat. French: Glauconyctère argentée, Murin à bajoues argenté, Barbastelle argentée. German: Silberne Schmetterlingsfledermaus. Italian: Glauconitterìde argentàta, Glauconicterìde argentàta. Tshokwe (Angola): Kafukufuku-mutoma.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008d; IUCN, 2009).

Assessment History
Global
2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008d; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004g; IUCN, 2004). 1996: LR/lc [assessed as part of *Chalinolobus argentatus*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
Glauconycteris argentata is threatened in the western and eastern parts of its range by deforestation resulting from logging activities, and the conversion of land to agricultural use (Jacobs *et al.*, 2008d; IUCN, 2009).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008d) [in IUCN (2009)] report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further studies are needed into the distribution, natural history and threats to this little recorded species.

GENERAL DISTRIBUTION:
Glauconycteris argentata is widespread in Central and East Africa. It ranges from Cameroon and Equatorial Guinea (Rio Muni), into the Democratic Republic of the Congo, Rwanda, Burundi, Uganda, Kenya, Tanzania and possibly northern Malawi, with the southernmost record from northwestern Angola. The range is not well-known, and the species is expected to be distributed more widely than is currently known.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 562); Burundi (Hayman *et al.*, 1966); Cameroon; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 562); Equatorial Guinea (Jones, 1971); Gabon (1st record: Peereboom *et al.*, 2012 3); Kenya (Aggundey and Schlitter, 1984); Malawi (Ansell and Dowsett, 1988: 39; Monadjem *et al.*, 2010d: 562); Rwanda (Baeten *et al.*, 1984); Tanzania (Stanley and Goodman, 2011: 43).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

ECHOLOCATION:
Peereboom *et al.* (2012: 4) report the following values: F_{min}: 28.42 - 34.45 (31.59 ± 1.48) kHz; F_{max}: 77.95 - 101.60 (89.16 ± 7.11) kHz, F_{peak}: 40.26 - 47.14 (43.96 ± 1.8) kHz, duration: 2.0 - 3.0 (2.4 ± 0.31) ms; first harm: 81.82 - 104.60 (94.04 ± 8.55), and interpulse interval: 24 - 128 (55 ± 34) ms.

From Kenya, López-Baucells *et al.* (2017: 24) reported some different values: F_{min}: 16.32 - 40.62 (35.20 ± 3.11) kHz, F_{max}: 41.37 - 75.09 (56.45 ± 9.40) kHz, F_{peak}: 36.19 - 44.77 (40.38 ± 1.68) kHz, duration: 0.7 - 8.52 (4.03 ± 1.86) ms, slope: -48.51 - -0.69 (-5.28 ± 6.19) kHz/ms.

From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 41 calls of 2 bats: F_{peak}: 42.5 ± 0.5 (42.2 - 42.9) kHz, F_{min}: 40.6 ± 0.1 (40.5 - 40.6) kHz, F_{max}: 75.1 ± 4.3 (64.8 - 78.2) kHz, duration: 1.7 ± 0.1 (1.6 - 1.8) ms.

MOLECULAR BIOLOGY:
Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
Recorded from lowland tropical moist forest and moist savanna habitats.

ROOST:
At Uzungwa Scarp Forest Reserve, Tanzania, Trentin and Rovero (2011: 51) reported a group of 10 females and their young to roost underneath the leaves of palm trees.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 85 minutes, and the digestibility rate about 78.9 %.

POPULATION:
Structure and Density
This is a rarely recorded, poorly known species (Jacobs *et al.*, 2008d; IUCN, 2009).

Trend
2008: Unknown (Jacobs *et al.*, 2008d; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Trentin and Rovero (2011: 51) observed about 10 adult females with young in December 2005 at Uzungwa Scarp Forest Reserve, Tanzania.

VIRUSES:
Phenuiviridae
Phlebovirus
de Jong *et al.* (2011: 11), Luis *et al.* (2013: Suppl.), and Willoughby *et al.* (2017: Suppl.) report the occurrence of Rift Valley fever virus.

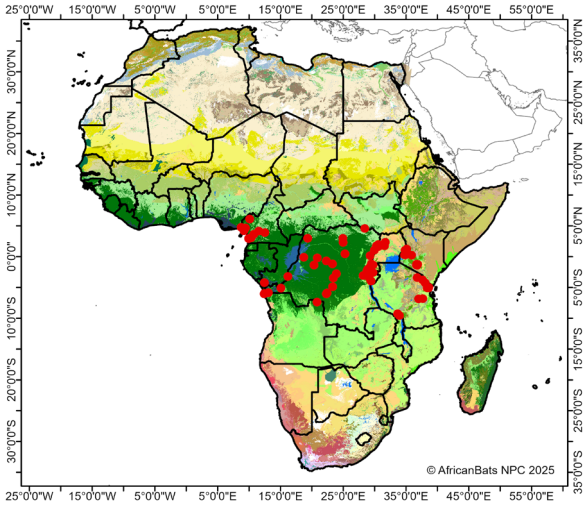

Figure 306. Distribution of *Glauconycteris argentata*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Burundi, Cameroon, Congo, Congo (Democratic Republic of the), Kenya, Rwanda, South Sudan, Tanzania, Uganda.

Glauconycteris atra Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, 2017

*2017. *Glauconycteris atra* Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, J. Syst. Evol. Res., 56 (1): 6, fig 2 (for 2018). Publication date: 22 August 2017. Type locality: Congo (Democratic Republic of the): Tshopo province: Yaengo [00 20 56 N 24 28 55 E, 400 m]. Holotype: MNHN ZM-2016-2792: ad ♀, skull and alcoholic. Collected by: Alexandre Hassanin, Guy-Crispin Gembu Tungaluna, Prescott Musaba Akawa, Raphaël Colombo, Tamás Görföl and Vuong Tam Tu; collection date: 5 December 2013; original number: K13-215. - Etymology: Atra refers to the colour of the pelage, which is dark and gloomy (blackish brown) (see Hassanin *et al.*, 2017: 6). (Current Combination).

COMMON NAMES:
English: Blackish Butterfly Bat. French: Glauconyctère sombre. German: Dunkle Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Known only from three localities in the riparian zone on the left bank of the Congo River (DRC).

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

Glauconycteris beatrix Thomas, 1901

*1901. *Glauconycteris beatrix* Thomas, Ann. Mag. nat. Hist., ser 7, 8 (45): 256. Publication date: 1 September 1901 [Goto Description]. Holotype: NHMUK 1898.5.4.19: ♀. Collected by: George Latimer Bates Esq. Collection

date: January 1898. - Comments: Equatoria Guinea: Rio Muni, Benito River, 15 mi. (24 km) from mouth. (Grubb *et al.* (1998: 89) mention "Benito River, French Congo, fifteen miles from mouth [Mbini River, in Equatorial Guinea]". (Current Combination).

1998. *Glauconycteris beatrix beatrix:* Grubb, Jones, Davies, Edberg, Starin and Hill, Mammals of Ghana, Sierra Leone and The Gambia, 89. (Name Combination).

? *Chalinolobus beatrix:* (Name Combination).

TAXONOMY:
Koopman (1993a: 199) included *humeralis*; see Koopman (1971: 7, 8), but see Simmons (2005).

COMMON NAMES:
Castilian (Spain): Murciélago Mariposa. Czech: netopýr rovníkový. English: Beatrix Bufferfly Bat, Beatrix's Bat. French: Glauconyctère de Béatrix, Murin à bajoues de Béatrice, Barbastelle de Béatrix. German: Kleine Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1, 2001) in view of its wide distribution, presumed large population (especially in Central Africa), and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008e; IUCN, 2009; Monadjem *et al.*, 2017cp).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cp). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008e; IUCN, 2009). 2004: NT ver 3.1 (2001) (Jacobs *et al.*, 2004f; IUCN, 2004). 1996: LR/nt [assessed as *Chalinolobus beatrix*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
This species is threatened by general habitat loss, often resulting from logging activities and the conversion of land to agricultural use (Jacobs *et al.*, 2008e; IUCN, 2009; Monadjem *et al.*, 2017cp).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008e) [in IUCN (2009)] and Monadjem *et al.* (2017cp) suggest that this species has been recorded from a number of protected areas and further studies are needed into the distribution, natural history and threats to this little-known bat.

GENERAL DISTRIBUTION:
Glauconycteris beatrix is distributed in West and Central Africa. It ranges from Côte d'Ivoire in the west, through Ghana and Nigeria to Cameroon and Equatorial Guinea (Rio Muni and Bioko), with scattered records from Gabon, Central African Republic, Angola and the Democratic Republic of the Congo.

Native: Angola (Eger and Schlitter, 2001; Monadjem *et al.*, 2010d: 562); Cameroon; Central African Republic (Heller *et al.*, 1994; Lunde *et al.*, 2001: 537); Congo (Bates *et al.*, 2013: 324 - 1st authenticated record); Congo (The Democratic Republic of the) (Monadjem *et al.*, 2010d: 562); Côte d'Ivoire; Equatorial Guinea; Gabon; Ghana; Guinea-Bissau (Rainho and Ranco, 2001: 69); Nigeria (Happold, 1987).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Sanborn (1953: 166) reports a male specimen, collected in Gabon, which looks very similar to the description of *G. beatrix*, but has a small tuft of white hairs on each shoulder, but he also indicates that this character is sometimes variable, as was already mentioned by Hayman and Jones (1950: 762).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
In their study on the reversibility of the mandibular symphyseal fusion, Scott *et al.* (2012: 2943) mention that in this species the symphysis is unfused with smooth surfaces.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987) and Heller *et al.* (1994: 6).

MOLECULAR BIOLOGY:
Karyotype
Volleth and Heller (2008) reported 2*n* = 22, FN = 40, only bi-armed chromosomes and an autosome-X translocation for a female from the Democratic Republic of Congo. Porter *et al.* (2010) report for Gabon 2*n* = 22, with all chromosomes being distinctly biarmed, with ten pairs are metacentric or slightly submetacentric and one pair (the smallest) is subtelocentric. 2 *n* = 22 was also reported by Volleth and Eick (2012: 167), who also mention a segment number of 24.

Sotero-Caio *et al.* (2017: 3) indicate that the pericentromeric regions of the chromosomes show an increased amount of heterochromatin.

Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
This species is generally associated with lowland tropical moist forest (Happold, 1987).

ROOST:
There appears to be little information available on the roosting habits of this species, but presumably it can be found within hollow trees and dense vegetation (Jacobs *et al.*, 2008e).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 76 minutes, and the digestibility rate about 80.1 %.

POPULATION:
Structure and Density
This appears to be a rare, or at least a rarely recorded, species (Jacobs *et al.*, 2008e; IUCN, 2009; Monadjem *et al.*, 2017cp).

Trend
2016: Unknown (Monadjem *et al.*, 2017cp).
2008: Unknown (Jacobs *et al.*, 2008e; IUCN, 2009).

VIRUSES:
Coronaviridae - Coronaviruses
SARS-CoV
One faecal sample, collected in Febuary 2008 in Ghana, tested negative for coronavirus (CoV) RNA (Pfefferle *et al.*, 2009).

Paramyxoviridae
Drexler *et al.* (2012a: Suppl. Table S1) indicated that the single specimen they examined from Ghana did not test positive for *Repirovirus, Henipavirus, Morbillivirus, Rubulavirus* or *Pneumovirus*.

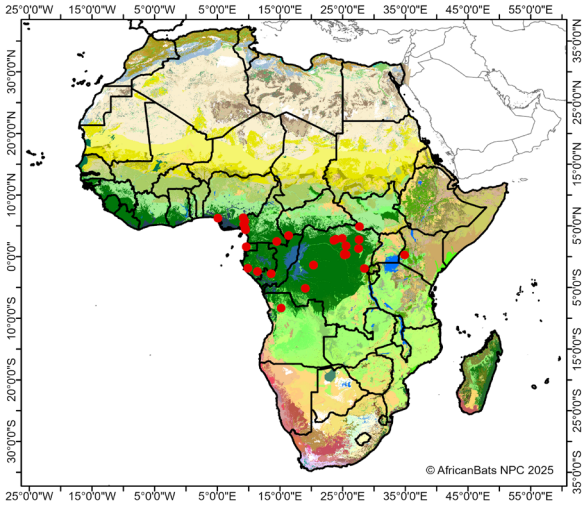

Figure 308. Distribution of *Glauconycteris beatrix*.

Glauconycteris cf. beatrix Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, 2017

2017. *G[lauconycteris] cf. beatrix:* Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, J. Syst. Evol. Res., 56 (1): 7 (for 2018). Publication date: 22 August 2017.
*2017. *Glauconycteris cf. beatrix:* Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, J. Zool. Syst. Evol. Res., 56 (1): Suppl (for 2018). Publication date: 22 August.
? *Glauconycteris beatrix:* (Name Combination).

TAXONOMY:
In their study on the multilocus phylogeny of *Glauconycteris* specimens from the DRC, Hassanin *et al.* (2017: 7) found a number of specimens in the collection of the ROM that were identified as *G. beatrix* but scored very different in their analyses as compared to other specimens assigned to this species. Their scores were much more like those of *G. curryae*, which seemed to be related to the length of the tail and the skull profile. Their analyses of the mitochondrial tree (*CO1, Cytb* and *12S* genes), however, showed these specimens not to be directly related to either *beatrix* or *curryae*, but closer to *humeralis*. Further investigation is necessary to elucidate this problem.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

POPULATION:
Structure and Density
Unknown.

Glauconycteris cf. humeralis Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, 2017

2017. *G[lauconycteris] cf. humeralis:* Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, J. Syst. Evol. Res., 56 (1): 6 (for 2018). Publication date: 22 August 2017.
*2017. *Glauconycteris cf. humeralis:* Hassanin, Colombo, Gembu, Merle, Tu, Görföl, Musaba Akawa, Csorba, Kearney, Monadjem and Ing, J. Zool. Syst. Evol. Res., 56 (1): Suppl (for 2018). Publication date: 22 August 2017.

TAXONOMY:
For their study on the multilocus phylogeny of *Glauconycteris* specimens from the DRC, Hassanin *et al.* (2017: 6) used data collected from two specimens from the Central African Republic, which were originally identified as *G. humeralis*. Their analyses indicated that these specimens were quite different from the other *humeralis* included and suggested that they might represent a new species. Unfortunately, however, these two animals were released after the biopsy was taken. Therefore, Hassanin *et al.* (2017: 16) did not describe this species as new.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Glauconycteris curryae Eger and Schlitter, 2001

2001. *Glauconycteris curryae:* Eger, Acta Chiropt., 3 (2): 248. (Current Combination, Emendation, Current Spelling).
*2001. *Glauconycteris curryi* Eger and Schlitter, Acta Chiropt., 3 (1): 2, figs 1 - 4. Type locality: Cameroon: Bipindi, 10 km W [03 05 N 10 25 E, ca. 300 m]. [Goto Description]. Holotype: ROM 56243: ad ♀, skin and skull. Collected by: Randolph Lee Peterson, Robert M. Glen and Philip Imbayi; collection date: 19 February 1970. Note: netted over a pool in a vast stand of bamboo, by a river (see Eger and Schlitter (2001: 2). - Etymology: Named in honour of Noreen Curry, in recognition of her interest in bats and her support of Royal Ontario Museum field research in Africa and bat education at the ROM (see Eger and Schlitter, 2001).
? *Chalinolobus curryi:*

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: netopýr konžský. English: Curry's Butterfly Bat, Curry's Bat. French: Glauconyctère de Curry. German: Currys Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) since it has only recently been described, and there is still very little information on its extent of occurrence, status, threats and ecological requirements (Schlitter, 2008b; IUCN, 2009; Schlitter, 2019c).

Assessment History
Global
2018: DD ver 3.1 (2001) (Schlitter, 2019c). 2008: DD ver 3.1 (2001) (Schlitter, 2008b; IUCN, 2009). 2004: DD ver 3.1 (2001) (Schlitter, 2004f; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Schlitter, 2008b; IUCN, 2009; Schlitter, 2019c).

CONSERVATION ACTIONS:
Schlitter (2008b) [in IUCN (2009)] and Schlitter (2019c) suggests that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed into the distribution, natural history and threats to this species.

GENERAL DISTRIBUTION:
Glauconycteris curryae is a Central African species, known only from southern Cameroon, Gabon and a single locality in the Democratic Republic of the Congo (Yalosemba North of the River).

Native: Cameroon; Congo (The Democratic Republic of the), Gabon.

MOLECULAR BIOLOGY:
Karyotype
Volleth *et al.* (2023a: 8) mention this species has the largest amount of constitutive heterochromatin (cH) (> 40% of the total autosome length) of all the species they examined, and a karyotype composed of only 22 chromosomes.

HABITAT:
This species has been recorded from lowland tropical moist forest and swamp forest (Schlitter, 2008b).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 79 minutes, and the digestibility rate about 79.7 %.

POPULATION:
Structure and Density
Population size unknown (Schlitter, 2008b; IUCN, 2009). The area where this species has been recorded is often
inaccessible and it is difficult to catch this species (Schlitter, 2019c).

Trend
2018: Unknown (Schlitter, 2019c). 2008: Unknown (Schlitter, 2008b; IUCN, 2009).

Glauconycteris egeria Thomas, 1913

*1913. *Glauconycteris egeria* Thomas, Ann. Mag. nat. Hist., ser 8, 11 (61): 144. Publication date: 1 January 1913. Type locality: Cameroon: Western province: Bibundi [04 15 N 08 58 E]. [Goto Description]. Holotype: NHMUK 1912.12.13.3: ♂. Original number: 22. Presented/Donated by: Prof. E. Lampe (Wiesbaden Museum). (Current Combination).
2015. *Chalinolo busegeria:* Carr et al., Ecosystem profile, 18. Publication date: 31 December 2015. (Lapsus).
? *Chalinolobus egeria:* (Name Combination).
? *Chalinolobus egerius:* (Name Combination).
? *G[lauconycteris] cf egeria:* (Name Combination).
? *Glauconycteris poensis:* (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: netopýr bibundinský. English: Bibundi Bufferfly Bat, Bibundi Bat. French: Glauconyctère de Bibundi, Murin à bajoues de Bibundi, Barbastelle du Bibundi. German: Bibundi Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Jacobs *et al.*, 2008f; IUCN, 2009; Jacobs *et al.*, 2019b).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019b). 2008: DD ver 3.1 (2001) (Jacobs *et al.*, 2008f; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004n; IUCN, 2004). 1996: LR/lc [concern assessed as *Chalinolobus egeria*] (Baillie and Groombridge, 1996: 137).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Jacobs *et al.*, 2008f; IUCN, 2009; Jacobs *et al.*, 2019b).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008f) [in IUCN (2009)] and Jacobs *et al.* (2019b) report that it has been recorded from the Dzanga-Sangha Special Dense Forest Reserve in the Central African Republic (Lunde *et al.*, 2001), and may be present in additional protected areas. Further field surveys are needed to better determine the distribution, natural history and possible threats to this little-known bat.

GENERAL DISTRIBUTION:
Currently only been recorded from three localities. The type locality is Bibundi in the Western Province of Cameroon (Thomas, 1913b); three individuals (as *G.* cf. *egeria*) were collected from Dzanga-Sangha Special Dense Forest Reserve in the Central African Republic (Lunde *et al.*, 2001); the species indicated as being present in western Uganda by Koopman (1993a: 199), although further details are needed of the collection site in this country (Jacobs *et al.*, 2008f; IUCN, 2009).

Native: Cameroon (Thomas, 1913b); Central African Republic (Lunde *et al.*, 2001); Nigeria (Tanshi *et al.*, 2022a: 317).

Presence uncertain: Uganda (Koopman, 1993a; Simmons, 2005: 487).

ECHOLOCATION:
From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 24 calls of 2 bats: F_{peak}: 26.3 ± 2.5 (21.5 - 37.0) kHz, F_{min}: 22.0 ± 2.1 (19.9 - 26.1) kHz, F_{max}: 53.8 ± 2.6 (47.3 - 56.2) kHz, duration: 2.6 ± 0.6 (1.6 - 3.3) ms.

HABITAT:
Lunde *et al.* (2001) recorded three specimens (allocated to *G.* cf. *egeria*) collected in dense secondary tropical lowland forest and along a forest road. Bakwo Fils *et al.* (2021b: 6) reported one specimen collected in undisturbed Afromontane forest in Cameroon.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 81 minutes, and the digestibility rate about 79.5 %.

POPULATION:
Structure and Density
This species is known from very few specimens (Jacobs *et al.*, 2008f; IUCN, 2009; Jacobs *et al.*, 2019b).

Tend
2018: Unknown (Jacobs *et al.*, 2019b). 2008: Unknown (Jacobs *et al.*, 2008f; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Cameroon, Central African Republic, Nigeria, Uganda.

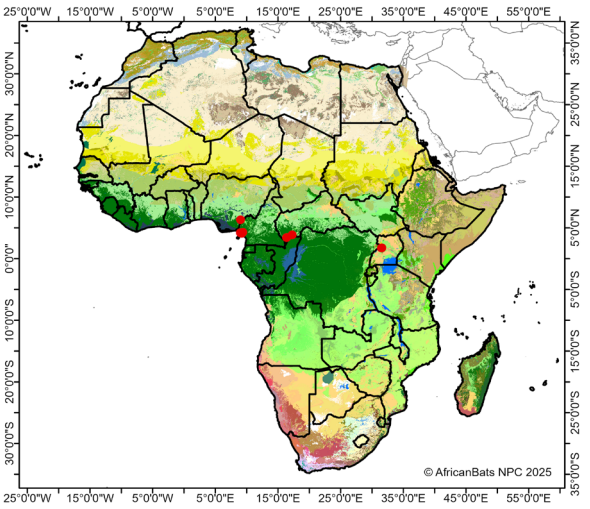

Figure 312. Distribution of *Glauconycteris egeria*.

Glauconycteris gleni Peterson and Smith, 1973

*1973. *Glauconycteris gleni* Peterson and Smith, Life Sci. Occ. Pap., R. Ont. Mus., 22: 3, figs 1 - 4. Publication date: 17 August 1973. Type locality: Cameroon: near Lomie [ca. 03 10 N 13 37 E]. [Goto Description]. Holotype: ROM 57125: ad ♀, skin and skull. Collected by: Robert M. Glen and Vincent N. Ngam; collection date: 16 June 1970. - Etymology: In honour of Mr. Robert Glenn, Nairobi, Kenya, who collected the holotype, assisted in the collection of the Uganda series of the new species, and who has been a field companion extraordinaire. (see Peterson and Smith, 1973: 1). (Current Combination).
? *Chalinolobus gleni:* (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: netopýr Glenův. English: Glen's Butterfly Bat, Glen's Wattled Bat. French: Glauconyctère de Glen, Murin à bajoues de Glen, Barbastelle de Glen. German: Glens Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Jacobs *et al.*, 2008g; IUCN, 2009; Jacobs *et al.*, 2019a).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019a). 2008: DD ver 3.1 (2001) (Jacobs *et al.*, 2008g; IUCN, 2009). 2004: VU D1 ver 3.1 (2001) (Jacobs *et al.*, 2004m; IUCN, 2004). 1996: LR/nt [assessed as *Chalinolobus gleni*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It is presumably threatened in parts of its range by logging and the conversion of forest habitat to agricultural use (Jacobs *et al.*, 2008g; IUCN, 2009; Jacobs *et al.*, 2019a).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008g) [in IUCN (2009)] and Jacobs *et al.* (2019a) report that there appear to be no direct conservation measures in place for this species. It is not known if the species is present within any protected areas. Additional studies are needed into the distribution, abundance, general ecology and potential threats to this species.

GENERAL DISTRIBUTION:
Glauconycteris gleni is a poorly known species and has only been recorded from the three localities in Africa. The type locality 'near Lomie' in Cameroon, from a single site in western Uganda and Tanzania (1st record: Stanley and Foley, 2008: 119).

Native: Cameroon, Tanzania (Stanley and Foley, 2008: 119); Uganda.

HABITAT:
This poorly known bat is associated with lowland tropical moist forest.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 92 minutes, and the digestibility rate about 78.1 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Jacobs *et al.*, 2008g; IUCN, 2009; Jacobs *et al.*, 2019a).

Trend
2018: Unknown (Jacobs *et al.*, 2019a). 2008: Unknown (Jacobs *et al.*, 2008g; IUCN, 2009).

Glauconycteris humeralis J.A. Allen, 1917

*1917. *Glauconycteris humeralis* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 448, text-fig 7 A. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Medje [02 25 N 27 18 E, 800 m]. [Goto Description]. Holotype: AMNH 49013: ad ♀, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 7 September 1910; original number: 956. (Current Combination).
? *Chalinolobus humeralis:* (Name Combination).
? *Glauconycteris beatrix humeralis:* (Name Combination).
? *Glauconycteris beatrix:* (Name Combination).
? *Glauconycteris cf. humeralis R13-98*

TAXONOMY:
Included in *beatrix* by Koopman (1993a: 199), considered a subspecies of *beatrix* by Eger and Schlitter (2001), but considered a valid species by Simmons (2005).

COMMON NAMES:
Chinese: 花蝶蝠. Czech: netopýr medžeský. English: Allen's Spotted Bat. French: Glauconyctère tachetée. German: Gefleckte Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Schlitter, 2008c; IUCN, 2009; Schlitter, 2019d).

Assessment History
Global
2018: DD ver 3.1 (2001) (Schlitter, 2019d). 2008: DD ver 3.1 (2001) (Schlitter, 2008c; IUCN, 2009).

2004: DD ver 3.1 (2001) (Schlitter, 2004k; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known. It may be threatened within parts of its range by deforestation resulting from logging and mining activities, and the conversion of forest to farmland (Schlitter, 2008c; IUCN, 2009; Schlitter, 2019d).

CONSERVATION ACTIONS:
Schlitter (2008c) [in IUCN (2009)] and Schlitter (2019d) reports that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected areas. Further research is needed into the distribution, natural history and threats to this poorly known forest species.

GENERAL DISTRIBUTION:
Native: Congo (The Democratic Republic of the) (Stephan *et al.*, 1987: 71; Heller *et al.*, 1994: 6; Eger and Schlitter, 2001: 7); Tanzania (Stanley and Foley, 2008: 119); Uganda.

Presence uncertain: Kenya (Aggundey and Schlitter, 1984).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 65 minutes, and the digestibility rate about 81.9 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Schlitter, 2008c; IUCN, 2009; Schlitter, 2019d).

Trend
2018: Unknown (Schlitter, 2019d). 2008: Unknown (Schlitter, 2008c; IUCN, 2009).

"Africa", Congo (Democratic Republic of the), Kenya, Tanzania, Uganda.

Glauconycteris kenyacola Peterson, 1982

*1982. *Glauconycteris kenyacola* Peterson, Can. J. Zool., 60: 2521, figs 1 - 4. Type locality: Kenya: Coast province: on Galole road: Garsen, 8.5 km N [02 12 S 40 05 E]. [Goto Description]. Holotype: ROM 71305: ad ♀, skin and skull. Collected by: Judith L. Eger and Robert M. Glen; collection date: 30 December 1970. - Etymology: From the geographical scientific Latin substantive *Kènya* and the Latin suffix -còla (-còla) "denoting one who inhabits", i.e. the species is an inhabitant of Kenya (see Peterson, 1982: 2522; Lanza *et al.*, 2015: 355. (Current Combination).
? *Chalinolobus kenyacola:* (Name Combination).
? *Chalinolobus kenyacolus (?):* (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Chinese: 肯尼亚蝶蝠. Czech: netopýr keňský. English: Kenyan Butterfly Bat, Kenyan Wattled Bat, Kenya Barbastelle. French: Glauconyctère du Kenya, Murin à bajoues du Kenya, Barbastelle du Kenya. German: Kenya-Schmetterlingsfledermaus. Italian: Glauconitterìde keniòta, Glauconicterìde keniòta.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status (Jacobs *et al.*, 2008h; IUCN, 2009; Jacobs *et al.*, 2019f).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019f). 2008: DD ver 3.1 (2001) (Jacobs *et al.*, 2008h; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004l; IUCN, 2004). 1996: DD [assessed as *Chalinolobus kenyacola*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are unclear. If it is associated with coastal forest habitats, it is likely to be threatened by extraction of wood and conversion of land to agricultural use (Jacobs *et al.*, 2008h; IUCN, 2009; Jacobs *et al.*, 2019f).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008h) [in IUCN (2009)] and Jacobs *et al.* (2019f) report that it is not known if this species is present in any protected area. There is a need for additional field surveys to better understand the distribution, natural history and possible threats to this little-known species.

GENERAL DISTRIBUTION:
Glauconycteris kenyacola has only been recorded from the type locality of 'Galole Road, 8.5 km north of Garsen, Coast Province, Kenya' (Peterson, 1982).

Native: Kenya (Peterson, 1982; Aggundey and Schlitter, 1984).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 74 minutes, and the digestibility rate about 80.4 %.

POPULATION:
Structure and Density
This species is known only from the type collection (Jacobs *et al.*, 2008h; IUCN, 2009; Jacobs *et al.*, 2019f).

Trend
2018: Unknown (Jacobs *et al.*, 2019f). 2008: Unknown (Jacobs *et al.*, 2008h; IUCN, 2009).

Glauconycteris machadoi Hayman, 1963

*1963. *Glauconycteris machadoi* Hayman, Publ. Cult. Comp. Diamantes Angola, Lisboa, 66: 107. Type locality: Angola: Lac Calundo [11 48 S 20 52 E]. [Goto Description]. Holotype: NHMUK 1962.2074. - Etymology: In honour of Dr. A. de Barros Machado, whose researches into the zoology of the Lunda District of Angola have proved so fruitful in many directions (see Hayman, 1963: 107)... (Current Combination).
? *Chalinolobus machadoi:* (Name Combination).

TAXONOMY:
Included in *variegata* as a melanistic population by Koopman (1993a: 200), but considered a valid species by Simmons (2005).

COMMON NAMES:
Czech: netopýr Machadův. English: Machado's Butterfly Bat. French: Glauconyctère de Machado. German: Machados Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status (Schlitter, 2008d; IUCN, 2009; Schlitter, 2019a).

Assessment History
Global
2018: DD ver 3.1 (2001) (Schlitter, 2019a). 2008: DD ver 3.1 (2001) (Schlitter, 2008d; IUCN, 2009). 2004: DD ver 3.1 (2001) (Schlitter, 2004d; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Schlitter, 2008d; IUCN, 2009; Schlitter, 2019a).

CONSERVATION ACTIONS:
Schlitter (2008d) [in IUCN (2009)] and Schlitter (2019a) reports that this species does not appear to be present in a protected area. Further taxonomic studies are needed for this species, as is field research into the distribution, natural history and possible threats to this little-known species.

GENERAL DISTRIBUTION:
Glauconycteris machadoi has only been recorded from the type locality of 'Lac Calundo'. in eastern Angola (see Rambaldini, 2010: 252).

Native: Angola (Hayman, 1963).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 79 minutes, and the digestibility rate about 79.7 %.

POPULATION:
Structure and Density
It is known only from the holotype (Schlitter, 2008d; IUCN, 2009; Schlitter, 2019a).

Trend
2018: Unknown (Schlitter, 2019a). 2008: Unknown (Schlitter, 2008d; IUCN, 2009).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola.

Glauconycteris poensis (J. E. Gray, 1842)

*1842. *Kerivoula poensis* J. E. Gray, Ann. Mag. nat. Hist., [ser 1], 10 (65): 258. Publication date: 1 December 1842. Type locality: Nigeria: Lower Niger River: Abo [=Aboh] [05 33 N 06 32 E]. Holotype: NHMUK 1842.11.4.33. - Comments: Type locality originally "Fernando Po", but in reality Abo, Lower Niger: see Allen and Thomson, Exp. Niger, 2: 479, 1848 in Allen, 1939a: 88, Grubb *et al.*, 1998: 89). Dobson (1878: 256) mentions an ad skull, as type presented by T. Thompson, Esq. R.N., originating from Fernando Po.
1868. *Vesperus (Hesperoptenus) kraussii* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 638. Publication date: 1868. Type locality: Nigeria: S Nigeria: Yoruba. - Comments: Type specimen: SMNH ???, ad ♀ (see Dobson, 1878: 255). (Name Combination).
? *Chalinolobus poensis:* (Name Combination).
? *Glauconycteris poensis:* (Name Combination, Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: netopýr abonský. English: Abo Butterfly Bat, Abo Bat. French: Glauconyctère d'Abo, Murin à bajoues d'Abo, Barbastelle d'Abo. German: Abo-Schmetterlingsfledermaus, Westafrikanische Nachtfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017cq).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cq). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008l; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004k; IUCN, 2004). 1996: LR/nt [assessed as *Chalinolobus poensis*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
It is presumably threatened in parts of its range by habitat loss resulting from logging and similar activities (Jacobs *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017cq).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008l) [in IUCN (2009)] and Monadjem *et al.* (2017cq) report that there appear to be no direct conservation measures in place. It is not known if the species is present in any protected area. Further field surveys are needed to better determine the distribution of this species, and to gather additional information on the natural history of this little-known bat.

GENERAL DISTRIBUTION:
Glauconycteris poensis is largely distributed in West and Central Africa, with a possible record from northeastern Tanzania. It ranges from Senegal in the west, through much of West Africa to Cameroon, Equatorial Guinea (the island of Bioko) and the Democratic Republic of the Congo in Central Africa.

Native: Benin (Capo-Chichi *et al.*, 2004: 162); Cameroon; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966); Côte d'Ivoire; Equatorial Guinea (Bioko); Ghana (Jeffrey, 1975; Decher and Fahr, 2007: 20); Guinea (Fahr *et al.*, 2006a: 74); Guinea-Bissau (Rainho and Ranco, 2001: 68); Liberia (Koopman, 1989b; Koopman *et al.*, 1995; Monadjem and Fahr, 2007: 50); Nigeria (Happold, 1987); Senegal; Sierra Leone; Tanzania (Stanley and Foley, 2008: 119); Togo.

Presence uncertain: Kenya.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Hayman and Jones (1950) mention a large variation in shoulder spots and flank stripes in individuals from Sierra Leone, sometimes being asymmetrical (a spot on one shoulder only). During their study of *Glauconycteris*, Hassanin *et al.* (2017: 16) never found asymmetrical spots in *G. poensis*, and they therefore caution the statement by Hayman and Jones (1950) and indicate that the specimens from Sierra Leone should be re-examined to confirm their identification.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987) and Heller *et al.* (1994: 6).

ECHOLOCATION:
In Benin, the bat's call was categorized as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype by Roemer *et al.* (2021: Suppl.).

MOLECULAR BIOLOGY:
Karyotype
Porter *et al.* (2010) report for Gabon $2n = 22$, with all chromosomes being distinctly biarmed, with ten pairs are metacentric or slightly submetacentric and one pair (the smallest) is subtelocentric. The lack of chromosomal heteromorphism in the male suggests a neo-XY sex determining system in this species.

Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
Associated with lowland tropical moist forest (Happold, 1987).

In the Mount Nimba area, Monadjem *et al.* (2016y: 368) found this species widely present in forested habitats, in degraded secondary forests as well as on the edge of a small village, at altitudes between 450 and 880 m.

ROOST:
Roost in holes in trees, on the fronds of coconut palms, and presumably in similar vegetation (Rosevear, 1965; Jeffrey, 1975; Happold, 1987).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 73 minutes, and the digestibility rate about 80.6 %.

POPULATION:
Structure and Density
Colonies are formed of small groups of animals, up to eight individuals. While the species is generally rare, it is considered to be one of the more common forest species of the genus *Glauconycteris* (Jacobs *et al.*, 2008l; IUCN, 2009; Monadjem *et al.*, 2017cq).

Trend
2016: Unknown (Monadjem *et al.*, 2017cq).
2008: Unknown (Jacobs *et al.*, 2008l; IUCN, 2009).

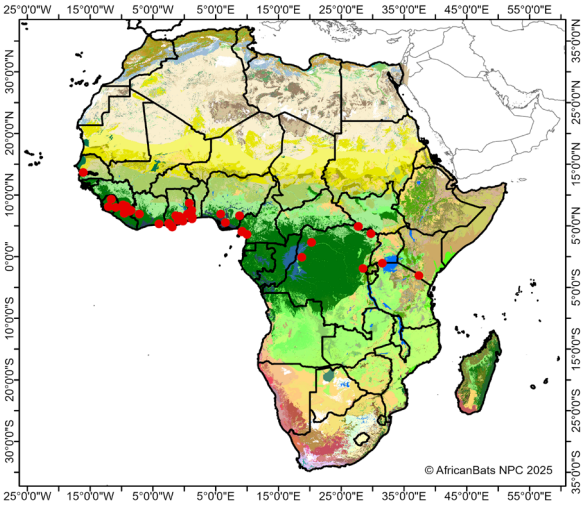

Figure 317. Distribution of *Glauconycteris poensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Benin, Cameroon, Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, Guinea, Liberia, Nigeria, Senegal, Sierra Leone, South Sudan, Tanzania, Togo.

Glauconycteris superba Hayman, 1939

*1939. *Glauconycteris superba* Hayman, Ann. Mag. nat. Hist., ser 11, 3 (14): 219, figs 1 - 2. Publication date: 1 February 1939. Type locality: Congo (Democratic Republic of the): Oriental province: Ituri District: about 30 mi (45 km) ENE of Medje: Pawa [02 32 N 27 40 E]. [Goto Description]. Holotype: RMCA 14765: ad ♂, skull and alcoholic. Collected by: Dr. Albert Dubois. Hayman (1939: 220) mentions that this specimen is probably a male as the sexual organs were cut away by Dr. Dubois when preparing the specimen. (Current Combination).

1947. *Glauconycteris superba sheila* Hayman, Ann. Mag. nat. Hist., ser 11, 13 (103): 503 (for 1946). Publication date: 7 August 1947. Type locality: Ghana: Central province: Oda district: Oda [05 55 N 00 56 W]. [Goto Description]. Holotype: NHMUK 1947.10: ad ♀, skull and alcoholic. Collected by: George Soper Cansdale; collection date: 6 December 1946; original number: 807. - Etymology: In honour of Mrs. Cansale, wife of the collector (see Hayman, 1947c: 550).

2013. *Niumbaha superba:* Reeder, Helgen, Vodzak, Lunde and Ejotre. (Name Combination).

? *Chalinolobus superbus:* (Name Combination).

TAXONOMY:
See Simmons (2005).

Reeder *et al.* (2013: 93) proposed to place *superba* into a separate, new genus: *Niumbaha* Reeder, Helgen, Vodzak, Lunde and Ejotre, 2013 as they found most external features to be different from *Glauconycteris sensu stricto*. However, as this view is not yet confirmed, we tentatively retain this species in the genus *Glauconycteris*.

Using *Cytb* and RAG2 data, Hassanin *et al.* (2017: 1) found that *superba* is a sister-group of *G. variegata*, which seems to confirm that *Niumbaha* should probably be considered a synonym of *Glauconycteris*.

COMMON NAMES:
Czech: netopýr iturijský. English: Superb Butterfly Bat, Pied Butterfly Bat, Pied Bat, Badger bat, Panda Bat. French: Glauconyctère pie, Murin à bajoues pie, Barbastelle bariolée. German: Schwarz-Weiße Schmetterlingsfledermaus, Große Schmetterlingsfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Fahr *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017af).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017af). 2008: LC ver 3.1 (2001) (Fahr *et al.*, 2008; IUCN, 2009). 2004: VU B2ab(iii) ver 3.1 (2001) (Fahr *et al.*, 2004; IUCN, 2004). 1996: VU [assessed as *Chalinolobus superbus*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
As it has only been recorded from closed forest, it may be threatened by deforestation due to general logging and conversion of land to agricultural use (Fahr *et al.*, 2008; IUCN, 2009; Monadjem *et al.*, 2017af).

CONSERVATION ACTIONS:
Fahr *et al.* (2008) [in IUCN (2009)] and Monadjem *et al.* (2017af) report that there appear to be no direct conservation measures in place for this species. It may be protected within the Ituri Forest, although this needs to be confirmed. There is a need for further directed field surveys to better determine the distribution, natural history and possible threats to this species.

GENERAL DISTRIBUTION:
Recorded from Côte d'Ivoire (locality not given) (Peterson and Smith, 1973); from Oda in Oda Province, Ghana (Hayman, 1947c; Grubb *et al.*, 1998); and from the Ituri Forest in northeastern Congo (Hayman, 1939; Hayman *et al.*, 1966). It has previously been reported to occur in Uganda, however, this is now considered to be in error. It may be present in Sierra Leone, however, it has yet to have been recorded in this country (Grubb *et al.*, 1998).

In 2013, two new records were reported: one from the Democratic Republic of the Congo (Gembu Tungaluna *et al.*, 2013), and one from South Sudan (Reeder *et al.*, 2013).

Native: Congo (The Democratic Republic of the) (Hayman, 1939; Hayman *et al.*, 1966; Gembu Tungaluna *et al.*, 2013); Côte d'Ivoire (Peterson and Smith, 1973); Ghana (Hayman, 1947c; Grubb *et al.*, 1998), South Sudan (Reeder *et al.*, 2013).

Presence uncertain: Sierra Leone (Grubb *et al.*, 1998).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Based on a series of 10 specimens, Ing *et al.* (2016: 479) found that both males and females have the same coloration pattern: three white markings on the head; a large white ruff on the throat, which is disconnected from two large white lateral stripes; and two white spots on the shoulders. One specimen had three shoulderspots. They also have four white stripes on the back. Around the sexual organs, the white colour is not pure, but yellowish, possibly the result of polution by bodily fluids.

Based on the Fa (47.5 mm) and Tibia (21.3 mm), Ing *et al.* (2016: 482) suspect that the holotype of *G. superba* is rather a female than "probably a male" as indicated by Hayman (1939).

SEXUAL DIMORPHISM:
On a series consisting of four ♀♀ and six♂♂, Ing *et al.* (2016: 479) found the females to be 5 % larger (Fa, Tib and 5th finger) and 10 % heavier than males.

ECHOLOCATION:
Ing *et al.* (2016: 481) found that the bats emitted sounds alternating between two distinct frequencies: **A**: range: 20.5 - 57.0 kHz, F_{min}: 22.9 ± 1.4 (20.5 - 25.1) kHz, F_{max}: 36.8 ± 6.6 (29.1 - 57.0) kHz, F_{peak}: 25.7 ± 2.2 (22.4 - 30.9) kHz, bandwidth: 13.8 ± 6.3 (5.9 - 32.6) kHz, duration: 5.6 ± 1.9 (3.1 - 9.6) ms; and **B**: range: 27.3 - 73.3 kHz, F_{min}: 29.8 ± 1.3 (27.3 - 31.3) kHz, F_{max}: 57.0 - 13.5 (38.8 - 73.3) kHz, F_{peak}: 33.0 ± 3.0 (28.8 - 38.2) kHz, bandwidth: 27.1 ± 13.2 (9.1 - 43.3) kHz, duration: 6.4 ± 1.8 (4.0 - 10.1) ms. The B type of call is produced when the wing beat becomes constant.

HABITAT:
This species is associated with 'heavy' or closed lowland tropical moist forest (Rosevear, 1965; Hayman and Hill, 1971).

Based on wing measurements, however, Ing *et al.* (2016: 482) found that *G. superba* has long wings, which are adapted for high-speed flight. The high wing loading values, furthermore, indicate low manoeuvrability. These are features which are generally found in bats flying in uncluttered or open space, i.e., above the canopy.

HABITS:
After being released, the bats flew at speeds of about 1 to 9 m/s (average 4 - 6 m/s) (Ing *et al.*, 2016: 482).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 81 minutes, and the digestibility rate about 79.5 %.

POPULATION:
Structure and Density
It is currently known only from three specimens. It is very rare, or at least rarely collected (Hayman and Hill, 1971; Grubb *et al.*, 1998).

Trend
2008: Unknown (Fahr *et al.*, 2008; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Two of the four females that were captured on Mbiye island (DRC) by Ing *et al.* (2016: 479) in December 2013 were lactating.

VIRUSES:
Circoviridae
Bat associated circovirus 12
This virus was reported by Vidovszky *et al.* (2023: Suppl.) from bats from the DRC.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Congo (Democratic Republic of the), Côte d'Ivoire, Ghana, South Sudan.

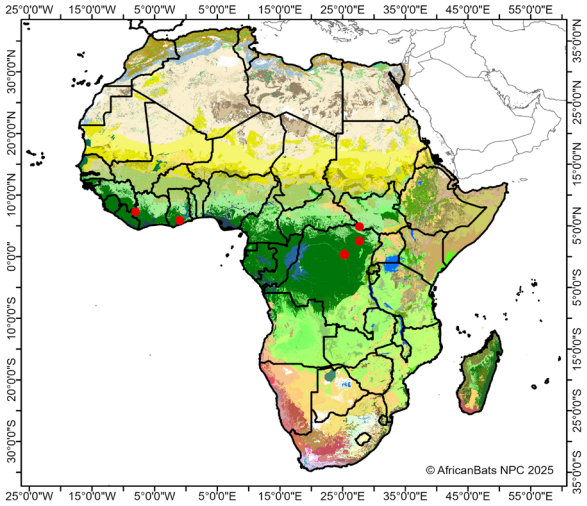

Figure 318. Distribution of *Glauconycteris superba*.

Glauconycteris variegata (Tomes, 1861)

*1861. *Scotophilus variegatus* Tomes, Proc. zool. Soc. Lond., 1861, I: 31, 36. Publication date: May 1861. Type locality: Namibia: Ovamboland: about 32 km west of Ondongwa: Otjoro [=Otjihoro] [ca. 17 54 S 15 38 E]. [Goto Description]. Syntype: NHMUK 1907.1.1.437: skin and skull. Collected by: 1 Anderson; collection date: 1 December 1859. See Tomes (1861b: 39). Syntype: NHMUK 1907.1.1.438: skin and skull. Collection date: 1 December 1859. See Tomes (1861b: 39). Syntype: ZMB 3033: ♂, skin and skull. Collected by: Andersson; collection date: 1 December 1859. See Turni and Kock (2008). - Comments: For details about the type locality, see Shortridge (1934), Meester *et al.* (1986: 54). - Etymology: From the feminine scientific Latin adjective *variegàta*, meaning "variegated", referring to the dark reticular pattern on the wings (see Lanza *et al.*, 2015: 356).

1905. *Glauconycteris papilio* Thomas, Ann. Mag. nat. Hist., ser 7, 15 (85): 77. Publication date: 1 January 1905. Type locality: Uganda: Entebbe [00 04 N 32 28 E, 3 800 ft]. [Goto Description]. Holotype: NHMUK 1899.8.4.14: ♀, skin and skull. Collected by: Sir F.J. Jackson Esq. Collection date: 10 April 1895. Presented/Donated by: Sir F.J. Jackson Esq. Thomas (1905a: 77), who also mentions specimens from "Gambaga, Gold Coast (Giffard), and Tette, Zambesi (Boyd Alexander)".

1915. *Glauconycteris phalæna* Thomas, Ann. Mag. nat. Hist., 8, 15 (90): 560. Publication date: 1 June 1915. Type locality: South Sudan: White Nile province: Malakal district: Fashoda, near [09 53 00 N 32 07 00 E, 271 m]. [Goto Description]. Holotype: NHMUK 1915.3.6.67: ad ♀. Collected by: Willoughby P. Lowe; collection date: 27 January 1914; original number: 71. - Etymology: From the Greek for moth (see Jaeger, 1972).

1926. *Glauconycteris variegatus:* Thomas, Ann. Mag. nat. Hist., ser 9, 17 (103): 609. Publication date: 1 May 1926. (Name Combination, Alternate Spelling).

1996. *Glauconycteris variegate:* Yalden, Largen, Kock and Hillman, Trop. Zool., 9: 142. (Lapsus).

2014. *Scotophyllus v[ariegata] variegata:* Rahoum, SJS, 6 (1): 45. Publication date: February 2014. - Comments: Rahoum (2014: 45) refers to Hill and Morris (1971) for the name "*Scotophyllus v. variegata*", but that publication doesn't contain that name, but the correct *Glauconycteris variegata variegata*. (Lapsus).

? *Chalinolobus (Glauconycteris) variegata:* (Name Combination, Alternate Spelling).

? *Chalinolobus (Glauconycteris) variegatus:* (Name Combination).

? *Chalinolobus variegatus:* (Name Combination).

? *Glauconycteris variegata papilio:* (Name Combination).

? *Glauconycteris variegata variegata:* (Name Combination).

? *Glauconycteris variegata:* (Current Combination).

TAXONOMY:
Koopman (1971: 6; Koopman, 1993a: 200) included *machadoi*, and believed it to be a melanistic mutant population, but see Simmons (2005).

COMMON NAMES:
Afrikaans: Vlindervlermuis. Chinese: 彩蝶蝠. Czech: netopýr motýlí. English: Variegated Butterfly Bat, Butterfly Bat, Leaf-winged bat. French: Glauconyctère papillon, Murin à bajoues papillon, Chauve-souris réticulée, Chauve-souris papillon. German: Genetzte Schmetterlingsfledermaus. Italian: Glauconitterìde variegàta, Glauconicterìde variegàta. Malawian: Liputiputi, Ndemiya, Namsimsi, Namzeze. Portuguese: Morcego borboleta.

ETYMOLOGY OF COMMON NAME:
The colloquial name may be derived from the dark reticulated pattern on the wings, which has led to their being called leaf-winged bats Taylor, 2005). Although it is said that they resemble a large butterfly in flight, they are by no means butterfly-like in this respect (Taylor, 2005).

Figure 319. *Glauconycteris variegata* (ECJS-??/2010), caught at Rocktail Bay, Northern KwaZulu Natal, South Africa.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Rambaldini (2010: 255) refers to Avery (1991), who mentioned finding fossil remains in very late Holocene layers at Border Cave, KwaZulu Natal.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008j; IUCN, 2009; Rambaldini, 2010: 256; Monadjem *et al.*, 2017cr).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cr). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008j; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004j; IUCN, 2004). 1996: LR/lc [assessed as *Chalinolobus variegatus*] (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) [assessed as (Schoeman *et al.*, 2016c).2004: NT ver 3.1 (2001) [assessed as *G. variegatus*] (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
In view of the species wide range and availability of extensive suitable habitat, there are no major threats to this species. This species is threatened in parts of its range by habitat loss resulting from logging activities and the conversion of land to agricultural use (Jacobs *et al.*, 2008j; IUCN, 2009; Monadjem *et al.*, 2017cr).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008j) [in IUCN (2009)] and Monadjem *et al.* (2017cr) report that there appear to be no direct conservation measures in place. In view of the species wide distribution it is presumably present in some protected areas.

GENERAL DISTRIBUTION:
Glauconycteris variegata is widely, but patchily, recorded throughout much of sub-Saharan Africa. It ranges from Senegal and The Gambia in West Africa, through West and Central Africa to Ethiopia and Somalia in the east, from here it ranges south through East Africa and southern Africa, being recorded as far south as northeastern South Africa.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 976,983 km^2.

Rambaldini (2010: 254-255) confirms that there are no records from the central regions of The Democratic Republic of the Congo, northern Congo Republic, northeastern Gabon, Equatorial Guinea, and the southern parts of Cameroon, Nigeria and Benin. Furthermore, it seems missing from the coastal areas of southwestern Ghana, Côte d'Ivoire, Liberia and Sierra Leone.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 562); Benin (Capo-Chichi *et al.*, 2004: 162); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 562); Burkina Faso (Kangoyé *et al.*, 2012: 6025; 2015a: 618); Cameroon; Chad; Congo; Congo (The Democratic Republic of the) (Schouteden, 1944; Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 562); Ethiopia (Yalden *et al.*, 1996; Lavrenchenko *et al.*, 2004b: 137); Gabon; Gambia; Ghana; Kenya; Malawi (Happold *et al.*, 1988; Ansell and Dowsett, 1988; Happold and Happold, 1997b: 821; Monadjem *et al.*, 2010d: 562); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 562; Monadjem *et al.*, 2010c: 383); Namibia (Cotterill, 2004a: 262; Monadjem *et al.*, 2010d: 562); Nigeria (Happold, 1987); Rwanda; Senegal; Somalia; South Africa (Monadjem *et al.*, 2010d: 562); Sudan (Koopman, 1975); Swaziland; Tanzania; Togo; Uganda (Kityo and Kerbis, 1996: 62); Zambia (Ansell, 1957; Ansell, 1969; Ansell, 1973; Ansell, 1974; Monadjem *et al.*, 2010d: 562); Zimbabwe (Monadjem *et al.*, 2010d: 563).

DENTAL FORMULA:
The permanent dental formula is as follows: $I^2/_3$, $C^1/_1$, $PM^1/_2$, $M^3/_3$ = 32.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 8.6 Pa, aspect ratio 6.2 for a wingspan of 30 cm and a wing area of 148 cm^2 and a body mass of 13 g.

SEXUAL DIMORPHISM:
Rambaldini (2010: 253) indicates that females are slightly larger than males in body dimensions, but not in weight.

ECHOLOCATION:
Rambaldini (2010: 255) mentions that the echolocation vocalizations are high-intensity, frequency-modulated calls typically starting from 70 kHz and ending at 30 kHz, and are sometimes including a 2nd harmonic, and rarely a 3rd one.

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats): F_{peak}: 37.5 kHz and duration: 5.3 ms.

For Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 8 calls: Inpterpulse interval: 89.9 ± 36.1 (48.2 - 148.0) ms; F_{max}: 37.6 ± 2.7 (34.6 - 42.6) kHz; Start slope: -17.7 ± 7.3 (-12.1 - -5.9) kHz/ms; End slope: -6.4 ± 4.6 (-0.1 - -4.7) kHz/ms; Ledge duration: 0.6 ± 0.1 (0.4 - 0.8) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993) reported 2*n* = 18, FN = 32, BA = 16, a medium sized subtelocentric X chromosome, and a small metacentric Y chromosome, for specimens from South Africa.

Genetics
See Hoofer and Van Den Bussche (2003).

HABITAT:
Glauconycteris variegata is an inhabitant ot savannah, woodland, or open country–bushveldt habitats (see Rambaldini, 2010: 255).

ROOST:
Thatched roofs of abandoned huts and among dense vegetation (Allen *et al.*, 1917; Ansell and Dowsett, 1988; Taylor, 1998).

Happold and Happold (2023: 136) mention that these bats were found roosting singly, in pairs or in groups of three to 12 individuals.

DIET:
Glauconycteris variegata eats airborne prey, primarily soft-bodied insects such as moths (see Kingdon, 1974; Fenton *et al.*, 1977a).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 94 minutes, and the digestibility rate about 77.9 %.

POPULATION:
Structure and Density
Colonies of this species are small, and there are believed to be less than 10,000 individuals in total (Jacobs *et al.*, 2008j; IUCN, 2009; Monadjem *et al.*, 2017cr).

Trend
2016: Unknown (Monadjem *et al.*, 2017cr). 2008: Unknown (Jacobs *et al.*, 2008j; IUCN, 2009, Rambaldini, 2010: 256).

REPRODUCTION AND ONTOGENY:
Anciaux de Faveaux (1970) in Rambaldini (2010: 255) indicates that this species is monoestrus, but that the seasonal reproductive cycle can change across its range. Kingdon (1974) reported sexually active males from southern Uganda in July and October, whereas Monard (1935) did not find any sexually active adults in July in Angola. Lang and Chapin (1917b) reported pregnant females from the Democratic Republic of the Congo in March. From Zimbabwe, Smithers and Wilson (1979) reported pregnant females in August.

Bernard and Cumming (1997) [in Krutzsch (2000: 116)] suggested that *H. caffer* poses some kind of a problem as it is clearly monoestrous in some parts of its range but possibly bimodally or continuously polyoestrous in other parts.

PARASITES:
BACTERIA
Dietrich *et al.* (2016b: 3) found one out of three bats tested positive for *Rickettsia* in Rocktail Bay (RSA). Also from the RSA, Dietrich *et al.* (2018a: 4) reported the presence of *Leptospira kirschneri*.

PROTOZOA
Kassahun *et al.* (2015: 168) examined eight Ethiopian *G. variegata* specimens and found one of them (from Bedele) to be infected by *Leishmania* parasites (see also Azami-Conesa *et al.*, 2021: Suppl.; de Souza *et al.*, 2023: 5). Baleela *et al.* (2020: 360) reported *Leishmania donovani* from these bats in Sudan.

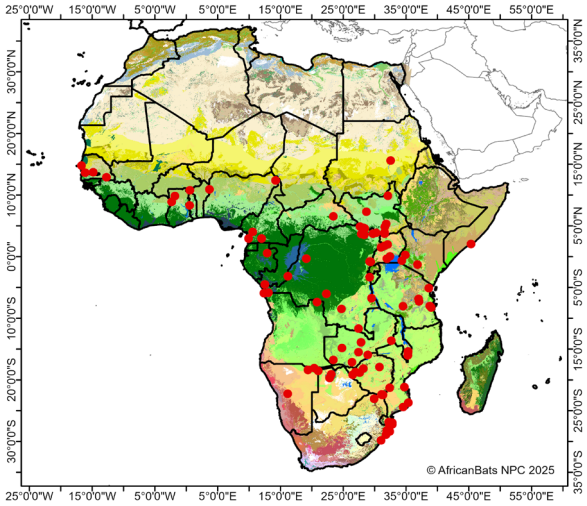

Figure 320. Distribution of *Glauconycteris variegata*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Benin, Botswana, Cameroon, Central African Republic, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Ethiopia, Gabon, Ghana, Kenya, Malawi, Mozambique, Namibia, Nigeria, Senegal, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

TRIBE Pipistrellini Tate, 1942

1942. *Pipistrellini* Tate, Bull. Am. Mus. Nat. Hist., 80 (7): 221, 231. Publication date: 27 November 1942. - Comments: Type genus: *Pipistrellus* Kaup, 1829. Introduced as tribe, and originally including the genera *Pipistrellus* Kaup, 1829 and *Glischropus* Dobson, 1875 (see Jackson and Groves, 2015: 274).

Genus ***Nyctalus*** Bowdich, 1825

*1825. *Nyctalus* Bowdich, Excur. Madeira and Porto Santo, 36, and footnote. Publication date: 1825. - Comments: Type species: *Nyctalus verrucosus* Bowdich, 1825 (=*Vespertilio leisleri* Kuhl, 1817). - Etymology: From the Greek "*νυκταλός*" (="*νυσταλός*"), meaning drowsy, referring to its crepuscular habits (see Palmer, 1904: 464). From the Greek "*nyctos*" meaning night and "*ala*" meaning wing (see Kapteyn, 1995: 115). (Current Combination).

1829. *Pterygistes* Kaup, Skizzierte Entwicklungs-Geschichte Natürliche Systematik der Europäische Thierwelt, 1: 90. Publication date: 1829. - Comments: Type species: *Vespertilio noctula* Schreber, 1774. - Etymology: From the Greek "*πτερυγίζω*", meaning to flutter, referring to the manner of flight (see Palmer, 1904: 596).

1839. *Vesperugo* Keyserling and Blasius, Arch. Naturgesch. Berlin, 5 (1): 312. Publication date: 1839. - Comments: In part (see Allen, 1939a: 92; Pavlinov *et al.*, 1995: 104). Included 13 species now referred to *Eptesicus, Pipistrellus, Neoromicia, Hypsugo*.

1842. *Noctulinia* J. E. Gray, Ann. Mag. nat. Hist., [ser 1], 10 (65): 258. Publication date: 1 December 1842. - Comments: Mentioned as "in part" by Allen (1939a: 92). Contained two species (*Noctulinia proterus* Kuhl, 1818 =*Nyctalus noctula* Schreber, 1774, and *N. fulvus* Grey, 1843 =*Scotophilus kuhlii* Leach, 1821; see Allen (1939a: 92), one a synonym of *Vespertilio noctula* Schreber, 1774 (see Corbet and Hill, 1992: 143). - Etymology: From the Latin of, or belonging to night (from "*noctus*" = "*nox*", meaning night), referring to the animal's crepuscular habits (see Palmer, 1904: 461).

1856. *Panugo* Kolenati, Allg. deutsche naturh. Zeitung, NF, 2 (2): 131. Publication date: 1856. - Comments: Type species: *Vespertilio noctula* Schreber, 1774 and *Vespertilio leisleri* Kuhl, 1817.

1872. *Noctulina* Macalister, Ann. Mag. nat. Hist., ser 4, 9 (53): 402. Publication date: 1 May 1872.

1914. *Noctulinia* Cabrera, Fauna Ibérica, 123. - Comments: (also mentioned by Allen (1939a: 92), Corbet (1978: 54), and Simmons (2005))?.

2002. *Nyctalis:* Sheshurak and Kedrov, Plecotus et al., pars spec: 62. (Lapsus).

2019. *Nyactulus:* Fagre and Kading, Viruses, 11 (3): 215 (p 4). Publication date: 3 March 2019. (Lapsus).

TAXONOMY:
Species referred by Koopman (1994) in the *Stenopterus* group are placed into *Pipistrellus* by Corbet and Hill (1992) and Hoofer and Van Den Bussche (2003: 38). Whereas Simmons (2005) placed it as a subgenus of *Hypsugo*.

Currently (Simmons and Cirranello, 2023b) recognized species of the genus *Nyctalus*: *aviator* Thomas, 1911 - Japan, Korea, E and C China; ***azoreum*** (Thomas, 1901); *furvus* Imaizumi and Yoshiyuki, 1968 - Japan, Korea; ***lasiopterus*** (Schreber, 1780); ***leisleri*** (Kuhl, 1817); *montanus* (Barrett-Hamilton, 1906) - Afghanistan, Pakistan, N India, Nepal (?), N Myanmar; *noctula* (Schreber, 1774); *plancyi* (Gerbe, 1880) - N China, Philippines.

COMMON NAMES:
Czech: lesní netopýři (lesní létači). English: Noctules, Noctule Bats. French: Noctules, Chauves-souris à nez large. German: Abendsegler. Ukrainian: Вечірниця (= Vechirnytsya).

GENERAL DISTRIBUTION:
Species of the genus *Nyctalus* are distributed across the entire Palaerctic region, and enter only marginally into the Indomalay region (Koopman, 1994; Simmons, 2005)

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa".

Nyctalus azoreum (Thomas, 1901)

*1901. *Pterygistes azoreum* Thomas, Ann. Mag. nat. Hist., ser 7, 8 (43): 33. Publication date: 1 July 1901. Type locality: Azores (Portugal): St. Michael. [Goto Description]. Holotype: NHMUK 1865.10.2.1: ♂. Collected by: Frederick DuCane Godman Esq. Presented/Donated by: Frederick DuCane Godman Esq. - Etymology: The name refers to the Island group where the species occurs.
? *Nyctalus azoreum:* (Name Combination, Current Combination).
? *Nyctalus leisleri azoreum:* (Name Combination).

TAXONOMY:
Listed as a subspecies of *N. leisleri* by Corbet (1978) and Koopman (1994: 118). But recognised as a species by Palmeirim (1991), Koopman (1993a: 216), Horáček *et al.* (2000: 133), Salgueiro *et al.* (2004: 3357), Simmons (2005: 471), Salgueiro *et al.* (2006: 169) and Salgueiro *et al.* (2007: 1163; 2010: 26).

COMMON NAMES:

Welsh: Ystlum mawr yr Asores.

SIMILAR SPECIES:
Salgueiro *et al.* (2010: 26) provide a summary of the differences between *N. azoreum* and its closest relative *N. leisleri*. *N. azoreum* is darker and considerably smaller. It is also present in a broader ecological niche, occupying a variety of roosts like buildings, coastal cliffs and trees, whereas *leisleri* is primarily a tree dweller. Finally, it has an echolocation call with a higher peak frequency than its continental counterpart, and it is often active during the day.

CONSERVATION STATUS:
Global Justification
Piraccini (2016d) report that this species' population has been estimated at 2,000-5,000 individuals and the most abundant subpopulation numbers less than 1,000 individuals. For these reasons this species meets the criteria for being assessed as Vulnerable (VU C2a(i)). This species is endemic to the Azores, where it has a small population and range. It is suspected to be declining as a result of disturbance and destruction of colonies, loss and degradation of natural and semi-natural habitats and pesticide use. There is no direct information on dispersal between islands, but genetic research suggests that dispersal is restricted, and so the population is precautionarily regarded as being severely fragmented; further research would be required to confirm this. For these reasons, it may be approaching the Endangered category, which is suggested by Conenna *et al.* (2017: Suppl.).

Assessment History
Global
2016: VU C2a(i) ver 3.1 (2001) (Piraccini, 2016d).
1994: VU A2c, B1+2c ver 2.3 (1994).

MAJOR THREATS:
Human persecution, and the destruction of roost sites, are likely to be the main threats (A. Rainho *pers. comm.* 2006 in Piraccini (2016d)). Habitat loss and degradation, use of pesticides and the spread of exotic plant species may also have a detrimental effect on the species. It is suspected that the extreme scarcity of the species on Santa Maria is attributable to habitat loss and degradation. This species is particularly vulnerable to persecution because it flies during the day, making colonies obvious and easy to find (A. Rainho *pers. comm.* 2006 in Piraccini (2016d)).

Sherwin *et al.* (2012: 174) identified the small distribution range, the species' aerial hawking feeding style and its long-distance dispersal to be the major risk factors linked with climatic change.

CONSERVATION ACTIONS:
There is no specific national legislation. It is protected under Bern Convention and included in Annex IV of EU Habitats and Species Directive. There are proposals for protection and monitoring of roosts, public awareness (with special reference to roosts), reduction of adverse agricultural practices, preservation and restoration of natural habitat, use of lights that attract insects (e.g., mercury), and further studies of the species' biology (Rainho *et al.*, 2002). A bat monitoring program, based on annual acoustic surveys, is currently under development (A. Rainho *pers. comm.* in Piraccini (2016d)).

GENERAL DISTRIBUTION:
Nyctalus azoreum is endemic to the archipelago of the Azores, where it is present on seven of the nine islands (Rainho, 2017: 161).

Native: Azores (Palmeirim, 1991; Koopman, 1993a: 216; Speakman and Webb, 1993; Horáček *et al.*, 2000: 133; Salgueiro *et al.*, 2004: 3357; Simmons, 2005: 471; Salgueiro *et al.*, 2006: 169; Salgueiro *et al.*, 2007: 1163).

BIOGEOGRAPHY:
Molecular data suggest that *N. azoreum* originated from a European population of *N. leisleri*, and that the colonisation of the Azores occurred at the end of the Pleistocene (Salgueiro *et al.*, 2006). Salgueiro *et al.* (2006) suggest the minimum divergence time of insular (Azores) and continental lineages is comprised between 0 and 55,000 years BP. This corresponds roughly to a late Pleistocene/Holocene divergence, which is consistent with previous estimates based on demographic parameters (12,000 and 25,000 years BP) calculated by Salgueiro *et al.* (2004). As humans only colonized the Azores less than 600 years ago, molecular estimates of divergence times suggest that the first bats which arrived on the archipelago were unlikely to be brought by man (Salgueiro *et al.*, 2006).

ECHOLOCATION:
Rainho (2021: 2) mentions this species has an average peak frequency of 32.1 kHz, whereas Dechmann and Ruczynski (2023: 420) indicate a main frequency between 27.3 and 32.9 kHz and duration of 16.8 ms.

MOLECULAR BIOLOGY:
Genetics
Moussy *et al.* (2012: 188), referring to Salgueiro *et al.* (2004; 2007), indicate that *N. azoreum* is one of the species that shows significant genetic differentiation and/or haplotype segregation between islands or groups of islands but not within them.

Boston *et al.* (2015) examined the mitochondrial DNA of *N. azoreum* and *N. leisleri* and found that two separate lineages were present and that *N. azoreum* forms one lineage with *N. leisleri* from Britain and Ireland, whereas the second lineage consists of continental European *N. leisleri*.

HABITS:
Speakman and Webb (1993: 28) refer to Moore (1975) to point out that *N. azoreum* is one of those exceptional bats, which fly during the day. However, this behaviour was found to be spatially restricted (Mikula *et al.*, 2024: 161). Irwin and Speakman (2003: 185) furthermore found that *N. azoreum* clusters when emerging from their roosts. This was quite unexpected as no flying predators are present on the Azores which could capture bats while leaving the roosts.

DIET:
Dechmann and Ruczynski (2023: 420) indicate that these bats can often be seen foraging during the afternoon, which would allow them to take advantage of the insect abundance peak in the early evening.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 133 minutes, and the digestibility rate about 74.3 %.

POPULATION:
Structure and Density
Based on a survey, conducted in September-October 1988, Speakman and Webb (1993: 27) estimated the population of *N. azoreum* to consists of between 1,750 (from daytime activity) and 23,650 (from night-time activity) animals. The latter figure would lead to a population

density of 1 bat per 10 ha. Surveys in 2002, 2003 and 2004 found the Azorean Bat (*Nyctalus azoreum*) quite abundant on San Miguel, Faial, Terceira and San Jorge, but rare on Graciosa and extremely rare on Santa Maria. It is absent from Flores and Corvo. There is no quantitative information on population trend, but it is suspected that the species may be declining as a result of habitat degradation, destruction of or exclusion from roosts (both in trees and buildings), and human persecution. Local environmental groups report that numerous colonies have disappeared (A. Rainho *pers. comm.* 2006 in Piraccini (2016d)). The total population is estimated at 2,000-5,000 individuals, and there are fewer than 1,000 individuals on San Miguel, where the species is most abundant (Cabral *et al.*, 2005; J.M. Palmeirim, A. Rainho and L. Rodrigues *pers. comm.* 2006 in Piraccini (2016d)).

Trend
2016: Decreasing (Piraccini, 2016d).

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) report this species as being polytocous (more than one young per litter). Maternity colonies are found between April and September/October (Dechmann and Ruczynski (2023: 428), and juveniles are born in June/July.

CONSERVATION STATUS:
Global Justification
Deforestation, particularly the loss of old trees, is a problem in many parts of the range and is likely to be causing a population decline. The range is fragmented and the colonies tend to be mainly small (Hutson *et al.*, 2008a; IUCN, 2009). Dozens of individuals have been found dead at wind farms from Spain (C. Ibáñez, S. Sánchez and J.T. Alcalde *pers. comm* in Alcaldé *et al.* (2016)). A critical decline is suspected in Ukraine and European Russia (Vlaschenko *et al.*, 2010; 2016). Although there are no precise figures on population decline it seems reasonable to list this species as Vulnerable given what is currently known about the threats, the population numbers and the range. It qualifies as VU under criteria A4c and C2a(i) (Alcaldé *et al.*, 2016).

Assessment History
Global
2016: VU A4c; C2a(i) ver 3.1 (2001) (Alcaldé *et al.*, 2016). 2008: NT ver 3.1 (2001) (Hutson *et al.*, 2008a; IUCN, 2009). 1996: LR/nt ver 2.3 (1994).

Regional
None known.

MAJOR THREATS:
Little is known about potential threats, but loss of mature woodland and loss of or disturbance to roost sites (in old trees and buildings) may have a negative impact on the species. In Cádiz (Southern Spain) it is estimated that a hundred Giant Noctules are killed each year by wind turbines (Ibáñez and Sánchez-Navarro, submitted), and more individuals have been found in other regions such as Soria and Navarra (Alcalde pers. comm. 2015). Some individuals were found dead at wind farms in Spain (J.T. Alcalde *pers. comm.,* 2006 in Hutson *et al.* (2008a) in IUCN (2009)), and all pups were found dead in 2005 at one of the two known colonies in Spain (located in a city park). The cause of these deaths was not known (J.T. Alcalde *pers. comm.,* 2006 [in Hutson *et al.* (2008a) in IUCN (2009)]). One colony disappeared in Spain due to the cutting of old trees in a city park (Juste, 2007), and the same seems to have happened in a Ukrainian forest (Vlaschenko *et al.*, 2010). Little is known about potential threats, but loss of mature woodland and loss of or disturbance to roost sites (old trees) have a negative impact on the species (Bakwo Fils and Kaleme, 2016b).

Small distribution range, cave/tree roosting, and the aerial hawking feeding style were considered to be risk factors linked with climatic change by Sherwin *et al.* (2012: 174). Piccioli Cappelli *et al.* (2021: 10) identified this species (together with *Rhinolophus mehelyi* as running the highest risk of extinction due to climate change in Europe and North-west Africa.

CONSERVATION ACTIONS:
Hutson *et al.* (2008a) [in IUCN (2009)] report that it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention, in parts of its range where these apply. It is included in Annex IV of EU Habitats and Species Directive. No specific conservation actions are known. It occurs in a number of national parks and protected areas within its range (K. Tsytsulina *pers. comm*., 2005)). However, in Spain the two known colonies are outside protected areas (Juste, 2007). It seems that it has declined in Ukraine and European Russia (Vlaschenko *et al.*, 2010; 2016). More information is needed on population size and trends, ecology, and potential threats (Juste, 2007).

GENERAL DISTRIBUTION:
Nyctalus lasiopterus has a very scattered distribution through central and southern Europe (Iberia to the Balkans, Urals) and north Africa (Morocco [only three records in northwest Morocco, the first of which was reported as *N. noctula* by Laurent (1937d), but see Palmeirim (1982: 402)], Libya [five records in Cyrenaica], and possibly Algeria [one record identified as *Nyctalus noctula* by Loche (1867), but the specimen is lost]). There are an increasing number of records from Turkey (Karataş *et al.*, 2007). Outside the Mediterranean region the range extends eastwards through Asia Minor to the Caucasus, northern Iran, Kazakhstan and the Urals in Russia. Of the Mediterranean islands, recorded on Sicily. Until 1999, it had been recorded in 120-130 localities in Europe (Benzal, 1999). It occurs up to 1,900 m in Switzerland

Native: Azerbaijan; Belarus; Bulgaria; Cyprus (Benda *et al.*, 2007: 71); Croatia; Czech Republic; France; Georgia; Germany; Gibraltar; Greece; Hungary; Iran, Islamic Republic of; Italy (Sicilia); Kazakhstan; Libyan Arab Jamahiriya; Macedonia, the former Yugoslav Republic of; Moldova; Monaco; Morocco (El Ibrahimi and Rguibi Idrissi, 2015: 363; Dbiba *et al.*, 2025: 7); Poland; Portugal; Romania; Russian Federation;

Slovakia; Slovenia; Spain; Switzerland; Turkey; Turkmenistan; Ukraine.

Presence uncertain: Algeria; Andorra; Bosnia and Herzegovina; Uzbekistan.

GEOGRAPHIC VARIATION:
Benda *et al.* (2014c: 91) found that the Libyan representatives of the species are on average smaller in the forearm and skull sizes than specimens from other parts of the distribution area. Also, their rostra are relatively long and narrow.

FUNCTIONAL MORPHOLOGY:
Naďo *et al.* (2019: 592) point out that these bats echolocation calls (low frequency and high intensity) are perfectly suited to detect large and fast airborne prey (e.g., birds) at great distances. Furthermore, the swift wing beats allow them to fly fast and change their flight altitude very rapidly; e.g., to high altitudes (124 to 367 m above the ground) where there is little competition and potential food might be abundant.

ECHOLOCATION:
Walters *et al.* (2012: suppl.) report the following figures for 26 calls (22 sequences) from French bats: duration: 22.87 ± 2.92 ms, F_{max}: 17.00 ± 4.68 kHz, F_{min}: 13.28 ± 1.55 kHz, bandwidth: 3.72 ± 3.24 kHz, F_{peak}: 14.29 ± 1.66 kHz.

MOLECULAR BIOLOGY:
Karyotype
Arslan and Zima (2014: 12) reported 2*n* = 42, FNa = 50, FN = 54, a medium-sized metacentric X, and a small acrocentric Y. The autosomal complement contains four large metacentric, one small submetacentric and 15 acrocentric autosomal pairs.

HABITS:
Naďo *et al.* (2019: 588) indicate that *Nyctalus lasiopterus* have very large foraging areas (to over 1,000 km^2 and can travel distances to over 100 km per night.

ROOST:
The only specimen found in a roost in Libya by Benda *et al.* (2014c: 87) was in a fist-sized hole in an overhang, some 6 m above the ground. This represented the first non-tree roost site found for this species.

In Slovakia, Naďo *et al.* (2019: 589) found these bats to roost only in old aspen trees (*Populus tremula*), which were often suffering from hardwood rot. The inhabited cavities were between 4 and 17 m above the ground.

DIET:
In Russia, Smirnov and Vekhnik (2013: 207) found that the diet of *N. lasiopterus* included the following orders of insects: Orthoptera, Coleoptera, Lepidoptera, Diptera, Homoptera, and Neuroptera. They also found an amount of feathers: Out of 14 faecal pellets, the feathers made up 80 - 90 % of the total faecal volume in six pellets, 50 - 60 % in three pellets, 20 - 40 % in four pellets, and less than 10 % in one pellet.

Andreas (2010: 266) referred to three hypotheses concerning the occurrence of feathers in the bat's faeces: "The first possibility was that *N. lasiopterus* is not able to distinguish between flying feathers and its usual preys and eats a lot of this indigestible material. The second possibility was that *N. lasiopterus* regularly feeds on birds and consumes prey that can represent some 30 % of its body weight on the wing. The third possibility can be a predation in tree hollows.", of which Popa-Lisseanu *et al.* (2007: 1) proved the second to be correct, especially during the migration season of the small passerine birds. Benda *et al.* (2012a: 455) furthermore indicate that carnivory is probably a local and/or seasonal phenomenon.

Digestive tracts from five bats collected in Cyrenaica, Libya, contained moths, carabid beetles, heteropterans, neuropterans, and cockroaches (Benda *et al.*, 2014c: 93). 30 faecal pellets from Cyprus contained mainly Hymenoptera, Auchenorrhyncha and Scarabaeid beetles, and also some moths and heteropterans Andreas (2010: 266).

The wide range of food taxa led Ibáñez and Juste (2023: 450) to suggest that *Nyctalus lasiopterus* is a generalist/opportunistic predator.

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 204 minutes, and the digestibility rate about 70.2 %.

POPULATION:
Structure and Density
The patchy distribution and low population density in most of range suggest a relatively small global population. Breeding colonies are typically small (up to 35 females), and few are known. Only two larger-sized (50 - 100 females) breeding colonies are known in the world. It is rare throughout the range in the Russian Federation (K. Tsytsulina *pers. comm.,* in Hutson *et al.*, 2008a) [in IUCN, 2009)]). There is a strong population in northern Hungary (Hutson *et al.*, 2008a; IUCN, 2009). The species is difficult to

survey, and difficult to capture with mist nets as it hunts 10-20 m above the ground (K. Tsytsulina *in litt.* 2005 in Alcaldé *et al.* (2016)) or even higher. Although the global population trend is unknown, a decline is suspected in Ukraine and Russia, and in Spain (stronghold of the species), mortality caused by wind farms could noticeably reduce the population (Bakwo Fils and Kaleme, 2016b).

Trend
2016: Decreasing (Vlaschenko *et al.*, 2010).
2008: Decreasing (Hutson *et al.*, 2008a; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Tuttle and Stevenson (1982: 123) indicate that females are sexually mature at about four months, and males at about 16 months.

From Japan, Maeda (1972: 270) reported that in captivity, young were born between 26 June and 13 July. Six of the nine captive females had two young each (= polytocy, see Garbino *et al.*, 2021: Suppl.), while the others had one. The dissection of 10 free-living females indicated that seven had twin embryos (one in each uterine horn). Of the fifteen young born in the laboratory, 10 were females, but of eight embryos from free-living females, five were males. This resulted in an overall sex ratio (♂/♀) of 0.77.

POSTNATAL DEVELOPMENT:
Maeda (1972: 272 - 276) reported that twin young were born either naked or with very few hairs on their backs, whereas single young had scattered, thin hairs. The body hair starts to grow from the dorsal side of the rump to the head and to the ventral sides and reaches the same length as in the adults at about 40 days, but its colour is still darker. For singletons, the eyes opened after four to seven days, but in twins this happened only after seven to 11 days. In some animals there were four days between the opening of one of the eyes and the second. The body size of the single young was larger than for twins, and single young grew up to become larger adults. At birth, the young's hind foot already measured 83 % of the adult size, and their thumbs were 77 % of the adult size, whereas the forearm length was only 36 %, and the fingers were even smaller (23, 24 and 27 % respectively for fingers 3, 4 and 5). At 40 to 45 days, the forearm reaches almost adult size. For the fifth finger, this takes 45 to 50 days and for the third and fourth fingers, this is 50 to 55 days. The hind feet and thumbs were almost fully grown after 20 to 28 days. The body weight increases to about 22 to 30 grams at about 30 days after birth and then decreases until the young starts to feed itself. The young started to fly between 40 and 45 days of age.

PARASITES:
In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Argasidae: *Carios vespertilionis* Latreille, 1802; and Spinturnicidae: *Spinturnix acuminata acuminata* (C.L. Koch, 1836).

ARACHNIDA
Argasidae
Sándor *et al.* (2021a: 4) reported the presence of *Carios vespertilionis* Latreille, 1802.

VIRUSES:
Coronaviridae
Alphacoronavirus
Kohl and Kurth (2014: 3112) report this virus from bats in Spain.

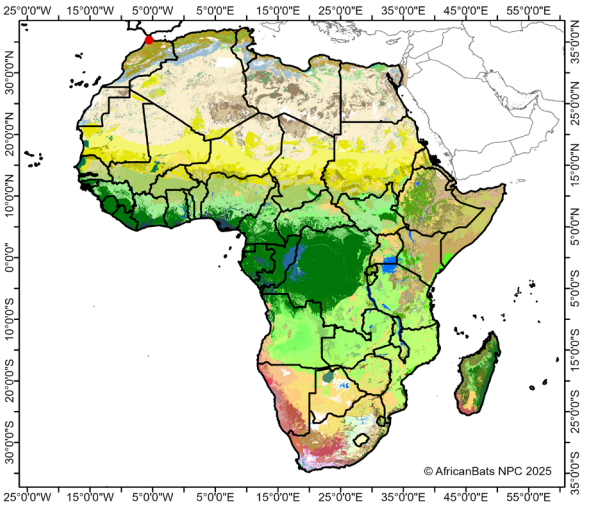

Figure 322. Distribution of *Nyctalus lasiopterus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Morocco.

Nyctalus leisleri (Kuhl, 1817)

*1817. *Vespertilio Leisleri* Kuhl, Die Deutschen Fledermäuse, Hanau, 14, 46. Type locality: Germany: Hessen: Hanau [50 07 N 08 56 E]. Syntype: ZMB 471: skin and skull. See Turni and Kock (2008). Syntype: ZMB 472: skull only. See Turni and Kock (2008). - Comments: Koopman (1992) mentions 1817 as year of publication. Corbet and Hill (1992: 144), however, mention "1819: 46". Baagøe (2001: 90) mentions 1818. - Etymology: In honour of Philipp Achilles Leisler (1772 - 1813) (see Kozhurina, 2002: 16).

1819. *Vespertilio dasykarpos* Kuhl, Die Deutschen Fledermäuse, Hanau, 49. - Comments: Alternative for *leisleri*: see Ellerman and Morrison-Scott (1951: 159).

1825. *Nyctalus verrucosus* Bowdich, Excur. Madeira and Porto Santo, 36, and footnote. Publication date: 1825. Type locality: Madeira (Portugal): "Madeira" [32 44 N 15 58 W]. [Goto Description].
1839. *Vespertilio pachygnathus* Michahelles, in: Wagner, Schreber's Säugeth, Suppl 1: pl 55b. Type locality: Croatia: Dalmatia.
1906. *Pterygistes madeiræ* Barrett-Hamilton, Ann. Mag. nat. Hist., ser 7, 17 (97): 98. Publication date: 1 January 1906. Type locality: Madeira (Portugal): "Madeira" [32 44 N 15 58 W]. [Goto Description]. Holotype: NHMUK 1907.1.1.392: ♀, skull and alcoholic. - Comments: Type specimen procured by Mason, nr 1 Tomes collection (see Barrett-Hamilton, 1906: 99).
? *Nyctalus leisleri:* (Name Combination, Current Combination).

TAXONOMY:
Includes *verrucosus*, see Corbet (1978: 55), who also included *azoreum*; but see Palmeirim (1991) and Salgueiro *et al.* (2006). Based on mitochondrial DNA, Boston *et al.* (2007: 120) indicate that Irish populations belong to the same lineage as *azoreum* and differ from *leisleri* in the rest of Europe, but this is not confirmed by Boston *et al.* (2008).

Simmons (2005: 472) recognises *verrucosus* Bowditch, 1825 as a valid subspecies.

COMMON NAMES:
Albanian: Noktulë e Leisler-it. Armenian: Փոքր իրիկնաչղջիկ. Azerbaijani: Kicik axşam yarasası. Basque: Leisler gau-saguzar. Belarusian: Вячэрніца малая. Turkish: Küçük Ağaç Yarasası. Ukrainian: Вечірниця мала [= Vechirnytsya mala]. Welsh: Ystlum Leisler.

CONSERVATION STATUS:
Global Justification
The species is widespread and abundant, and there is no evidence of current significant population decline. Consequently, it is assessed as Least Concern LC ver 3.1 (2001) (Hutson *et al.*, 2008l; IUCN, 2009; Juste and Paunović, 2016c).

Assessment History
Global
2016: LC ver 3.1 (2001) (Juste and Paunović, 2016c). 2008: LC ver 3.1 (2001) (Hutson *et al.*, 2008l; IUCN, 2009). 1996: LR/nt ver 2.3 (1994).

Regional
None known.

MAJOR THREATS:
Threats include disturbance to and destruction of roosts in trees and buildings, and loss or degradation of foraging habitat. However, these are not thought to be major threats at present (Hutson *et al.*, 2008l; IUCN, 2009; Juste and Paunović, 2016c).

The major risk factors related to climatic change were identified by Sherwin *et al.* (2012: 174) as being cave/tree roosting and aerial hawking.

CONSERVATION ACTIONS:
Juste and Paunović (2016c) supports Hutson *et al.* (2008l) [in IUCN (2009)] who reported that it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention, in parts of its range where these apply. It is included in Annex IV of EU Habitats and Species Directive, and there is some habitat protection through Natura 2000. It occurs in protected areas

throughout its range. No specific conservation actions known.

GENERAL DISTRIBUTION:
Nyctalus leisleri is largely a western Palaearctic species (Europe and north-west Africa), with scattered records in the western parts of the eastern Palaearctic (Pakistan, Afghanistan, the Himalayas). It is widely distributed in Europe from southern Scotland and Ireland more or less along southern edge of the Baltic Sea south and parts of Mediterranean coast to western Russia. It is present on Madeira and the Canary Islands (on Tenerife and La Palma only) but absent from southwestern Italy and Sicily, eastern Spain, most of Fennoscandia and northern Russia. In North Africa it is recorded from Mediterranean montane Morocco and Algeria and there is one record from Cyrenaica (Libya). It occurs from sea level to 2,400 m.

Native: Afghanistan; Albania; Algeria (Hanák and Gaisler, 1983: 585; Gaisler, 1984: 89); Andorra; Armenia; Austria; Azerbaijan; Belarus; Belgium; Bosnia and Herzegovina; Bulgaria; China; Croatia; Cyprus (Benda *et al.*, 2007: 71); Czech Republic; France (Corse); Georgia; Germany; Gibraltar; Greece; Hungary; India; Iran, Islamic Republic of; Ireland; Italy; Kazakhstan; Latvia; Libyan Arab Jamahiriya (Hanák and Gaisler, 1983: 585); Liechtenstein; Lithuania; Luxembourg; Macedonia, the former Yugoslav Republic of; Moldova; Montenegro; Morocco (Benda *et al.*, 2004d; 2010a: 158; El Ibrahimi and Rguibi Idrissi, 2015: 363; Dbiba *et al.*, 2025: 7); Netherlands; Pakistan; Poland; Portugal (Madeira); Romania; Russian Federation; Serbia; Slovakia; Slovenia; Spain (Canary Is.); Sweden; Switzerland; Turkey; Ukraine; United Kingdom.

BIOGEOGRAPHY:
Molecular data suggest that *N. leisleri* from the Canary Islands probably came from North Africa (Morocco) population (Salgueiro *et al.* (2006).

DENTAL FORMULA:
Matthews (1950: 12) describes the milk dentition, consisting of two trilobed incisors, one canine with one large central lobe and two very small lateral lobes, and two trilobed premolars in the upper cheek. The lower cheek contains two trilobed incisors and one bilobed one, a well-developed, trilobed canine, and two trilobed premolars (but the posterior lobe of the second one is very much reduced).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 19.3 Pa, aspect ratio 7.9 and tip shape index of 1.19 for a wingspan of 26 cm and a wing area of 86 cm^2 and a body mass of 17 g.

ECHOLOCATION:
For 6 Greek specimens, Papadatou *et al.* (2008b: 132) report a start frequency of 47.5 ± 3.67 kHz, a terminating frequency of 27.0 ± 1.10 kHz, a peak frequency of 31.7 ± 0.87 kHz, and a bandwidth of 12.3 ± 2.96 kHz. The duration of the call is 4.2 ± 1.30 ms, and the interpulse interval is 153.4 ± 62.36 ms.
Walters *et al.* (2012: suppl.) present the following numbers for 76 calls from bats from France, Greece, Switzerland and the UK: duration: 9.39 ± 3.86 ms, F_{max}: 42.20 ± 14.77 kHz, F_{min}: 25.75 ± 2.75 kHz, bandwidth: 16.45 ± 12.45 kHz, F_{peak}: 28.61 ± 5.27 kHz.

Benda *et al.* (2012a: 183) present two series of data for specimens from Iran: **1**: F_{start}, 47.4 ± 4.2 (41.7 - 56.2) kHz, F_{end}: 30.3 ± 0.8 (28.7 - 31.3) kHz, F_{peak}: 34.0 ± 1.1 (31.2 - 35.2) kHz, duration: 3.8 ± 1.1 (2.6 - 6.8) ms, and interpulse interval: 112.8 ± 63.2 (48.2 - 262.9) ms; **2** (hand released): F_{start}: 43.3 ± 2.7 (40.4 - 46.7) kHz, F_{end}: 26.3 ± 0.8 (24.8 - 26.8) kHz, F_{peak}: 28.4 ± 0.4 (28.0 - 28.9) kHz, duration: 6.1 ± 0.3 (5.7 - 6.5) ms, and interpulse interval: 106.2 ± 2.0 (104.9 - 109.3) ms.

Luo *et al.* (2019a: Supp.) reported the following data: F_{peak}: 30.7 kHz, F_{start}: 55 kHz, F_{end}: 27.7 kHz, Band width: 27.3 kHz, and duration: 5.3 ms.

MOLECULAR BIOLOGY:
Karyotype
Arslan and Zima (2014: 12) reported 2*n* = 44 + Bs, FNa = 50, FN = 54, a medium-sized metacentric X, and a dot-like acrocentric Y. The autosomal component consists of three large metacentric, one small submetacentric and 17 acrocentric autosomal pairs. They also indicate that this set can also include 1 to 3 dot-like supernumerary chromosomes (Bs). In one Turkish male, Arslan and Zima (2014: 12) furthermore found a dot-like supernumerary chromosome, leading to 2*n* = 45.

Genetics
Molecular analyses performed by Boston *et al.* (2015: 1) revealed that two distinct mitochondrial DNA lineages are present: an eastern lineage of *N. leisleri* distributed throughout continental Europe and a western lineage, including *N. leisleri* from Ireland and Britain, but also *N. azoreum* from the Azores.

HABITAT:
In Switzerland, Szentkuti *et al.* (2013: 110) found that foraging *N. leisleri* selected deciduous

woodlands over other habitat types (pasture, confirous forest and settlements). They also reported that the bat's nightly mean (± SE) distance travelled was 1,969 ± 1,754 m, and that the maximum distance between the most distant location and the previous roost was on average (4,678 ± 1,082; 1,080 - 13,614 m).

On Madeira, Ferreira *et al.* (2022a: 1) found that *Nyctalus leisleri verrucosus* was negatively influenced by Laurisilva (primary forest) cover and that its activities were negatively affected by increasing altitude.

On the Canary islands, Agirre-Mendi (2005: 233) reported this species to occur from sea level to up to 2,100 m, where it lives in woodlands covered with *Pinus canariensis*, subtropical rain forests (laurisilva), but also in man-made rural areas and high-mountain zones.

ROOST:
In southern Switzerland, Spada *et al.* (2008: 81) found that *N. leisleri* prefers to roost in live chestnut trees (*Castanea sativa*), with large diameter and in absence of vegetation near the entrance.

On the Canary Islands, Trujillo and Barone (1991: 102) reported these bats to roost in an abandoned building and a single bat in a bat box in a *Pinus canariensis* forest.

DIET:
Gonçalves *et al.* (2024: 4) found that - on Madeira - the majority of the preys consisted of Lepidoptera (50.5 %), followed by Coleoptera (17.5 %), Diptera (13.6 %), Hemiptera (7.8 %), and Neuroptera (5.3 %). Within the Lepidoptera most of the prey taxa belonged to the Noctuidae (18 %), followed by Cerambycidae (16.5 %), Blastobasidae (8.7 %), Limoniidae (8.3 %), and Geometridae (8.3 %). At species level, *Arhopalus ferus* (Mulsant, 1839) (Cerambicidae - 15.0 %) was most frequently counted, followed by *Gymnoscelis rufifasciata* (Haworth, 1809) (Geometridae - 5.8%), and *Agonopterix scopariella* (Heinemann, 1870) (Depressariidae - 5.3%). Of the 44 taxa consumed by this species, 29.5 % are considered agricultural pests and 15.9 % possible agricultural pests. They also found that male bats have a much broader dietary niche than females.

Kaňuch *et al.* (2005: 253) identified seven orders of insects in 154 faecal pellets examined from Slovakian bats. These belonged to the Aphididae (Homoptera), Heteroptera, Chrysopidae (Neuroptera), Coleoptera, Ichneumonidae and Formicidae (Hymenoptera), Lepidoptera, Nematocera and Brachycera (Diptera). The most important group (in both frequency [100 %] and volume [55.7 %]) were Lepidoptera.
Benda *et al.* (2012a: 460 - 461) indicate that European studies showed that this species' diet is relatively variable depending on the foraging habitat. In forests, Lepidoptera and nematoceran Diptera are most often present, whereas in the landscapes with a larger proportion of pastures the dung flies (Scatophagidae) and scarabaeid beetles were more significantly represented. Other groups that were present include Trichoptera, Neuroptera, and Hymenoptera. In more arid habitats in the Middle East, Hymenoptera (Formicoidea), Trichoptera, and Coleoptera (namely Carabidae and Curculionidae) are the main groups present in the diet.

On the Canary Islands, it was found to feed on Lepidoptera (Noctuidae) (Agirre-Mendi, 2005: 234).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 102 minutes, and the digestibility rate about 77.0 %.

POPULATION:
Structure and Density
It is widespread although patchily distributed in Europe. Common in parts of range (e.g., Ireland), scarce in other parts (Stebbings and Griffith, 1986). Local extinctions have been reported for the central part of Russian Federation (K. Tsytsulina *pers. comm.* 2005), although the species remains common in other parts of Russia and the Caucasus (S. Kruskop *pers. comm.,* 2005). In North Africa it is limited by the distribution of suitable habitat, but is particularly abundant in Djurdjura, NE Algeria (Hutson *et al.*, 2008l; IUCN, 2009; Juste and Paunović, 2016c).

Trend
2016: Unknown (Juste and Paunović, 2016c).

LIFESPAN:
Szekely *et al.* (2015: Suppl.) report a maximum longevity of 16 years.

ACTIVITY AND BEHAVIOUR:
On the Canary Islands, *Nyctalus leisleri* remains active during the winter on lower and middle altitudes (Agirre-Mendi, 2005: 234).

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) report this species as being polytocous (more than one young per litter).

On the Canary Islands, Trujillo and Barone (1991: 102) mentioned two nursing females in May-June.

MATING:
On the Canary Islands, mating occurs in September-October (Agirre-Mendi, 2005: 234).

PARASITES:
The Nematode *Molinostrongylus vespertilionis* Morosov and Spassky, 1961 was reported by Genov *et al.* (1992) from Hungary, Moldova and Ukraine.

Estrada-Peña and Sanchez (1988: 305) described *Steatonyssus (Steatonyssus) balcellsi* from a *N. leisleri* specimen from Frontera, Canary Islands.

In Slovakia, Kaňuch *et al.* (2005: 252) reported the presence of the following ectoparasites: mites: *Steatonyssus spinosus* (family Dermanyssidae), *Macronyssus flavus* (Macronyssidae), *Spinturnix helvetiae* (Spinturnicidae); fleas: *Ischnopsyllus intermedius, I. variabilis* (Ischnopsyllidae); and flies: *Nycteribia latreillii, N. (Acrocholidia) vexata* (Nycteribiidae).

They found that 100 out of 177 (56.5 %) of the examined bats carried at least one parasite, but only 15.3 % of these had two different species of parasites. Only *S. spinosus* and *S. helvetiae* were found abundantly (resp. 31.3 and 55.4 %), all other species occurred on less than 5 % of the bats.

Sándor *et al.* (2021a: 4) reported the presence of the argasid tick *Carios vespertilionis* Latreille, 1802.

VIRUSES:
Coronaviridae
Alphacoronavirus
This virus was reported from bats from Germany by Kohl and Kurth (2014: 3112).

Betacoronavirus
The virus was reported by Kohl and Kurth (2014: 3112) from Bulgaria and Germany.

Orthomyxoviridae
Despite sampling and testing of 64 individuals of this species, no evidence of influenza A-like viruses (*Orthomyxoviridae*) were obtained (Fereidouni *et al.*, 2015).

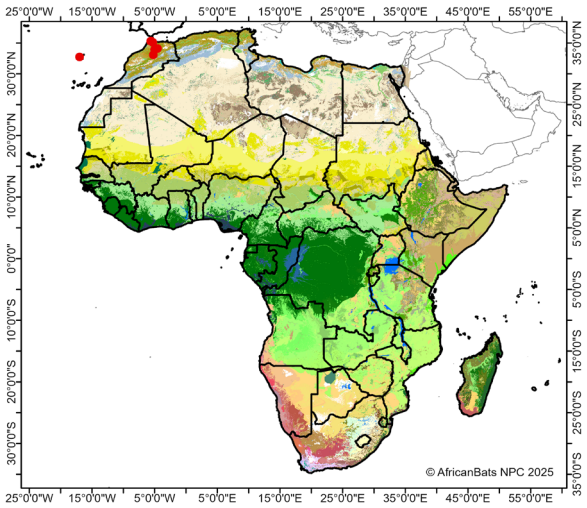

Figure 323. Distribution of *Nyctalus leisleri*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Azores (Portugal), Madeira (Portugal), Morocco.

Genus ***Pipistrellus*** Kaup, 1829

*1829. *Pipistrellus* Kaup, Skizzierte Entwicklungs-Geschichte Natürliche Systematik der Europäische Thierwelt, 1: 98. Publication date: 1829. - Comments: Type species: *Vespertilio pipistrellus* Schreber, 1774, by monotypy. Not *Pipistrellus* Gistel, 1848 (Insecta, Diptera, Hybotidae) (see Jackson and Groves, 2015: 274). - Etymology: From the italian "*pipistrello*" meaning bat (see Fujita and Kunz, 1984: 4; Flannery, 1995a: 393). From the Latin "*pipio* meaning squeaking and "*strellus*", which is an attiona indicating a "small animal" (see Kapteyn, 1995: 83). - Phonetics: pip'-is-trell'-us. - ZooBank: D3BD2230-B730-40BA-95D0-E95484EF21C7. (Current Combination).

1837. *Pipistrella* Bonaparte, Iconografia Fauna italiana. - Comments: Icon. fauna Ital.

1838. *Romicia* J. E. Gray, Mag. Zool. Bot., Edinburgh, 2 (12): 495. Publication date: 1 February 1838. - Comments: Type species: *Romicia calcarata* Gray, 1838 (=*Vespertilio kuhlii* Kuhl, 1817), by monotypy.

1839. *Vesperugo* Keyserling and Blasius, Arch. Naturgesch. Berlin, 5 (1): 312. Publication date: 1839. - Comments: In part (see Allen, 1939a: 92; Pavlinov *et al.*, 1995: 104). Included 13 species now referred to *Eptesicus, Pipistrellus, Neoromicia, Hypsugo*.

1840. *Romicius* Blyth, Cuvier's Animal Kingdom, 75. Publication date: 1840. - Comments: Variant of *Romicia* (see Allen, 1939a: 93; Meester *et al.*, 1986: 50), or invalid emendation (see Jackson and Groves, 2015: 274). (Emendation).

1856. *Nannugo* Kolenati, Allg. deutsche naturh. Zeitung, NF, 2 (2): 131. Publication date: 1856. - Comments: Included *Vespertilio nathusii* Keyserling and Blasius, *V. kuhlii* Kuhl and *V. pipistrellus* Schreber (see Ellerman and Morrison-Scott, 1951: 152; Corbet and Hill, 1992: 133). - Etymology: From the Greek "*νάννος*", meaning dwarf and the suffix -ugo (in analogy with *Hypsugo* and *Vesperugo*) (see Palmer, 1904: 447).

1868. *Alobus* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 707 (for 1867). Publication date: 1868 [Goto Description]. - Comments: Type species: *Vespertilio temminckii* Cretzschmar, 1826 (=*Pipistrellus rueppellii*

Fischer, 1829), by monotypy. Not of Le Conte, 1856 (Insecta, Coleoptera, Scarabaeidae) (see Jackson and Groves, 2015: 274).

1899. *Euvesperugo* Acloque, Faune de France, Mammifères, 35. - Comments: In part: Included six species, one of which was *Vespertilio pipistrellus* Schreber, 1774 (see Ellerman and Morrison-Scott, 1951: 162; Meester *et al.*, 1986: 50). Cabrera (1914: 123) also included it in part into *Nyctalus*.

1926. *Eptesicops* Roberts, Ann. Transv. Mus., 11: 245. Publication date: 14 September 1926. - Comments: Type species: *Scotophilus rusticus* Tomes, 1861, by original designation (see Jackson and Groves, 2015: 275).

1946. *Vansonia* Roberts, Ann. Transv. Mus., 20 (4): 304 [Goto Description]. - Comments: Type species: *Pipistrellus vernayi* Roberts, 1932 (=*Vespertilio rüppellii* Fischer, 1829), by original designation. Not *Vansonia* Schein, 1956 (Insecta, Coleoptera, Scarabaeidae) (see Jackson and Groves, 2015: 275). - Etymology: The name *Vansonia* refers to George van Son, entomologist of the Transvaal Museum (see Lanza *et al.*, 2015: 382). .

1951. *Pipiestrellus:* Watson, Uganda J., 15 (1): xx. (Lapsus).

1987. *Attalepharca* Menu, Palaeovert., 17 (3): 78, 126. Publication date: 15 November 1987 [Goto Description]. - Comments: No type species designated, therefore not available (see Corbet and Hill, 1992: 133).

1987. *Nycterikaupius* Menu, Palaeovert., 17 (3): 108, pl 4, fig 1. Publication date: 15 November 1987 [Goto Description]. - Comments: In part. The species assigned to this genus by Menu (1987: 109) are currently (sensu Monadjem *et al.*, 2020a: 1140) included in the genera *Laephotis, Neoromicia, Pipistrellus* and *Pseudoromicia*.

1992. *Attelepharca:* Corbet and Hill, The mammals of the Indomalayan Region: A systematic review, 131. (Lapsus).

1994. *Atellepharca:* Corbet and Hill, J. Mamm., 75 (1): 241. Publication date: February 1994. (Lapsus).

1999. *Pipistallus:* Salleh, Hang, Rahman and Abdulla, ASEAN Review of Biodiversity and Environmental Conservation (ARBEC), 1. Publication date: September - October 1999. (Lapsus).

2000. *Pipistrellis:* Qui, Han, Qi and Yufen, Acta Anthrop. Sin., 4 (1): 19. (Lapsus).

2007. *Pipistrellus (Afropipistrellus):* Thorn, Kock and Cuisin, Mammalia, 71 (1/2).

2008. *Pipistrillus:* Selim, Nahla and Shelfeh, Tishreen Univ. J. Res. Sci. Stud. - Biol. Sci. Ser., 30 (1): 247. (Lapsus).

2008. *Pipstrillus:* Selim, Nahla and Shelfeh, Tishreen Univ. J. Res. Sci. Stud. - Biol. Sci. Ser., 30 (1): 247. (Lapsus).

2018. *Pipistrelus:* Malekani, Musaba, Gembu, Bugentho, Toengaho, Badjedjea, Ngabu, Mutombo, Laudisoit, Ewango, Van Cakenberghe, Verheyen, Asimonyo, Masudi, Bongo and Ngbolua, Nat. Conserv. Res., 3 (2): 68. Publication date: January 2018. (Lapsus).

2019. *Pipistellus:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).

? *Pipistrellus sp. IVK-2011*

? *Pipistrellus sp.:*

? *Vansoni:* (Lapsus).

TAXONOMY:

For synonyms see Ellerman and Morrison-Scott (1951: 162); but also see Hill (1976: 25); Kitchener *et al.* (1986); and Menu (1984). *Hypsugo* was considered a full genus by Tiunov (1986). Hill and Harrison (1987) would transfer *Neoromicia* and *Vespadelus* to *Pipistrellus* from *Eptesicus*.

Based on the analysis of three nuclear genes (RAG2, APOB, and DMP1), Zhukova *et al.* (2023a: 302) found that the genus *Pipistrellus* is paraphyletic in respect to *Nyctalus* and *Glischropus*, and they suggest that the genus - as currently conceived - should probably be divided in two or three separate genera or that *Nyctalus* and *Glischropus* should be considered subgenera of *Pipistrellus*

Currently (Simmons and Cirranello, 2023b) recognized subgenera and species of the genus *Pipistrellus*:

Alionoctula Kruskop, Solovyeva and Kaznadzey, 2018: *stenopterus* (Dobson, 1875) – western Malaysia, Sumatra, Riau Arch., northern Borneo, Mindanao (Philippines) (Simmons, 2005: 478).

Pipistrellus Kaup, 1829: *abramus* (Temminck, 1838) – southern Ussuri region (Russia and China), Taiwan, southern and central Japan, Korea, Vietnam, Burma, India (Simmons, 2005: 473); *adamsi* Kitchener, Caputi and Jones, 1986 – Queensland and Northern Territory (Australia) (Simmons, 2005: 473); ***aero*** Heller, 1912; *angulatus* (Peters, 1880) – New Guinea, Bismarck Arch., Bougainville Isl and Solomon Isls, adjacent small islands (Simmons, 2005: 473); *ceylonicus* (Kelaart, 1852) – Pakistan, India, Sri Lanka, Bangladesh, Burma, Kwangsi and Hainan (China), Vietnam, Borneo (Simmons, 2005: 474); *collinus* Thomas, 1920 – Highlands of Papua New Guinea (Simmons, 2005: 474); *coromandra* (Gray, 1838) – Afghanistan, Bangladesh, India (including Nicobar Isls), Sri Lanka, Pakistan, Nepal, Bhutan, Burma, Cambodia, Thailand, southern China (Simmons, 2005: 474); *creticus* Benda, 2009 – Crete; *dhofarensis* Benda, Reiter, Uhrin and Varadínová, 2016 – E Yemen and SW Oman; *endoi* Imaizumi, 1959 – Honshu (Japan) (Simmons, 2005: 474); ***etula*** Torrent, Juste, Garin, Aihartza, Dalton, Mamba, Tanshi, Powell, Padidar, Garcia Mudarra, Richards and Monadjem, 2025; ***hanaki*** Hulva and Benda, 2004; ***hesperidus*** (Temminck, 1840); ***inexspectatus*** Aellen, 1959; *javanicus* (Gray, 1838) – eastern Afghanistan, northern Pakistan, northern and central India, southeastern Tibet (China), Burma, Thailand, Vietnam, through southeast Asia to Lesser Sunda Isls and the Philippines (Simmons, 2005: 475); ***kuhlii*** (Kuhl,

1817); ***maderensis*** (Dobson, 1878); *minahassae* (A.B. Meyer, 1899) – northern Sulawesi (Simmons, 2005: 476); *murrayi* Andrews, 1900 – Christmas Island (extinct); ***nanulus*** Thomas, 1904; *nathusii* (Keyserling and Blasius, 1839) – western Europe to Urals and Caucasus and western Asia Minor, southern England (Simmons, 2005: 476); *papuanus* (Peters and Doria, 1881) – Seram, Aru Isls, Baik-Supiori, New Guinea, New Ireland (Bismarck Arch.) adjacent small islands (Simmons, 2005: 476); *paterculus* Thomas, 1915 – northern India, Burma, Thailand, Vietnam, and southwestern China (Simmons, 2005: 477); ***permixtus*** Aellen, 1957; ***pipistrellus*** (Schreber, 1774); *pygmaeus* (Leach, 1825) – British Isles, southern Scandinavia south to Spain, Portugal, Corsica, Sardinina, Italy, Slovenia and Greece, east to Ukaraine and western Russia, northern Algeria, Tunisia, Libya (Cyrenaica only) (Simmons, 2005: 477); ***raceyi*** Bates, Ratrimomanarivo, Harrison and Goodman, 2006; ***rusticus*** (Tomes, 1861); ***simandouensis*** Monadjem, Richards, Decher and Hutterer, 2020; *sturdeei* Thomas, 1915 – Bonin Isls (Japan) (Simmons, 2005: 478); *tenuis* (Temminck, 1840) – Afghanistan to the Moluccas, southern China, Laos, Vietnam, Cocos Keeling Isl and Christmas Isl (Simmons, 2005: 479); *wattsi* Kitchener, Caputi and Jones, 1986 – southeastern Papua New Guinea and Sanari Isl (Simmons, 2005: 479); *westralis* Koopman, 1984 – northern Australia from Kimberly to eastern Gulf of Carpentaria (Simmons, 2005: 479).

COMMON NAMES:
Czech: zakrslí netopýři. English: Pipistrelle Bats, Pipistrelles. French: Pipistrelles. German: Zwergfledermäuse, Pipistrellen. Italian: Pipistrèlli. Ukrainian: Нетопир [= Netopir].

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Tragus: Monadjem *et al.* (2013c: 204) line drawing of tragi of specimen DNSM 13220 referred to a *Pipistrellus* 1 from Mount Nimba, Liberia.

ECHOLOCATION:
Rakotondramanana *et al.* (2014: 80) studied the echolocation calls of Madagascan "*Pipistrellus sensu lato*" bat (including *Pipistrellus, Neoromicia* and *Hypsugo* in two different flight cages: A (12 x 3 x 3 m) and B (5.4 x 1.4 x 1.5 m), and found that the same bats used different types of calls depending on the cage they were flying in. In the large cage (A), the signal showed a frequency-modulated part followed by a short quasi-constant frequency (FM/QCF) component, whereas in the small cage (B) the QCF component was lacking. These authors, therefore, also warn against extrapolating the results of echolocation calls captured in flight cages.

PREDATORS:
Demeler (1981: 133) found remains of a "*Pipistrellus*" in pellets of *Bubo africanus* (Temminck, 1821) in the Yankari Game Reserve (Nigeria).

Mikula *et al.* (2016: Supplemental data) mention a *Pipistrellus* sp. being taken by a Grey-headed bushshrike (*Malaconotus blanchoti* Stephens, 1826).

In Algeria, Djilali *et al.* (2016: 161) found remains of 6 *Pipistrellus* specimens in 516 preys (1.2 %) captured by the Short-eared Owl (*Asio flammeus* (Pontoppidan, 1763)).

Goodman *et al.* (2015c: 78) found the remains of five *Pipistrellus/Neoromicia* sp. individuals in pellets of Bat Hawk *Macheiramphus alcinus* Bonaparte, 1850 in western central Madagascar.

PARASITES:
DIPTERA
Nycteribiidae
Dick *et al.* (2023: 73) mentioned that *Basilia (Basilia) ansifera* Theodor, 1956 has been found on unidentified *Pipistrellus* bats from Côte d'Ivoire and Sudan. They also found *Basilia (Basilia) robusta* Theodor, 1956 on a *Pipistrellus aero* or *hesperidus* from Ol Jogi Conservancy (Kenya).

VIRUSES:
Paramyxoviridae
Mortlock *et al.* (2015: 1841) reported that twenty out of forty examined "*Pipistrellus*" specimens from the same colony in the DRC tested positive for *Paramyxovirus* sequences, all of which were nearly identical.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Algeria, Angola, Burundi, Cameroon, Canary Islands (Spain), Central African Republic, Congo (Democratic Republic of the), Egypt, Ethiopia, Gabon, Ghana, Guinea-Bissau, Kenya, Liberia, Madagascar, Malawi, Namibia, Nigeria, Senegal, Sierra Leone, South Africa, South Sudan, Tanzania, Togo, Tunisia, Uganda.

Pipistrellus etula Torrent, Juste, Garin, Aihartza, Dalton, Mamba, Tanshi, Powell, Padidar, Garcia Mudarra, Richards and Monadjem, 2025

*2025. *Pipistrellus etula* Torrent, Juste, Garin, Aihartza, Dalton, Mamba, Tanshi, Powell, Padidar, Garcia Mudarra, Richards and Monadjem, Zool. J. Linn. Soc., 204 (2): 13,14, figs 8 - 10, 12. Publication date: 13 June 2025.

Holotype: EBD 19203M: ad ♂, skull and alcoholic. Collected by: Javier Juste; collection date: 14 April 1989. Paratype: EBD 19086M: ♂. Collected by: Javier Juste; collection date: 13 April 1989. Paratype: EBD 19087M: ♂. Collected by: Javier Juste; collection date: 15 April 1989. Paratype: EBD 19088M: ♀. Collected by: Javier Juste; collection date: 15 April 1989. - Etymology: '*etula*' means island or nation in the language of the original Bubi people of Bioko Island (Torrent *et al.*, 2025b: 14)..

COMMON NAMES:
English: Bioko pipistrelle

DENTAL FORMULA:
I 2/3, C 1/1, P 2/3, M 2/3 = 34.

ECHOLOCATION:
Torrent *et al.* (2025b: 7) recorded the following values for three specimens: F_{max}: 40.1 ± 1.32 (37.5 - 42.0) kHz, F_{start}: 101.3 ± 6.19 (83.0 - 114.9) kHz and F_{end}: 31.5 ± 2.94 (24.2 - 35.3) kHz.

Subgenus *Pipistrellus (Pipistrellus)* Kaup, 1829

2004. *Pipistrellus sp. II:* Hulva, Horáček, Strelkov and Benda, Mol. Phylog. Evol., 32 (3): 1025. Publication date: September 2004. (Name Combination).
? *Pipistrellus (Pipistrellus):* (Name Combination).

TAXONOMY:
Zhukova *et al.* (2025: 15) reviewed the Pipistrellini and recognized two species groups in the subgenus *Pipistrellus,* containing the following species:
"*pipistrellus*": *hanaki, pipistrellus, pygmaeus*
"*kuhlii*": *hesperidus, kuhlii, maderensis, nanulus, raceyi, rusticus, simandouensis.*
They were unable to evaluate the status of i*nexspectatus.*

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Guinea.

Pipistrellus (Pipistrellus) 'incertae-sedis'

1858. *Nannugo Kolenatii* Müller, Lotos (Prag), 8: 75, figs 1 - 4. Type locality: Egypt: "Egypt". [Goto Description].
1862. *Vespertilio (Nannugo) Kolenatii:* Koch, Nass. Naturw. Jahrb., 18: 397.
2013. *Pipistrellus cf. hesperidus:* Koubínová, Irwin, Hulva, Koubek and Zima, Front. Zool., 10: 5. - Comments: Koubínová *et al.* (2013: 7) found differences in diploid chromosome number and/or in chromosome morphology between the populations from Senegal and other regions in Africa. Torrent *et al.* (2025b: 20) found that these Senegalese specimens cluster with *Pipistrellus rusticus* and are unrelated to *Pipistrellus hesperidus* s.s. and might possibly be named *Pipistrellus marrensis* Thiomas and Hinton, 1923, but this qill require further investigation. (Name Combination).
? *Pipistrellus (Pipistrellus) 'incertae-sedis'*

TAXONOMY:
Müller (1858: 75) called *Nannugo Kolenati* one of the smallest Nord African bat species. Its German name "Die weissgesäumte Buschfledermaus" indicates that a white edge on the wing membrane was present.

Koch (1862: 397) considers this form a relative of *Nannugo marginatus*, which in turn is a synonym of *P. kuhlii*. Except for these two publications, no other references to this form were found.

The description does not enable us to assign this name to either *Pipistrellus kuhlii* Kuhl, 1817 or *Pipistrellus deserti* Thomas, 1902. In the latter case this name might be a senior synonym, provided *aegyptius* Fischer, 1829 is to be ignored. However, this name clearly does qualify for the status of "*nomen oblitum*", and should, therefore, probably be ignored.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

Pipistrellus (Pipistrellus) aero Heller, 1912

*1912. *Pipistrellus aero* Heller, Smiths. Misc. Coll., 60 (12): 3. Publication date: 4 November 1912. Type locality: Kenya: Mathews Range: Mount Gargues [00 57 N 37 24 E, 7 100 ft]. [Goto Description]. Holotype: USNM 181812: ad ♂, skin and skull. Collected by: Edmund Heller; collection date: 26 August 1911; original number: 4110.

1971. *Pipistrellus [(Pipistrellus)] aero:* Hayman and Hill, Mammals of Africa: Chiroptera, 41. (Name Combination, Current Combination).

1971. *Pipistrellus altae:* Hayman and Hill, Mammals of Africa: Chiroptera, 43. - Comments: Hayman and Hill (1971) refer to specimens in the NHMUK labelled as "*P. altae*" but do not mention an original author.

? *Pipistrellus (Pipistrellus) aero:* (Current Combination).

TAXONOMY:
The Ethiopian specimens in the British Museum are clearly *P. kuhlii*; see Hayman and Hill (1971: 41). Koopman (1994: 114) states that this species is probably a subspecies of *P. aegyptius* (= *deserti*).

COMMON NAMES:
Chinese: 东非伏翼. Czech: netopýr gargueský. English: Mt Gargues Pipistrelle Bat, Aerial Pipistrelle Bat, Mt Gargues Pipistrelle, Mount Gargues Pipistrelle, Kenya Pipistrelle. French: Pipistrelle du Kenya. German: Luftige Zwergfledermaus, Luftige Pipistrelle, Mount-Gargues Zwergfledermaus.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status (Jacobs *et al.*, 2008q; IUCN, 2009; Jacobs *et al.*, 2019g).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019g). 2008: DD ver 3.1 (2001) (Jacobs *et al.*, 2008q; IUCN, 2009). 2004: VU D2 ver 3.1 (2001) (Jacobs *et al.*, 2004ae; IUCN, 2004). 1996: DD (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Jacobs *et al.*, 2008q; IUCN, 2009; Jacobs *et al.*, 2019g).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008q) [in IUCN (2009)] and Jacobs *et al.* (2019g) report that it has been recorded in the Matthews Range Forest Reserve and Marsabit National Reserve. Further studies are needed into the distribution, natural history and possible threats to this little-known species.

GENERAL DISTRIBUTION:
Pipistrellus aero is endemic to northwestern Kenya, where it is known only from three localities (Mount Garguez; Marsabit Lake and Ngong). It is also present in adjacent Ethiopia.

Native: Ethiopia (Lavrenchenko *et al.*, 2004b: 135); Kenya.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 69 minutes, and the digestibility rate about 81.2 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Jacobs *et al.*, 2008q; IUCN, 2009; Jacobs *et al.*, 2019g).

Trend
2018: Unknown (Jacobs *et al.*, 2019g). 2008: Unknown (Jacobs *et al.*, 2008q; IUCN, 2009).

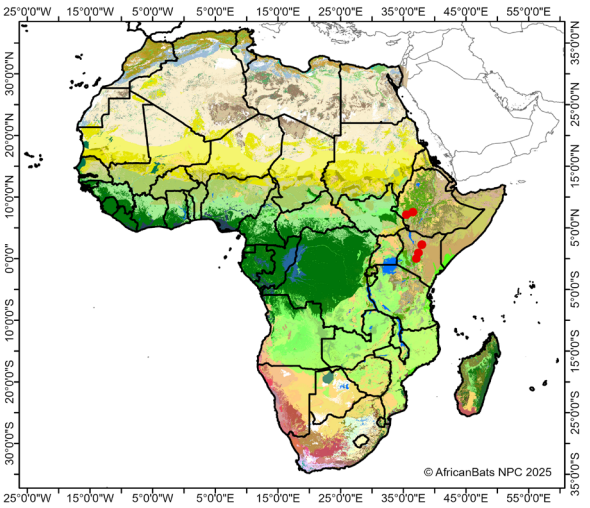

Figure 324. Distribution of *Pipistrellus (Pipistrellus) aero*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia, Kenya.

Pipistrellus (Pipistrellus) hanaki Hulva and Benda, 2004

*2004. *Pipistrellus hanaki* Hulva and Benda, in: Benda, Hulva and Gaisler, Acta Chiropt., 6 (2): 207. Type locality: Libya: Cyrenaica: Al Jabal Al Akhdar district:: (ca. 5 km) SW of Al Bayda: Wadi al Kuf [32 44 N 21 41 E, 495 m]. [Goto Description]. Holotype: NMP 49897: ad ♂, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 19 May 2002. 3 paratypes: see Benda *et al.* (2004b: 207). Paratype: NMP 49890: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 18 May 2002; original number: pb2135. Collected at: 'Arqub Ash Shafshaf, ca. 3 km south of Al Hilal, Cyrenaica, Libya; 32.87°N, 22.18°E. (see Benda in Mlíkovský *et al.*, 2011: 136). Paratype: NMP 49891: ad ♂, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 18 May 2002; original number: pb2136. Collected at: 'Arqub Ash Shafshaf, ca. 3 km south of Al Hilal, Cyrenaica, Libya; 32.87°N, 22.18°E. (see Benda in Mlíkovský *et al.*, 2011: 136). Paratype: NMP 49892: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 18 May 2002; original number: pb2137. Collected at: 'Arqub Ash Shafshaf, ca. 3 km south of Al Hilal, Cyrenaica, Libya; 32.87°N, 22.18°E. (see Benda in Mlíkovský *et al.*, 2011: 136). Paratype: NMP 49894: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 19 May 2002; original number: pb2142. Paratype: NMP 49895: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 19 May 2002; original number: pb2143. Paratype: NMP 49896: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 19 May 2002; original number: pb2144. Paratype: NMP 49902: sad ♂, alcoholic (skull not removed). Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2150. Collected at a small cave in the central part of Wadi Al Kuf, 8 km southwest of Massah, Cyrenaica, Libya; 32.70 N 21.58 E (see Benda in Mlíkovský *et al.*, 2011: 136). Paratype: NMP 49903: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2151. Collected a :a small cave in the central part of Wadi Al Kuf, 8 km southwest of Massah, Cyrenaica, Libya; 32.70 N 21.58 E (see Benda in Mlíkovský *et al.*, 2011: 136). Paratype: NMP 49904: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2152. Collected at a small cave in the central part of Wadi Al Kuf, 8 km southwest of Massah, Cyrenaica, Libya; 32.70 N 21.58 E (see Benda in Mlíkovský *et al.*, 2011: 136). - Etymology: In honour of prof. Vladimír Hanák (Prague, Czech Republic), who signficantly contributed to the knowledge of the Palaearctic bat fauna (see Benda *et al.*, 2004b: 208).

2004. *Pipistrellus sp. I:* Hulva, Horáček, Strelkov and Benda, Mol. Phylog. Evol., 32 (3): 1025. Publication date: September 2004. (Name Combination).

2020. *Pipistrellus (Pipistrellus) hanaki:* Simmons and Cirranello, BatNames.org. (Current Combination).

TAXONOMY:
See Benda *et al.* (2004b; 2009a).

Evin *et al.* (2011: 2095 - 2097) confirm that *hanaki* is composed of two different lineages: *P. hanaki hanaki* from Libya and *P. hanaki creticus* Benda, 2008 from Crete, which differ also in size and shape of the skull.

COMMON NAMES:
Albanian: Pipistrel i Hanak-ut. Armenian: Հանակի փոքրաչղջիկ. Azerbaijani: Hanaki cırtdan şəbpərəsi. Basque: Hanak pipistrelo. Belarusian: Нетапыр Ганака. Bosnian: Hanakov šišmiš. Breton: Pipistrell Libia. Bulgarian: Прилепче на Ханак. Castilian (Spain): Murciélago de Hanak. Catalan (Spain): Pipistrel·la de Hanak. Croatian: Hanakov patuljasti šišmiš. Czech: Netopýr Hanákův, Netopýr kyrénský. Danish: Hanaks flagermus. Dutch: Hanaks dwergvleermuis, Hanak's dwergvleermuis. English: Hanak's Pipistrelle. Estonian: Liibüa nahkhiir. Finnish: Libyanlepakko. French: Pipistrelle de Libye. Frisian: Hanaks dwerchflearmûs. Galician (Spain): Morcego de Hanak. Georgian: ჰანაკის ღამური. German: Hanaks Zwergfledermaus, Hanaks Pipistrelle. Greek: Ναvουχτερίδα του Hanak. Hungarian: Hanák-törpedenevér. Irish Gaelic: Ialtóg Hanak. Italian: Pipistrello di Hanak. Latvian: Hanaka sikspārnis. Lithuanian: Hanako šikšniukas. Luxembourgish: Libesch Zwergfliedermaus. Macedonian: Ханаков лилјак. Maltese: Pipistrell ta' Hanak. Montenegrin: Libijski patuljasti slijepi mišić. Norwegian: Kyrenaikaflaggermus. Polish: Karlik cyrenejski. Portuguese: Morcego de Hanak. Rhaeto-Romance: Pipistrel da Hanak. Romanian: Liliacul pitic a lui Hanak. Russian: Нетопырь Ганака. Serbian: Либијски сл[ij]епи мишић [= Libijski sl[ij]epi mišić]. Scottish Gaelic: Ialtag Hanak. Slovak: večernica Hanákova. Slovenian: Libijski drobni netopir. Swedish: Kretapipistrell. Turkish: Hanak'ın Cüce Yarasası. Ukrainian: Нетопир Ганака. Welsh: Ystlum lleiaf Hanak.

SIMILAR SPECIES:
Pipistrellus hanaki differs from its nearest relatives *P. pipistrellus* and *P. pygmaeus* chromosomally, and by its larger skull and teeth, and a number of other characters (Benda *et al.*, 2004b).

CONSERVATION STATUS:
Global Justification
This recently described species, little or no data is available on population size and trend, distribution, or potential threats. Assessed as Data Deficient DD ver 3.1 (2001) (Aulagnier and Palmeirim, 2008a; IUCN, 2009).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2008: DD ver 3.1 (2001) (Aulagnier and Palmeirim, 2008a; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
Unknown (Aulagnier and Palmeirim, 2008a; Thorn *et al.*, 2009).

CONSERVATION ACTIONS:
Unknown (Aulagnier and Palmeirim, 2008a; IUCN, 2009).

GENERAL DISTRIBUTION:
Pipistrellus hanaki is known only from a small area on the Libyan coast (in the Cyrenaica area) (Benda *et al.*, 2004b), and from Crete (Greece) (see Benda *et al.*, 2009b).

Native: Greece (Benda *et al.*, 2009b); Libyan Arab Jamahiriya (Benda *et al.*, 2004b).

GEOGRAPHIC VARIATION:
Georgiakakis and Benda (2021: 2) indicate that the endemic Cretan population (representing the subspecies *creticus* Benda, 2009) differs from the northern African populations in both morphometric and genetic traits, but not significantly enough to represent separate species.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Penis
Georgiakakis and Benda (2021: 4) mention that the skin of the whole penis is pale greyish brown with unpigmented hairs. The glans penis is simple, without long medial stripe on dorsal side of praeputium.

DETAILED MORPHOLOGY:
Baculum
The baculum is a long thin bone (1.8 mm) bifurcated on both epiphyses. The proximal end is 0.4 mm wide and the distal one 0.1 mm (Georgiakakis and Benda, 2021: 4).

Herdina *et al.* (2013: 68) indicate that *P. hanaki* can not be separated from either *P. pipistrellus* or *P. pygmaeus* by the shape of its baculum. They found that the proximal third of the baculum shows the most interspecific variation between these three species, whereas the shape of the curve in lateral view shows the most individual variation.

ECHOLOCATION:
Georgiakakis and Russo (2012: 168) report that the echolocation call has a FM-QCF structure, consisting of a frequency modulated component followed by an almost constant frequency part. They (p. 169) also were able to distinguish two types of social calls: type 'A' (primarily emitted by foraging bats) with a maximum energy frequency (FMAXE) of about 27.7 kHz, and a duration of 19.9 ms, of which type 'B' had a maximum energy frequency of all components (Freq) of about 20.9 kHz and a bandwidth of 28 kHz, and a duration of 24.8 ms. The number of calls of type 'B' increased from July to October and then decreased again, whereas those of type 'A' decreased from July to November.

Russo *et al.* (2025a: 5) found that 21 of the *Pipistrellus hanaki* echolocation call recordings were classified as *Pipistrellus pipistrellus* in their discriminant function analyses. However, the thrills of *P. hanaki* were completely separate from all other species (*kuhlii, maderensis, nathusii, pipistrellus* and *pygmaeus*).

MOLECULAR BIOLOGY:
Genetics
See Benda *et al.* (2004b), Hulva *et al.* (2004).

DIET:
From Libya, Benda *et al.* (2014c: 60) reported the following food items: Smaller Lepidoptera and small Coleoptera (Scarabaeidae, Carabidae, Staphylinidae). Two digestive tracts contained high volumes of cockroaches (Blattodea), and small amounts of Nematocera (Culicidae and Chironomidae) as well as Hymenoptera (Ichneumonoidea).

Georgiakakis and Benda (2021: 9) indicate that the presence of diurnal brachyceran Diptera may isuggest that *P. hanaki* starts foraging very early and/or forages very close to vegetation and possibly glean the prey from foliage.

POPULATION:
Structure and Density
Unknown (Aulagnier and Palmeirim, 2008a; IUCN, 2009).

Trend
2008: Unknown (Aulagnier and Palmeirim, 2008a; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Smotherman *et al.* (2016: 537) refer to Georgiakakis and Russo (2012) in describing the song structure for this species as consisting of different syllable types in basic motif. These bats sing while flying.

REPRODUCTION AND ONTOGENY:
Benda *et al.* (2014c: 55) reported pregnant females (each containing one foetus) collected on 17, 18, and 19 May 2002 at different localities in Libya (see also Georgiakakis and Benda, 2021: 7).

Garbino *et al.* (2021: Suppl.), however, mention that this species has more than one young per litter.

PARASITES:
Benda *et al.* (2014c: 60) reported the presence of two Nycteribiid bat flies: *Basilia daganiae* Theodor and Moscona, 1954 and *Basilia mediterranea* Hůrka, 1970.

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following bat flies: Nycteribiidae: *Basilia daganiae* Theodor and Moscona, 1954, and *Basilia mediterranea* Hůrka, 1970.

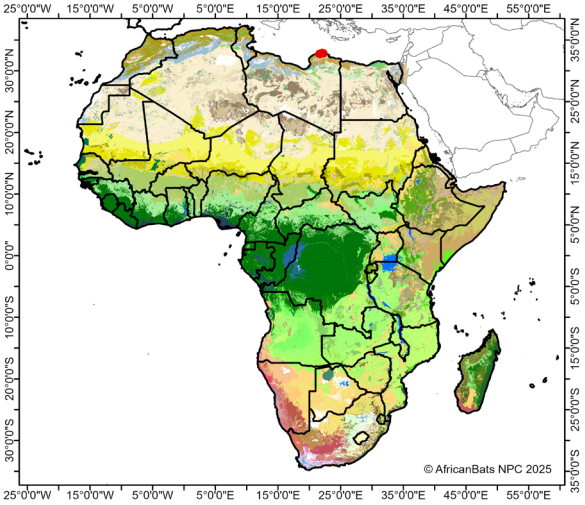

Figure 325. Distribution of *Pipistrellus (Pipistrellus) hanaki*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Libya.

Pipistrellus (Pipistrellus) hesperidus (Temminck, 1840)

1832. *Vespertilio platycephalus* Temminck, in: Smuts, Enumer. Mamm. Capensium, 107. Type locality: South Africa: Cape Town [33 56 S 18 28 E].

*1840. *Vespertilio hesperida* Temminck, Monographies de mammalogie ou description de quelques genres de mammifères, dont les espèces ont été observées dans les différens musées de l'Europe, 2 (13): 211. Publication date: 1840. Type locality: Eritrea: Abyssinia: Red Sea, shores of the [ca. 09 N 39 E]. [Goto Description]. Lectotype: SMF 12381: ad ♂, skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1842. Old catalog number II.N.9*. - Etymology: From the feminine scientific Latin adjective *hespèrida*, meaning "evening animal", deriving from the feminine Greek substantive "*ἑσπέρα*" (hespèra), meaning "evening", as this bat, as almost all Chiroptera, begins to fly at dusk (see Lanza *et al.*, 2015: 410).

1969. *Vesperugo hespirida:* Kock, Abh. Senckenberg. naturforsch. Ges., 521: 206. (Name Combination, Lapsus).

2001. *Pipistrellus hesperidus:* Kock, Senckenb. biol., 81 (1/2): 277. (Name Combination).

2002. *Pipistrellus cf. kuhlii:* Kearney, Volleth, Contrafatto and Taylor, Acta Chiropt., 4 (1): 55. - Comments: Not of Kuhl, 1817.

2013. *Pipistrellus cf. hesperidus:* Koubínová, Irwin, Hulva, Koubek and Zima, Front. Zool., 10: 5. - Comments: Koubínová *et al.* (2013: 7) found differences in diploid chromosome number and/or in chromosome morphology between the populations from Senegal and other regions in Africa. Torrent *et al.* (2025b: 20) found that these Senegalese specimens cluster with *Pipistrellus rusticus* and are unrelated to *Pipistrellus hesperidus* s.s. and might possibly be named *Pipistrellus marrensis* Thiomas and Hinton, 1923, but this qill require further investigation. (Name Combination).

2013. *Pipistrellus hesperidares:* McCulloch, Barcoding of South African bat species and evaluation of their natural exposure to lyssaviruses, 120. Publication date: July 2013. (Lapsus).

2020. *Pipistrellus (Pipistrellus) hesperidus:* Simmons and Cirranello, BatNames.org. (Current Combination).

? *Pipistrellus (Pipistrellus) kuhlii:*

? *Pipistrellus hesperidus 3:*

? *Pipistrellus hesperidus fuscatus:* (Name Combination).

? *Pipistrellus kuhlii:* - Comments: Not of Kuhl, 1817.

TAXONOMY:
Pipistrellus hesperidus was separated from *kuhlii* by Kock (2001b: 277).

Vespertilio platycephalus Temminck, 1832 is according to Roberts (1951) a synonym of *P. kuhlii*, which would make this the senior synonym. However, both Allen (1939a) and Ellerman *et al.* (1953) regard this taxon as unidentifiable, besides which it seems to fall outside the known distribution of this species (Meester *et al.*, 1986: 52).

Koubínová *et al.* (2013: 8) suggest that three subspecies might deserve elevation to species rank: *hesperidus* (North-eastern Africa), *fuscatus* (Afro-tropical regions other than Southern Africa and Madagascar), and *subtilis* (Southern Africa and Madagascar), but they also indicate that the cyt *b* of Senegalese "*hesperidus*" differs considerably (13 %) from that in populations from South Africa, and might need to be considered a distinct species.

COMMON NAMES:
Chinese: 暗黑伏翼. Czech: netopýr jižní. English: African pipistrelle, Dusky pipistrelle. French: Pipistrelle hespéride, Pipistrelle sombre. German: Abendstern-Zwergfledermaus, Abendstern-Pipistrelle, Netzhäutigen Dämmerungsfledermaus, Flachköpfige Dämmerungsfledermaus. Italian: Pipistrèllo seràle.

ETYMOLOGY OF COMMON NAME:
Since sub-Saharan Africa populations are specifically distinct from Kuhl's pipistrelle occurring in the Palaearctic region (Kock 2001?a), the name African pipistrelle serves to distinguish it from Kuhl's pipistrelle (Bronner *et al.*, 2003; Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Mickleburgh *et al.*, 2008dp; IUCN, 2009; Piraccini, 2016e).

Assessment History
Global
2016: LC ver 3.1 (2001) (Piraccini, 2016e). 2008: LC ver 3.1 (2001) (Mickleburgh *et al.*, 2008dp; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessed as part of *P. kuhlii*] (IUCN, 2004).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016p). 2004: LC ver 3.1 (2001) (Friedmann and Daly, 2004). 1986 - Indeterminate [assessed as *P. kuhlii*] (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Mickleburgh *et al.*, 2008dp; IUCN, 2009; Piraccini, 2016e).

CONSERVATION ACTIONS:
Mickleburgh *et al.* (2008dp) [in IUCN (2009)] and Piraccini (2016e) report that in view of the species wide range it is presumably present in a number of protected areas. It has been recorded from the Parc National de Kirindy-Mitea on Madagascar (Bates *et al.*, 2006). Additional taxonomic studies are needed to better define the extent of the species range relative to other species of *Pipistrellus*.

GENERAL DISTRIBUTION:
Pipistrellus hesperidus has been recorded over much of sub-Saharan Africa. It ranges from the Cape Verde Islands, to Liberia and Côte d'Ivoire, to Nigeria, Cameroon and Equatorial Guinea (Bioko), western Democratic Republic of the Congo, southern Sudan, Ethiopia, Eritrea and Somalia, into Kenya and Uganda, Rwanda, Burundi, Tanzania, Malawi, Mozambique, Zambia, Zimbabwe, Angola being found as far south as eastern and southern South Africa and possibly Swaziland. There are a few records of this species from central western Madagascar (Bates *et al.*, 2006: 317).

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 820,815 km^2.

In the RSA, the species' distribution is strongly associated with annual precipitation (Babiker Salata, 2012: 49).

The current identity of bats from the Arabian Peninsula formerly allocated to *Pipistrellus kuhlii* is unclear and some records might refer to *P. hesperidus*. Simmons (2005) also indicates that this species is present in the Canary Islands (Spain). However, this distribution needs to be confirmed. Records from North Africa are referable to *Pipistrellus kuhlii*.

Taylor *et al.* (2018b: 63) predict the species might occur in Angola.

Benda *et al.* (2025: 88) indicate that the West African populations (Senegal to Cameroon) might might be erroneously assigned to this species,

Native: Botswana (Monadjem *et al.*, 2010d: 571); Burundi; Cameroon (Eisentraut, 1968: 171 - as "*P. kuhlii* - 1st record from West Africa); Cape Verde; Congo (The Democratic Republic of the); Equatorial Guinea (Bioko); Eritrea; Eswatini (Monadjem *et al.*, 2010d: 572, Monadjem *et al.*, 2021: 5); Ethiopia (Lavrenchenko *et al.*, 2004b: 134); Kenya; Liberia (Fahr, 2007a: 104); Madagascar (Bates *et al.*, 2006: 317); Malawi (Ansell, 1974; Happold *et al.*, 1988; Monadjem *et*

al., 2010d: 571); Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 571; Monadjem *et al.*, 2010c: 384); Nigeria; Rwanda; South Africa (Monadjem *et al.*, 2010d: 571); Tanzania (Stanley and Goodman, 2011: 47); Uganda; Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 572); Zimbabwe (Cotterill, 2004a: 261; Monadjem *et al.*, 2010d: 572).
Presence uncertain: Spain (Canary Islands).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987) as *P. kuhlii* and Kearney *et al.* (2002) as *P* cf. *kuhlii*.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Schoeman and Jacobs (2008)] mention a wing loading value of 8.5 Pa, aspect ratio 5.5 for a wingspan of 21 cm and a wing area of 80 cm^2 and a body mass of 7 g.

ECHOLOCATION:
Schoeman and Waddington (2011: 291) mention a peak frequency of 56.3 ± 2.1 kHz and a duration of 2.2 ± 0.2 ms for specimens from Durban, South Africa.

In Soutpansberg, South Africa, Taylor *et al.* (2013b: 17) recorded the following parameters for 19 calls: F_{max}: 66.9 ± 8.91 (48.5 - 82.0) kHz, F_{min}: 44.9 ± 1.53 (41.3 - 47.2) kHz, F_{knee}: 50.3 ± 2.50 (44.9 - 54.7) kHz, F_{char}: 45.8 ± 1.78 (41.5 - 49.1) kHz, duration: 2.6 ± 0.85 (1.7 - 5.0) ms.

Linden *et al.* (2014: 40) reported the following parameters from the Soutpansberg area (RSA): F_{min}:41 - 47 kHz, F_{char}: 42 - 49 kHz, F_{knee}: 45 - 55 kHz, slope: 154 - 829 OPS, duration: 2 - 5 ms.

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 50 (45 - 55) kHz.

3871 calls of 129 bats from southern KwaZulu-Natal and Eastern Cape (RSA), reported by Moir (2020: 30) and Moir *et al.* (2021a: 371), had the following characteristics: F_{max}: 73.11 ± 7.87 (50.96 - 91.36) kHz, F_{min}: 45.63 ± 1.44 (42.60 - 49.81) kHz, F_{char}: 46.04 ± 1.42 (42.79 - 49.92) khz, F_{knee}: 49.65 ± 2.27 (44.11 - 54.55) kHz, and duration: 2.59 ± 0.66 (1.43 - 4.31) ms.

Monadjem *et al.* (2017c: 179) reported the following values for Eswatini: F_{min}: 45.3 ± 1.87 (41.7 - 49.1) kHz, F_{knee}: 49.6 ± 2.42 (44.6 - 54.3) kHz, F_c: 46.0 ± 1.83 (42.5 - 50.0) kHz, and duration: 3.1 ± 0.63 (2.3 - 4.5) ms.

Adams and Kwiecinski (2018: 4) recorded two calls in the Kalahari Desert: F_{char}: 43.3 ± 3.1 kHz, F_{max}: 53.6 ± 1.6 kHz, F_{min}: 42.9 ± 3.4 kHz, duration: 2.3 ± 0.3 ms.

16 "*Pipistrellus* cf. *hesperidus*" calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 51.75 ± 5.32 kHz, F_{min}: 40.87 ± 11.16 kHz, F_{knee}: 45.43 ± 0.74 kHz, F_{char}: 44.56 ± 0.96 kHz, slope: 22.01 ± 15.95 OPS, duration: 4.03 ± 1.48 ms.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 59.1 kHz, F_{start}: NA kHz, F_{end}: NA kHz, Band width: NA kHz, and duration: 2.5 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 99 calls of 4 bats: F_{max}: 52.59 ± 4.32 kHz, F_{min}: 44.75 ± 3.24 kHz, F_{knee}: 46.89 ± 1.16 kHz, F_{char}: 45.46 ± 1.05 kHz, slope: 21.95 ± 2040.74 OPS, duration: 5.03 ± 1.75 ms. 15 calls recorded at the Venatia mine by Cory-Toussaint and Taylor (2022: Table S1) had a duration of 3.35 ± 0.51 49 ms,.F_{min}: 13 ± 2.15 kHz, F_{max}: 62.43 ± 6.49 kHz, F_{knee}: 52.53 ± 1.32 kHz and F:50.28 ± 1.10 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 42 *Pipisrellus hesperidus* calls from the Kruger Park (RSA): F_{min}: 44.6 ± 1.6 (39.6 47.8) kHz, Duration: 3.3 ± 1.0 (2.0 5.9) ms, F_{max}: 63.0 ± 11.1 (48.7 86.6) kHz, F_{knee}: 48.5 ± 2.8 (44.3 54.9) kHz, F_{char}: 45.3 ± 1.6 (42.1 49.2) kHz,

61 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 41 - 47 kHz, F_{max}: 48 - 82 kHz, F_{char}: 42 - 49 kHz, F_{knee}: 45 - 55 kHz and duration 2 - 5 ms.

For 2 calls from 5 *Pipistrellus hesperidus* bats from Telperion Nature Reserve (RSA), De Jong *et al.* (2025: 322) reported the following parameters: F_{char}: 46.66 ± 0.79 kHz, F_{knee}: 48.33 ± 2.29 kHz, F_{min}: 46.48 ± 0.78 kHz, F_{max}: 78.24 ± 17.90 kHz, Bandwidth: 31.76 ± 17.70 kHz, Duration: 3.29 ± 1.14 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 55) reported F_{char}: 45.30 ± 1.60 kHz, F_{max}: 63.00 ± 11.1 kHz and F_{min}: 44.60 ± 1.60 kHz.

MOLECULAR BIOLOGY:
Karyotype
Rautenbach *et al.* (1993), Volleth *et al.* (2001) and Kearney *et al.* (2002) all reported $2n$ = 42, FN = 50, BA = 10, and a metacentric X chromosome,

for specimens from South Africa and Madagascar. These results were the same as those obtained for *P. rusticus* (Kearney *et al.*, 2002). Rautenbach *et al.* (1993) also reported an acrocentric Y chromosome. GTG banding also identified that *P. hesperidus* and *P. rusticus* share the same Robertsonian fusion of chromosomes 11/12 (Kearney *et al.*, 2002). Volleth and Eick (2012: 169) indicate that the EMA segment order on chromosomal arm 2 of *P. hesperidus* is the same as that on human chromosome 4, but differs from that on chromosome 10 of *Rhinolophus hipposideros*, and conclude that the EMA segment order in the Vespertilioniformes is probably the ancentral one.

Koubínová *et al.* (2013: 3) report a different karyotype for 3 ♂♂ and 1 ♀ from Senegal: 2*n* = 46, Fna = 58, FN = 62, X = metacentric, and Y = dot-like. They also found that the cytochrome *b* in their specimens differed for about 13 % from that of South African specimens, which led them to the conclusion that Senegalese *P.* cf. *hesperidus* likely represents a different species.

Genetics
In South Africa, Moir *et al.* (2021c: 1595) found gene dispersal probably to be male-mediated and females were philopatric.

HABITAT:
Cooper-Bohannon *et al.* (2016: Table S2) indicate that, in southern Africa, *P. hesperidus* occurs primarily in Savanna (47 %), SW arid (20 %) and Afromontane (15 %) habitats.

Moir *et al.* (2021c: 1596) suggest that the removal of riparian vegetation by sugarcane farming and plantation forestry practices may deter this species from using watercourses, thereby hindering possible dispersal events.

In Madagascar, Ravelomanantsoa *et al.* (2019: 110) caught it in open spaces in a dry deciduous forest and near a banana plantation.

ROOST:
In South Africa, Czenze *et al.* (2021: 3) found these bats roosting in spots where the temperature approached normothermic body temperature.

Happold and Happold (2023: 155) mention these bats roost in groups of up to 12 individuals.

DIET:
Naidoo *et al.* (2011: 26) reported the following volume percentages from the Umbilo River (KwaZulu Natal, RSA): during summer: Lepidoptera (7.8 ± 2.8), Coleoptera (12.3 ± 5.5), Hemiptera (32.8 ± 2.8), Diptera (37.8 ± 8.1), and Trichoptera (9.2 ± 7.1); during winter: Lepidoptera (16.9 ± 19.0), Coleoptera (20.4 ± 20.3), Hemiptera (12.6 ± 13.2), Diptera (13.7 ± 5.1), and Trichoptera (36.4 ± 38.7). From the Westville River, they reported for the summer: Lepidoptera (10.0 ± 4.5), Coleoptera (8.0 ± 3.8), Hemiptera (31.2 ± 10.7), Diptera (42.7 ± 11.4), Trichoptera (2.7 ± 0), and Hymenoptera (5.4 ± 8.7).

From the Limpopo province (RSA), Taylor *et al.* (2017b: 245, 252 - 254) report the following food items, belonging to six insect orders: Lepidoptera (*Araeopteron* sp. + *Toxocampinae tathorhynchus* + *Eutelia polychorda* + *Chiasmia interrupta* + *Ennominae* sp. + *Isturgia roraria* + *Sena* sp. + *Sena prompta* + *Xenopseustis* sp. + *Athetis ignava* + *Copitarsia* sp. + *Cortyta canescens* + *Enmonodia capensis* + *Mythimna impura* + *Mythimna oxygala* + *Pandesma robusta* + *Pericyma atrifusa* + *Spodoptera exigua* + *Tycomarptes* sp. + *Maurilia arcuata* + *Pseudautomeris irene* + *Arotrura JFL201* + *Agrius convolvuli* + unmatched), Coleoptera (unmatched), Orthoptera (*Neoconocephalus spiza* + unmatched), Hemiptera (*Nezara viridula*), Diptera (*Culex quinquefasciatus* + 2 unmatched) and Blattodea (unmatched).

Bailey *et al.* (2019: 372) found that the Allotonic Frequency Hypothesis (eared moths are less available to syntonic bats due to their ability to detect these bat's echolocation, but become available around lights due to a reduction in efficacy of the moth's defences) is true for *Pipistrellus hesperidus*.

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 63 minutes, and the digestibility rate about 82.1 %.

PREDATORS:
Mikula *et al.* (2016: Supplemental data) mention the following avian predators: Little sparrowhawk (*Accipiter minullus* (Daudin, 1800)); Southern fiscal (*Lanius collaris* Linnaeus, 1766). They also mention "*P. kuhli*" being preyed upon by the Lanner falcon (*Falco biarmicus* Temminck, 1825), the Eurasian hobby (*Falco subbuteo* Linnaeus, 1758), the Common kestrel (*Falco tinnunculus* Linnaeus, 1758), but some of these records might involve *P. hesperidus*. Their references to the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) probably all refer to *P. hesperidus* as these all point to sub-Saharan countries.

POPULATION:
Structure and Density

There is little information available on the abundance of this species, however, it is not very common in southern Africa (Skinner and Chimimba, 2005: 301; Mickleburgh *et al.*, 2008dp; IUCN, 2009; Piraccini, 2016e).

Trend
2016: Unknown (Piraccini, 2016e). 2008: Unknown (Mickleburgh *et al.*, 2008dp; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Stanley and Goodman (2011: 46 - 47) report on two females collected in early July 1991 in the West Usambara Mountains (Tanzania) of which one had an embryo in each uterine horn (leading to polytocy, see Garbino *et al.*, 2021: Suppl.). Three other females, collected on 1 September 1992, did not show any signs of reproduction.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned that pregnant females were collected in October.

In Malawi, the young were born in the wet season (Happold and Happold, 1990b: 567).

PARASITES:
Basilia robusta Theodor 1956 (Haeselbarth *et al.*, 1966: 111 - host recorded as *P. kuhlii*). Beaucournu and Noblet (1985: 635) also mention the possible presence of *Basalia daganiae* Theodor and Moscona, 1954 on a "*P. kuhlii*" from Kenya.

Clément *et al.* (2019a: 5) reported on one southern African bat infected by *Trypanosoma vespertilionis*_AF1. *T. vespertilionis* and *T. dionisii* were reported by Babyesiza *et al.* (2025: 4) from Uganda.

The bat fly "*Basilia* sp. 3" was reported from "*Pipistrellus* cf. *hesperidus*" by Ramasindrazana *et al.* (2017: 4).

Ramasindrazana *et al.* (2016: 6) report the presence of *Litosoma* Clade 2 (Nematoda: Onchocercidae) in Madagascan "*P.* cf. *hesperidus*".

The flea *Ischnopsyllus emminus* Jordan and Rothschild, 1921 was reported on "*P. kuhlii*" from Malawi by Beaucournu and Kock (1996).

The bat bugs *Cacodmus ignotus* Rothschild, 1912 and *Cacodmus sparsilis* Rothschild, 1914 (Hemiptera: Cimicidae) were reported from South Africa by Hornok *et al.* (2017a: 3). *Cacodmus villosus* (Stål, 1855) was reported from Ethiopia by Szentiványi *et al.* (2022: 12).

Hornok *et al.* (2017b: 3) found larvae of the tick *Argas transgariepinus* White, 1846 (Ixodida: Argasidae) on a *P. hesperidus* from Makhado, RSA. Hornok *et al.* (2019: 2) probably refer to the same bat and tick and indicate that the latter was infected with *Rickettsia* sp. bacteria.

Dick *et al.* (2023: 74) found the nycteribiid fly *Basilia (Basilia) robusta* Theodor, 1956 on Kenyan *Pipistrellus hesperidus*:and *Pipistrellus* cf. *hesperidus*.

VIRUSES:
Coronaviridae
Anthony *et al.* (2017b: Suppl.) mention the beta-coronavirus MERS_like_CoV. Anthony *et al.* (2017a: 1) described a MERS_like CoV (strain PREDICT/PDF-2180 - subgenus *Merbecovirus*; see Markotter *et al.*, 2020: 5) from *P.* cf. *hesperidus* from Uganda.

Paramyxoviridae
1 out of 11 Madagascan specimens tested by Mélade *et al.* (2016b: 4) was positive for paramyxoviruses.

Rhabdoviridae - Rabies like viruses
Lyssavirus - Rabies related viruses
Rabies
Oelofsen and Smith (1993) tested [as *P. kuhlii*] one individual brain, from Christiana, Free State Province South Africa by means of the "Rapid rabies enzyme immunodiagnosis" (RREID) test (Diagnostic Pasteur), and this did not test positive.

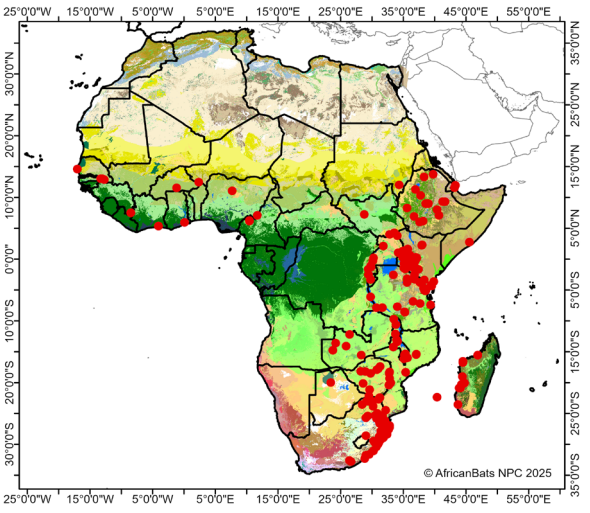

Figure 326. Distribution of *Pipistrellus (Pipistrellus) hesperidus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Botswana, Burkina Faso, Cameroon, Côte d'Ivoire, Djibouti, Eritrea, Eswatini, Ethiopia, French Southern and Antarctic Lands, Ghana,

Kenya, Liberia, Madagascar, Malawi, Mozambique, Niger, Nigeria, Rwanda, Senegal, Somalia, South Africa, South Sudan, Sudan, Tanzania, Uganda, Zambia, Zimbabwe.

Pipistrellus (Pipistrellus) hesperidus broomi Roberts, 1948

*1948. *Pipistrellus (Romicia) kuhlii broomi* Roberts, Special Publication of the Royal Society of South Africa, Robert Broom Commemorative volume, 9. Type locality: South Africa: KwaZulu-Natal: Durban: Malvern [29 53 S 30 56 E, 275 m]. Holotype: TM 1085: ad ♀. Collected by: Henry Paul William Lyster Jameson; collection date: 10 January 1908; original number: 425. Smithers *et al.* (1987: 463) also mention that three specimens have the number TM 1085 (both other specimens are probably TM 1081 [*P. nanus*] and TM 1087 [*P.* cf. *fuscatus* -> *P. hesperidus*]. - Comments: Type locality more likely to be Tzaneen Estates, Tzaneen, northeastern Transvaal (R.H.N. Smithers, in litt): see Meester *et al.* (1986: 52). However, see also Smithers *et al.* (1987: 463) for a discussion on the type locality and type specimen. They confirm "Malvern" as type locality.
1951. *Romicia kuhlii broomi:* Roberts, Mammals of South Africa, 82. (Name Combination).
1953. *Pipistrellus (Pipistrellus) kuhli broomi:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 78. (Name Combination).
1957. *P[ipistrellus] k[uhli] broomi:* Ansell, Ann. Mag. nat. Hist., ser 12, 10 (115): 538. Publication date: 29 October 1957. (Name Combination).
1968. *P[ipistrellus] k[uhlii] broomi:* Hill, Bonn. zool. Beitr., 19 (1/2): 44. (Name Combination, Alternate Spelling).
1969. *Pipistrellus (Romicia) kuhli broomi:* Kock, Abh. Senckenberg. naturforsch. Ges., 521: 167. - Comments: Alternate spelling for the name used by Roberts (1948). (Alternate Spelling).
1971. *Pipistrellus [(Pipistrellus)] kuhlii broomi:* Hayman and Hill, Mammals of Africa: Chiroptera, 40. (Name Combination, Alternate Spelling).
1992. *Pipistrellus kuhli broomi:* Trujillo, Murcielagos de las Islas Canarias, 23. (Name Combination).
? *Pipistrellus (Pipistrellus) hesperidus broomi:* (Current Combination).
? *Pipistrellus hesperidus broomi:* (Name Combination).
? *Pipistrellus kuhlii broomi:* (Name Combination).

GENERAL DISTRIBUTION:
KwaZulu-Natal (RSA).

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
South Africa.

Pipistrellus (Pipistrellus) hesperidus hesperidus (Temminck, 1840)

*1840. *Vespertilio hesperida* Temminck, Monographies de mammalogie ou description de quelques genres de mammifères, dont les espèces ont été observées dans les différens musées de l'Europe, 2 (13): 211. Publication date: 1840. Type locality: Eritrea: Abyssinia: Red Sea, shores of the [ca. 09 N 39 E]. [Goto Description]. Lectotype: SMF 12381: ad ♂, skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1842. Old catalog number II.N.9*. - Etymology: From the feminine scientific Latin adjective *hespèrida*, meaning "evening animal", deriving from the feminine Greek substantive "*ἑσπέρα*" (hespèra), meaning "evening", as this bat, as almost all Chiroptera, begins to fly at dusk (see Lanza *et al.*, 2015: 410).
1901. *Pipistrellus Kuhlii fuscatus* Thomas, Ann. Mag. nat. Hist., ser 7, 8 (43): 34. Publication date: 1 July 1901. Type locality: Kenya: Naivasha [00 46 S 36 21 E]. [Goto Description]. Holotype: NHMUK 1901.8.9.96: ad ♂, skull and alcoholic. Collected by: Sir Harry Hamilton Johnston; collection date: 19 October 1900. Presented/Donated by: Sir Harry Hamilton Johnston.
1913. *Pipistrellus kuhli fuscatus:* Roberts, Ann. Transv. Mus., 4: 67. - Comments: Alternate spelling for the name used by Thomas, 1901. (Alternate Spelling).
1951. *Pipistrellus (Pipistrellus) kuhlii fuscatus:* Swynnerton and Hayman, J. East Afr. Nat. Hist. Soc., 20 (6-7) (90): 297 (for 1950).
? *Pipistrellus (Pipistrellus) hesperidus hesperidus:* (Current Combination).
? *Pipistrellus hesperidus hesperidus:* (Name Combination).

GENERAL DISTRIBUTION:
Sub-Saharan Africa with the exception of the extreme southeastern part of the continent.

Pipistrellus (Pipistrellus) inexspectatus Aellen, 1959

*1959. *Pipistrellus inexspectatus* Aellen, Archs Sci. Genève, 12 (2): 226. Type locality: Cameroon: Upper Benoue Valley: Ngaaouyanga [07 59 N 13 36 E]. [Goto Description]. Holotype: MHNC |TS324|: ad ♂, alcoholic (skull not removed). Collected by: Villy Aellen and Albert Monard; collection date: 11 July 1947; original number: 954. See Aellen (1959a: 226).
1966. *P[ipistrellus] inexpectatus:* Hayman, Misonne and Verheyen, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., (8) 154: 52. (Lapsus).
1971. *Pipistrellus [(Pipistrellus)] inexpectatus:* Hayman and Hill, Mammals of Africa: Chiroptera, 41. (Name Combination, Lapsus).
1987. *Nycterikaupius inexpectatus:* Menu, Palaeovert., 17 (3): 109. Publication date: 15 November 1987. (Name Combination, Lapsus).
1987. *Pipistrellus (Pipistrellus) inexspectatus:* Hill and Harrison, Bull. Br. Mus. (nat. Hist.) Zool., 52 (7): 281. (Name Combination, Current Combination).
1993. *Pipistrellus (Hypsugo) inexspectatus:* Koopman, in: Wilson and Reeder, Mammal species of the World (2nd Edition): Chiroptera, 220. (Name Combination).
2020. *Pipistrellus cf. inexspectatus:* Monadjem, Richards, Decher, Hutterer, Mamba, Guyton, Naskrecki, Markotter, Wipfler, Kropff and Dalton, Zool. J. Linn. Soc., 191 (2): 553. Publication date: 4 September 2020. (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: netopýr kamerunský. English: Aellen's Pipistrelle Bat, Aellen's Pipistrelle, Central Africa Pipistrelle. French: Pipistrelle d'Aellen, Pipistrelle d'Afrique centrale. German: Unerwartete Zwergfledermaus, Unerwartete Pipistrelle.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Fahr, 2008q; IUCN, 2009; Fahr, 2019d).

Assessment History
Global
2018: DD ver 3.1 (2001) (Fahr, 2019d). 2008: DD ver 3.1 (2001) (Fahr, 2008q; IUCN, 2009). 2004: DD ver 3.1 (2001) (Fahr, 2004i; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known (Fahr, 2008q; IUCN, 2009; Fahr, 2019d).

CONSERVATION ACTIONS:
Fahr (2008q) [in IUCN (2009)] and Fahr (2019d) reports that it is not known if the species is present in any protected areas. Further field surveys are needed to better understand the distribution, natural history and possible threats to this little known bats species.

GENERAL DISTRIBUTION:
Pipistrellus inexspectatus has been recorded from a few localities in West and Central Africa. It has been reported from Sierra Leone, Ghana, Benin and Nigeria and Cameroon.

There are also uncertain records from east Sudan and Uganda, although the specimens in question are difficult to certainly allocate to *Pipistrellus*

inexspectatus (Koopman, 1975). The records of *P. inexspectatus* from the Democratic Republic of the Congo and Kenya are now allocated to *Pipistrellus eisentrauti* (Koopman *et al.*, 1995; Simmons, 2005).

Mamba *et al.* (2020: 135) reported a female specimen from Guinea as "*Pipistrellus* cf. *inexspectatus*", but its identity still needs to be confirmed.

Rudi Haslauer (pers. comm.) pointed out that the specimens from Kenya (mentioned in previous issues of ACR) might not represent this species either. The MCZ online catalogue showed that they were re-identified in early 2021 as belonging to "*Afropipistrellus grandidieri*".

In previous issues, we had this species mentioned as occurring on Madagascar. However, MCZ 45112 from near Cape Saint Vincent was originally part of the Grandidier collection and some other specimens supposedly collected on Madagascar by Grandidier were actually collected on the African mainland (e.g., coastal Kenya for the type of *Nycteris madagascariensis*, see Demos *et al.* (2021: 28-30). Demos *et al.* (2021: 28, 30) also state that Grandidier's second trip to Madagascar (in 1901) took him to the east coast of the island, whereas the coordinates for Cape Saint Vincent place this on the west coast. So possibly this specimen might also have been collected on the African mainland and not on the island of Madagascar. Given that this specimen only consists of a skull, its identification is uncertain.

Native: Benin; Burkina Faso (Kangoyé *et al.*, 2012: 6026; 2015a: 621); Cameroon; Ghana; Nigeria; Sierra Leone.

Presence uncertain: Sudan; Uganda.

ECHOLOCATION:
One FM/QCF call from Maroua (Cameroon), reported by Manga Mongombe (2012: 79) had the following parameters: F_{max}: 54.7 kHz, F_{min}: 47.7 kHz, F_{mean}: 51.2 kHz, F_{knee}: 54.7 kHZ, F_{char}: 47.7 kHz, and duration: 0.46 ms.

HABITAT:
In Cameroon, Bakwo Fils *et al.* (2021b: 6) reported on one specimen that was found in disturbed habitats in the Afromontane forest biome.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 69 minutes, and the digestibility rate about 81.2 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Fahr, 2008q; IUCN, 2009; Fahr, 2019d).

Trend
2018: Unknown (Fahr, 2019d). 2008: Unknown (Fahr, 2008q; IUCN, 2009).

VIRUSES:
Coronaviridae
Gonzalez and Banerjee (2022: 8) reported HCoV-229E from this bat.

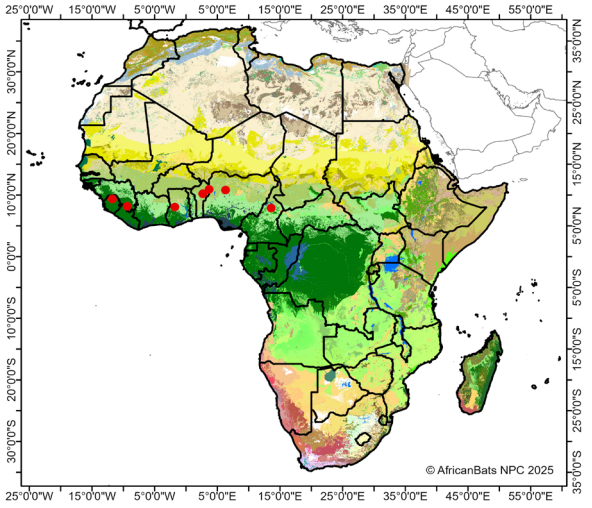

Figure 327. Distribution of *Pipistrellus (Pipistrellus) inexspectatus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Benin, Cameroon, Côte d'Ivoire, Ghana, Guinea, Kenya, Nigeria, Sierra Leone.

Pipistrellus (Pipistrellus) kuhlii (Kuhl, 1817)

*1817. *Vespertilio Kuhlii* Kuhl, Die Deutschen Fledermäuse, Hanau, 14. Type locality: Italy: Friuli-Venezia Giulia and Trieste. - Comments: Koopman (1993a: 221) mentioned 1817 as year of publication, whereas Meester *et al.* (1986: 51), Harrison and Bates (1991: 85), Corbet and Hill (1992: 137) and Bates and Harrison (1997: 179) mention "1819: Ann. Wetterau Ges. Naturk., 4 (2) 199".

1829. *[Vespertilio pipistrellus var.] ß Aegyptius* J.B. Fischer, Synopsis Mamm, 105. Publication date: 1829. Type locality: Egypt: Qena province: Luxor [25 41 N 32 39 E]. [Goto Description]. - Comments: Ellerman and Morrison-Scott (1951: 168) and Harrison (1964a: 151) mention Thebes as type locality.

1830. *Vespertilio marginatus* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 74, pl 29a. Type locality: "Africa": Nile valley or eastern desert of Egypt. [Goto Description]. Holotype: SMF 4307: ad

♀, skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1822. Don 1882; old catalog II.N.10.a: see Mertens (1925: 21). - Comments: Kock (1969a: 167) mentions "Arabia Petraea (=Sinai) und Nubien" as type locality. The publication date of Cretzschmar's work is sometimes indicated as "1826" (as mentioned on the title page), but also as "1827", "1828", "1830-1831".

1838. *Scotophilus Kuhlii:* J. E. Gray, Mag. Zool. Bot., Edinburgh, 2 (12): 497. (Name Combination).

2008. *Pipstrillus Kuhli:* Selim, Nahla and Shelfeh, Tishreen Univ. J. Res. Sci. Stud. - Biol. Sci. Ser., 30 (1): 247. (Name Combination, Lapsus).
2019. *Pipistrellus cf. deserti:* Batsleer, Portelli, Borg, Kiefer, Veith and Dekeukeleire, Hystrix, It. J. Mamm., 30 (2): 175. (Name Combination).
2020. *Pipistrellus kulli:* Borloti, Dinis and Vasconcelos, Genes, 11 (2) 877: 9. Publication date: 1 August 2020. - Comments: The name *Pipistrellus kulli* was used in combination with a sonogram, of which Borloti *et al.* (2020) aren't certain it belongs to *Pipistrellus kuhlii*, but rather to *Pipistrellus hesperidus* or a *Neoromicia*. (Lapsus).
2023. *Pipestrellus kuhlii:* Weber, Nagy, Markotter, Schaer, Puechmaille, Sutton, Dávalos, Dusabe, Ejotre, Fenton, Knörnschild, López-Baucells, Medellin, Metz, Mubareka, Nsengimana, O'Mara, Racey, Tuttle, Twizeyimana, Vicente-Santos, Tschapka, Voigt, Wikelski, Dechmann and Reeder, Biol. Lett., 19 (11) (20230358): Suppl. Publication date: 15 November 2023. (Lapsus).
? *Nannugo marginatus:*
? *Pipistrellus (Pipistrellus) deserti:*
? *Pipistrellus (Pipistrellus) kuhlii:* (Name Combination).
? *Pipistrellus kuhli:* (Alternate Spelling).
? *Pipistrellus kuhlii pallidus:* (Name Combination).

GENERAL COMMENTS:
During their long-term study, Locatelli *et al.* (2019: 96) found that the body condition of bats carrying bands or PIT-tags did not differ from that of bats that were untagged.

TAXONOMY:
Koopman (1994: 114) states that the allocation of many populations to subspecies is uncertain. Additionally, sub-Saharan specimens belong to *hesperidus*.

Although most authors have considered *P. deserti* as a separate species (Heim de Balsac, 1934a, 1936, Allen, 1939a, Ellerman and Morrison-Scott, 1951, Kock, 1969a, Kock, 1999b, Hayman and Hill, 1971, Gaisler *et al.*, 1972, Koopman, 1975, 1993a, 1994, Anciaux de Faveaux, 1976b, Hanák and Elgadi, 1984, Qumsiyeh, 1985, Gaisler and Kowalski, 1986, Hill and Harrison, 1987, Le Berre, 1990, Kowalski and Rzebik-Kowalska, 1991, Horáček *et al.*, 2000), others (Corbet, 1978, Aulagnier and Thevenot, 1986, Pavlinov *et al.*, 1995, Benda and Ruedi, 2004, Benda *et al.*, 2004d, perhaps Rode, 1947) doubted the full species status and regarded it as conspecific with *P. kuhlii*, but *P. deserti* and *P. kuhlii* are two separate morphotypes which differ clearly in size (Gaisler *et al.*, 1972, Kowalski and Rzebik-Kowalska, 1991). As these forms do not occur in sympatry (but see Kowalski and Rzebik-Kowalska, 1991), they may perhaps represent two ecogeographic or ecomorphotypic forms of one species. However, this question requires profound revision of the whole *P. kuhlii* complex both on morphologic and genetic bases (see Kock, 2001b). Mayer *et al.* (2007) reported genetic evidence that *P. deserti* are not distinct from *P. kuhlii*, while García-Mudarra *et al.* (2009) found a differentiation in the cytochrome *b*. Benda *et al.* (2014c: 75) indicate that the presence of bats of the *deserti* morphotype within two separate lineages of *P. kuhlii*, the Libyan-Egyptian and Morrocan, suggests two directions of origin of this morphotype, the west-Saharan and east-Saharan, which in turn indicate that the *deserti* morphotype is a local variation (ecomorphotype) of *P. kuhlii*, which does not deserve taxonomic expression even at the subspecific level.

Benda *et al.* (2014a: 419) presented sufficient prove to support the view that significant differences between the two morphotypes are grouped by geographic origin, and that *P. deserti* should be considered a junior synonym of *P. kuhlii*.

However, Loumassine *et al.* (2020: 3) found both *P. kuhlii kuhlii* and *P. kuhlii deserti* active around streetlights in Ouahabi and Debdaba. This syntopic occurrence contradicts the geographic separation of both "subspecies".

The authorship and description date for *Vespertilio kuhlii* has been debated for years. It has been assigned to either Kuhl, Natterer or "Natterer (in Kuhl)". The publication year was mentioned as either 1817 or 1819. This confusing situation has been cleared by Bogdanowicz and Kock (1998), who fixed author and date to Kuhl, 1817.

Similarly, the authorship of *marginatus* has been assigned to various authors: Cretzschmar, 1826-1830, Rüppell, 1826, Wagner, 1840, Bonaparte, 1841, and Kolenati, 1856.

In the synonyms list for this species, we did not make a difference for the author and/or year of

publication mentioned by the various publications when dealing with *kuhlii*.

COMMON NAMES:
Afrikaans: Kuhl se vlermuis, Kuhl-vlermuis. Albanian: Pipistrel i Kuhl-it. Arabian: Khaffash. Armenian: Միջերկրածովային փոքրաչղջիկ. Azerbaijani: Küli şəbpərəsi. Basque: Kuhl pipistrelo, Kuhl saguzar. Belarusian: Нетапыр міжземнаморскі, Нетапыр Куля. Bosnian: Kulijev šišmiš. Breton: Pipistrell Kuhl. Bulgarian: Средиземноморско прилепче. Castilian (Spain): Murciélago de borde claro. Russian: Нетопырь средиземноморский, Средиземноморский нетопырь [= Sredizemnomorskij netopyr], Нетопырь Куля. Serbian: Б[ј]елоруби слепи мишић [= B[j]elorubi slepi mišić]. Scottish Gaelic: Ialtag Kuhl. Slovak: Večernica južná. Slovenian: Belorobi netopir. Swedish: Parkpipistrell, Kuhls fladdermus. Turkish: Beyazşeritli Yarasa. Ukrainian: Нетопир білосмугий [= Netopir bilosmuhyy]. Welsh: Ystlum lleiaf Kuhl.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
González-Dionis *et al.* (2021: 9) reported the first fossil remains of *P. kuhll* on Lanzarote (Canary Islands).

CONSERVATION STATUS:
Global Justification
The species is widespread and abundant, and populations are increasing in parts of the range. Consequently, it is assessed as Least Concern (LC ver 3.1 (2001)) (Aulagnier *et al.*, 2008b; IUCN, 2009; Juste and Paunović, 2016d).

Assessment History
Global
2016: LC ver 3.1 (2001) (Juste and Paunović, 2016d). 2008: LC ver 3.1 (2001) (Aulagnier *et al.*, 2008b; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessment included *P. hesperidus*] (Aulagnier, 2004c; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

For *P. deserti*, the Assessment History was:
2008: LC ver 3.1 (2001) (Benda *et al.*, 2008d; IUCN, 2009). 2004: LC ver 3.1 (2001) (Benda, 2004a; IUCN, 2004). 1996: LR/lc [assessed as *P. aegyptius*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
No major threats are known. Use of pesticides to eradicate mosquitos (especially in urban areas) may be a threat in places (Aulagnier *et al.*, 2008b; IUCN, 2009; Juste and Paunović, 2016d).

Sherwin *et al.* (2012: 174) name aerial hawking and its long-distance dispersal to be the most important risk factors related to climatic change. Bilgin *et al.* (2012: 434) indicate that climatic change is already influencing this species as it has been expanding its range northwards over the past 15 years.

CONSERVATION ACTIONS:
Juste and Paunović (2016d) supports Aulagnier *et al.* (2008b) [in IUCN (2009)] who report that it is protected by national law in most European range states. It is also protected under international legislation in parts of its range through the Bonn Convention (Eurobats) and Bern Convention, and is included in Annex IV of EU Habitats and Species Directive It is found in a number of protected areas. No specific conservation actions are known.

GENERAL DISTRIBUTION:
Pipistrellus kuhlii is widespread in North Africa, Europe and Asia. It has a large range extending from Iberia through southern Europe through the Near East and the Caucasus to Kazakhstan, Pakistan, and India (Molur *et al.*, 2002). There is a single record from China (Smith and Xie, 2008). The northern limit of its range in Europe was

formerly ca. 45°N, but the species has been expanding northwards. It arrived 1994 in Vienna/Austria (48°N) and was more recently recorded to 50°N in France and 51°N in Ukraine. It has been expanding northwards in Russia for the last half century from 46° N to c.53°N, with the highest record made at almost 57°N (S. Kruskop *pers. comm.*, 2006 in Aulagnier *et al.*, 2008b). It occurs from sea level to 2,000 m.

Borloti *et al.* (2020: 17) re-identified the only available *P. kuhlii* museum voucher specimen (MZUF 10597) as belonging to *Hypsugo savii* and indicated that the only evidence of *P. kuhlii* being present on the Cape Verdian Islands is a number of echolocation calls, which could be misclassified *P. hesperidus* or *Neoromicia*.

Native: Afghanistan; Albania; Algeria; Andorra; Angola; Armenia; Austria; Azerbaijan; Bosnia and Herzegovina; Burkina Faso (as *P. deserti*); Bulgaria; Croatia; Cyprus (Benda *et al.*, 2007: 71); Czech Republic (Reiter *et al.*, 2007: 47); Egypt; France [Corsica]; Georgia; Germany; Gibraltar; Greece [Crete]; Holy See [Vatican City State]; Hungary; India; Iran, Islamic Republic of; Iraq; Israel; Italy [Sardinia, Sicily]; Jordan; Kazakhstan; Kuwait; Lebanon (Horáček *et al.*, 2008: 59); Libyan Arab Jamahiriya; Macedonia, the former Yugoslav Republic of; Malta; Monaco; Montenegro; Morocco (Benda *et al.*, 2004d; 2010a: 158; El Ibrahimi and Rguibi Idrissi, 2015: 362; Dbiba *et al.*, 2025: 7); Oman; Pakistan; Palestinian Territory, Occupied; Portugal; Romania; Russian Federation; San Marino; Saudi Arabia; Serbia; Slovakia; Slovenia; Spain [Baleares, Canary Is.] (Azzaroli Puccetti and Zava, 1988); Sudan (as *P. deserti*); Switzerland; Syrian Arab Republic; Tunisia (Dalhoumi *et al.*, 2014: 53; 2016b: 867; 2019b: 26; 2023: 1); Turkey; Ukraine; United Arab Emirates (Anonymus, 2008: 38); Western Sahara (Benda *et al.*, 2010a: 161); Yemen.

Presence uncertain: China. Additionally, its presence (as *P. deserti*) was reported as uncertain from Cape Verdian Islands, Ghana, Kenya, Nigeria, Senegal, and Somalia.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Alagaili *et al.* (2011: 466) describe the timing and moulting patterns of *P. kuhlii* specimens from Saudi Arabia. They found that males were moulting from the end of April to the end of August, whereas females were moulting from the end of May/beginning of June to the end of August. The later moulting in females was probably related to the fact that females gave birth between mid-April and mid-May. The moulting itself starts at the back of the head and on the lower back and spreads from there over the entire head and back. Ventrally, the moult starts on the neck, around the nipples and along the sides of the body, then making its way to the centre of the chest.

DENTAL FORMULA:
Dorst (1949: 45-46, fig. 1) provides a description of the milk dentition of *P. kuhlii*. He also indicated (p. 47) that the milk teeth show some sort or heterodonty with the premolars being of different shape when compared with the incisors and canines, which look more similar to one another. These latter teeth help the young to cling to the mother's nipples.

DETAILED MORPHOLOGY:
Ibraheem and Shelfeh (2008) report on the anatomy and histology of the digestive tract of Syrian *P. kuhlii*.

Selim *et al.* (2008: 247) studied the microscopical structure of the tongue of Egyptian and Syrian *P. kuhlii* specimens and found some differences between them.

Massoud and Abumandour (2020: 1) examined the structure of the tongue of nine bats from Egypt. These have a lingual prominence on the dorsum of lingual body. The lingual epithelium had an outer covering of nucleated epithelium, and they also found entoglossal plates which consisted of a cartilaginous element. The ligual root of the tongue has two laterally situated circumvallate papillae.

The retinal structure was investigated by Aboelnour *et al.* (2020), who did not find any aberrant structures. The structure of the eye lens was examined by Aboelnour *et al.* (2024).

FUNCTIONAL MORPHOLOGY:
Gearhart *et al.* (2019: 1) studied the evaporative water loss of these bats in Israel and found that the total evaporative water loss was lower in hyperarid environments (deserts) as compared with bats from more mesic environments. This difference was especially noticeable in the significantly lower cutaneous water loss, which might be the result of modified lipids in the outer layer of the skin.

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 8.5 Pa, aspect ratio 6.3 for a wingspan of 19 cm and a wing area of 54 cm^2 and a body mass of 5 g.

Eitan *et al.* (2022: 5) found that *P. kuhlii* widens it gape to narrow the vertical echolocation beam

width and reduce the zone of ensonification. The gape can be adjusted rapidly according to the particular task (search versus approach beams).

SEXUAL DIMORPHISM:
In a year-round study in Tunisia, Dalhoumi *et al.* (2016a: 157) found adult females to be significantly heavier than males.

ECHOLOCATION:
For 31 Greek specimens, Papadatou *et al.* (2008b: 133) report a start frequency of 59.8 ± 14.75 kHz, a terminating frequency of 37.5 ± 1.33 kHz, a peak frequency of 39.7 ± 1.46 kHz, and a bandwidth of 9.4 ± 2.85 kHz. The duration of the call is 6.4 ± 1.38 ms, and the interpulse interval is 124.7 ± 44.55 ms.

Walters *et al.* (2012: suppl.) mention the following numbers for 47 calls of bats from France, Greece, Italy and Switzerland: duration: 5.62 ± 1.43 ms, F_{max}: 53.57 ± 10.08 kHz, F_{min}: 36.87 ± 2.15 kHz, bandwidth: 16.70 ± 9.93 kHz, F_{peak}: 39.77 ± 2.63 kHz.

In Jordan, Benda *et al.* (2010b: 204) reported the following parameters for 76 calls: F_{start}: 51.7 ± 6.2 (41.4 - 65.6) kHz, F_{end}: 39.1 ± 1.1 (41.4 - 65.6) kHz, F_{peak}: 41.1 ± 1.1 (37.2 - 43.2) kHz, duration: 6.4 ± 1.7 (3.4 - 10) ms, interpulse interval: 112.9 ± 38.0 (70.0 - 279.0) ms. For 37 calls from Iran, Benda *et al.* (2012a: 183) report: F_{start}: 48.9 ± 4.5 (43.26 - 60.5) kHz, F_{end}: 41.1 ± 1.6 (38.7 - 44.3) kHz, F_{peak}: 42.2 ± 1.9 (39.1 - 46.8) kHz, duration: 6.1 ± 1.3 (4.0 - 9.0) ms, and interpulse interval: 106.5 ± 38.7 (54.4 - 231.9) ms.

In Israel, the following values were recorded by Hackett *et al.* (2016: 223) for 84 calls: Pulse duration: 4.57 ± 2.05 ms, F_{start}: 51.27 ± 4.54 (40 - 71.2) kHz, F_{end}: 40.58 ± 1.54 (37 - 43.9) kHz, F_{peak}: 41.48 ± 1.53 (37 - 42.8) kHz.

Luo *et al.* (2019a: Supp.) reported the following data (from 2 calls): F_{peak}: 41.4, 39.7 kHz, F_{start}: 72, 59.8 kHz, F_{end}: 39.6, 37.5 kHz, Band width: 32.4, 22.3 kHz, and duration: 5.7, 6.4 ms.

Boonman *et al.* (2013b: 6) determined the detection range to be between 2 and 3.5 m at 20 dB and 4 and 7 m at 0 dB.

Corcoran and Moss (2017: 4560) refer to Amichai *et al.* (2015), who found that *P. kuhlii* solved the jamming problem of extreme acoustic interference from conspecifics not by adjusting call frequency but by emitting calls of hither intensity, longer duration, and calling more often. This suggests that the bats try to increase the signal-to-noise ratio rather than avoiding spectral overlap.

In the Bechar region (Algeria), Loumassine *et al.* (2020: 2) reported F_{max} and F_{end} for *P. kuhlii kuhlii* and *P. kuhlii deserti* to be respectively 42.59 ± 1.14, 38.72 ± 1.63 kHz and 46.32 ± 1.56, 41.43 ± 1.92 kHz. *Pipistrellus kuhlii* bats from Constantine emit call with an F_{max} of 38.71 ± 1.03 kHz (Ait-Abdesselam *et al.*, 2025: 40).

Bats from Tunisia were found to have F_{start}: 59.60 ± 10.97 (39.7 - 101.6) kHz, F_{end}: 42.13 ± 1.91 (36.8 - 48.4) kHz, F_{max}: 42.91 ± 1.91 (36.9 - 49.5) kHz, duration: 6.10 ± 1.18 (3.6 - 11.8) ms and Interpulse interval: 181.81 ± 82.16 (8.4 - 716.5) ms (Dalhoumi *et al.*, 2023: 5). Dalhoumi *et al.* (2023: 9) also found profound differences in the call parameters between various locations, which they suggest might be adaptations to different habitat types.

MOLECULAR BIOLOGY:
Karyotype
Both Baker *et al.* (1974) and Iliopoulou-Georgudaki and Giagia (1986) reported 2*n* = 44, FN = 50, and BA = 8. However, Baker *et al.* (1974) reported a submetacentric X chromosome and an acrocentric Y chromosome, whereas Iliopoulou-Georgudaki and Giagia (1986) reported metacentric X and Y chromosomes. Rushton (1970: 465) reported 2*n* = 44, FN = 50, X = metacentric and Y = acrocentric. Arslan and Zima (2014: 13) indicate that the autosomal set consists of three large and one small metacentric pairs, 15 acrocentric pairs and two dot-like pairs, and both sex chromosomes are medium-sized. According to Capanna and Manfredi Romanini (1971: 474) the autosomal chromosomes consist of 3 metacentric pairs, 1 submetacentric and 17 acrocentrics.

Protein / allozyme
Andriollo *et al.* (2015: 1) examined the COI gene in in European and North African *P. kuhlii* populations and found that all North African nuclear genotypes were grouped in a highly distinct subpopulation when compared with European samples sharing the same mitochondrial barcodes. In their figure 1 (p. 3), they show that the North African populations (including *deserti* have very similar haplotypes with the eastern European populations from the Balkan and Italy but differ considerably from the western lineage found in France and Spain. Batsleer *et al.* (2019: 172) analysed part of the 16S rRNA from some Maltese specimens and found them to belong to a lineage occurring in northern Africa.

Genetics
See Mayer *et al.* (2007), García-Mudarra *et al.* (2009).

Locatelli *et al.* (2016: 423) determined the complete mitogenome and found it to contain 16,991 base pairs with 37 genes (13 protein-coding genes, 22 tRNA genes, 2 rRNA) and 1 control region.

Bray *et al.* (2013: 5) indicate that widespread species - such as *P. kuhlii* - have extensive genetic diversity.

HABITAT:
In Tunisia, Dalhoumi *et al.* (2018: 1) found this species to forage mainly around water bodies and streetlights. During summer, they also foraged in open Acacia woodlands (*Acacia tortilis raddiana*).

ROOST:
All of the roost found in Libya by Benda *et al.* (2014c: 64) were in ruins, with one exception for a single male in a rock fissure in an overhang.

DIET:
Benda *et al.* (2012a: 448) report that the diet is very variable over the species' distribution range: Diptera, Lepidoptera, Hymenoptera (particularly Formicoidea), Auchenorrhyncha, Coleoptera, and Heteroptera comprised a major part of the diet. For Iran, they found Coleoptera, Heteroptera, and Auchenorrhyncha to be the most important food items.

Also in Libya, Benda *et al.* (2014c: 77) report a very variable diet for *P. kuhlii*, where smaller moths (Lepidoptera) and beetles (Coleoptera) were the most important types of prey. The beetles belonged to the families Scarabaeidae, Carabidae (frequently Harpalini), Staphylinidae, Tenebrionidae, Chrysomelidae. Furthermore, ants (Hymenoptera: Formicoidea) formed a major part of the diet. Additionally, medium-sized brachyceran Diptera (Muscidae, Asilidae) were identified, as well as Neuroptera (Chrysopidae and Hemerobiidae).

Abdel-Hamid and Alqahtani (2022: 103494-103495) reported that in the Nile Valley, the diet of this bat consisted of (volume/frequency %) 29/87.3 % Hymenoptera, 9/36.5 % Coleoptera, 27/74.6 % Lepidoptera and 32 % unknown materials. They also found 3/4.8 % of fruits.

A long-term study (17 years) by Locatelli *et al.* (2019) in southern Europe indicated that *P. kuhlii* specimens had an optimal body condition when there was a combination of warmer spring-summers and cooler winters. They also found that higher spring humidity combined with intermediate precipitation and humidity levels recorded during the summers prior to the capture were favourable for these bats. These conditions are probably linked with a larger abundance of insect prey.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 67 minutes, and the digestibility rate about 81.4 %.

PREDATORS:
Reuven (1991: 79) reported on *P. kuhlii* being captured by a Lanner Falcon (*Falco biarmicus* Temminck, 1825) in Israel. Mikula *et al.* (2016: Supplemental data) furthermore mention the same predator from either Botswana, Egypt, Ethiopia, Kenya, Nigeria, Sudan or South Africa. Part of these records might actually be for *P. hesperidus*. This is also the case for their record involving the Peregrine falcon (*Falco peregrinus* Tunstall, 1771).

Souttou *et al.* (2018: 136) found *P. kuhlii* to be a major part of the diet of the Common Kestrel (*Falco tinnunculus* Linnaeus, 1758) in Dergana (Algeria), where it made up to 16.4 % of the birds prey. In a second locality (El Harrach) if made up 0.7 % of the prey (and 0 % in seven other localities). In another locality in Algeria, Souttou *et al.* (2006: 177) found that *P. kuhlii* made up 4.7 to 9.4 % of the prey of fledgling common kestrels, making it the third most frequent prey species.

POPULATION:
Structure and Density
It is a relatively abundant species in the Mediterranean region and Middle East. Populations in South Asia seem to be stable and doing well (Molur *et al.*, 2002). Summer colonies typically number 30-100 individuals. In Iran and the Caucasus, the species' range is increasing, and it is displacing *P. pipistrellus* (M. Sharifi and K. Tsytsulina *pers. comm.*, 2005 in Aulagnier *et al.*, 2008b). The northern border of the species' range is also expanding. It is very numerous in urban areas across much of its range (Aulagnier *et al.*, 2008b; IUCN, 2009; Juste and Paunović, 2016d).

As *P. deserti*, it was reported to be the most common species in Sahara oases (Benda *et al.*, 2008d; IUCN, 2009).

Trend
2016: Unknown (Juste and Paunović, 2016d). 2008: Unknown (Aulagnier *et al.*, 2008b; IUCN, 2009). *P. kuhlii* populations within the Asia Minor and Levant region are unknown population trend,

under predictive climate change scenarios (Bilgin *et al.*, 2012: 433).

LIFESPAN:
Szekely *et al.* (2015: Suppl.) and Lagunas-Rangel (2019: 2) report a maximum longevity of 8 years.

ACTIVITY AND BEHAVIOUR:
In the Negev Desert, Polak *et al.* (2011: 24) found that *P. kuhlii* had a significantly higher flight speed when flying in areas with streetlamps, than in in dark areas. They also found that flight height was higher in dark areas than in lighted areas (> 1 m).

Smotherman *et al.* (2016: 537) refer to Barak and Yom-Tov (1991) and Russo and Jones (1999) in describing the song-like structure for *P. kuhlii* as simple syllable type in a basic motif. Singing occurs while flying.

REPRODUCTION AND ONTOGENY:
Deleuil and Labbe (1955b: 238) reported three lactating females from El Hamaïn (Tunisia) on 24 July 1955. From the same country, Dalhoumi *et al.* (2018: 1) reported pregnant females from March to June, lactating females in June, and flying juveniles from June to August. Dalhoumi *et al.* (2015: 265) found that females were most often pregnant in May and lactating in June.

In Libya, Benda *et al.* (2014c: 71) report on four pregnant females collected on 16 April, 16 on 20 April, 2 on 8 May, 3 on 22 May, and 1 on 23 May. Lactating females were found on 8, 21, 26 and 27 May. Szekely *et al.* (2015: Suppl.) report that weaning occurs after 60 days.

In the United Arab Emirates, Davis (2007: 8) indicates that females are sexually mature in their first year, and that two young are born (= polytocy, see Garbino *et al.*, 2021: Suppl.).

POSTNATAL DEVELOPMENT:
Sharifi *et al.* (2012: 1235) studied the development of Iranian *P. kuhlii* specimens born in captivity and found that, at birth, young had a mean body mass of 1.04 ± 0.08 g and a forearm length of 11.48 ± 0.45 mm. During the first 23 days of their live, their body mass and forearm length increased on average with 0.10 ± 0.10 g/d and 0.64 ± 0.61 mm/d. Wingspan, handwing length and area, armwing length and area, and total wing area increased linearly until the age of the 1st flight (at 33 days), after which growth rates significantly declined. At the age of 60 d, the young had an average weight of 5.47 ± 0.07 g (87.56 % of the adult) and the mean forearm length of 35.97 ± 0.86 mm (89.46 % of the adult length).

PARASITES:
Kock *et al.* (1998b: 236) reported *Cacodmus villosus* (Stål, 1855) (Cimicidae) from bats from Malawi.

Korine *et al.* (2012: 1435) experimentally infested *P. kuhlii* specimens with the flea *Xenopsylla ramesis*, whose normal host is Sundevall's jird (*Meriones crassus*). They found that both male and female fleas engorged less blood from the bats than from the jird (and less than from *R. aegyptiacus* specimens tested during the same study). They also found that the survival time of the fleas was shorter when fed on *P. kuhlii* blood. Furthermore, fleas feeding from torpid bats were found to engorge more blood than those feeding from normothermic bats.

From Algeria, Bendjeddou *et al.* (2013: 325) reported *Phthiridium biarticulatum* Hermann, 1804 (Diptera: Nycteribiidae), *Cimex pipistrelli* Jenyns, 1839 (Hemiptera: Cimicidae), and *Ischnopsyllus octactenus* (Kolenati, 1856) (Siphonaptera: Ischnopsyllidae).

Bendjeddou *et al.* (2017: 15) mention the following ectoparasites: Siphonaptera: *Nycteridopsylla longiceps* Rothschild, 1908 and *Ischnopsyllus octactenus* (Kolenati, 1856); Heteroptera: *Cimex pipistrelli* Jenyns, 1839 and *Cacodmus vicinus* Horváth, 1934; Arachnida: *Hyalomma dromedarii* Koch, 1844.

Bendjoudi *et al.* (2019: 71) and Khelfaoui *et al.* (2018: 68) furthermore reported *Ixodes ricinus* (Linnaeus, 1758), *Steatonyssus occidentalis* (Ewing, 1933)

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Argasidae: *Carios vespertilionis* Latreille, 1802, *Ornithodoros coniceps* (Canestrini, 1890); Cicimidae: *Cacodmus vicinus* Horváth, 1934, *Cimex lectularius* Linnaeus, 1758, *Cimex pipistrelli* Jenyns, 1839; Ischnopsyllidae: *Ischnopsyllus consimilis* (Wahlgren, 1904), *Ischnopsyllus octactenus* (Kolenati, 1856), *Nycteridopsylla longiceps* Rothschild, 1908; Ixodidae: *Ixodes ricinus* (Linnaeus, 1758), *Ixodes vespertilionis* Koch, 1844; Macronyssidae: *Hyalomma dromedarii* Koch, 1844, *Steatonyssus occidentalis* (Ewing, 1933); and Spinturnicidae: *Spinturnix acuminata acuminata* (C.L. Koch, 1836).

Selmi *et al.* (2021: 1) reported on a Tunisian "*Pipistrellus pipistrellus*" infested by the rat flea (*Xenopsylla cheopis*) and mites of the genus

Macronyssus. Spleen and liver samples of that bat contained DNA of *Anaplasmataceae* bacteria, more specifically *Ehrlichia canis*. However, fig 1a clearly shows the presence of a white margin at the edge of the wing membrane, which suggests that the bat involved is actually a representative of *Pipistrellus kuhlii*.

Benda *et al.* (2014c: 80) report the following ectoparasites from Libya: Argasidae: *Argas vespertilionis* (Latreille, 1802); Macronyssidae: *Steatonyssus periblepharus* Kolenati, 1858; Spinturnicidae: *Spinturnix acuminata* group; Cimicidae: *Cimex lectularius* Linnaeus, 1758, *Cacodmus vicinus* Horváth, 1934; Ischnopsyllidae: *Ischnopsyllus consimilis* (Wahlgren, 1904)

From Jordan, Benda *et al.* (2010b: 285) mention *Argas vespertilionis* (Latreille, 1802) (Argasidae), *Steatonyssus periblepharus* Kolenati, 1858 (Macronyssidae), and *Cacodmus vicinus* Kolenati, 1858 (Cimicidae).

Other parasites that were previously reported from the Middle East include the bat flies: *Nycteribia schmidlii* Schiner, 1853, *N. vexata* Westwood, 1835, *Penicillidia conspicua* Speiser, 1901, and *Basilia daganiae* Theodor and Moscona, 1954; the bat fleas *Ischnopsyllus octactenus* (Kolenati, 1856) (also from Tunisia by Beaucournu and Kock, 1996), *I. consimilis* (Wahlgren, 1904) *Xenopsylla cheopis* (Rothschild, 1903) and *Leptopsylla sengis* (Schoenherr, 1911); and the mite species *Spinturnix acuminatus* (Koch, 1836) and *Steatonyssus periblepharus* Kolenati, 1858.

Benda *et al.* (2012a: 449) report the following ectoparasites from Iran: Spinturnicidae: *Spinturnix* sp., *Meristaspis lateralis* Kolenati, 1857; Macronyssidae: *Steatonyssus periblepharus* Kolenati, 1858; Ischnopsyllidae: *Ischnopsyllus octactenus* (Kolenati, 1856). They also mention the presence of the bat flies *Basilia daganiae* Theodor et Moscona, 1954 in the Levant, *Ischnopsyllus consimilis* (Wahlgren, 1904) in Egypt, Israel and Lebanon, the bed bug *Cimex lectularius* Linnaeus, 1758 in Iraq, and *Cacodmus vicinus* Horváth, 1934 in Cyprus, Syria, Israel, Jordan, and Egypt.

Trypanosoma (Schizotrypanum) vespertilionis Battaglia, 1904 was reported from *P. kuhlii* specimens from the Assiut Governate, Egypt by Fahmy *et al.* (1978: 251). Based on older references, Austen and Barbosa (2021: 7) reported *Trypanosoma (Megatrypanum) heybergi* Rodhain, 1923 from the DRC, and *Trypanosoma (Megatrypanum) megadermae* Wenyon, 1909 from either Sudan or Egypt.

Duszynski (2002: 16) indicates that Arabian *P. kuhlii* is the type host of *Eimeria chiropteri* Alyousif, 1999, *Eimeria kuhliensis* Alyousif, 1999, and *Eimeria pipistrellus* Alyousif, Al-Dakhil and Al-Shawa, 1999.

Greiman *et al.* (2016: 1006) reported the presence of a Trematode belonging to the genus *Lecithodendrium* Looss, 1896 in *P. kuhlii marginatus* from Egypt.

DIPTERA
Nycteribiidae
Basilia bathybothyra from Palestine, Egypt and Cyprus (Haeselbarth *et al.*, 1966: 110).

Ševčík *et al.* (2012: 35) report on the presence of the bat fly *Basilia daganiae* Theodor and Moscona, 1954 on bats from Cyprus. Beaucournu and Noblet (1985: 636) also plot a record for this bat fly in Egypt.

VIRUSES:
Astroviridae
El Taweel *et al.* (2020: 5) found viruses belonging to the genus Mamastrovirus in "*P. aegyptius*" bats from Egypt.

Coronaviridae
SARS-CoV
During Febuary 2008 in Ghana, one fecal sample of "*P. deserti*" tested negative for coronavirus (CoV) RNA by Pfefferle *et al.* (2009).

Alphacoronavirus
Kohl and Kurth (2014: 3112) reported this virus from Spain and Italy.

Betacoronavirus
Kohl and Kurth (2014: 3112) reported this virus from Italy.

Paramyxoviridae
Drexler *et al.* (2012a: Suppl. Table S1) indicated that the single specimen of "*P. deserti*" they examined from Ghana did not test positive for *Repirovirus, Henipavirus, Morbillivirus, Rubulavirus* or *Pneumovirus*.

Phenuiviridae
Phlebovirus
de Jong *et al.* (2011: 11), Luis *et al.* (2013: suppl.), and Kohl and Kurth (2014: 3111) report the occurrence of Toscana virus.

Saeed *et al.* (2021b: 1004, 1005) found two "*P. deserti*" bats testing positive for Rift Valley Fever

phlebovirus, and suggested that this bat might play a role in the maintenance, transmission, and evolution of RVFV in humans and domestic animal populations.

Reoviridae
Orthoreovirus
Kohl and Kurth (2014: 3113) reported this virus from Germany and Italy.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Algeria, Canary Islands (Spain), Chad, Egypt, Libya, Madagascar, Morocco, Sudan, Tunisia.

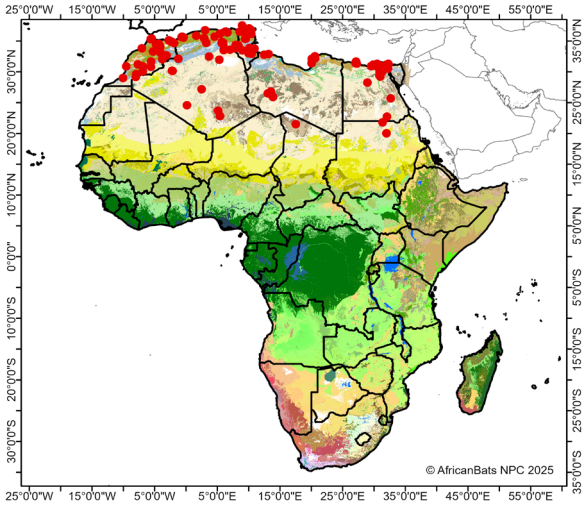

Figure 328. Distribution of *Pipistrellus (Pipistrellus) kuhlii*.

Pipistrellus (Pipistrellus) maderensis (Dobson, 1878)

*1878. *Vesperugo [(Vesperugo)] maderensis* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, p xxxix, 211, 231, pl 12, fig 5. Publication date: 15 June 1878. Type locality: Madeira (Portugal): "Madeira" [32 44 N 15 58 W]. [Goto Description]. Holotype: NHMUK 1855.8.16.34: ad ♀, skull and alcoholic. Collected by: William S. MacGillivray. - Etymology: The name refers to the island where the type specimen was collected.
1908. *P[ipistrellus] maderensis:* K. Andersen, Ann. Mag. nat. Hist., ser 8, 1 (5): 435. (Name Combination, Current Combination).
1922. *Pipistrellus maderensis:* Bannerman. - Comments: They Canary Islands: 153. (Name Combination).
1966. *Pipistrellus (Pipistrellus) maderensis:* Ellerman and Morrison-Scott, Checklist of Palaearctic and Indian Mammals 1758 to 1946. (Second Edition), 171. (Name Combination, Current Combination).
1999. *Pipistrellus madarensis:* Ohlendorf, Nyctalus (N.F.), 7: 193 - 195. (Lapsus).
2020. *Pipistrellus madeirensis:* Borloti, Dinis and Vasconcelos, Genes, 11 (8) 844: 3. Publication date: 1 August 2020. (Lapsus).

TAXONOMY:
Pestano *et al.* (2003b: 61) indicate that *P. maderensis* is more closely related to the Canary Island *P. kuhlii* clade than the latter is to *P. kuhlii* from outside the Canaries.

Jesus *et al.* (2013: 179) analyzed cytochrome b from Madeiran and Canary bats and found these to be sufficiently different to warrant subspecific distinction. However, as their data were preliminary, they did not officialize this view (see also Rocha, 2023: 522).

Evin *et al.* (2010: 35) suggest that a Kuhl's pipistrelle-like bat colonized the Canary Islands and differentiated during the middle Pleistocene to give rise to the *maderensis* clade.

COMMON NAMES:
Albanian: Pipistreli i Madeiras. Armenian: Մադեյրական փոքրաչղջիկ. Azerbaijani: Maderiya və ya Kanar şəbpərəsi. Basque: Pipistrelo madeirar. Belarusian: Нетапыр мадэрскі. Bosnian: Madeirski šišmiš. SIMILAR SPECIES:
Based on fossil material, González-Dionis *et al.* (2021: 13) were able to distinguish *P. maderensis* from *P. kuhlii* occurring on the Canary Islands. In the former, the paraloph, metaloph and metaconule in M1 and M2 are more developed than in the latter.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
No fossil records of *Pipistrellus maderensis* are known (Rocha, 2023: 523).

CONSERVATION STATUS:
Global Justification
The species is restricted to few islands in the Canaries and the Madeira islands (and possibly the Azores). The population numbers < 1,000 individuals and it is suspected to be declining as a result of habitat loss, use of agricultural pesticides, and disturbance to roosts. This species is also severely fragmented. It is assessed as Vulnerable (VU C2a(i)) but may be approaching the Endangered category (Alcaldé and Juste, 2016).

P. maderensis is protected under the Bern Convention and included in Annex IVof the EU Habitats Directive (Rocha, 2021: 7).

Assessment History
Global
2016: VU C2a(i) ver 3.1 (2001) (Alcaldé and Juste, 2016). 2008: VU A2c, B1 + 2c ver 2.3. 1994: VU A2c, B1 + 2c ver 2.3.

Regional
Portugal: 2005: CR; Spain: 2008: NT

MAJOR THREATS:
Sherwin *et al.* (2012: 174) name the small distribution range, water stress, the aerial hawking feeding style and the long-distance dispersal to be the most important risk factors linked with climatic change.

Jesus *et al.* (2013: 177) indicate that human activities (e.g., large-scale land use change, the use of biocids/pesticides and roost disturbance and destruction) as well as some natural events (e.g., floods and wildfires) form the major threats for this species. Additionally, introduced species such as *Rattus rattus* and *Felis catus* might pose important threats. The latter is also illustrated by Rocha (2015: 17), who reported on a domestic cat, which brought home three bats (of which one was identified as *P. maderensis*) over a period of one year.

Rocha (2021: 8) indicated that, on Madeira, the use multiple-funnel traps used to control pinewood nematodes (*Bursaphelenchus xylophilus* (Steiner & Buhrer 1934)) have been reported to capture Madeiran pipistrelles. The bats can not exit these traps as the walls are too smooth and subsequently die.

Sagot and Chaverri (2015: 1670) mention roost loss or disturbance, and habitat degradation or loss as major threats for this species.

Restoration of buildings, covering cracks where it roosts, is a threat to the species. Rain-gauges attract dozens of bats which are trapped there and die (Trujillo, 2007). Loss of natural habitat may be a threat, although the species is apparently adapted to man-made habitats. The use of agricultural pesticides may be a problem, and disturbance to roosts in buildings may also be of concern (Alcaldé and Juste, 2016).

CONSERVATION ACTIONS:
The species is protected through Bern Convention, and included in Annex IV of EU Habitats & Species Directive. Rainho and Palmeirim (2002) proposed the following actions: identification, protection and monitoring of roosts; preservation and restoration of natural habitats, reduction of pesticide use; and, study of the species' biology, ecology, genetics, and systematics. Trujillo (2002) additionally recommend a public awareness campaign aimed at reducing disturbance of breeding colonies in private houses.

GENERAL DISTRIBUTION:
Madeira Islands (Portugal, where Rainho (2017: 161) reports its presence on six islands); Canary Islands (Spain).

Borloti *et al.* (2020: 3) [referring to R(1383)] indicate that *P. maderensis* is only found on the western Canary Islands and Madeira, whereas the other islands are inhabited by *P. kuhlii*.

Rocha (2021: 4,2023: 524) and Teixeira *et al.* (2023: 4) reported this species from the Atlantic islands of Madeira and Porto Santo (?), the Azores and the Canary Islands.

GEOGRAPHIC VARIATION:
When comparing cytochrome *b* sequences from Madeiran and Canary Island specimens, Jesus *et al.* (2013: 119) found that the populations from

both island groups represent "sister populations", showing a much higher sequence divergence than that observed within groups.

Rocha (2021: 4) mentions that the animals from La Palma are slightly larger than those from other Canary Islands.

The study by Teixeira *et al.* (2023: 1) - covering bats from Madeira, the Canary Islands and the Azores - proved that these populations formed distinct Evolutionary Significant Units, with the haplotypes of bats from Madeira and the Canary Islands showed genetic differences between 2.4 and 3.3 %. (The Azoran population was not included as no GenBank material was available from that archipelago).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

Figure 329. Clockwise from top lateral, ventral and dorsal skull images of NHMUK 1955.8.16.34, holotype of *Vesperugo maderensis* Dobson, 1878.

SEXUAL DIMORPHISM:
Rocha (2021: 4) [referring to Trujillo and González (2011)] mentioned that the forearms of females are slightly larger than in males.

ECHOLOCATION:
Luo *et al.* (2019a: Supp.) reported the following data (from two calls): F_{peak}: 47.8, 44.6 kHz, F_{start}: 67, 50.9 kHz, F_{end}: 45.9, 43.7 kHz, Band width: 21.1, 7.2 kHz, and duration: 4.9, 6.7 ms.

Rocha (2021: 7) mentioned a peak frequency between 41.3 - 51.7 kHz. In open areas F_{peak} ranges from 41.3 to 48.9 kHz and a duration 2.5 - 9.5-ms. In cluttered environments, the calls are shorter (2.1 - 5.8 ms) and F_{peak} 42.3 - 51.7 kHz. Social calls on Madeira have peak frequencies between 14.9 and 28.9 kHz and a duration of 21 to 57 ms.

MOLECULAR BIOLOGY:
Genetics
See Pestano *et al.* (2003b), Mayer *et al.* (2007).

Nóbrega *et al.* (2023: 94) mention that the bats from Madeira and Porto Santo have a genetic distance of 0.04 %, suggesting gene flow between these two islands, although they can not exclude recent re-colonisation of Porto Santo by bats from Madeira.

HABITAT:
Ferreira *et al.* (2022a: 1) found *P. maderensis* to be the most common and widespread bat species on the island of Madeira and also found it was positively associated with landscape-scale shrubland, cropland and Laurisilva (primary forest) cover.

ROOST:
Rocha (2021: 6) mentioned that nursery colonies of these bats are generally found in buildings (wall fissures and under roofing tiles).

Nóbrega *et al.* (2023: 88) mention it is proned to roost in cliffs, tree holes and human-made structures.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 69 minutes, and the digestibility rate about 81.2 %.

Nóbrega *et al.* (2023: 92, 93) found insect prey belonging to five order, 12 families, 13 genera and 11 identified species in faecal samples from *P. maderensis* collected on Porto Santo (Madeira), including: Culicidae: *Culex pipiens* Linnaeus, 1758, *Culex theileri* Theobald, 1903; Chironomidae: *Chironomus transvaalensis* Kieffer, 1908, *Polypedilum nubifer* (Skuse, 1889); Depressariidae: *Depressaria marcella* Rebel, 1901; Tortricidae: *Epiphyas postvittana* (Walker, 1863); Noctuidae: *Peridroma saucia* (Hübner, 1808); Hemerobiidae: *Wesmaelius subnebulosus* (Stephens, 1836); Tineidae: *Oinophila v-flava* (Haworth, 1828), *Psychoda alternata* Say, 1824; Ichneumonidae: *Campoletis* Förster, 1868; Formicidae: *Nylanderia* Emery, 1906; Cicadellidae: *Psammotettix confinis* (Dahlbom, 1850); Tephritidae: *Capitites ramulosa* (Loew, 1844).

Gonçalves *et al.* (2024: 4) found that most of they prey belonged to the Lepidoptera (47.1 %), followed by Diptera (29.9 %), Trichoptera, Coleoptera, and Araneae (all 4.6 %). The Lepidopteran family Blastobasidae was the most consumed (23.0 %), followed by Limoniidae (13.8 %), Tineidae (8.0 %), and Psychodidae (6.9 %). At species level, *Blastobasis vittata* (Wollaston, 1858) was recorded the most (12.6 %) , followed by *Dicranomyia* sp. 1 (Limoniidae - 8.0 %), and *Opogona sacchari* (Tineidae - 4.6 %). Of the 31 prey species, 19.3 % were agricultural pests, 6.4 % were possible agricultural pests and 3.2 % were species with human health implications.

POPULATION:
Structure and Density
Queiroz *et al.* (2005) [in Jesus *et al.* (2013: "1")] indicate that the population on Madeira consists of about 1,000 individuals. They also indicate that on the Azores the total population is probably less than 300 (but they point out that the identity of these bats is uncertain). On Madeira and associated islands, it is abundant but very rare on Porto Santo (Alcaldé and Juste, 2016). The total population is estimated to be less than 1,000 individuals, and trends are unknown (Rainho *et al.*, 2002). On the Canary Islands it is relatively common and is the most frequently reported bat on all islands of occurrence, although no bat is abundant on the islands. Population size and trend have not been quantified (Trujillo, 2002), although declines are suspected as a result of threats including loss and degradation of habitats, pesticide use, and disturbance and destruction of roosts. On the Azores, *Pipistrellus* bats are rare or very rare on all islands of occurrence, and the total number of individuals is probably less than 300 (Rainho *et al.*, 2002).

Trend
2016: Decreasing (Alcaldé and Juste, 2016).

ACTIVITY AND BEHAVIOUR:
Referring to Russo *et al.* (2009), Smotherman *et al.* (2016: 537) indicate that the song-like structure for this species consists of a simple syllable type in a basic motif. Singing occurs while flying.

PARASITES:
When describing *Steatonyssus (Steatonyssus) balcellsi*, Estrada-Peña and Sanchez (1988: 305) also mentioned the presence of this mite on *P. maderensis* specimens from El Lagar and Aguamansa, Canary Islands.

Sándor *et al.* (2021a: 4) reported the presence of the argasid tick *Carios vespertilionis* Latreille, 1802.

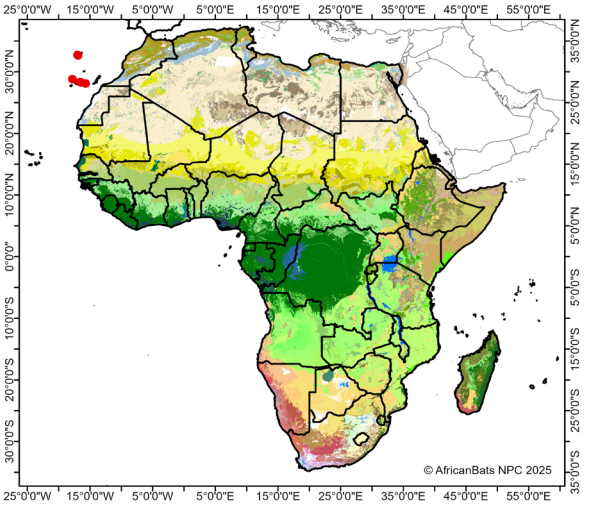

Figure 330. Distribution of *Pipistrellus (Pipistrellus) maderensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Canary Islands (Spain), Madeira (Portugal).

Pipistrellus (Pipistrellus) nanulus Thomas, 1904

*1904. *Pipistrellus nanulus* Thomas, Ann. Mag. nat. Hist., ser 7, 14 (81): 198. Publication date: 31 August 1904. Type locality: Cameroon: Efulen [02 46 N 10 42 E]. [Goto Description]. Holotype: NHMUK 1904.2.8.8: ad ♂, skull and alcoholic. Collected by: George Latimer Bates Esq.
1966. *Pipistrellus (Pipistrellus) nanulus:* Hayman, Misonne and Verheyen, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., (8) 154: 16. (Name Combination, Current Combination).
1994. *Pipistrellus (Vansonia) nanulus:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 116. (Name Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Castilian (Spain): Pipistrelo. Chinese: 中非小伏翼. Czech: netopýr efulenský. English: Tiny Pipistrelle Bat, Dwarf Pipistrelle Bat, Tiny Pipistrelle. French: Pipistrelle minuscule. German: Kleine Zwergfledermaus, Kleine Pipistrelle.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Fahr, 2008r; IUCN, 2009; Monadjem and Fahr, 2017g).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Pipistrellus nanulus*] (Monadjem and Fahr, 2017g). 2008: LC ver 3.1 (2001) (Fahr, 2008r; IUCN, 2009). 2004: LC ver 3.1 (2001) (Fahr, 2004h; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Fahr, 2008r; IUCN, 2009; Monadjem and Fahr, 2017g).

CONSERVATION ACTIONS:
Fahr (2008r) [in IUCN (2009)] and Monadjem and Fahr (2017g) report that *Pipistrellus nanulus* has been reported from the Mole National Park in Ghana (Grubb *et al.*, 1998). No direct conservation measures are currently needed for this widespread and seemingly adaptable species as a whole.

GENERAL DISTRIBUTION:
Pipistrellus nanulus is widespread in West and Central Africa, with an apparently disjunct population in East Africa. It ranges from Senegal eastwards, through most West African countries to Cameroon, from here it has been recorded from Equatorial Guinea (including the island of Bioko) and Gabon. In the east of the species range it has been recorded from eastern Democratic Republic of the Congo, Uganda and western Kenya (north of Lake Victoria).

Kruskop *et al.* (2016: 64) report two specimens from Ethiopia, which look very similar to *P. nanulus* from other parts of Africa, and although they do not mention any "cf." or "aff." as they do for other species, they hint that the identification need further confirmation.

Native: Benin (Capo-Chichi *et al.*, 2004: 163); Burkina Faso (Kangoyé *et al.*, 2015a: 621); Cameroon; Central African Republic; Congo (Bates *et al.*, 2013: 329 - 1st authenticated record); Congo (The Democratic Republic of the) (Monadjem *et al.*, 2010d: 572); Côte d'Ivoire; Equatorial Guinea (Bioko); Ethiopia (Kruskop *et al.*, 2016: 64); Gabon; Ghana (Decher and Fahr, 2007: 18); Guinea (Decher *et al.*, 2016: 274); Kenya; Liberia; Nigeria; Senegal; Sierra Leone; Uganda.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Tragus: Monadjem *et al.* (2013c: 204) line drawing of tragi of specimen DNSM 13234 from Mount Nimba, Liberia.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

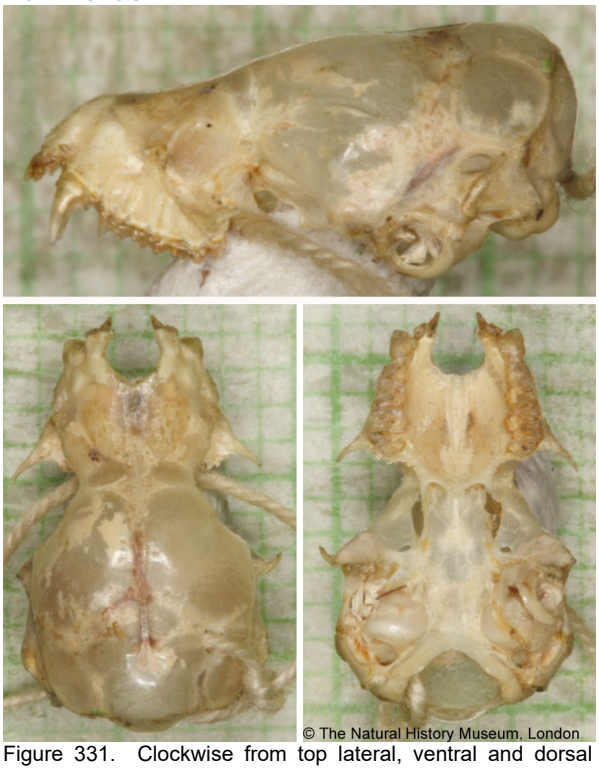

Figure 331. Clockwise from top lateral, ventral and dorsal skull images of NHMUK 1904.2.8.8, holotype of *Pipistrellus nanulus* Thomas, 1904.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987). *P. nanulus* and *H. c. bellieri* were much longer in total length than any of the *Neoromicia* species examined by Monadjem *et al.* (2013c). The shaft tip has a bifurcated structure with one projection that was slightly more distended than the other baculum shaft in both species was moderately ventrally curved, ending in a fluted base that was broader in *P. nanulus* (0.71 - 0.82 mm) than in *H. c. bellieri* (0.38 - 0.41 mm), a broad projection was clearly visible midway down the ventral surface of the shaft in *P. nanulus* (Monadjem *et al.*, 2013c: 197). Line drawing of dorsal and ventral bacula of specimen DNSM 13230 from Mount Nimba, Liberia are shown in Monadjem *et al.* (2013c: 204).

ECHOLOCATION:
Manga Mongombe (2012: 79) reported a FM/QCF call type for 1 calls from Maroua (Cameroon) and F_{max}: 65.5 kHz, F_{min}: 45.6 kHz, F_{mean}: 51.3 kHz, F_{knee}: 49.2 kHZ, F_{char}: 45.8 kHz, and duration: 2.89 ms.

From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 27 calls of 2 bats: F_{peak}: 57.3 ± 0.6 (57.0 - 58.0) kHz, F_{min}: 54.0 ± 1.6 (51.3 - 55.2) kHz, F_{max}: 106.0 ± 6.0 (100.6 - 113.5) kHz, duration: 2.4 ± 0.3 (2.2 - 2.9) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

MOLECULAR BIOLOGY:
Grunwald *et al.* (2025: 303) indicate that the populations from West and Central Africa differ slightly in their cyt *b* sequences (p- distance: 0.04) and further research is required to evaluate their exact relationship. They also found some dental differences between the animals from Cameroon and West Africa, which also require further investigation.

HABITAT:
The specimens recorded by Monadjem *et al.* (2016y: 371) from the Mount Nimba area were found in lowland forest habitats (420 - 480 m).

DIET:
Faecal pellets of 2 bats from Cameroon examined by Waghiiwimbom *et al.* (2019a: 156), contained the following volume (± SD) and frequency percentages: Lepidoptera (64 ± 7.11; 100), Diptera (19.7 ± 3.9; 73.6), Diptera (19.7 ± 3.9; 73.6), Coleoptera (14.3 ± 5.2; 67.7), Hymenoptera (1.2 ± 0.5; 25), Hemiptera (0.8 ± 0.4; 5).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 43 minutes, and the digestibility rate about 86.5 %.

POPULATION:
Structure and Density
This species is relatively common (Fahr, 2008r; IUCN, 2009; Monadjem and Fahr, 2017g).

Trend
2016: Unknown (Monadjem and Fahr, 2017g).
2008: Unknown (Fahr, Fahr, 2008r; IUCN, 2009).

PARASITES:
PROTOZOA
Thiombiano *et al.* (2023: 4) reported that one of the10 bats from Burkina Faso they examined had *Trypanosoma* cf. *dionisii* parasites.

VIRUSES:
Coronaviridae - Coronaviruses
SARS-CoV
During February 2008 in Ghana, Pfefferle *et al.* (2009) tested negative one faecal sample for coronavirus (CoV) RNA.

Herpesviridae
Cameron *et al.* (2020: 1) reported a new Herpesvirus from the Republic of Congo, belonging to the Gammaherpesvirinae

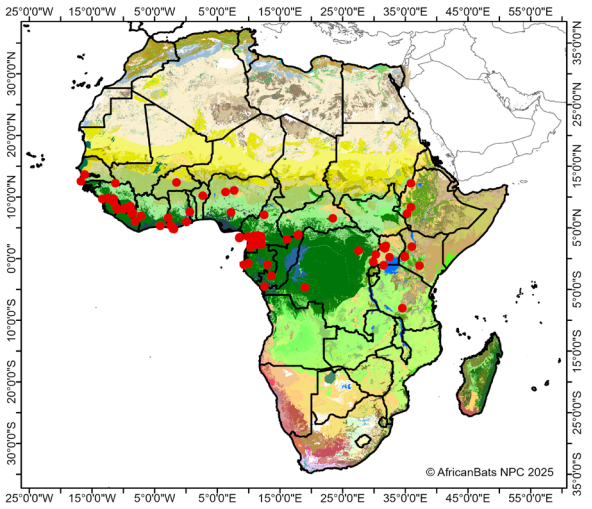

Figure 332. Distribution of *Pipistrellus (Pipistrellus) nanulus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Benin, Burkina Faso, Cameroon, Central African Republic, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Equatorial Guinea, Ethiopia, Gabon, Ghana, Guinea, Kenya, Liberia, Mali, Nigeria, Senegal, Sierra Leone, Tanzania, The Gambia, Togo, Uganda.

Pipistrellus (Pipistrellus) permixtus Aellen, 1957

*1957. *Pipistrellus (Pipistrellus) permixtus* Aellen, Rev. suisse Zool., 64 (6): 200. Type locality: Tanzania: Dar-es-Salaam [06 48 S 39 18 E]. [Goto Description]. Holotype: MZS 12c: ad ♀, skull and alcoholic. Collected by: Hürstel; collection date: 1905. (Current Combination).
1966. *[Pipistrellus] permixtus:* Koopman, The Puku, 4: 159. (Name Combination, Current Combination).
1982. *Pipistrellus permixtus:* Seal and Makey, ISIS Mammalian Taxonomic Director, ???. (Name Combination).

TAXONOMY:
This is a very illusive species. It is only known from the type specimen, which shows more affiliation to the European *P. nathusii* than to any of the African species. Since the type specimen was collected in Dar-es-Salaam, a port, it cannot be excluded that this animal was transported by ship from Europe to Africa.

COMMON NAMES:
Czech: netopýr tanganjický. English: Dar-es-Salaam Pipistrelle Bat, Dar-es-salaam Pipistrelle, Tanzania Pipistrelle. French: Pipistrelle de Tanzanie. German: Verwechselte Zwergfledermaus, Verwechselte Pipistrelle.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of recent information on its extent of occurrence, ecological requirements, threats and conservation status (Jacobs *et al.*, 2008v; IUCN, 2009; Jacobs *et al.*, 2019h).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jacobs *et al.*, 2019h). 2008: DD ver 3.1 (2001) (Jacobs *et al.*, 2008v; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004ac; IUCN, 2004). 1996: DD (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are poorly known. However, it may be confined to dry coastal forest habitat, which is significantly threatened by conversion to agricultural use and extraction of firewood and timber (Jacobs *et al.*, 2008v; IUCN, 2009; Jacobs *et al.*, 2019h).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008v) [in IUCN (2009)] and Jacobs *et al.* (2019h) report that there appear to be no direct conservation measures in place for this species, and it is not known if the species is present within any protected areas. Additional studies are needed into the distribution, abundance, breeding biology and general ecology of this species. There is a need to conserve remaining areas of dry coastal forest in much of East Africa.

GENERAL DISTRIBUTION:
Pipistrellus permixtus is known only from a single specimen collected close to Dar es Salaam in Tanzania.

Native: Tanzania.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 70 minutes, and the digestibility rate about 81.0 %.

POPULATION:
Structure and Density
No information available on the abundance of this bat (Jacobs *et al.*, 2008v; IUCN, 2009; Jacobs *et al.*, 2019h).

Trend
2018: Unknown (Jacobs *et al.*, 2019h). 2008: Unknown (Jacobs *et al.*, 2008v; IUCN, 2009).

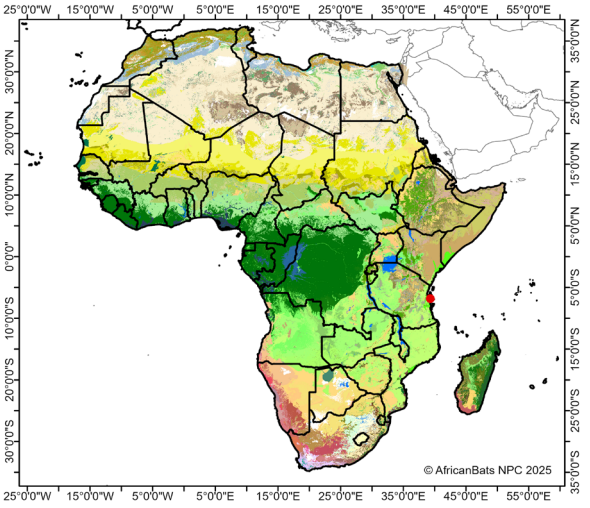

Figure 333. Distribution of *Pipistrellus (Pipistrellus) permixtus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Tanzania.

Pipistrellus (Pipistrellus) pipistrellus (Schreber, 1774)

*1774. *Vespertilio pipistrellus* Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, 1 (7): pl 54 + 1 (9): 167. Publication date: 1774. Type locality: France: "France". Neotype: NHMUK 1997.81: ad ♂. Collection date: October 1996. Designated by Anonymus (2003: 85). Locality of neotype: France: Normandy: Beauvais cathedral.

1839. *V[esperus (Vesperugo)] Pipistrellus:* Keyserling and Blasius, Arch. Naturgesch. Berlin, 5 (1): 321. (Name Combination).

1853. *V[esperugo (Vesperugo)] Pipistrellus:* Blasius, Arch. Naturgesch. Berlin, 19 (1): 36. (Name Combination).

1855. *Vespertilio (Vesperugo) pipistrellus:* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 5: 730. (Name Combination).

1970. *P[ipistrellus] pipistrelli:* Rushton, Ann. Génét. Sél. anim., 2 (4): 465. (Lapsus).
2023. *P[ipistrellus] pipestrellus:* Sidhoum, Boucheikhchoukh, Mechouk and Deak, Acta Trop., 247 (107004): 6. Publication date: 22 August 2023. (Lapsus).

Taxonomy:

Does not contain *pygmaeus* Leach, 1821. Genetic studies (e.g., Benda *et al.*, 2004b) provided evidence for a North-African lineage, possibly identified as a subspecies. Evin *et al.* (2011: 2096) also show that the shape of the skull of the Moroccon specimens differs from that of specimens from continental Europe and Corsica, and to a lesser extent, from the Middle East. Boston *et al.* (2014: 268) found *P. pipistrellus* to form a monophyletic group, but with a split between *P. pipistrellus* s. stricto and a possible paraphyletic group in Morocco, Algeria, Tunisia, Malta, Sicily, Corsica and Italy. Hulva *et al.* (2004; 2010) called this latter group "*P. pipistrellus* SW" and Puechmaille *et al.* (2012) suggest this group might represent a new species.

Common Names:

Albanian: Pipistrel i zakonshëm. Arabian: Khaffash. Armenian: Թզուկ փոքրաչղջիկ. Azerbaijani: Cırtdan şəbpərə. Basque: Pipistrelo arrunt, Saguzar. Belarusian: Нетапыр-карлік. Bosnian: Mali šišmiš, Patuljasti slijepi mišić. Breton: Pipistrell voutin. Bulgarian: Кафяво прилепче. Castilian (Spain): Murciélago comúin, Murciélago enan, Murciélago enano. Catalan (Spain): Rat penat comú, Pipistrel·la comuna. Croatian: Patuljasti šišmiš, Mali šišmiš. Czech: Netopýr hvízdavý, Nedopír hvízdavý, Netopýr malý, Letouň zakrpený, Netopýr pisklavý. Danish: Pipistrelflagermus, Dværgflagermus. Dutch: Gewone dwergvleermuis. English: Common Pipistrelle, Common Pipistrelle Bat, 45 kHz pipistrelle, Small house-bat. Estonian: Kääbus-nahkhiir. Swedish: Sydpipistrell, Pipistrell. Turkish: Cüce Yarasa. Ukrainian: Нетопир карлик, Нетопир малийНетопир пігмей [= Netopyr malyy, Netopir pihmey]. Welsh: Ystlum-lleiaf cyffredin.

Conservation Status:

Global Justification

The species is widespread and abundant, and there is no evidence of current significant population decline. Consequently, it is assessed as Least Concern (LC ver 3.1 (2001)) (Hutson *et al.*, 2008l; IUCN, 2009).

Assessment History
Global
2008: LC ver 3.1 (2001) (Hutson *et al.*, 2008l; IUCN, 2009). 2004: LC ver 3.1 (2001) (Aulagnier and Benda, 2004a; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
In parts of the range there is deliberate persecution as people do not want thousands of bats roosting in their buildings. As a high proportion of colonies are found in buildings, the species may be particularly vulnerable to other anthropogenic factors, such as disturbance, timber treatment and building renovation (Battersby, 2005; Hutson *et al.*, 2008l; IUCN, 2009).

Sherwin *et al.* (2012: 174) indicate that the aerial hawking feeding style and the long-distance dispersal are the most important risk factors related to climatic change.

CONSERVATION ACTIONS:
Hutson *et al.* (2008l) [in IUCN (2009)] report that it is protected under national law in most range states. It is also protected under international law through the Bonn Convention (Eurobats) and Bern Convention in parts of its range where these apply and is included in Annex IV of the EU Habitats and Species Directive. It occurs in many protected areas. No specific conservation actions are known.

Adoption of bat-friendly practices in the construction and maintenance of buildings is a proposed action.

GENERAL DISTRIBUTION:
Pipistrellus pipistrellus is a widespread western Palaearctic species with a range extending from the British Isles through southern Scandinavia, much of Europe (including all the Mediterranean countries, but with the exception of northern Fennoscandia) to the Volga and Caucasus; and through parts of north-western Africa (mountainous areas of Morocco, Algeria and Tunisia, also in Cyrenaica in Libya) and south-west Asia to central and eastern Asia (China, India, Myanmar). Its detailed distribution, as distinct from that of the recently differentiated *P. pygmaeus*, is still to be established. It occurs from sea level to 2,000 m.

A dubious record from Taiwan by Kishida (1924) is rejected by Lin *et al.* (2002: 509). A record from Myanmar by Bates and Harrison (1997: 167) is rejected by Bates *et al.*, 2005: 220).

Native: Afghanistan; Albania; Algeria; Andorra; Armenia; Austria; Azerbaijan; Belarus; Belgium; Bosnia and Herzegovina; Bulgaria; China; Croatia; Cyprus (Benda *et al.*, 2007: 71); Czech Republic; Denmark; Estonia; Finland; France [Corse]; Georgia; Germany; Gibraltar; Greece [East Aegean Is., Kriti]; Holy Seat [Vatican City State]; Hungary; India (Jammu-Kashmir); Iran, Islamic Republic of; Ireland; Israel; Italy (Sardinia, Sicily); Jordan (Benda *et al.*, 2010b: 185), Kazakhstan; Latvia; Lebanon (Horáček *et al.*, 2008: 59); Libyan Arab Jamahiriya; Liechtenstein; Lithuania; Luxembourg; Macedonia, the former Yugoslav Republic of; Malta; Moldova (Bondarenko, 2007: 23); Monaco; Montenegro; Morocco (Benda *et al.*, 2010a: 157; El Ibrahimi and Rguibi Idrissi, 2015: 361; Dbiba *et al.*, 2025: 7); Myanmar; Netherlands; Norway; Pakistan; Poland; Portugal; Romania; Russian Federation; San Marino; Serbia; Slovakia; Slovenia; Spain [Baleares]; Sweden; Switzerland; Taiwan, Province of China; Tunisia (Dalhoumi *et al.*, 2016b: 867); Turkey; Ukraine (Tyshchenko *et al.*, 2005: 181); United Kingdom.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

Other
Madej *et al.* (2012: 478) studied the skin structure and hair morphology of different body parts and found a number of areas with thin skin (wing and tail membrane) and other areas with thick skin (head and dorsum, abdomen, footpad). They also found that the density of the hairs was higher on the head than in the dorsal and ventral body parts. These differences might play a role for ectoparasites when choosing their preferred body region.

ECHOLOCATION:
The data for 47 animals from Greece are the following: F_{start}: 78.9 ± 15.79 kHz, F_{end}: 47.5 ± 1.43 kHz, F_{peak}: 48.6 ± 1.46 kHz, bandwidth: 6.5 ± 1.31 kHz, duration 5.7 ± 1.53 ms and interpulse interval: 94.9 ± 29.90 ms (Papadatou *et al.*, 2008b: 132).

Benda *et al.* (2010a: 163) report for 50 Moroccan specimens a starting frequency of 53.3 ± 4.6 (45.6 - 62.7) kHz, a maximum energy frequency of 47.9 ± 2.9 (42.9 - 51.8) kHz, an end frequency of 46.3 ± 3.0 (40.0 - 50.7) kHz, with a duration of 7.4 ± 1.7 (5.2 - 12.4) ms, and an inter-pulse interval of 123.9 ± 46.2 (73.4 - 250.1) ms.

Data presented by Walters *et al.* (2012: suppl.) for 47 calls by bats from France, Switzerland and the UK include: duration: 6.02 ± 2.10 ms, F_{max}: 58.06 ± 10.34 kHz, F_{min}: 44.77 ± 1.92 kHz, bandwidth: 13.29 ± 9.25 kHz, F_{peak}: 45.75 ± 2.03 kHz.

In Jordan, Benda *et al.* (2010b: 204) recorded the following parameters for 70 calls: F_{start}: 69.3 ± 14.8 (53.1 - 110.0) kHz, F_{end}: 48.4 ± 0.9 (46.8 - 50.5) kHz, F_{peak}: 51.2 ± 2.0 (48.2 - 57.9) kHz, duration: 5.7 ± 1.5 (2.8 - 8.0) ms, and Interpulse interval: 81.7 ± 22.2 (49.0 - 169.0) ms. For 54 Iranian calls, Benda *et al.* (2012a: 182) report: F_{start}: 57.1 ± 4.2 (50.2 - 60.8) kHz, F_{end}: 46.6 ± 2.2 (42.6 - 50.8) kHz, F_{peak}: 48.6 ± 2.4 (44.1 - 54.0) kHz, duration: 6.8 ± 1.5 (3.4 - 10.4) ms, and interpulse interval: 100.5 ± 26.5 (62.3 - 162.7) ms.

Götze *et al.* (2013: 61) indicate that frequency shifts occurring when *P. pipistrellus* specimens are flying together, are not linked with jamming avoidance, but with a switch from search calls to shorter approach calls, which have higher frequencies. The other bats are perceived as moving targets, hence the switch to the approach call.

In Morocco, Disca *et al.* (2014: 226) reported for "*Pipistrellus* cf. *pipistrellus*" a FM-QFC type of call with the following parameters: F_{start}: 75.5 ± 12.8 kHz, F_{end}: 47.7 ± 2.3 kHz, F_{peak}: 50.4 ± 2.4 kHz, $F_{QFC\text{-}peak}$: 49.9 ± 2.5 kHz, bandwidth: 27.8 ± 12.3 kHz, duration: 6.4 ± 1.1 ms.

Ait-Abdesselam *et al.* (2025: 40) reported an F_{max} of 47.72 ± 5.17 kHz for Algerian bats.

Molecular Biology:

Karyotype

Rushton (1970: 465) mentioned a diploid number (2*n*) of 42. Arslan and Zima (2014: 12) report 2*n* = 42-44, FNa = 48-50, FN = 52-54, a medium-sized (sub)metacentric X, and a dot-like acrocentric Y. The autosomal component contains three large metacentric, one small metacentric and 16/17 acrocentric pairs. However, they cannot exclude that some of the "aberrant" sets might represent *P. pygmaeus*.

Tolera *et al.* (2021: 127) reported the karyotype of Ethiopian bats with 2n = 36 and FN = 50. However, the identification as *Pipistrellus pipistrellus* seems highly unlikely.

Genetics

See Benda *et al.* (2004b), Hulva *et al.* (2004), Mayer *et al.* (2007), García-Mudarra *et al.* (2009). Batsleer *et al.* (2019: 172) analyses a fragment of the 16S rRNA, and found this to belong to two haplotypes, which clustered within a northern African clade, clearly differing from the European haplotypes.

Diet:

Benda *et al.* (2012a: 425 - 427) indicate that in Europe, *P. pipistrellus* mainly feeds on small swarming nematoceran Diptera, followed by Lepidoptera, Heteroptera and Hymenoptera. In the Middle East, the diet seems to be more variable and is dominated by smaller Coleoptera, Formicoidea, Heteroptera, smaller Lepidoptera, Ephemeroptera, Plecoptera, and Blattodea. In Iran, the most important food items are: Nematocera, Hymenoptera (Formicoidea), and Auchenorrhyncha.

Population:

Structure and Density

A widespread and abundant species, one of the most common bats in many parts of its range. Summer maternity colonies generally number 25 - 50 individuals, although colonies of as many as 200 have been recorded. In winter, it tends to occur singly or in small groups, although some very large groups have been recorded (e.g., up to 45,000 in caves in Romania and Slovakia) (Seamark, 2006d). Significant declines have been recorded in some European countries (e.g., Britain), although in Britain at least the trend may now have stabilised (Battersby, 2005). In Serbia, in the urban areas, *P. pipistrellus* has become less common due to displacement by *P. kuhlii* (M. Paunovic *pers. comm.*, 2007 in Hutson *et al.*, 2008l). The same is also reported from the Russian Federation.

Trend

2008: Stable (Hutson *et al.*, 2008l; IUCN, 2009).

Activity and behaviour:

Referring to amongst others Barlow and Jones (1997a,1997b), Smotherman *et al.* (2016: 537) describe the song-like structure for this species as simple syllable type in a basic motif. Singing occurs while flying.

Reproduction and ontogeny:

Ginther (1967: 580) mentioned that the embryo is more frequently located in the right uterine horn, whereas the Corpus luteum is about 50 % in the left ovary.

At birth, the young weights about 23.7 % of its mother's body mass (1.4 g versus 5.9 g), and its forearm length is about 35.6 % of that of its mother (11.4 versus 32.0 mm) (see Kurta and Kunz, 1987: 83).

PARASITES:
In Europe, Genov *et al.* (1992) reported the following Nematodes: *Molinostrongylus vespertilionis* Morosov and Spassky, 1961 (of which *P. pipistrellus* is the type host) and *M. alatus* (Ortlepp, 1932).

Benda *et al.* (2010b: 278) found the following ectoparasites on Jordanian *Pipistrellus pipistrellus*: Ticks: Argasidae: *Argas vespertilionis* (Latreille, 1802); mites (Macronyssidae): *Macronyssus* sp., *Steatonyssus periblepharus* Kolenati, 1858, *Parasteatonyssus hoogstraali* Keegan, 1956; bugs: Cimicidae: *Cacodmus vicinus* Keegan, 1956; bat flies: Nycteribiidae: *Basilia daganiae* Keegan, 1956; and fleas: Ischnopsyllidae sp. The latter might possibly belong to *Ischnopsyllus octactenus* (Kolenati, 1856), *I. dolosus* Dampf, 1912 or *I. consimilis* (Wahlgren, 1904) which were previously reported from *P. pipistrellus* from Turkey and Lebanon.

From Iran, Benda *et al.* (2012a: 428) reported the following ectoparasites: Ticks: Argasidae: *Argas vespertilionis* (Latreille, 1802), Ixodidae: *Dermacentor marginatus* (Sulzer, 1776), *Ixodes redikorzevi* Olenev, 1927; mites: Macronyssidae: *Steatonyssus* sp., Trombiculidae: *Schoutedenichia chilmirica* Kudrâšova, 1975; fleas: Ischnopsyllidae: *Ischnopsyllus octactenus* (Kolenati, 1856), Pulicidae: *Xenopsylla nuttalli* Ioff, 1930. From Azerbaijan, they mention another bat flea: *Ischnopsyllus dolosus* Dampf, 1912.

From Algeria, Bendjeddou *et al.* (2013: 325) reported the following parasites: *Cimex pipistrelli* Jenyns, 1839 (Hemiptera: Cimicidae) and *Ischnopsyllus octactenus* (Kolenati, 1856) (Siphonaptera: Ischnopsyllidae). Bendjeddou *et al.* (2017: 15) mentioned the following Heteroptera: *Cimex pipistrelli* Jenyns, 1839, *Cimex lectularius* Linnaeus, 1758 and *Cacodmus vicinus* Horváth, 1934.

The checklist of arthropod parasites of North African bats provided by Bendjeddou *et al.* (2023: 4 - 7) mentions the following species: Argasidae: *Carios vespertilionis* Latreille, 1802; Cicimidae: *Cacodmus vicinus* Horváth, 1934, *Cimex lectularius* Linnaeus, 1758, *Cimex pipistrelli* Jenyns, 1839; and Ischnopsyllidae: *Ischnopsyllus hispanicus* (Rothschild, 1898), *Ischnopsyllus octactenus* (Kolenati, 1856).

Beaucournu and Noblet (1985: 636) refer to Hůrka (1982) in plotting a record of *Basalia mediterranea* Hurka, 1970, parasitizing on *P. pipistrellus*.

VIRUSES:
Adenoviridae
Mastadenovirus
Reported from Germany by Kohl and Kurth (2014: 3111).

Bornaviridae
An unclassified genus belonging to this family was reported by Kohl and Kurth (2014: 3111) from France.

Coronaviridae
None of five Kenyan bats tested by Tao *et al.* (2017: Suppl.) tested positive for CoV.

Betacoronavirus
This virus was reported from the Netherlands by Kohl and Kurth (2014: 3112).

Herpesviridae
Betaherpesvirus
Reported by Kohl and Kurth (2014: 3113) from Germany.

Gammaherpesvirus
Reported by Kohl and Kurth (2014: 3113) from Germany.

Orthomyxoviridae
Despite sampling and testing of 44 individuals of this species, no evidence of influenza A-like viruses (*Orthomyxoviridae*) were obtained (Fereidouni *et al.*, 2015).

Paramyxoviridae
An unassigned virus was reported from Germany by Kohl and Kurth (2014: 3113).

Reoviridae
Orthoreovirus
Kohl and Kurth (2014: 3113) reported this virus from Germany.

Rhabdoviridae
"Various European bat lyssaviridae" were reported from various European countries by Kohl and Kurth (2014: 3114).

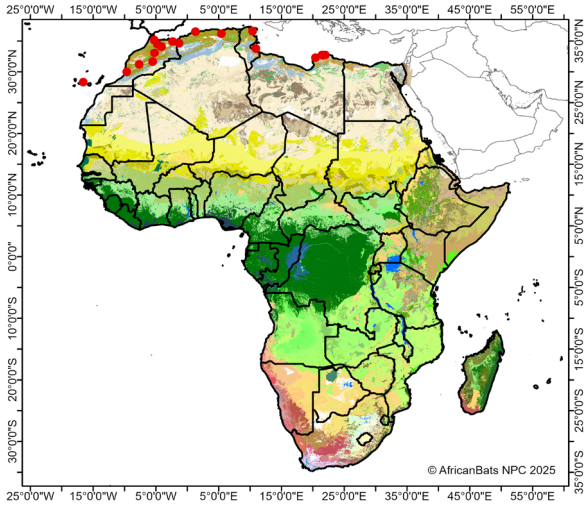

Figure 334. Distribution of *Pipistrellus (Pipistrellus) pipistrellus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Algeria, Canary Islands (Spain), Egypt, France, Libya, Morocco, Tunisia.

Pipistrellus (Pipistrellus) pygmaeus (Leach, 1825)

*1825. *Vespertilio Pygmæus* Leach, Zool. Journ., 1: 560. Type locality: United Kingdom: Chew valley. - Comments: Type locality: The original type locality was "England, Devonshire, near forest of Dartmoor, Spitchweek". The Neotype was collected in NE Somerset, Bath, Chew valley.

1999. *Pipistrellus pygmaeus:* Jones and Barratt, Bull. Zool. Nomencl., 56 (3): 182. Publication date: September 1999. (Name Combination).

2020. *Pipistrellus (Pipistrellus) pygmaeus:* Simmons and Cirranello, BatNames.org. (Name Combination).

TAXONOMY:
One of the most outspoken examples of cryptic species is formed by the "*Pipistrellus pipistrellus / pygmaeus*" species complex. Originally, both taxa were considered to represent one single species, but with the growing use of bat detectors, it became clear that two forms were present. In a first stage, these were called the "45 kHz phonic type" and the "55 kHz phonic type". Jones and van Parijs (1993) and Barratt *et al.* (1995) proved that two separate species were involved: *Pipistrellus pygmaeus* and *Pipistrellus pipistrellus*.

Based on López-Baucells *et al.* (2012), Disca *et al.* (2014: 211) include *P. pygmaeus* as a member of the Moroccan bat fauna, but they indicate that more prove (e.g., photos, detailed descriptions, echolocation data, …) would be welcome.

Herdina *et al.* (2014: 157) indicate that *P. pipistrellus* and *P. pygmaeus* specimens can be discriminated by measuring the projected length, height, and width of the baculum. Other morphological discrimination traits commonly used are "wing vein" pattern and shape and color of the penis, but these have not been validated on sets of genetically identified specimens.

COMMON NAMES:
Albanian: Pipistrel xhuxh. Armenian: Գաջաճ փոքրաչղջիկ. Azerbaijani: Kiçik şəbpərə. Basque: Pipistrelo mediterraneo. Belarusian: Нетапыр-пігмей. Bosnian: Patuljasti šišmiš. Breton: Pipistrell gorr. Bulgarian: Малко кафяво прилепче. Castilian (Spain): Murciélago pigmeo, Murciélago de Cabrera. Catalan (Spain): Pipistrel·la nana. Croatian: Močvarni patuljasti šišmiš. Czech: Netopýr nejmenší, Nedopír kařelný. Danish: Dværgflagermus. Dutch: Kleine dwergvleermuis. English: Midge Bat, Soprano Pipistrelle, Pygmy pipistrelle bat, 55 kHz pipistrelle, Mediterranean Lesser pipistrelle. Estonian: Pügmee-nahkhiir. Finnish: Kääpiölepakko. French: Pipistrelle soprane, Pipistrelle pygmée, le vespertilion pygmée. Frisian: Lytse dwerchflearmûs. Galician (Spain): Morcego anano. Georgian: პაწია ღამორი. German: Mückenfledermaus. Greek: Μικρονυχτερίδα. Hungarian: Szoprán törpedenevér. Irish Gaelic: Ialtóg shopránach. Italian: Pipistrello soprano, Pipistrello pigmeo, Pipistrello soprano. Latvian: Pigmejsikspārnis. Lithuanian: Šikšniukas mažylis. Luxembourgish: Méckefliedermaus. Macedonian: Џуџест лилјак, Kafeav Dzudzest Liljak. Maltese: Pipistrell Żgħir. Montenegrin: Patuljasti slijepi mišić. Norwegian: Dvergflaggermus. Polish: Karlik drobny. Portuguese: Morcego-pigmeu. Rhaeto-Romance: Pipistrel pigmeic, Pipistrel muschin.

Romanian: Liliacul pigmeu. Russian: Нетопырь малый (пигмей), Малый нетопырь [=Malyj Neopyr]. Serbian: Патуљасти сл[ij]епи мишић [= Patuljasti sl[ij]epi mišić]. Scottish Gaelic: Ialtag shopràn ach. Slovak: Večernica Leachova. Slovenian: Drobni netopir, Liliacul-pitic mediteranean. Swedish: Dvärgpipistrell, Dvärgfladdermus. Turkish: Akdeniz Cüce Yarasası. Ukrainian: Нетопир пігмей. Welsh: Ystlum-lleiaf soprano.

CONSERVATION STATUS:

Global Justification

The species is widespread and abundant, and there is no evidence of current significant population decline. Consequently, it is assessed as Least Concern (Benda *et al.*, 2016a).

Assessment History

Global

2016: LC ver. 3.1 (2001) (Benda *et al.*, 2016a).

Local

None known.

Legal Status

Benda *et al.* (2016a) report it is protected under national law in most range states. It is also protected under international law through the Bonn Convention (Eurobats) and Bern Convention in parts of its range where these apply and is included in Annex IV of the EU Habitats and Species Directive. It occurs in many protected areas.

MAJOR THREATS:

As maternity colonies tend to be found in buildings, the species may be vulnerable to anthropogenic factors, such as disturbance, timber treatment and building renovation (Battersby, 2005). However, this is not thought to be a major threat (Benda *et al.*, 2016a).

CONSERVATION ACTIONS:

Benda *et al.* (2016a) report that no specific conservation actions are known. They suggest that adoption of bat-friendly practices in the construction and maintenance of buildings is a proposed action. Although this species was only recently described, it is apparently widespread and abundant. However, further clarification of its distribution, population size and trend, habitat preferences, and ecology is required (Benda *et al.*, 2016a).

GENERAL DISTRIBUTION:

Native: Albania; Azerbaijan; Belarus; Belgium; Bosnia-Herzogovina; Bulgaria; Croatia; Cyprus; Czech Republic; Denmark; Estonia; Georgia; Germany; Great Britain; Greece; Iran; Ireland; Latvia; Lebanon (?); Moldova; Montenegro; Morocco (Dbiba *et al.*, 2025: 7); Portugal; Romania; Serbia; Slovakia; Spain; Sweden; Switzerland; Slovenia; The Netherlands; Turkey.

López-Baucells *et al.* (2012: 43) reported this species from the northern African Spanish enclave Ceuta, which is the first report of this species on the African continent.

POPULATION:

Structure and Density

Benda *et al.* (2016a) reports that *Pipistrellus pygmaeus* generally appears to be less abundant than *P. pipistrellus*, although it is nevertheless a widespread and abundant species. Summer colonies may be larger than *P. pipistrellus*, numbering up to 250 (or occasionally up to 3,000) individuals. It is not known if the species congregates in winter, or what size its winter colonies attain. Recent evidence of hybridisation with *P. pipistrellus* has been found in Central Europe by Sztencel-Jablonka and Bogdanowicz (2012).

Trends

2016: Unknown (Battersby, 2005).

VIRUSES:

Coronaviridae

Alphacoronavirus

Kohl and Kurth (2014: 3112) report this virus from German bats.

Orthomyxoviridae

Despite sampling and testing of 132 individuals of this species, no evidence of influenza A-like viruses (*Orthomyxoviridae*) were obtained (Fereidouni *et al.*, 2015).

Pipistrellus (Pipistrellus) raceyi Bates, Ratrimomanarivo, Harrison and Goodman, 2006

*2006. *Pipistrellus raceyi* Bates, Ratrimomanarivo, Harrison and Goodman, Acta Chiropt., 8 (2): 301. Type locality: Madagascar: Fianarantsoa province: Kianjavato [21 22.84 S 44 40.49 E, 75 m]. Holotype: FMNH 185567: ad ♂, skull and alcoholic. Collected by: Fania H. Ratrimomanarivo and E.N. Rakotonandrasana; collection date: 22 May 2005; original number: RHF 1281. - Etymology: In honour of Prof. Paul A. Racey, Regius professor of natural history, University of Aberdeen, UK, in recognition of his longstanding commitment to the study and conservation of bats worldwide and in particular to his on-going programme of capacity building and bat research in Madagascar (see Bates *et al.*, 2006: 305).

2020. *Pipistrellus (Pipistrellus) raceyi:* Simmons and Cirranello, BatNames.org. (Current Combination).

TAXONOMY:
Goodman *et al.* (2015a: 992) suggest that the eastern population (specimens from the Provinces of Fianarantsoa and Toamasina) and the western population (specimens from Province of Toliara) might warrant separation.

See also Bates *et al.* (2006).

COMMON NAMES:
English: Racey's Pipistrelle Bat. French: Pipistrelle de Racey. German: Raceys Zwergfledermaus, Raceys Pipistrelle.

CONSERVATION STATUS:
Global Justification
This species is listed as Data Deficient (DD ver 3.1 (2001)) because although preliminary evidence suggests that it is widely distributed in lowland areas of parts of eastern and western Madagascar and it exists in a range of vegetation types, there are insufficient data on its habitat requirements and major threats (Jenkins *et al.*, 2008j; IUCN, 2009; Jenkins *et al.*, 2019a).

Assessment History
Global
2018: DD ver 3.1 (2001) (Jenkins *et al.*, 2019a).
2008: DD ver 3.1 (2001) (Jenkins *et al.*, 2008j; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
No major threats are documented, but forest degradation may conceivably reduce availability of suitable foraging and roosting habitat in the west where this species presumably roosts in trees and appears to be associated with forest habitats (Jenkins *et al.*, 2008j; IUCN, 2009; Jenkins *et al.*, 2019a).

CONSERVATION ACTIONS:
Jenkins *et al.* (2008j) [in IUCN (2009)] and Jenkins *et al.* (2019a) report that even though this species roosts synanthropically in the east and may therefore be expected to be relatively common given the abundance of suitable roosting sites, it is only known from four locations across Madagascar despite the large survey effort on Malagasy bats in recent years. Of the four known localities, all receive some form of active forest management, and it is expected that deforestation at these sites has been and will be less than for non-protected forest. Further studies of this species are needed to investigate why it appears to be forest-dependent in the west but not in the east of its range.

GENERAL DISTRIBUTION:
Pipistrellus raceyi is an endemic species to Madagascar that is currently known from four localities (Bates *et al.*, 2006), two in the west (Mikea forest and Kirindy CFPF) and two in the east (Kianjavato and Tampolo forests), all below 80 m elevation (from 16 - 70 m asl.).

Native: Madagascar (Bates *et al.*, 2006).

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
See Bates *et al.* (2006).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
See Bates *et al.* (2006).

DETAILED MORPHOLOGY:
Other
For a description of the crania, teeth, ears and tragus see Bates *et al.* (2006).

HABITAT:
P. raceyi occurs In humid forest and agricultural areas in the east, and in intact and degraded dry forest in the west (Bates *et al.*, 2006; Garbutt, 2022: 102).

ROOST:
Synanthropic structures and vegetation for the typical roosting sites for this species on Madagascar according to Wilkinson *et al.* (2012: 160).

DIET:
Rakotondramanana *et al.* (2015: 77) reported the following volume percentages of food items: Coleoptera: 27.8 ± 20.00; Hymenoptera: 12.5 ± 17.15; Lepidoptera: 26.1 ± 23.05; Trichoptera: 1.9 ± 4.80; Isoptera: 30.0 ± 40.71; Homoptera: 1.5 ± 3.31; Arachnida: 0.1 ± 0.24. Expressed as frequency percentages, the values are: Coleoptera: 78.9 ± 29.48; Hymenoptera: 47.8 ± 41.81; Lepidoptera: 65.6 ± 44.35; Trichoptera: 10.0 ± 23.01; Isoptera: 37.8 ± 48.94; Homoptera: 12.2 ± 27.56; Arachnida: 1.7 ± 4.71. Based on the faeces of three animals, Rasoanoro *et al.* (2015: 64) found the following volume percentages: Aranea: 6.8 ± 1.47, Coleoptera: 32.5 ± 1.36, Diptera: 28.9 ± 4.15, Homoptera: 11.7 ± 2.18, Hymenoptera: 3.9 ± 2.20, and Lepidoptera: 16.3 ± 1.95.

PREDATORS:
Razakaratrimo *et al.* (2019: 114) mention the bat hawk (*Macheiramphus alcinus anderssoni* (Gurney, 1866)).

POPULATION:
Structure and Density
This recently described species is currently known only from 15 specimens (Bates *et al.*, 2006); however, with further survey work, it may be shown to more common (Jenkins *et al.*, 2008j; IUCN, 2009; Jenkins *et al.*, 2019a).

Trend
2018: Unknown (Jenkins *et al.*, 2019a). 2008: Unknown (Jenkins *et al.*, 2008j; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
See Bates *et al.* (2006).

VIRUSES:
Paramyxoviridae
Wilkinson *et al.* (2012: 160) tested 1 individuals from the Madagascar using RT-PCR specific for *Respirovirus*/*Morbillivirus*/*Henipahvirus* (RMH) and *Paramyxovirinae* (PMV) and found 0 positive results for viral nucleic acids.

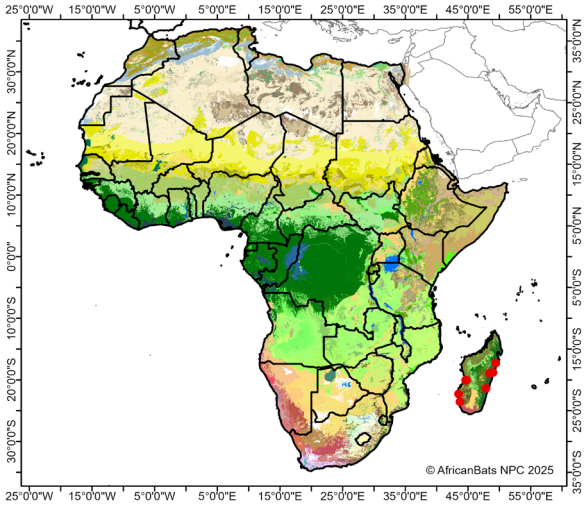

Figure 335. Distribution of *Pipistrellus (Pipistrellus) raceyi*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Madagascar.

Pipistrellus (Pipistrellus) rusticus (Tomes, 1861)

*1861. *Scotophilus rusticus* Tomes, Proc. zool. Soc. Lond., 1861, I: 31, 35. Publication date: May 1861. Type locality: Namibia: Ovamboland: Olifants Vlei [18 00 S 17 30 E]. [Goto Description]. Lectotype: NHMUK 1907.1.1.419: ad ♀, skin and skull. Collected by: 1 Anderson; original number: 176a. Paralectotype: NHMUK 1907.1.1.420: ad, skin and skull. Collected by: 1 Anderson; collection date: November 1899; original number: 176b. - Etymology: Lanza *et al.* (2015: 441) mention "The masculine Latin adjective *rùsticus* actually means "rural, country" i. e. farmland-loving. Tomes (1861b: 35) apparently used this adjective erroneously instead of the masculine Latin adjective *robiginosus* "rusty", referring to the fur dorsal colour of the species: 'On the upper surface it is dark brown at the roots, with the terminal half light cinnamon-brown […].' ".
1913. *Pipistrellus rusticus:* Roberts, Ann. Transv. Mus., 4: 67. (Name Combination).
1923. *Pipistrellus marrensis* Thomas and Hinton, Proc. zool. Soc. Lond., 1923, II: 249. Publication date: 6 July 1923. Type locality: Sudan: foothills S Jebel Marra: Darfur [12 54 N 24 21 E, 4 000 ft]. [Goto Description]. Holotype: NHMUK 1923.1.1.15: ad ♂. Collected by: Captain/Rear-Admiral Hubert Lynes and Willoughby P. Lowe; collection date: 3 April 1924; original number: 633.
1934. *Eptesicops rusticus:* Shortridge, Mammals of South West Africa, 60. (Name Combination).
1953. *Pipistrellus (Pipistrellus) rusticus:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 78. (Name Combination, Current Combination).
1959. *Pipistrellus (Eptesicops) rusticus:* Anonymus, Koedoe, 3: 58. (Name Combination).
1968. *Pipistrellus (Pipistrellus) rusticus rusticus:* Smithers, A check list and atlas of the mammals of Botswana (Africa), ???. (Name Combination).
1971. *Pipistrellus [(Pipistrellus)] rusticus marrensis:* Hayman and Hill, Mammals of Africa: Chiroptera, 40. (Name Combination).
1975. *P[ipistrellus] r[usticus] rusticus:* Wilson, Mus. Mem., Salisbury, 5: 141. (Name Combination).
2019. *Pipistellus rusticus:* Hranac, Marshall, Monadjem and Hayman, Epidemics, Suppl. Publication date: 16 November 2019. (Lapsus).
? *Pipistrellus rusticus marrensis:* (Name Combination).
? *Pipistrellus rusticus phasma:* (Name Combination).
? *Pipistrellus rusticus rusticus:* (Name Combination).

TAXONOMY:

Figure 336. A male *Pipistrellus (Pipistrellus) rusticus* (TM 48130) caught at Makalali-GR, Limpopo, South Africa.

See Simmons (2005).

COMMON NAMES:
Afrikaans: Roeskleurvlermuis. Chinese: 锈色伏翼. Czech: netopýr damarský. English: Rusty Bat, Rusty Pipistrelle Bat, Rusty Pipistrelle. French: Pipistrelle rustique, Pipistrelle rouille. German: Rostfarbene Zwergfledermaus, Rostfarbene Pipistrelle. Italian: Pipistrèllo rugginóso.

ETYMOLOGY OF COMMON NAME:
The colloquial name refers to the rusty colour of their fur (Taylor, 2005).

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008am; IUCN, 2009; Monadjem *et al.*, 2017cx).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Pipistrellus rusticus* (Monadjem *et al.*, 2017cx). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008am; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004ao; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016r). 2004: NT ver 3.1 (2001) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
There appear to be no major threats to this species as a whole (Jacobs *et al.*, 2008am; IUCN, 2009; Monadjem *et al.*, 2017cx).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008am) [in IUCN (2009)] and Monadjem *et al.* (2017cx) report that this species has been recorded from Mole National Park in Ghana (Grubb *et al.*, 1998). No direct conservation measures are currently needed for this species as a whole.

GENERAL DISTRIBUTION:
Pipistrellus rusticus has been widely, but patchily, recorded throughout much of sub-Saharan Africa. It is distributed from Senegal and The Gambia in the west, with easternmost records from Ethiopia close to the Somalia border area. It is found as far south as northern South Africa (where its distribution is mostly affected by precipitation seasonality; Babiker Salata (2012: 49)) and central Namibia. Other than records from southern Chad and northern Central African Republic, the species has not been recorded in Central Africa.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 842,481 km^2.

Fahr (2007a: 105) assigns the Liberian *rusticus* specimens tentatively to *hesperidus*.

Native: Angola (Taylor *et al.*, 2018b: 60); Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 572); Burkina Faso (Kangoyé *et al.*, 2015a: 621); Central African Republic (Kock *et al.*, 2002b: 87); Chad; Eswatini (Monadjem *et al.*, 2021: 5); Ethiopia; Gambia (Kock *et al.*, 2002b: 87); Ghana; Kenya; Malawi (Ansell and Dowsett, 1988: 40; Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 572); Mozambique; Namibia (Monadjem *et al.*, 2010d: 572); Nigeria; Senegal; South Africa (Monadjem *et al.*, 2010d: 572); Sudan (Kock *et al.*, 2002b: 87); Tanzania (Kock *et al.*, 2002b: 87); Uganda; Zambia (Ansell, 1969; Ansell, 1973; Monadjem *et al.*, 2010d: 572); Zimbabwe (Monadjem *et al.*, 2010d: 572).

DETAILED MORPHOLOGY:
Penis
Fasel *et al.* (2020: 1394) indicated that the penis if *Pipistrellus rusticus* could easily be separated from those of the five other pipistrelloid species they examined by means of its robust width, which is approximately 40 % of its length (in the other species this is less than 35 %). Its dorsal side is completely covered by short hairs, and the proximal section is violet in colour, which is also the case for the central line that ends at the distal end. In erect status, the penis is violet in colour (in the other species it is red) and curved.

Baculum
Hill and Harrison (1987) and Kearney *et al.* (2002).

ECHOLOCATION:
In Waterberg, South Africa, Taylor *et al.* (2013b: 17) recorded the following parameters for 1 call: F_{max}: 62.1 kHz, F_{min}: 55.3 kHz, F_{knee}: 57.6 kHz, F_{char}: 55.4 kHz, duration: 3.1 ms. 19 calls recorded at Mapungubwe National Park (RSA) by Parker and Bernard (2018: 57) had the following features: F_{char}: 55.20 ± 0.92 kHz, F_{max}: 64.41 ± 3.75 kHz, F_{min}: 54.00 ± 1.05 kHz, F_{knee}: 57.68 ± 1.34 kHz, duration: 4.70 ± 1.59 ms, and 6.11 ± 3.12 calls/sec.

Weier *et al.* (2020: Suppl.) reported on 11 calls from the Okavango River Basin with the following characteristics: F_{max}: 59.44 ± 5.07 kHz, F_{min}: 52.34 ± 0.99 kHz, F_{knee}: 53.55 ± 1.63 kHz, F_{char}: 52.87 ± 1.03 kHz, slope: 15.95 ± 30.29 OPS, duration: 3.24 ± 1.27 ms.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 9 *Pipistrellus rusticus* calls from the Kruger Park (RSA): F_{min}: 50.8 ± 2.9 (46.8 55.2) kHz, Duration: 2.4 ± 0.4 (2.1 3.1) ms, F_{max}: 70.3 ± 7.0 (62.7 82.0) kHz, F_{knee}: 48.2 ± 16.0 (5.9 57.9) kHz, F_{char}: 51.9 ± 2.4 (48.5 55.5) kHz.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 55.7 kHz and duration: 4.5 ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

56 pulses recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 55 kHz, F_{max}: 62 kHz, F_{char}: 55 kHz, F_{knee}: 58 kHz and duration 3 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 55) reported F_{char}: 55.20 ± 0.92 kHz, F_{max}: 64.41 ± 3.75 kHz and F_{min}: 54.00 ± 1.05 kHz.

For 14 calls from 2 *Pipistrellus rusticus* bats from Telperion Nature Reserve (RSA), De Jong *et al.* (2025: 322) reported the following parameters: F_{char}: 48.66 ± 0.83 kHz, F_{knee}: 52.76 ± 2.26 kHz, F_{min}: 48.26 ± 1.66 kHz, F_{max}: 79.26 ± 8.95 kHz, Bandwidth: 31.00 ± 8.26 kHz, Duration: 6.40 ± 1.84 ms.

From the MalaMala Game Reserve (KNP, RSA), Gumede *et al.* (2025: Appendix S1) reported F_{char}: 55.20 ± 0.92 kHz, F_{max}: 64.41 ± 3.75 kHz, F_{min}: 54.00 ± 1.05 kHz.

From Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 18 calls: Interpulse interval: 69.9 ± 13.5 (44.2 - 98.7) ms; F_{max}: 61.5 ± 4.5 (57.3 - 72.1) kHz; Start slope: -23.9 ± 4.3 (-12.0 - -29.3) kHz/ms; End slope: -7.2 ± 3.8 (-1.7 - -9.8) kHz/ms; Ledge duration: 0.5 ± 0.1 (0.3 - 0.6) ms.

MOLECULAR BIOLOGY:
Karyotype
Both Rautenbach *et al.* (1993) and Kearney *et al.* (2002) reported 2*n* = 42, FN = 50, BA = 10, and an acrocentric Y chromosome, for specimens from South Africa. However, while Rautenbach *et al.* (1993) reported a submetacentric X chromosome, Kearney *et al.* (2002) reported a metacentric X chromosome. GTG banding identified that *P. hesperidus* and *P. rusticus* share the same Robertsonian fusion of chromosomes 11/12 (Kearney *et al.*, 2002).

HABITAT:
In southern Africa, *P. rusticus* occurs in Savanna habitats (84 %; Cooper-Bohannon *et al.*, 2016: Table S2).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 59 minutes, and the digestibility rate about 83.0 %.

PREDATORS:
Malan *et al.* (2022: 167) reported ten individuals found in pellets from a bat hawk pair (*Macheiramphus alcinus* Bonaparte, 1850 from the RSA.

POPULATION:
Structure and Density
This species is locally common (Jacobs *et al.*, 2008am; IUCN, 2009; Monadjem *et al.*, 2017cx).

Trend
2016: Unknown (Monadjem *et al.*, 2017cx).
2008: Unknown (Jacobs *et al.*, 2008am; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
P. rusticus displays a clear disassociation between male and female gamete production (van der Merwe and Mostert, 2005: 45). Spermatogenesis occurs during summer, and by late autumn the testes have regressed and the caudae epididymidis are full of stored spermatozoa (van der Merwe and Rautenbach, 1990). Mating is initiated in autumn, and

spermatozoa from these inseminations are stored throughout the winter in the uteri of females (van der Merwe and Rautenbach, 1990; van der Merwe, 1994). Ovulation occurs late in winter to early spring and the released ova are fertilized by the spermatozoa stored within the female (van der Merwe and Mostert, 2005: 45).

van der Merwe and Rautenbach (1990: 538) found that 1 to 5 embryos might be present, but a maximum of two become implanted. The other embryos (up to morula stage) are resorbed (p. 540).

P. rusticus are seasonally monoestrous breeders and normally give birth to twins during the middle of November (van der Merwe and Rautenbach, 1990: 539; van der Merwe, 1994). However, occasional singletons have been recorded by van der Merwe and Rautenbach (1990). The uterus is bicornuate and a single foetus is carried in each of the uterine horns (van der Merwe and Rautenbach, 1990). *P. rusticus* is unique, in that although implantation is superficial, the amnion is formed by means of cavitation (van der Merwe, 1994). According to van der Merwe and Rautenbach (1990), embryonic development seems to be retarded just after implantation.
van der Merwe and Mostert (2005) investigated the reproductive pattern of female *P. rusticus* in South Africa by means of a histological examination of the ovarian follicles as well as early embryonic development. Female *P. rusticus* are seasonal monestrous breeders, initiating copulation in mid-autumn (April), storing sperm until the time of ovulation in late winter (August), and giving birth to twins in late spring (November). The period April until mid-August was characterized by sperm storage and increased follicular development. During mid-August the females ovulate, and excess sperm was discarded. Females released between three and five ova, while a maximum of two embryos implanted successfully. Only a single embryo implanted per uterine horn. Embryo movement through the Fallopian tubes appeared to be a rapid process. Redundant embryos were resorbed before implantation. The period from the end of August until mid-November was marked by Pregnancy. Females invariably carried twins (one foetus in each uterine horn). Large-scale follicle atresion, and very low levels of follicle development, characterized the period end of August until March. High incidences of polyovular follicles were recorded for all months of the year. No obvious form of reproductive asymmetry was recorded in *P. rusticus* (van der Merwe and Mostert, 2005).

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births taking place in November.

MATING:
For Northern Transvaal (RSA), van der Merwe and Rautenbach (1990: 538) indicate that copulation was initiated during April, and ovulation and fertilization takes place in the second half of August.

PARASITES:
HEMIPTERA
Cicimidae
Kock *et al.* (1998b: 236, 137) reported *Cacodmus sparsilis* Rothschild, 1914 and *Cacodmus villosus* (Stål, 1855).

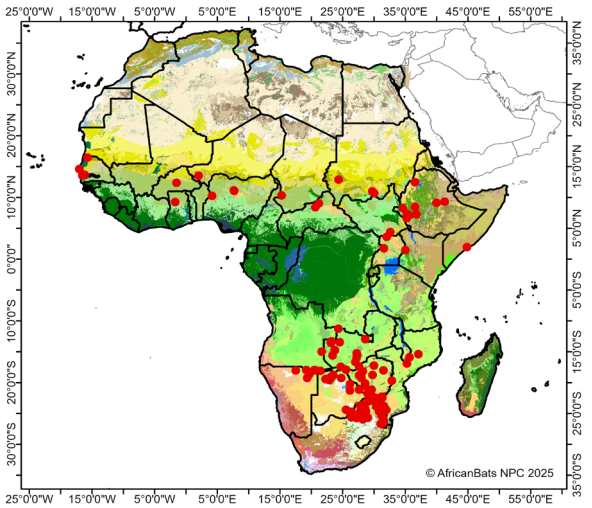

Figure 337. Distribution of *Pipistrellus (Pipistrellus) rusticus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:

Pipistrellus (Pipistrellus) simandouensis Monadjem, Richards, Decher and Hutterer, 2020

*2020. *Pipistrellus simandouensis* Monadjem, Richards, Decher and Hutterer, Zool. J. Linn. Soc., 191 (2): 556, 559, figs 4A-B, 5 - 9. Publication date: 4 September 2020. Type locality: Guinea: N'Zérékoré region: Beyla prefecture: Whiskey 1 [08 32 56 N 08 53 57 W, 950 m]. Holotype: ZFMK MAM-2008.0302: ad ♂, skull and alcoholic. Collected by: Jan Decher *et al.*; collection date: 25 February 2008; original number: JD 614. Paratype: ZFMK MAM-2008.0300: ad ♀. Collected by: Jan Decher *et al.*; collection date: 8 March 2008; original number: JD 656. Paratype: ZFMK MAM-2008.0301: ad ♂. Collected by: Jan Decher *et al.*; collection

date: 9 March 2008; original number: JD 661. - Etymology: Referring to the region where the type specimen was collected: the Simandou mountain range in eastern Guinea (Monadjem *et al.*, 2020d: 562).

? *Pipistrellus (Pipistrellus) simandouensis:* (Current Combination).

? *Pipistrellus cf. grandidieri:* (Name Combination).

TAXONOMY:
Based on cyt-*b* analyses and morphologic data, Monadjem *et al.* (2020d: 565) recognized the West African specimens formerly included in "*Pipistrellus grandidieri*" as a separate species.

COMMON NAMES:
English: Simandou serotine

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

GENERAL DISTRIBUTION:
Monadjem *et al.* (2020d: 563) indicate that this species is only known from two localities: Mount Nimba (Liberia) and the Simandou Range (Guinea). Specimens from Fouta Djallon might belong to this species, but genetic confirmation is still required.

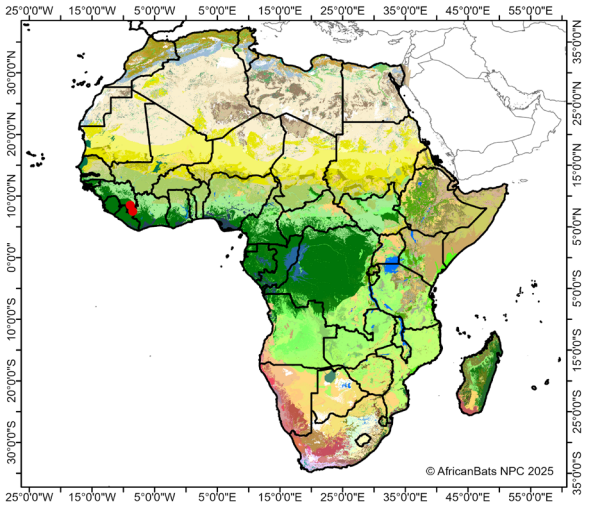

Figure 338. Distribution of *Pipistrellus (Pipistrellus) simandouensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Guinea, Liberia.

Pipistrellus (Pipistrellus) sp. aff. kuhlii Kuhl, 1817

*2001. *Pipistrellus cf kuhlii* Volleth, Bronner, Göpfert, Heller, von Helversen and Yong, Chromosome Res., 9 (1): 26. (Current Combination).

? *Pipistrellus (Pipistrellus) sp_aff_kuhlii*

TAXONOMY:
Volleth *et al.* (2001: 25) report a *Pipistrellus kuhlii*-like species from Madagascar, which they separated from the European *Pipistrellus* based on a different diploid chromosome number. This form might possibly be conspecific with *Pipistrellus hesperidus* Temminck, 1840, since Bates *et al.* (2006: 299) mention *P. hesperidus* from Madagascar.

CONSERVATION STATUS:
Global Justification
Currently not been globally assessed hence no justification.

Assessment History
Global
No assessment known, hence no history of assessment to report.

Regional
None known.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

Genus ***Scotoecus*** Thomas, 1901

*1901. *Scotœcus* Thomas, Ann. Mag. nat. Hist., ser 7, 7 (39): 263. Publication date: 1 March 1901 [Goto Description]. - Comments: Type species: *Scotophilus albofuscus* Thomas, 1890. - Etymology: From the Greek "*σκόοτος*", meaning darkness and "*όικέω*", meaning to dwell (see Palmer, 1904: 627).

1917. *Scotæcus:* Thomas, Ann. Mag. nat. Hist., ser 8, 19 (111): 280. (Lapsus).

? *Scotoecus sp.*
? *Scotoecus sp. DMR-2017*
? *Scotoecus sp. IVK-2011*
? *Scotoecus:* (Current Spelling).

TAXONOMY:
Scotoecus has been treated as a subgenus of *Nycticeius* (Ellerman *et al.*, 1953; Hayman and Hill, 1971), but more often as a full genus (Allen, 1939a; Rosevear, 1965; Kock, 1969a; Hill, 1974b; Koopman, 1975, 1978; Corbet and Hill, 1980; Swanepoel *et al.*, 1980; Honacki *et al.*, 1982). Of the two (Honacki *et al.*, 1982) or three (Corbet and Hill, 1980) recognized African species only *albofuscus* occurs in Southern Africa, having been recorded from a single locality in Mozambique.

Bronner *et al.* (2003) report the light-winged lesser house bat (*Scotoecus albofuscus*) in South Africa. This represents a significant extension in the known ranges of both species and testifies to the need for more intensive field surveys targeting poorly known taxa. Cotterill (2001d) also recorded *Scotoecus albigula* and *S. hindei* from Zinave, Mozambique, based on the re-identification of two museum specimens originally assigned to *Scotophilus viridis*. Compared with the light-winged *albofuscus*, species identification of the dark-winged taxa of *Scotoecus* (*albigula, hindei, hirundo, falabae*) is more complicated. Indeed, Koopman (1993a) included all these taxa in *S. hirundo*. A study of cranial variation involving a small sample of Malawian specimens (Taylor and van der Merwe (1998) revealed that *hindei, hirundo* and *albigula* are distinguishable on morphometric grounds, with *albigula* and *hindei* apparently having larger canines and cheekteeth (as well as larger skulls) than *hirundo*, while *albigula* and *hindei* differ from each other in skull proportions. However, we provisionally retain these within *S. hirundo*, pending a broader study of the dark-winged forms including a larger sample of specimens from across the range.

Benda *et al.* (2025: 92) reiterate that the taxonomy of the dark-winged species of the genus Scotoecus remains unresolved.

Currently (Simmons and Cirranello, 2023b) recognized species of the genus *Scotoecus*: ***albigula*** Thomas, 1909; ***albofuscus*** (Thomas, 1890); ***hindei*** Thomas, 1901; ***hirundo*** (de Winton, 1899); *pallidus* (Dobson, 1876) – Pakistan, northern India (Simmons, 2005: 465). Additionally, there is also the extinct ***†olduvensis*** Gunnell, Butler, Greenwood and Simmons, 2015.

COMMON NAMES:
Czech: vlaštovčí netopýři. English: Lesser House Bats, House Bats. French: Scotoèques, Chauves-souris des maisons. German: Kleine Hausfledermäuse. Italian: Scotoèchi.

GENERAL DISTRIBUTION:
Monadjem *et al.*, 2010d could not distinguish between *S. hindei* and *S. albigula* therefore they were combined for the distribution being recorded from Angola; Congo (Democratic Republic of the); Malawi; Mozambique; Zambia.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Patterson and Webala (2012: 43) indicate that male *Scotoecus* can easily be distinguished from any other Vespertlionid by the large size of its penis.

HABITS:
Rainho *et al.* (2023: 7) assigned the *Scotoecus* bats in Meru county (Kenya) to a medium-to-high flying bats guild occurring at altitudes between 3 and 15 m.

VIRUSES:
Coronaviridae
None of the 24 *Scotoecus* specimens tested by Tao *et al.* (2017: Suppl.) in Kenya were positive for CoV.

Alphacoronavirus
Tong *et al.* (2009) identified coronavirus RNA from the fecal material of *Scotoecus* spp.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya, Mozambique, South Sudan, Tanzania, Uganda.

Scotoecus albigula (Thomas, 1909)

*1909. *Scotœcus albigula* Thomas, Ann. Mag. nat. Hist., ser 8, 4 (24): 544. Publication date: 1 December 1909. Type locality: Kenya: Mount Elgon: Kirui [04 43 S 39 13 E, 6 000 ft]. [Goto Description]. Holotype: NHMUK 1910.4.1.24: ad ♂. Collected by: Robert ("Robin") Kemp Jr. Collection date: 5 September 1909; original number: 200. Formerly Rudd Collection. - Comments: Type locality coordinates mentioned as 00 50 N 34 40 E by Thorn *et al.* (2009: 58). - Etymology: From the feminine Latin adjective *àlba*, meaning "white" and the feminine Latin substantive *gùla*, meaning "throat", referring to the colour of the throat fur (see Lanza *et al.*, 2015: 460).

2010. *Scotoecus hindei/albigula:* Monadjem, Taylor, Cotterill and Schoeman, Bats of Southern and Central Africa. A biogeographic and taxonomic synthesis. Wits University Press, Johannesburg, 510.
? *Nycticeius (Scotoecus) hirundo albigula:* (Name Combination).
? *Scotoecus albigula:* (Current Combination, Current Spelling).
? *Scotoecus hindei albigula:* (Name Combination).
? *Scotoecus hirundo albigula:* (Name Combination).

TAXONOMY:
Considered a subspecies of *hindei* by Hill (1974b: 182), and Thorn and Kerbis Peterhans (2009: 58). Included in *hirundo* by Koopman (1993a: 226), but considered a valid species by Ansell and Dowsett (1988: 44), Simmons (2005).

COMMON NAMES:
Czech: netopýr bělohrdlý. English: White-throated Lesser House Bat, White-bellied Lesser House Bat. French: Scotoèque à gorge blanche. German: Weisskehl-Hausfledermaus. Italian: Scotoèco golabiànca. Tshokwe (Angola): Kafukufuku.

CONSERVATION STATUS:
Global Justification
Scotoecus albigula was included in *Scotoecus hirundo* by Jacobs *et al.* (2008af) in IUCN (2009) for the global assessment. Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008af; IUCN, 2009).

Assessment History
Global
2008: LC ver 3.1 (2001) [assessed as part of *Scotoecus hirundo*] (Jacobs *et al.*, 2008af; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs and Cotterill, 2004c; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
While the threats to this species are not well known, it is presumed not to have any major threats in view of the species wide distribution in habitats that are not rapidly declining throughout much of its recorded range (Jacobs *et al.*, 2008af; IUCN, 2009).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008af) [in IUCN (2009)] report that further studies are needed into the natural history and possible threats to this poorly known species.

GENERAL DISTRIBUTION:
Native: Angola; Kenya; Malawi; Mozambique (Monadjem *et al.*, 2010c: 384 as *S. hindei/albigula*); Somalia; Uganda; Zambia.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

ECHOLOCATION:
See Taylor *et al.* (2005).

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 89 minutes, and the digestibility rate about 78.5 %.

POPULATION:
Structure and Density
It is very rarely recorded, and there is little information is available on the population abundance or size of this species (Jacobs *et al.*, 2008af; IUCN, 2009).

Trend
2008: Unknown (Jacobs *et al.*, 2008af; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
Happold and Happold (1990b: 567) reported births in Malawi to take place early in the wet season.

PARASITES:
HEMIPTERA
Cimicidae
Kock *et al.* (1998b: 237) reported *Cacodmus sparsilis* Rothschild, 1914 on bats from Malawi.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Kenya, Malawi, Mozambique, Somalia, Tanzania, Uganda, Zambia.

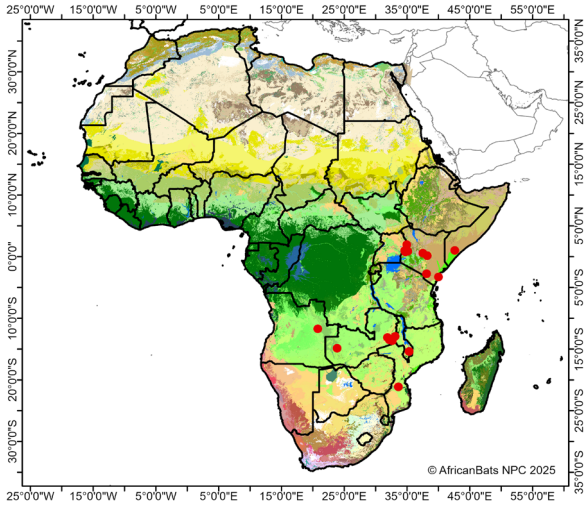

Figure 339. Distribution of *Scotoecus albigula*.

Scotoecus albofuscus (Thomas, 1890)

*1890. *Scotophilus albofuscus* Thomas, Ann. Mus. civ. Stor. nat. Genova, ser 2a, (OS 29) 9: 84. Publication date: 3 February 1890. Type locality: The Gambia: Bathurst [=Banjul] [13 28 N 16 39 W]. [Goto Description]. Holotype: NHMUK 1889.12.12.2: ad ♂, alcoholic (skull not removed). Collected by: Dr. Percy John Rendall.

1917. *Scotoecus woodi* Thomas, Ann. Mag. nat. Hist., ser 8, 19 (111): 280. Publication date: 1 March 1917. Type locality: Malawi: Shiré valley: Chiromo [16 32 S 35 09 E, 200 ft]. [Goto Description]. Holotype: NHMUK 1917.2.1.1: ad ♂. Collected by: Rodney Carrington Wood Esq. Collection date: 2 October 1916; original number: 173. Presented/Donated by: Rodney Carrington Wood Esq.

? *Scotoecus albofuscus albofuscus:* (Name Combination).

? *Scotoecus albofuscus woodi:* (Name Combination).

? *Scotoecus albofuscus:* (Name Combination, Current Combination).

TAXONOMY:

See Simmons (2005).

COMMON NAMES:

Afrikaans: Thomas se vlermuis, Thomas-vlermuis. Chinese: 淡翼宽吻. Czech: netopýr gambiánský. English: Thomas' House Bat, Light-winged Lesser House Bat, Thomas's Lesser House Bat. French: Scotoèque à ailes pâles, Scotophile du crépuscule, Chauve-souris de Thomas. German: Weißflügel-Hausfledermaus. Malawian: Liputiputi, Ndemiya, Namzeze. Portuguese: Morcego pequeno das casas.

CONSERVATION STATUS:

Global Justification

Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Jacobs, 2008l; IUCN, 2009; Jacobs, 2019b).

Assessment History

Global

2018: DD ver 3.1 (2001) (Jacobs, 2019b). 2008: DD ver 3.1 (2001) (Jacobs, 2008l; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs, 2004h; IUCN, 2004). 1996: LR/nt (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: NT D2 ver 3.1 (2001) (Richards *et al.*, 2016f). 2004: VU D2 ver 3.1 (2001) (Friedmann and Daly, 2004).

MAJOR THREATS:

The threats to this species are not known (Jacobs, 2008l; IUCN, 2009; Jacobs, 2019b).

CONSERVATION ACTIONS:

Jacobs (2008l) [in IUCN (2009)] and Jacobs (2019b) reports that there appear to be no direct conservation measures in place. It has been recorded from Zinave National Park on the Save River in Mozambique, and presumably is present in additional protected areas. Further studies are needed into the distribution, natural history and possible threats to this widespread but seemingly very poorly known species.

GENERAL DISTRIBUTION:

Scotoecus albofuscus has been widely, but patchily recorded over much of West Africa and East Africa, with some records from Central Africa. It ranges from The Gambia and Senegal in the west, through West Africa to eastern Nigeria, it is then distributed from northern Uganda and southern Kenya, through Tanzania, southeastern Democratic Republic of the Congo,

southern Malawi, Mozambique and southeastern South Africa. The range is poorly known, and the species might be more widespread.

Native: Benin (Capo-Chichi *et al.*, 2004: 163); Burkina Faso (Kangoyé *et al.*, 2012: 6026; 2015a: 626); Cameroon (Waghiiwimbom *et al.*, 2019b: 6), Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 573); Côte d'Ivoire; Gambia; Ghana; Kenya; Malawi (Happold and Happold, 1997b: 819; Cotterill, 2001d; Monadjem *et al.*, 2010d: 573); Mozambique (Cotterill, 2001d; Monadjem *et al.*, 2010d: 573); Nigeria; Senegal; Sierra Leone; South Africa (Kearney and Taylor, 1997: 53; Monadjem *et al.*, 2010d: 573); Sudan; Tanzania; Uganda (Kityo and Kerbis, 1996: 62); Zambia (Monadjem *et al.*, 2010d: 573).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

ECHOLOCATION:
Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 39.3 kHz and duration: 3.3 ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 58 minutes, and the digestibility rate about 83.0 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Jacobs, 2008l; IUCN, 2009; Jacobs, 2019b).

Trend
2018: Unknown (Jacobs, 2019b). 2008: Unknown (Jacobs, 2008l; IUCN, 2009).

? *Scotoecus hirundo hindei:* (Name Combination).

TAXONOMY:
Included in *hirundo* by Kock (1969a: 192), Koopman (1993a: 226), but considered a valid species by Ansell and Dowsett (1988: 44), Simmons (2005).

Figure 341. *Scotoecus hindei* (ECJS-36/2008), from Lafupa camp, Zambia.

COMMON NAMES:
Czech: netopýr Hindeův. English: Hinde's Lesser House Bat. French: Scotoèque de Hinde. German: Hindes Hausfledermaus. Italian: Scotoèco di Hìnde.

CONSERVATION STATUS:
Global Justification
Scotoecus hindei was included in *Scotoecus hirundo* by Jacobs *et al.* (2008af) in IUCN (2009) for assessment. Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008af; IUCN, 2009).

Assessment History
Global
2008: LC ver 3.1 (2001) [assessed as part of *Scotoecus hirundo*] (Jacobs *et al.*, 2008af; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004q; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
While the threats to this species are not well known, it is presumed not to have any major threats in view of the species wide distribution in habitats that are not rapidly declining throughout much of its recorded range (Jacobs *et al.*, 2008af; IUCN, 2009).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008af) [in IUCN (2009)] report that further studies are needed into the natural history and possible threats to this poorly known species.

GENERAL DISTRIBUTION:
Native: Cameroon; Congo, Democratic Republic of the; Ethiopia (Lavrenchenko *et al.*, 2004b: 141); Kenya; Malawi; Mozambique (Monadjem *et al.*, 2010c: 384 as *S. hindei/albigula*); Nigeria; Somalia; Sudan; Tanzania; Zambia.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

ECHOLOCATION:
See Taylor *et al.* (2005).

MOLECULAR BIOLOGY:
Karyotype
Nagorsen *et al.* (1976: 9) reported 2*n* = 30, FN = 50, BA = 22, a subtelocentric X chromosome and a submetacentric Y chromosome.

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 90 minutes, and the digestibility rate about 78.3 %.

POPULATION:
Structure and Density
It is very rarely recorded, and there is little information available on the population abundance or size of this species (Jacobs *et al.*, 2008af; IUCN, 2009).

Trend
2008: Unknown (Jacobs *et al.*, 2008af; IUCN, 2009).

REPRODUCTION AND ONTOGENY:
In Malawi, the births take place early in the wet season (Happold and Happold, 1990b: 567).

PARASITES:
PROTOZOA
Babyesiza *et al.* (2025: 4) found *Trypanosoma vespertilionis* in four out of the five *Scotoecus hindei* bats they examined.

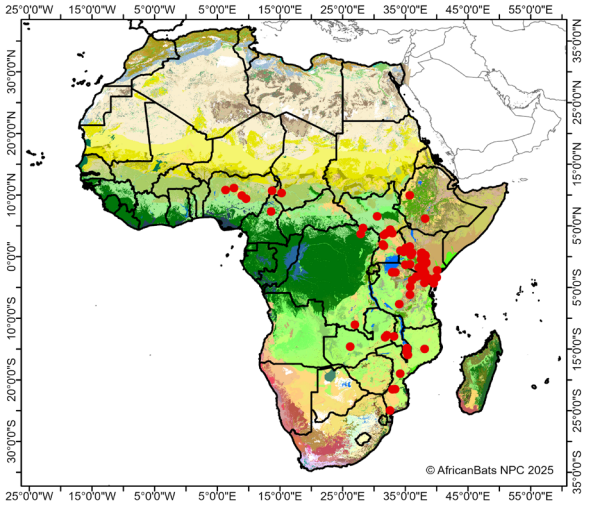

Figure 342. Distribution of *Scotoecus hindei*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Cameroon, Congo (Democratic Republic of the), Ethiopia, Kenya, Malawi, Mozambique, Nigeria, South Sudan, Tanzania, Uganda, Zambia.

Scotoecus hirundo (de Winton, 1899)

*1899. *Scotophilus hirundo* de Winton, Ann. Mag. nat. Hist., ser 7, 4 (23): 355. Publication date: 1 November 1899. Type locality: Ghana: Gambaga [10 32 N 00 26 W]. [Goto Description]. Holotype: NHMUK 1899.6.15.8. - Etymology: From the feminine Latin noun, in apposition, *hirùndo*, meaning "swallow", referring to the species' appearance (see Lanza *et al.*, 2015: 471).

1923. *Scotoecus artinii* de Beaux, Atti Soc. ital. Sci. nat., 62: 98. Publication date: July 1923. Type locality: Kenya: Northern Guaso Nyiro: Archer's Post [00 39 N 37 41 E, 2 000 ft]. [Goto Description]. Holotype: MSNM 1443: ad ♀, skin and skull. Collected by: L. Franchetti and L. Tonker; collection date: 26 December 1919. 2 paratypes: see De Beaux (1923: 98). Paratype: MSNG 45844: alcoholic (skull not removed). Collected by: L. Franchetti and L. Tonker; collection date: 26 December 1919. See Gippoliti (2024: 3). - Etymology: In honour of prof. E. Artini, director of the Museo Civico di Storia Naturale di Milano (see De Beaux, 1923: 98).

2013. *Scotoecus cf. hirundo:* Koubínová, Irwin, Hulva, Koubek and Zima, Front. Zool., 10: 5. - Comments: Koubínová *et al.* (2013: 7) showed that the karyotype from Senegal (2*n*=30, FN=50, aFN=46) had a reduced number of arms than reported previously from the Ivory Coast (2n=30, FN=54, Fna=50 Volleth *et al.* (2006)), and suggested that this may represent a distinct species. Further investigations are needed to compare other related species of *Scotecus*, as both the cytogenetics only compared the specimens from Sengal with that of Ivory Coast. (Name Combination).

? *Scotoecus hirundo artinii:* (Name Combination).

? *Scotoecus hirundo:* - Comments: . (Name Combination, Current Combination).

TAXONOMY:

Koopman (1993a: 226) included *hindei*; see Hayman and Hill (1971: 36) and Robbins (1980: 84); but see also Hill (1974b).

COMMON NAMES:

Chinese: 暗翼宽吻蝠. Czech: netopýr vlaštovčí. English: Dark-winged Lesser House Bat, Swallow Lesser House Bat. French: Scotoèque hirundine, Scotophile à ailes noires. German: Schwarzflügel-Hausfledermaus. Italian: Scotoèco róndine. Malawian: Liputiputi, Ndemiya, Namzeze.

CONSERVATION STATUS:

Global Justification

Although this species is known mainly from isolated records from a large area, it is listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Jacobs *et al.*, 2008af; IUCN, 2009; Cotterill *et al.*, 2017).

Assessment History

Global

2016: LC ver 3.1 (2001) [includes *S. albigula* and *S. hindei*] (Cotterill *et al.*, 2017). 2008: LC ver 3.1 (2001) [includes *S. albigula* and *S. hindei*] (Jacobs *et al.*, 2008af; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs, 2004g; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

None known.

MAJOR THREATS:

While the threats to this species are not well known, it is presumed not to have any major threats in view of the species wide distribution in habitats that are not rapidly declining throughout much of its recorded range (Jacobs *et al.*, 2008af; IUCN, 2009; Cotterill *et al.*, 2017).

CONSERVATION ACTIONS:

There appear to be no direct conservation measures in place. It has been recorded from the Zinave National Park in Mozambique (Cotterill, 2001d), and from the Mole National Park in Ghana (Grubb *et al.*, 1998), and in view of its wide range, is presumably present in additional protected areas. Further studies are needed into the natural history and possible threats to this poorly known species (Jacobs *et al.*, 2008af; IUCN, 2009; Cotterill *et al.*, 2017).

GENERAL DISTRIBUTION:

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 555,102 km^2.

Native: Benin (Capo-Chichi *et al.*, 2004: 163); Burkina Faso (Kangoyé *et al.*, 2012: 6026; 2015a: 626); Cameroon; Côte d'Ivoire (Volleth *et al.*, 2006); Ethiopia; Ghana; Guinea-Bissau (Rainho and Ranco, 2001: 59); Senegal; Tanzania; Uganda (Kityo and Kerbis, 1996: 63).

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

Scott *et al.* (2012: 2943) report that the mandibular symphysis is completely fused in this species.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

ECHOLOCATION:
Two FM/QCF calls from Maroua (Cameroon) were reported by Manga Mongombe (2012: 79) having the following parameters: F_{max}: 58.4 (57.2 - 59.6) kHz, F_{min}: 54.5 (54.2 - 54.8) kHz, F_{mean}: 56.6 (55.9 - 57.2) kHz, F_{knee}: 58.2 (57.2 - 59.2) kHZ, F_{char}: 54.7 (54.5 - 54.8) kHz, and duration: 0.87 (0.82 - 0.91) ms.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype.

MOLECULAR BIOLOGY:
Karyotype
Volleth *et al.* (2006) reported 2*n* = 30, FN = 50, BA = 22, and a subtelocentric X chromosome for a female from Ivory Coast.

Koubínová *et al.* (2013: 3) report the following karyotype for 1 ♂ from Senegal: 2*n* = 30, Fna = 46, FN = 50, X = metacentric, and Y = dot-like (probably acrocentric). They also found that the Senegalese specimen differed for 1.6 % in its *rag2* gene when compared with a specimen from Tanzania, which is more than in other non-cryptic species. As such they assign their specimen to *S.* cf. *hirundo*.

Genetics
See Hoofer and Van Den Bussche (2003) from Tanzania.

HABITAT:
In southern Africa, this species inhabits Savanna habitats (84 %; Cooper-Bohannon *et al.*, 2016: Table S2).

DIET:
Feacal pellets of 2 bats from Cameroon examined by Waghiiwimbom *et al.* (2019a: 156), contained the following volume (± SD) and frequency percentages: Lepidoptera (44.4 ± 5.8; 95), Diptera (39.7 ± 9.2; 98.3), Coleoptera (13.5 ± 4.1; 70.4), Hymenoptera (2.3 ± 1.5; 26.4), Nauroptera (1.4 ± 1.4; 3.3), Trichoptera (0.2 ± 0.2; 3.3).

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 85 minutes, and the digestibility rate about 78.9 %.

POPULATION:
Structure and Density
It is very rarely recorded, and there is little information is available on the population abundance or size of this species (Jacobs *et al.*, 2008af; IUCN, 2009; Cotterill *et al.*, 2017).

Trend
2016: Unknown (Cotterill *et al.*, 2017). 2008: Unknown (Jacobs *et al.*, 2008af; IUCN, 2009).

PARASITES:
HEMIPTERA
Cimicidae
Szentiványi *et al.* (2022: 12) reported *Cacodmus vicinus* Horváth, 1934 from Senegal.

DIPTERA
Nycteribiidae
Dick *et al.* (2023: 73) found *Basilia (Basilia) ansifera* Theodor, 1956 has been found on *Scotoecus hirundo* from the Samburu National Game Reserve (Kenya).

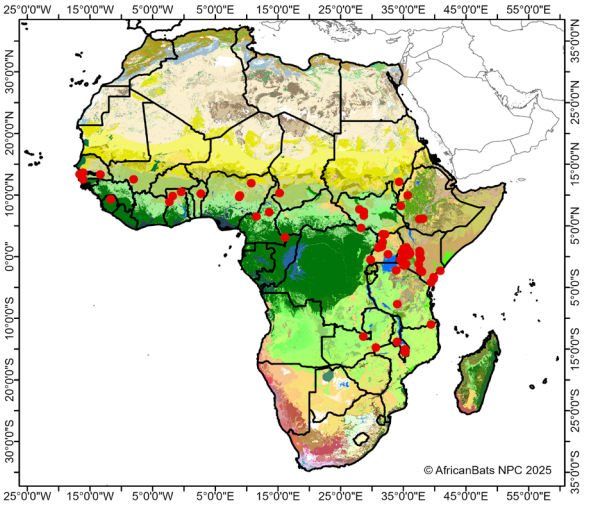

Figure 343. Distribution of *Scotoecus hirundo*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Benin, Cameroon, Central African Republic, Côte d'Ivoire, Ethiopia, Ghana, Kenya, Malawi, Mali, Nigeria, Senegal, Sierra Leone, South Sudan, Sudan, Tanzania, The Gambia, Uganda, Zambia.

†*Scotoecus olduvensis* Gunnell, Butler, Greenwood and Simmons, 2015

*2015. *Scotoecus olduvensis* Gunnell, Butler, Greenwood and Simmons, Am. Mus. Novit., 3846: 1, 10, figs 6B, 7. Publication date: 16 December 2015. Type locality: Tanzania: Arusha province: Olduvai Gorge: Bed I, FLK NI, Layer 3. - Etymology: Named for Olduvai Gorge, Tanzania (Gunnell *et al.*, 2015a: 10).

SIMILAR SPECIES:
The teeth of *S. olduvensis* are on average 12 % larger than those of its congeners (Gunnell *et al.*, 2015a: 10)..

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Timeframe:
Pleistocene (Brown *et al.*, 2019: Suppl.).

Genus ***Vansonia*** Roberts, 1946

1946. *Vansonia* Roberts, Ann. Transv. Mus., 20 (4): 304 [Goto Description]. - Comments: Type species: *Pipistrellus vernayi* Roberts, 1932 (=*Vespertilio rüppellii* Fischer, 1829), by original designation. Not *Vansonia* Schein, 1956 (Insecta, Coleoptera, Scarabaeidae) (see Jackson and Groves, 2015: 275). - Etymology: The name *Vansonia* refers to George van Son, entomologist of the Transvaal Museum (see Lanza *et al.*, 2015: 382). .

Vansonia rueppellii (J.B. Fischer, 1829)

1826. *Vespertilio temminckii* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 17: pl 6. Type locality: Sudan: Northern province: Dongola [19 10 N 30 27 E]. [Goto Description]. Lectotype: SMF 4308: ad ♂, skin only. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1824. Old catalog: II.N.11.b: see Mertens (1925: 22).
Lectotype of both *Vespertilio temminckii* and *V[espertilio] Rüppelii*. - Comments: Preoccupied by *temmincki* Horsfield, 1824 (a *Scotophilus*): see Allen (1939a: 95), Meester *et al.* (1986: 51), Simmons (2005). The publication date of Cretzschmar's work is sometimes indicated as "1826" (as mentioned on the title page), but also as "1827", "1828", "1830-1831".

*1829. *V[espertilio] Rüppelii* J.B. Fischer, Synopsis Mamm, 109. Publication date: 1829. Type locality: Sudan: Northern province: Dongola [19 10 N 30 27 E]. [Goto Description]. Paralectotype: RMNH MAM.35913: ad ♀, mounted skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1824. Paralectotype: RMNH MAM.35914: ad ♂, mounted skin (skull not removed). Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1824. - Comments: Mertens (1925: 22) mentions that the specimen designated as lectotype for *temminckii* is also the lectotype for *rüppellii*. - Etymology: The type (*Vespertilio temminckii*) was described in Rüppell's (1827) *Atlas zu der Reise im Nordlichen Afrika* and renamed by Fischer (1829) after Rüppell (*V. rüppellii*) (see Taylor, 2005).

Taxonomy:

Figure 344. *Vansonia rueppellii* (ECJS-126/2009) caught in the Okavango, Botswana.

Renaming of *V. temminckii* Cretzschmar, 1826 (see Allen, 1939a: 95). Mentioned in the subgenus *Vansonia* by Koopman (1994: 116). Mentioned in the subgenus *Hypsugo* inc. sedis by Pavlinov *et al.* (1995: 107).

Meester *et al.* (1986) state that Ellerman *et al.* (1953: 79) do not recognize *Vansonia*, and instead place *Pipistrellus rueppellii* in the subgenus *Scotozous*, as do later authors (Rosevear, 1965; Hayman and Hill, 1971: 41; Smithers, 1983). Corbet and Hill (1980: 68), however, retain *Scotozous* as a full genus for the Indian *S. dormeri* Dobson, 1875, and both J.E. Hill (in litt.) and K.F. Koopman (in litt.) agree that it is incorrect to use this name for *rueppellii*. *Vansonia* is therefore the prior subgeneric name for this species. Benda *et al.* (2014c: 81; 2016b: 322) place *rueppellii* in the genus *Vansonia*.

Helbig *et al.* (2010: 168) suggest that *rueppellii* needs to be transferred to a genus that needs to be newly created or resurrected from the current synonymy. Also Koubínová *et al.* (2013: 8) found evidence in the cyt *b* gene to support the transfer of *rueppellii* to a distinct genus, but they indicate that further investigations on material from the type countries of *P. rueppellii* [=Sudan] and the type locality of *P. vernayi* (the type species of *Vansonia* [Maun, Ngamiland, Botswana] are needed to confirm the relationship with *Vansonia*.

Although no material from Sudan nor Botswana was included in the cyt *b* sequence analyses performed by Monadjem *et al.* (2020a: 1122), their results indicate that *rueppellii* is quite different from the other African *Pipistrellus* species, and supports the views held by other authors (e.g., Benda *et al.*, 2014b: 51); 2014c: 81; Dietz and Kiefer, 2016: 351).

The original name was spelled as *Rüppelii*, so the present spelling should probably be *rueppelii*. However, this spelling was only found one single time in all of the literature data: as a misspelling in Koopman (1975). There are a number of earlier authors which use *rueppelli* (e.g., Anderson and de Winton, 1902). Older literature data are: Wagner (1855) as *Vespertilio (Vesperugo) rüppelli*, Kolenati (1860) as *Panugo rüppelii*, and Heuglin (1877) as *Vesperugo rüppellii*. So the earliest record we were able to find was Wagner (1855), who already used the double "ll" (and double "ii"), but still used "ü", as did Heuglin (1877). Only Kolenati (1860) used a single "l". So if we consider Wagner to be the first reviewer, the name should be spelled as "*rueppellii*" with double "ll" and double "ii" and with "ue" since diacritics are no longer allowed in scientific names.

Common Names:

Afrikaans: Rüppell se vlermuis, Rüppell-vlermuis. Arabian: Khaffash. Chinese: 吕氏伏翼. Czech: netopýr Rüppellův, netopýr dvoubarvý. Dutch: Rüppells dwergvleermuis. English: Rüppell's Bat, Ruppell's Pipistrelle, Rüppel's Pipistrelle Bat, Rüppel's Pipistrelle. French: Pipistrelle de Rueppel, Pipistrelle de Rüppell. German: Rüppells Zwergfledermaus, Rüppells Pipistrelle,

Dongola-Dämmerungsfledermaus. Hebrew: Atalfon Rippel. Italian: Pipistrèllo di Rùppell.

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
Butler and Greenwood (1965) found in the early Pleistocene at Olduvai material which they referred to as "cf *Pipistrellus* (*Scotozous*) *rueppelli* (Fischer)" (see Butler, 1978).

CONSERVATION STATUS:
Global Justification
A widespread species with no known major threats, hence is assessed as Least Concern (LC ver 3.1 (2001)) (Jacobs *et al.*, 2008a; IUCN, 2009; Monadjem *et al.*, 2017c).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as "*Pipistrellus rueppellii*" (Monadjem *et al.*, 2017c). 2008: LC ver 3.1 (2001) (Jacobs *et al.*, 2008a; IUCN, 2009). 2004: LC ver 3.1 (2001) (Jacobs *et al.*, 2004ag; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016q). 2004 - considered a vagrant not assessed, only one locality in SA (Augrabies Falls) (Friedmann and Daly, 2004). 1986: Indeterminate (Smithers, 1986).

MAJOR THREATS:
Use of pesticides against locusts is a threat (Jacobs *et al.*, 2008a; IUCN, 2009; Monadjem *et al.*, 2017c).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008a) [in IUCN (2009)] and Monadjem *et al.* (2017c) report that no specific measures are known. A study on the impacts of pesticides is required, especially ways in which the impact might be minimised.

GENERAL DISTRIBUTION:
Vansonia rueppellii has been recorded throughout Africa, with scattered records from southwest Asia. North African records include a disjunct distribution being recorded from a small part of eastern Morocco into western Algeria, Tunisia, a single record from eastern Libya (on the border with Egypt; Benda *et al.*, 2004a) and then in a broad strip in Egypt including all of the Nile River valley and delta and extending to the Red Sea (but not in the south) and the westernmost part of the Sinai. West African records are from the Senegal coast and the Senegal/Mauritania border. The largest contiguous range consists of a strip stretching from northern Sudan down to northern Zimbabwe, which at its widest point ranges from western Zambia to western Mozambique. Occurs up to 1,100 m in Morocco.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 477,914 km^2.

Bates *et al.* (2013: 339) reject the occurrence of *V. rueppellii* in the Republic of Congo as Malbrant and Maclatchy (1949) only suggested that it 'likely' occurs in that country.

Native: Algeria; Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 572); Benin; Botswana (Archer, 1977; Monadjem *et al.*, 2010d: 572); Burkina Faso; Burundi; Cameroon; Central African Republic (Benda *et al.*, 2004a: 91); Chad; Congo (The Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 572); Egypt (Sinai); Equatorial Guinea; Ethiopia; Gabon; Gambia; Ghana; Guinea; Guinea-Bissau; Iraq; Israel; Kenya; Liberia; Libyan Arab Jamahiriya (Benda *et al.*, 2004a: 91); Madagascar (Goodman *et al.*, 2022: 1898); Malawi (Ansell and Dowsett, 1988: 40; Happold *et al.*, 1988; Monadjem *et al.*, 2010d: 572); Mali; Mauritania (Padial and Ibáñez, 2005: 240); Morocco (Benda *et al.*, 2004d; 2010a; El Ibrahimi and Rguibi Idrissi, 2015: 362; Dbiba *et al.*, 2025: 7); Mozambique; Namibia (Monadjem *et al.*, 2010d: 572); Nigeria (Benda *et al.*, 2004a: 91); Rwanda; Senegal; Sierra Leone; Somalia; South Africa (Monadjem *et al.*, 2010d: 572); Sudan; Tanzania (including Unguja [O'Brien, 2011: 290]); Togo; Tunisia; Uganda (Kityo and Kerbis, 1996: 62); Yemen; Zambia (Monadjem *et al.*, 2010d: 572); Zimbabwe (Monadjem *et al.*, 2010d: 572).

Presence uncertain: Kuwait.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987) and Kearney *et al.* (2002).

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 6.8 Pa, aspect ratio 6.3 for a wingspan of 25 cm and a wing area of 101 cm^2 and a body mass of 7 g.

ECHOLOCATION:
See Jacobs (1996), Taylor (1999b) and Taylor *et al.* (2005).

Disca *et al.* (2014: 226) indicate that the type of call is FM-QFC. They also provide two different sets of parameters: A - long) F_{start}: 93.0 ± 8.9 kHz,

F_{end}: 51.7 ± 0.7 kHz, F_{peak}: 53.6 ± 1.3 kHz, bandwidth: 41.3 ± 8.6 kHz, duration: 6.1 ± 1.2 ms; B - short) F_{start}: 68.2 ± 6.1 kHz, F_{end}: 52.8 ± 1.7 kHz, F_{peak}: 55.8 ± 2.0 kHz, bandwidth: 15.4 ± 6.7 kHz, duration: 2.4 ± 0.5 ms. The "B" type has not been reported from *Pipistrellus* before, and the peak frequencies of both types differ from those observed in Kenya (37.3 ± 0.8 kHz) and Zimbabwe (45 kHz).

84 calls from Israeli bats were reported by Hackett *et al.* (2016: 223): F_{start}: 62.24 ± 3.75 (55.5 - 72.0) kHz, F_{end}: 51.94 ± 0.88 (50.0 - 54.7) kHz, F_{peak}: 52.19 ± 0.97 (50.0 - 55.0) kHz, pulse duration: 4.22 ± 0.39 ms.

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats): F_{peak}: 52.19 kHz, F_{start}: 62.24 kHz, F_{end}: 51.94 kHz, Band width: 10.3 kHz, and duration: 4.22 ms.

In Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 8 calls: Interpulse interval: 80.8 ± 36.7 (55.5 - 168.9) ms; F_{max}: 49.9 ± 2.2 (46.5 - 53.7) kHz; Start slope: -23.1 ± 4.0 (-19.0 - -28.2) kHz/ms; End slope: -7.4 ± 5.1 (-10.7 - 0.4) kHz/ms; Ledge duration: 0.5 ± 0.1 (0.4 - 0.5) ms. They also indicate that the F_{max} value is 10 kHz higher than the one reported by Monadjem *et al.* (2020f, and that the interpulse interval is much lower than the value reported by Kearney *et al.* (2010): 80.8 ms versus 131.7 ms.

Molecular Biology:

Karyotype

Rautenbach *et al.* (1993) reported 2*n* = 36, FN = 54, BA = 20, a submetacentric X chromosome, and an acrocentric Y chromosome, for specimens from South Africa.

Protein / allozyme

Based on the analysis of eight mitochondrial and nuclear genes, Koubínová (2013: 7) found that "*P. rueppellii*" was basal to the whole *Pipistrellus* / *Nyctalus* clade, and possibly might be placed in a genus of its own.

Genetics

See Mayer *et al.* (2007).

Habitat:

In southern Africa, this species occurs primarily in Savanna (82 %) and Afromontane (11 %) habitats (Cooper-Bohannon *et al.*, 2016: Table S2).

In Madagascar, it is found in disturbed marshland dominated by *Bismarckia* palms.

Diet:

Benda *et al.* (2014c: 86) analysed the content of the digestive tract of the single specimen they captured and found it contained 50 % by the volume of brachyceran Diptera, 30% of Lepidoptera and 20% of nematoceran Diptera.

Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 74 minutes, and the digestibility rate about 80.4 %.

Predators:

Mikula *et al.* (2016: Supplemental data) mention the Bat hawk (*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

Population:

Structure and Density

Unknown, because it is primarily known only from mist net captures (Jacobs *et al.*, 2008a; IUCN, 2009; Monadjem *et al.*, 2017c).

Trend

2016: Unknown (Monadjem *et al.*, 2017c). 2008: Unknown (Jacobs *et al.*, 2008a; IUCN, 2009).

Reproduction and ontogeny:

Happold and Happold (1990b: 567) mention juveniles in November and December in western Zambia, and very young subadults in late December in Malawi.

Garbino *et al.* (2021: Suppl.) mention that this species has more than one young per litter.

Parasites:

SIPHONAPTERA

Ischnopsyllidae

Ischnopsyllus emminus Jordan and Rothschild, 1921 was reported from Malawi by Beaucournu and Kock (1996).

IXOIDIDA

Hornok *et al.* (2017b: 3) collected a larva of *Argas vespertilionis* (Latreille, 1796) from a *P.* cf. *rueppellii* from South Horr, Kenya. Hornok *et al.* (2019: 2) probably refer to the same bat and tick and mentioned that the tick itself was infected by *Rickettsia* sp. Bacteria.

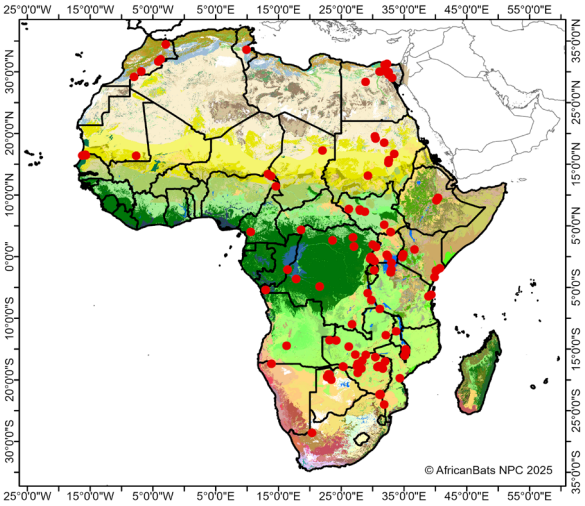

Figure 345. Distribution of *Vansonia rueppellii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Botswana, Cameroon, Central African Republic, Chad, Congo (Democratic Republic of the), Egypt, Ethiopia, Kenya, Malawi, Mauritania, Morocco, Mozambique, Namibia, Nigeria, Rwanda, Senegal, South Africa, South Sudan, Sudan, Tanzania, Togo, Tunisia, Uganda, Zambia, Zimbabwe.

Vansonia rueppellii fuscipes (Thomas, 1913)

*1913. *Pipistrellus fuscipes* Thomas, Ann. Mag. nat. Hist., ser 8, 11 (63): 315. Publication date: 1 March 1913. Type locality: Uganda: Entebbe, 60 mi (90 km) W [00 04 N 32 20 E, 3 700 ft]. [Goto Description]. Holotype: NHMUK 1906.7.1.5: ad ♂, skin and cranium only (no mandibula). Collected by: R.E. Dent and The Ruwenzori Expedition; collection date: 29 November 1905; original number: 1. See Thomas (1913b: 315).
1939. *Pipistrellus rüppellii fuscipes:* G.M. Allen, Bull. Mus. comp. Zool., 83: 96. (Name Combination).
1951. *Pipistrellus (Scotozous) ruppellii fuscipes:* Swynnerton and Hayman, J. East Afr. Nat. Hist. Soc., 20 (6-7) (90): 293 (for 1950). (Name Combination).
1960. *Pipistrellus ruppelli fuscipes:* Harrison, J. East Afr. Nat. Hist. Soc., 23 (7)(104): 294. Publication date: December 1860. (Name Combination, Alternate Spelling).
1966. *Pipistrellus (Scotozous) rüppelli fuscipes:* Hayman, Misonne and Verheyen, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., (8) 154: 55. (Name Combination).
1975. *P[ipistrellus] r[ueppelli] fuscipes:* Koopman, Bull. Am. Mus. Nat. Hist., 154 (4): 404. (Name Combination).
1984. *Pipistrellus (Scotozous) rueppelli fuscipes:* Anciaux de Faveaux, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch. (Name Combination).
1994. *P[ipistrellus (Vansonia)] r[ueppelli] fuscipes:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 116. (Name Combination).
? *Pipistrellus (Pipistrellus) rueppellii fuscipes:* (Name Combination).
? *Pipistrellus (Vansonia) rueppellii fuscipes:* (Name Combination).
? *Pipistrellus rueppellii fuscipes:* (Name Combination).
? *Vansonia rueppellii fuscipes:* (Current Combination).

GENERAL DISTRIBUTION:
Ethiopia to northern Angola.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
South Sudan, Tanzania, Uganda.

Vansonia rueppellii pulcher (Dobson, 1875)

*1875. *Vesperugo pulcher* Dobson, Proc. zool. Soc. Lond., 1875, III: 471. Publication date: October 1875. Type locality: Tanzania: Zanzibar [ca. 06 10 S 39 12 E]. [Goto Description]. Holotype: NHMUK 1868.12.22.3: ad ♂, alcoholic (skull not removed). Presented/Donated by: Dr. Kirk.
1878. *Vesperugo (Vesperugo) pulcher:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 233. Publication date: 15 June 1878. (Name Combination).
1902. *P[ipistrellus] pulcher:* Anderson and de Winton, Zoology of Egypt: Mammalia, 129. (Name Combination).
1910. *Pipistrellus pulcher:* Thomas and Wroughton, Trans. Linn. Soc. Lond., 19 (5) (63): 489. (Name Combination).
1984. *Pipistrellus (Scotozous) rueppelli pulcher:* Anciaux de Faveaux, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch. (Name Combination).
1994. *P[ipistrellus (Vansonia)] r[ueppelli] pulcher:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 116. (Name Combination).
? *Pipistrellus (Pipistrellus) rueppellii pulcher:* (Name Combination).
? *Pipistrellus rueppellii pulcher:* (Name Combination).
? *Vansonia rueppellii pulcher:* (Current Combination).

GENERAL DISTRIBUTION:
Northeastern Tanzania and Zanzibar.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Tanzania.

Vansonia rueppellii rueppellii (J.B. Fischer, 1829)

1827. *Vespertilio temminckii* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 17: pl 6. Type locality: Sudan: Northern province: Dongola [19 10 N 30 27 E]. Lectotype: SMF 4308: ad ♂, skin only. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1824. Old catalog: II.N.11.b: see Mertens (1925: 22).
Lectotype of both *Vespertilio temminckii* and *V[espertilio] Rüppelii*. - Comments: Preoccupied by *temmincki* Horsfield, 1824 (a *Scotophilus*): see Allen (1939a: 95), Meester *et al.* (1986: 51), Simmons (2005). The publication date of Cretzschmar's work is sometimes indicated as "1826" (as mentioned on the title page), but also as "1827", "1828", "1830-1831".
*1829. *Vespertilio ruppellii* J.B. Fischer, Synopsis Mamm, 109. Publication date: 1829. Type locality: Sudan: Northern province: Dongola [19 10 N 30 27 E].
1866. *Vesperugo hypoleucus* Heuglin and Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 54 (1) 10: 546. Publication date: 1866. Type locality: Sudan: between Kéréri, Halfaye & Surerát on the Nile: Sennaar, near Khartoum, [ca. 15 35 N 33 38 E]. [Goto Description]. Holotype: NMW 24574: ad, skin and skull. Collection date: August 1853. - Comments: Meester *et al.* (1986: 51) assigned it to Fitzinger only.
1866. *Vesperugo sennaariensis* Heuglin and Fitzinger, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 54 (1) 10: 546. Publication date: 1866. Type locality: Sudan: Khartoum [15 40 N 32 35 E, 380 m]. [Goto Description]. - Comments: Nomen nudum (see Allen, 1939a: 95; Meester *et al.*, 1986: 51).
1877. *Vesperugo senarensis* Heuglin, Reise in Nordost Afrika, 2: 32. Publication date: 1877 [Goto Description]. - Comments: Nomen nudum (see Allen, 1939a: 95; Meester *et al.*, 1986: 51).
1939. *Pipistrellus rüppellii rüppellii:* G.M. Allen, Bull. Mus. comp. Zool., 83: 95. (Name Combination).
1955. *Pipistrellus ruppelli ruppelli:* Sanborn and Hoogstraal, J. Egypt. Publ. Health Ass., 30 (4): xxx.
1958. *Pipistrellus (Scotozous) rueppelli rueppeli:* Anciaux de Faveaux, Bull. IFAN, (A) 20 (1): 273. (Name Combination, Alternate Spelling).
1962. *Pipistrellus ruppelii ruppelii:* Heyneman and Macy, J. Egypt. Publ. Health Ass., 37 (4): 123. (Alternate Spelling).
1964. *Scotozous r[üppelli] rüppelli:* Niethammer, Alexander Koenigs Reisen am Nil, 72. (Name Combination).
1966. *Pipistrellus (Scotozous) rüppelli rüppelli:* Ellerman and Morrison-Scott, Checklist of Palaearctic and Indian Mammals 1758 to 1946. (Second Edition), 172. (Name Combination).
1974. *Pipistrellus rueppelli rueppelli:* Largen, Kock and Yalden, Mon. Zool. ital., (NS) 16 (Suppl 5): 222, 245.
1978. *Pipistrellus rüppelli rüppelli:* Madkour, Zool. Anz., 201 (5/6): 387. (Alternate Spelling).
1983. *P[ipistrellus (Vansonia)] r[ueppellii] rueppellii:* Smithers, Mammals Southern African subreg, 97. (Name Combination).
1984. *Pipistrellus rueppellii rueppellii:* Rautenbach, Schlitter and Braack, Koedoe, 27: ???. (Name Combination).
1988. *Pipistrellus (Pipistrellus) rueppellii rueppellii:* Ansell and Dowsett, Mammals of Malawi, 39. (Name Combination).
1994. *P[ipistrellus (Vansonia)] r[ueppelli] rueppelli:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 116. (Alternate Spelling).
2014. *V[ansonia] r[ueppellii] rueppellii:* Benda, Spitzenberger, Hanák, Andreas, Reiter, Ševčík, Šmíd and Uhrin, Acta Soc. Zool. Bohem., 78: 85. Publication date: 22 December 2014. (Current Combination).

MAJOR THREATS:
Sherwin *et al.* (2012: 174) consider water stress and the aerial hawking feeding style to be risk factors related with climatic change.

GENERAL DISTRIBUTION:
Egypt to Nigeria and Central Sudan.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Egypt, Ethiopia, South Sudan, Sudan, Tanzania.

Vansonia rueppellii senegalensis (Dorst, 1960)

*1960. *Pipistrellus Rüppelli senegalensis* Dorst, Bull. Mus. natn. Hist. nat., Paris, sér 2, 31: 473 (for 1959). Type locality: Senegal: Richard Toll [16 48 N 15 42 W]. [Goto Description]. Holotype: MNHN ZM-MO-1960-81: ad ♀, skull and alcoholic. Collected by: Francis Roux; collection date: September 1958.
1965. *Pipistrellus (Scotozous) rueppelli senegalensis:* Rosevear, Bats of West Africa, 272. (Name Combination).
1972. *P[ipistrellus] ruepelli senegalensis:* Adam and Hubert, Mammalia, 36 (1): 59. (Lapsus).
1972. *Pipistrellus rueppeli senegalensis:* Adam and Hubert, Mammalia, 36 (1): 64. (Name Combination).
1972. *Pipistrellus rueppelli senegalis:* Adam and Hubert, Mammalia, 36 (1): 59. (Lapsus).
1982. *Pipistrellus ruppelli senegalensis:* Verschuren, Mém. IFAN, 92: 307. (Alternate Spelling).
1994. *P[ipistrellus (Vansonia)] r[ueppelli] senegalensis:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 116. (Name Combination).
1998. *P[ipistrellus (Pipistrellus)] r[ueppellii] senegalensis:* Grubb, Jones, Davies, Edberg, Starin and Hill, Mammals of Ghana, Sierra Leone and The Gambia, 84.
2014. *V[ansonia] r[ueppellii] senegalensis:* Benda, Spitzenberger, Hanák, Andreas, Reiter, Ševčík, Šmíd and Uhrin, Acta Soc. Zool. Bohem., 78: 85. Publication date: 22 December 2014. (Current Combination).
? *Pipistrellus (Pipistrellus) rueppellii senegalensis:* (Name Combination).
? *Pipistrellus rueppellii senegalensis:* (Name Combination).

GENERAL DISTRIBUTION:
Algeria to Senegal.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Senegal.

Vansonia rueppellii vernayi (Roberts, 1932)

*1932. *Pipistrellus vernayi* Roberts, Ann. Transv. Mus., 15 (1): 16. Publication date: 1 October 1932. Type locality: Botswana: Ngamiland: Maun [19 59 S 23 25 E]. [Goto Description]. Holotype: TM 6546: ad ♂. Collected by: The Vernay-Lang Kalahari Expedition 1930; collection date: 29 May 1930; original number: 648.
1933. *Pipistrellus leucomelas* Monard, Bull. Soc. Neuchât. Sci. nat., 57: 47 (for 1932?). Publication date: 1933. Type locality: Angola: South-Central Angola: Vila da Ponte [14 25 S 16 15 E].
1939. *Pipistrellus rüppellii vernayi:* G.M. Allen, Bull. Mus. comp. Zool., 83: 96. (Name Combination).
1946. *[Vansonia] vernayi:* Roberts, Ann. Transv. Mus., 20 (4): 304. (Name Combination).
1951. *Vansonia vernayi:* Roberts, Mammals of South Africa, 82. (Name Combination).
1953. *Pipistrellus (Scotozous) rueppelli vernayi:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 78. (Name Combination).
1978. *Pipistrellus rueppelli vernayi:* Ansell, Mammals of Zambia, 24. (Name Combination).
1983. *P[ipistrellus (Scotozous)] r[ueppellii] vernayi:* Smithers, Mammals Southern African subreg, 97. (Name Combination).
1984. *Pipistrellus (Scotozous) rueppelli leucomelas:* Anciaux de Faveaux, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., 244: 49.
1986. *Pipistrellus (Vansonia) rueppellii vernayi:* Meester, Rautenbach, Dippenaar and Baker, Transv. Mus. Monogr., 5: 51. (Name Combination).
1994. *P[ipistrellus (Vansonia)] r[ueppelli] leucomelas:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 116.
? *Pipistrellus (Pipistrellus) rueppellii vernayi:* (Name Combination).
? *Pipistrellus (Vansonia) rueppellii leucomelas:*
? *Pipistrellus rueppellii leucomelas:* (Name Combination).
? *Pipistrellus rueppellii vernayi:* (Current Spelling).
? *Vansonia rueppellii vernayi:* (Current Combination).

TAXONOMY:
If *vernayi* and *leucomelas* indeed represent the same form, then it might become important to check the actual publication date of *leucomelas*. This name was published in the 1932 issue of the "Bulletin de la Société Neuchâteloise de Sciences Naturelles", but the issue seemed to have appeared in 1933. Otherwise, this name might have priority over *Pipistrellus vernayi* which was published on 1 October 1932.

At present, we synonymize both names and consider *vernayi* to be the oldest name.

Kock (1969a: 174) points out that *leucomelas* might be a homonym of *Vespertilio leucomela* Cretzschmar, 1830.

GENERAL DISTRIBUTION:
Malawi to Transvaal and Southern Angola.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Botswana, South Africa, Zambia.

TRIBE Plecotini J. E. Gray, 1866

*1866. *Plecotini* J. E. Gray, Ann. Mag. nat. Hist., ser 3, 17 (98): 90. Publication date: 1 February 1866.
1897. *Plecotinæ* Miller, N. Am. Fauna, 13: 41, 46. Publication date: 16 October 1897. - Comments: Type genus: *Plecotus* E. Geoffroy, 1818. Originally included the genera *Euderma* H. Allen, 1891 and *Plecotus* E. Geoffroy, 1818 (see Jackson and Groves, 2015: 270).
2025. *Plectoini:* Guan, Huang, Huang, Zhou, Yang, Yu, Guo, Feng, Wu, Hu and Wei, Sci. China Life Sci., xxx: 3. Publication date: 18 July 2025. (Lapsus).

Genus ***Barbastella*** J. E. Gray, 1821

*1821. *Barbastella* J. E. Gray, London Med. Repos., 15 (1): 300. Publication date: 1 April 1821. - Comments: Type species: *Vespertilio barbastellus* Schreber, 1774. - Etymology: From Latin "*barba*" meaning bearded and "*stella*" meaning star (see Rydell and Bogdanowicz, 1997: 5). (Current Combination).
1825. *Barbastellus* J. E. Gray, Ann. Philos., 10 (5): 243. Publication date: November 1825. (Alternate Spelling).
1839. *Synotus* Keyserling and Blasius, Arch. Naturgesch. Berlin, 5 (1): 305. Publication date: 1839. - Comments: Type species: *Vespertilio barbastellus* Schreber, 1774. - Etymology: From the Greek "*σύν*", meaning together and "*οὖς*" or "*ὠτός*", meaning ear (see Palmer, 1904: 657).

TAXONOMY:
See Simmons (2005), Kruskop *et al.* (2019).

Currently (Simmons and Cirranello, 2024a) recognized species of the genus *Barbastella*: ***barbastellus*** (Schreber, 1774); *beijingensis* Zhang, Han, Jones, Lin, Zhang, Zhu, Huang and Zhang, 2007 – China; *caspica* Satunin, 1908 – Caucasus, Transcaucasia; *darjelingensis* Hodgson, 1855 – Afghanistan, Iran; India, Nepal, and W China, Japan, perhaps Indo-China (Laos, Vietnam), Taiwan; ***leucomelas*** (Cretzschmar, 1826); *pacifica* Kruskop, Kawai and Tiunov, 2019 – Japan.

COMMON NAMES:
Czech: ďasíci, strostlouchové, saukušanové, širokouší ušanové, netopýři širokouší. English: Barbastelle Bats, Barbastelles. French: Barbastelles. German: Mopsfledermäuse. Широковух (= Shyrokovukh).

Barbastella barbastellus (Schreber, 1774)

*1774.	*Vespertilio barbastellus* Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, 1 (8): pl 55 + 1 (9): 168. Publication date: 1774. Type locality: France: Burgundy. - Etymology: From Latin "*barba*" meaning bearded and "*stella*" meaning star (see Rydell and Bogdanowicz, 1997: 5).
1838.	*Barbastellus communis* J. E. Gray, Mag. Zool. Bot., Edinburgh, 2 (12): 495. Publication date: 1 February 1838. Type locality: : Burgundy and Germany. - Comments: Renaming of *V. barbastellus* Schreber, 1774.
1985.	*Vespertilio barbestellus:* Qumsiyeh, Spec. Publ. Mus. Texas Tech. Univ., 23: 63. (Lapsus).
2002.	*Barbastella barbastellus guanchae* Trujillo, Ibáñez and Juste, Rev. suisse Zool., 109 (3): 544, , figs 1- 2. Publication date: September 2002. Type locality: Canary Islands (Spain): Tenerife island: La Guancha: "Barranco de La Cantera". [Goto Description]. Holotype: MNH 109: ad ♂. Collected by: Domingo Trujillo; collection date: 1 September 1987. Paratype: EBD 16024M: Collected by: Domingo Trujillo, Carlos J. Ibáñez Uargui and E. Barone; collection date: 15 - 20 September 1987. Agulo, La Gomera Island. Paratype: EBD 16028M: Collected by: Domingo Trujillo, Carlos J. Ibáñez Uargui and E. Barone; collection date: 15 - 20 September 1987. Agulo, La Gomera Island. Paratype: MNH 110: Collected by: Domingo Trujillo, Carlos J. Ibáñez Uargui and E. Barone; collection date: 15 - 20 September 1987. Agulo, La Gomera island. Paratype: MNH 111: Collected by: Domingo Trujillo, Carlos J. Ibáñez Uargui and E. Barone; collection date: 15 - 20 September 1987. Agulo, La Gomera island. - Comments: MNH = Museo de La Naturaleza e El Hombre, Santa Cruz de Tenerife, Spain. Trujillo *et al.* (2002) mention 4 paratypes, EBD 16024M, 16028M, MNH 111, 110; 3 ♀♀ + 1 ♂ from Agulo, La Gomera Island, collector Domingo Trujillo, Carlos Ibáñez & E. Barone, 15-20 September 1987). (Name Combination).
?	*Barbastella barbastellus:* (Current Combination).

TAXONOMY:
Does not include *leucomelas*, see Rydell and Bogdanowicz (1997: 1, Mammalian Species, 557); but see Qumsiyeh (1985) and Horáček *et al.* (2000: 133), although the latter authors still consider *leucomelas* to be a valid species.

The population from the Canary Islands is at present regarded as an endemic subspecies *B. b. guanchae* (Trujillo *et al.*, 2002). Western Mediterranean and Canary Island forms reviewed by Juste *et al.* (2003).

COMMON NAMES:
Albanian: Barbastela e zakonshme. Armenian: Եվրոպական լայնականջ չղջիկ. Azerbaijani: Avropa enliqulağı. Basque: Baso-saguzar, Baso-saguzar arrunt. Belarusian: Шыракавух еўрапейскі. CONSERVATION STATUS:

Global Justification

Although this species has a large range, it is generally rare, occurring in low density and numbers. It is mainly sedentary. The population is fragmented and linked to particular kinds of old forest habitats, which are declining. The species does not easily colonise new areas. Declines are widely reported in most of its range with a few exceptions in recent years. The status of this species is linked to forestry practices and the decline in the number of old trees (one colony may use up to 30 old trees with holes each summer season). Has specific habitat and diet requirements (Hutson *et al.*, 2008b; IUCN, 2009). Listed as Near Threatened (approaching A4c), as it is suspected that population declines will approach 30% over a 15 year period including both the past and the future (Hutson *et al.*, 2008b; IUCN, 2009; Piraccini, 2016c).

Assessment History

Global

2016: NT ver 3.1 (2001) (Piraccini, 2016c). 2008: NT ver 3.1 (2001) (Hutson *et al.*, 2008b; IUCN, 2009). 1996: VU A2c ver 2.3 (1994).

Legal Status

It is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention where these apply. It is included in Annex II (and IV) of EU Habitats and Species Directive, and hence requires special measures for conservation including designation of Special Areas for Conservation. Some habitat protection through Natura 2000.

MAJOR THREATS:

Loss of old mature woodland and ancient trees with loose bark or wood crevices (reforested areas are not suitable for this species); disturbance and loss of underground habitats, disturbance and loss of roost sites in older buildings (Hutson *et al.*, 2008b; IUCN, 2009). In Germany, habitat loss and fragmentation (caused by inter alia infrastructure development, forestry, and the renovation or demolition of old buildings used as roost sites), and disturbance (e.g., from cave tourism) are major threats (Schulenberg, 2005); accidental mortality (roadkill) is also a problem (Rudolph *et al.*, 2003).

CONSERVATION ACTIONS:

Hutson *et al.* (2008b) [in IUCN (2009)] indicate that research is underway to establish conservation requirements for this species. Recommendations include adopting forestry practices that maintain old trees in sufficient numbers.

GENERAL DISTRIBUTION:

Barbastella barbastellus is largely restricted to central and southern Europe, although its range extends into the Caucasus, Anatolia, Morocco (North Africa) and the Canary Islands (La Gomera and Tenerife only). It has recently been recorded from Iran on the Arabian Peninsula. It occurs to 1,800 m in the Alps (Spitzenberger, 2002), 1,900 m in the Caucasus and 2,260 m in the Pyrenees (Mitchell-Jones *et al.*, 1999).

Native: Andorra; Armenia; Austria; Azerbaijan; Belarus; Bosnia and Herzegovina; Bulgaria; Croatia; Czech Republic; Denmark; France; Georgia; Germany; Greece; Holy See [Vatican City State]; Hungary; Iran (Benda *et al.*, 2008b) [in Karami *et al.*, 2009: 69]); Ireland; Italy (Sardinia, Sicily); Latvia; Liechtenstein; Lithuania; Luxembourg; Macedonia, the former Yugoslav Republic of; Moldova; Monaco; Montenegro; Morocco (Benda *et al.*, 2010a: 158; Rebelo *et al.*, 2012: 2763; El Ibrahimi and Rguibi Idrissi, 2015: 364; Dbiba *et al.*, 2025: 7); Netherlands; Poland; Portugal; Romania; Russian Federation; San Marino; Serbia; Slovakia; Slovenia; Spain [Baleares, Canary Is.]; Sweden; Switzerland; Ukraine; United Kingdom.

Presence uncertain: Norway; Senegal; Turkey.

FUNCTIONAL MORPHOLOGY:

Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 9.1 Pa, aspect ratio 6.0 and tip shape index of 2.33 for a wingspan of 26 cm and a wing area of 111 cm^2 and a body mass of 10 g.

ECHOLOCATION:

Walters *et al.* (2012: suppl.) report the following figures for 28 calls from bats from France, Slovenia, Switzerland and the UK: duration: 3.57 ± 1.84 ms, F_{max}: 43.23 ± 8.31 kHz, F_{min}: 28.87 ± 3.18 kHz, bandwidth: 14.36 ± 8.29 kHz, F_{peak}: 35.48 ± 4.32 kHz.

Barataud (2011: 95) indicates that Barbastelles alter their echolocation signals to mislead their prey, which primilary consists of tympanic moths. He reports (p. 96) two sets of data from France: A) F_{start}: 37.5 ± 1.8 kHz, F_{end}: 27.6 ± 1.1 kHz, F_{peak}: 34.5 ± 1.5 kHz, bandwidth: 9.8 ± 2.0 kHz, duration: 3.2 ± 0.9 ms, interpulse interval: 82.6 ±

40.2 ms (based on 18 calls); B) F_{start}: 45.5 ± 2.1 kHz, F_{end}: 34.2 ± 4.0 kHz, F_{peak}: 43.1 ± 2.3 kHz, bandwidth: 11.3 ± 3.8 kHz, duration: 5.9 ± 2.5 ms, interpulse interval: 58.5 ± 8.4 ms (based on 17 calls). These calls are alternately emitted. The interval between type A and type B calls was 58.5 ± 8.4 ms, and between type B and type A 82.6 ± 40.2 ms.

Luo *et al.* (2019a: Supp.) reported the following data (from two calls): F_{peak}: 38.9, 33.2 kHz, F_{start}: 43.9, 39.4 kHz, F_{end}: 28.9, 28 kHz, Band width: 15, 11.4 kHz, and duration: 4.3, 3.4 ms.

Molecular Biology:

Karyotype

Capanna (1968: 624) reported 2*n* = 32. Rushton (1970: 463) reported 2 *n* = 32, FN = 50, X = metacentric, Y = minute. Arslan and Zima (2014: 14) mention 2*n* = 32, FNa = 50, FN = 54, a metacentric X and an acrocentric Y.

Genetics

See García-Mudarra *et al.* (2009).

Roost:

In Hungary, Görföl *et al.* (2018: 184) found that *B. barbastellus* almost always roosted behind loose bark of native tree species (oak, maple and elm), and frequently switched roosts. The roosts were generally found in dead trees or in dead branches of old trees.

Migration:

Movements up to 290 km in Austria (Kepka, 1960).

Diet:

Andreas *et al.* (2012: 81) indicate that, in the Czech Republic, this bat's main food source are larger species of moths. At the end of Autumn (November) the bats switched to smaller preys (e.g., *Operophtera brumata*, wingspan <= 30 mm) as the larger species were no longer flying around. These findings confirmed that *B. barbastellus* is primarily an aerial hawking species.

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 79 minutes, and the digestibility rate about 79.7 %.

Population:

Structure

See Piraccini (2016c) and Hutson *et al.* (2008b) and IUCN (2009) for information on European populations.

Density

See Piraccini (2016c) and Hutson *et al.* (2008b) and IUCN (2009) for information on European populations.

Trend

2016: Decreasing (Piraccini, 2016c). 2008: Decreasing (Hutson *et al.*, 2008b; IUCN, 2009). In Africa, population size and trends are unknown (Hutson *et al.*, 2008b; IUCN, 2009; Piraccini, 2016c).

Viruses:

Despite sampling and testing of 35 individuals of this species, no evidence of influenza A-like viruses (Orthomyxoviridae) were obtained (Fereidouni *et al.*, 2015).

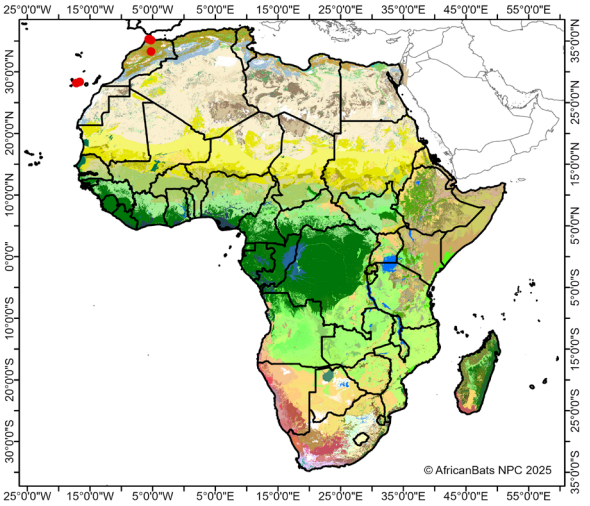

Figure 346. Distribution of *Barbastella barbastellus*.

Distribution based on voucher specimens:

Canary Islands (Spain), Morocco.

Barbastella leucomelas (Cretzschmar, 1826)

*1826. *Vespertilio leucomelas* Cretzschmar, in: Rüppell, Atlas Reise Nördlichen Afrika, Zoologie Säugethiere, 1: 73, pl 28b [Goto Description]. Lectotype: SMF 4373: mounted skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1860; original number: II.M.1.a. See Mertens (1925: 21). Paralectotype: RMNH MAM.35738: ad, mounted skin and skull. Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1826. Paralectotype: RMNH MAM.35739: ad, mounted skin (skull not removed). Collected by: Wilhem Peter Edward Simon Rüppell; collection date: 1826. - Comments: For an extensive discussion on the type locality see Benda *et al.* (2008f: 50 - 54), who conclude: "From the Rüppell's (1829) descriptions and according to his traveling schedule, it is fully clear, that in his concept the 'Arabia Petraea' represent 'the area of the Sinaitic peninsula to the south of the connecting line between the towns of Suez and Aqaba', as pointed out above, see also Fig. 52. Since it seems to be appropriate to consider localities given by Cretzschmar to be in

accordance with those given by the collector, with the above 'area' is most convenient to associate the type locality of the species Vespertilio leucomelas Cretzschmar, 1830 = Barbastella leucomelas (Cretzschmar, 1830). In this area the type series lectotype: SMF II.M.1.a = SMF 4343; paralectotype: SMF II.M.1.b = SMF 12393; Mertens (1925), Kock (1969a) was collected in 1822 and/or 1826."
Benda and Mlíkovský (2008: 36) mention "Several authors believed that the name *Vespertilio leucomelas* was published in 1826, i.e. in the year when "Rüppell's Atlas" (see Cretzschmar, 1826) begun to be issued. According to Mertens (1925: 19), the sheets 18-19 associated with Tables 27-30 of Cretzschmar (1826-1830), containing also the description of *V. leucomelas* (sheet 18 and Table 28, respectively), were published in 1830 (see also Kock, 1969a, Corbet and Hill, 1992, Bates and Harrison, 1997, and/or Rydell and Bogdanowicz, 1997).". - Etymology: From the Greek "leucos" and "melas".

? *Barbastella barbastellus leucomelas:* (Name Combination).

? *Barbastella leucomelas:* (Current Combination).

TAXONOMY:

Included in *barbastellus* by Kock (1969a: 176). Horáček *et al.* (2000: 133 - 134) indicate that western *leucomelas* might be conspecific with *barbastellus*, but retain it as a valid species. If both are conspecific, the correct name for the eastern Barbastelle would be *Barbastella darjelingensis* Hodgson, in Horsfield, 1855. Zhang (2007: 1393) indicate that *leucomelas* from Sichuan, Taiwan, and Japan is different from the Egyptian one, and should therefore not be considered conspecific with *darjelingensis*.

.

Benda *et al.* (2008f: 49) confirmed that *leucomelas* represents a separate species.

COMMON NAMES:

Arabian: Khaffash. Czech: ďasík arabský (netopýr skalní). Dutch: Arabische mopsvleermuis. English: Eastern Barbastelle, Eastern Barbastelle Bat, Arabian barbastelle, Sinai Barbestelle, Asiatic Barbastelle, Asian Barbastelle. French: Barbastelle orientale. German: Östliche Mopsfledermaus. Hebrew: בלומף שחור, Blumaf Shahor. Russian: Азиатская широкоушка [= Aeiatskaya shirokouchka].

CONSERVATION STATUS:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)), although it seems to be rare, it is very widespread and is unlikely to be declining fast enough to qualify for listing in a more threatened category (Benda *et al.*, 2008b; IUCN, 2009; Monadjem *et al.*, 2017cz).

Assessment History

Global

2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017cz). 2008: LC ver 3.1 (2001) (Benda *et al.*, 2008b; IUCN, 2009). 1996: Lower Risk/least concern.

Regional

None known.

Legal Status

It is included in Eurobats (Bonn Convention) and so should be protected in party range states (e.g., Georgia).

MAJOR THREATS:

More information is needed regarding threats to this species throughout its range. In South Asia (India, Nepal, and Pakistan) deforestation has decreased the area and quality of the species' habitat. Activities associated with war may be a threat to this species in all parts of its western Palaearctic range (damage and disturbance to caves and old buildings, disruption to habitat) (Benda *et al.*, 2008b; IUCN, 2009; Monadjem *et al.*, 2017cz).

CONSERVATION ACTIONS:

Further surveys and monitoring are needed for this species to determine the current population status, range and major threats (Benda *et al.*, 2008b; IUCN, 2009; Monadjem *et al.*, 2017cz).
It probably occurs in several protected areas throughout its range (Benda *et al.*, 2008b; IUCN, 2009; Monadjem *et al.*, 2017cz).

GENERAL DISTRIBUTION:

Barbastella leucomelas was considered to be a very widespread species, with a distribution reaching from the Caucasus eastwards to Iran, Afghanistan and India, and onwards to China and Japan. These populations were, however, reassigned to *B. darjelingensis*. In the western part of the distribution area, there were isolated populations known from Sinai (Egypt) and the southern tip of Israel, as well as Eritrea in North Africa (Benda *et al.*, 2008b). It occurs up to 2,500 m asl.

Native: Eritrea, Egypt (Sinai); Israel, Jordan (Benda *et al.*, 2010b: 185; Kruskop *et al.*, 2019: 463), and Saudi Arabia.

ECHOLOCATION:

In Jordan, Benda *et al.* (2010b: 204) recorded three different types of calls, which they called A, A2, and B. These calls had the following parameters: A: Start frequency: 37.1 ± 1.3 (34.9 - 40.3) kHz, End frequency: 29.2 ± 1.1 (27.7 - 31.8)

kHz, Peak frequency: 33.8 ± 1.0 (32.7 - 36.0) kHz, Pulse duration: 2.9 ± 0.4 (1.9 - 3.5) ms, and Inter-pulse duration: 76.8 ± 39.3 (50.5 - 146.0) ms. A2: Inter-pulse duration: 125.8 ± 30.5 (94.0 - 201.0) ms. B: Start frequency: 44.1 ± 0.5 (43.0 - 45.0) kHz, End frequency: 34.3 ± 2.9 (29.8 - 38.5) kHz, Peak frequency: 42.7 ± 1.3 (40.0 - 44.2) kHz, Pulse duration: 13.0 ± 4.2 (6.9 - 17.6) ms, and Inter-pulse duration: 52.6 ± 6.4 (43.0 - 65.0) ms.

In Israel, *B. leucomelas* alternates between two call types (Hackett *et al.*, 2016: 223, 225): type I (8 calls): Pulse duration: 1.81 ± 0.11 ms, F_{start}: 35.85 ± 0.71 kHz, F_{end}: 29.70 ± 0.53 kHz, F_{peak}: 33.20 ± 0 kHz. Type II (6 calls): Pulse duration: 4.62 ± 0.40 ms, F_{start}: 43.90 ± 0 (43.8 - 44.0) kHz, F_{end}: 32.33 ± 2.67 (29.1 - 35.2) kHz, F_{peak}: 39.83 ± 0.75 (38.9 - 41.1) kHz.

ROOST:
It roosts in caves, tunnels, crevices, old buildings, mines, tree hollows, and can be found beneath bark (Benda *et al.*, 2008b).

POPULATION:
Structure
It is a sedentary insectivore, with 3 - 8 females in nursery colonies, with females normally living separately to males (Benda *et al.*, 2008b).

Density
Considering its wide range there seems to be little information available about the population of this species. Within its range in Africa the population size and trends are currently unknown. In Southwest Asia, it is considered to be rare and is poorly known. In 2005, the species was found in Sinai (Egypt) in surveys for the first time in 180 years (D. Kock *pers. comm.,* in Benda *et al.*, 2008b). For the former Soviet Union, the species is listed in the second edition of the Red Book of the USSR (1984) as Rare but was considered to be "least concern" (K. Tsytsulina *pers. comm.,* in Benda *et al.*, 2008b). In Japan, it has been observed only rarely except in Hokkaido. In the past 30 years there have also been records from the prefectures of Iwate, Saitama, Gifu and Ehime (Abe *et al.*, 2005).

Trend
2016: Unknown (Monadjem *et al.*, 2017cz). 2008: Unknown (Benda *et al.*, 2008b; IUCN, 2009).

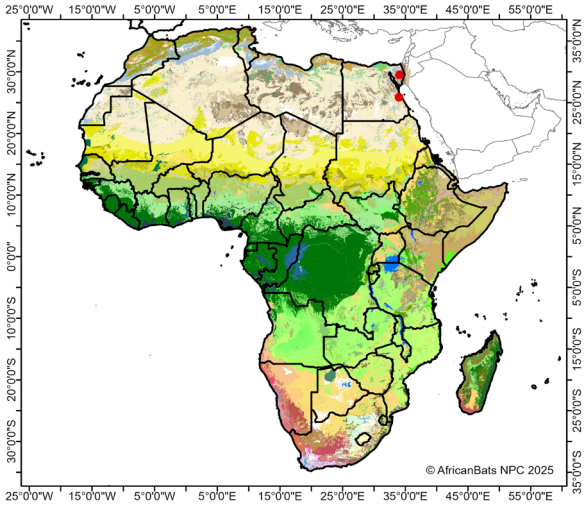

Figure 347. Distribution of *Barbastella leucomelas*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Egypt.

Genus ***Otonycteris*** Peters, 1859

*1859. *Otonycteris* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 223. Publication date: 1859 [Goto Description]. - Comments: Type species: *Otonycteris hemprichi* Peters, 1859. This publication covers a meeting held on 28 February 1859. - Etymology: From the Greek "*οὖς*" or "*ὠτός*", meaning ear and "*νυκτερις*", meaning bat (see Palmer, 1904: 489; Gharaibeh and Qumsiyeh, 1995: 3). (Current Combination).

TAXONOMY:
Koopman (1993a) and McKenna and Bell (1997) placed it in the tribe Nycticeini, but recent phylogentic analysis have grouped this taxon within the tribe Plecontini (Bogdanowicz *et al.*, 1998; Qumsiyeh and Bickham, 1993; Simmons, 2005: 481). Pine *et al.* (1971) and Hoofer and Van Den Bussche (2001) who suggest a close relationship between *Otonycteris* and *Antrozous* which presently is within the subfamily Antrozoinae (Simmons, 2005). Simmons (2005: 498) places the subfamily Antrozoinae within the Vespertilionidae based on recent molecular studies based on DNA sequence data (Hoofer and Van Den Bussche, 2001), a placement in line with more traditional classifications (Miller, 1897; Hill and Smith, 1984; Koopman, 1993a, 1994; McKenna and Bell, 1997). But, Simmons (1998) who raised this group to family level also moved it to the family Molossidae. Simmons (2005: 498) retained Antrozoinae as a subfamily level within the Vespertilionidae, but its placement is unclear and further studies are needed to clarify it.

Miller (1907) suggested *Otonycteris* shares relationships with *Eptesicus*, *Scoetocus* and *Scotomanes*. Hill and Harrison (1987) included *Otonycteris* in the Plecotini but included

Rhogeessa, *Baedon*, and *Nycticeius*. While Koopman (1993a) suggested that the genus *Otonycteris* is a distinct genus with no relationship to other vespertilionidae species.

Earlier systematics recognised six species, which Ellerman and Morrison-Scott (1951) synonymised all recognised forms within a single species *O. hemprichii*. Benda and Gvoždík (2010: 97) showed using morphological and molecular data, that a second species should be recognised *O. leucophaea* (Severcov, 1873) from central Asia.

Currently (Simmons and Cirranello, 2023b) recognized species of the genus *Otonycteris*: ***hemprichii*** Peters, 1859; *leucophaea* (Severtzov, 1873) - Turkmenistan, Uzbekistan, Kirghizia, Tadzhikistan, Afghanistan, Iran, Pakistan and Kashmir.

COMMON NAMES:
Czech: pustinní ušani. English: Desert Bats, Desert Long-eared Bats, Long-eared Desert Bats, Desert Big-eared Bats. French: Oreillards du désert. German: Wüsten-Großohren.

GEOGRAPHIC VARIATION:
Benda and Gvoždík (2010: 87) using morphological comparison across the entire genus range supports the existence of three morphotypes which correspond to their geographic origin:

O. h. hemprichii Peters, 1859 - small and medium-sized bats from North Africa and the Levant with relatively wide and short rostra, wide braincases, large tympanic bullae and high coronoid processes of the mandible and rather small and robust bacula.

O. h. cinerea Satunin, 1909 and *O. h. jin* Cheesman and Hinton, 1924 - large bats from Iran and Saudi Arabia with relatively narrow and short rostra, narrow braincases, large tympanic bullae and high coronoid processes of the mandible and rather small, robust bacula.

O. leucophaea (Severcov, 1873) - medium-sized bats from Central Asia with relatively wide and long rostra, medium-wide braincase, small tympanic bullae, and low coronoid process of the mandible and rather large and narrow bacula.

Otonycteris hemprichii Peters, 1859

*1859. *Otonycteris Hemprichii* Peters, Monatsb. k. preuss. Akad. Wiss. Berlin, 223. Publication date: 1859. Type locality: Egypt: Nile Valley S of Assuan (Egypt) & Chondek (Sudan). [Goto Description]. Syntype: ZMB 441: skull in skin. Collected by: Friedrich Wilhelm Hemprich and Christian Gottfried Ehrenberg; collection date: September 1821 - 21 July 1822. See Qumsiyeh (1985: 59); Turni and Kock (2008). Syntype: ZMB 442: skull in skin. Collected by: Friedrich Wilhelm Hemprich and Christian Gottfried Ehrenberg; collection date: September 1821 - 21 July 1822. See Qumsiyeh (1985: 59); Turni and Kock (2008). - Comments: This publication covers a meeting held on 28 February 1859. Type locality restricted by Kock (1969a: 183 - 184), since originally no locality was given. - Etymology: In honour of Friedrich Wilhelm Hemprich (1796 - 1825) (see Kozhurina, 2002: 15). (Current Combination).

1866. *Plecotus ustus* Fitzinger and Heuglin, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 54 (1) 10: 546. Publication date: 1866. Type locality: Sudan: Northern province: Wadi Halfa [21 55 N 31 20 E]. Holotype: NMW 8604: skull only. Collected by: Theodor Von Heuglin. See Benda and Gvoždík (2010: 101). - Comments: *Nomen nudum*: see Anderson and de Winton (1902: 118), Ellerman and Morrison-Scott (1951: 180), Allen (1939a: 93), Kock (1969a: 183), Qumsiyeh (1985: 59), Gharaibeh and Qumsiyeh (1995: 1).

1902. *Otonycteris petersi* Anderson, Zoology of Egypt: Mammalia. Revised and completed by W.E. de Winton, F.Z.S. Hugh Ress, Ltd., London, 120. Type locality: Iraq: Fao: Persian Gulf. - Comments: Extralimital.

1909. *Otonycteris cinereus* Satunin, Materials on the knowledge of mammals of Caucasus and Transcaspian Regions, XII-XVI. Izvestiya Kavkazskago Muzyeya (Tiflis). [in Russian, with German summary], 4: 281. Type locality: : "Nukendzag, Ge country, Persian Beluchestan". - Comments: Nevertheless, Ognev (1928: 579) restricted the type locality to "Zirkuh country, near Bamrud, Khorasan" (= Zarakkuh country, near Bamrud, Khorassan, E Iran) and this change was accepted by subsequent authors (Etemad, 1967, 1969; DeBlase, 1980; Baranova et al., 1981; Gharaibeth and Qumsiyeh, 1995).
Extralimital.

TAXONOMY:
Reviewed by Harrison and Bates (1991), Horáček (1991), Bates and Harrison (1997) and Benda and Gvoždík (2010).

Most of the forms currently attributed to the species rank of *O. hemprichii* (Simmons, 2005: 481), were originally described as separate species: *O. petersi* Anderson, 1902 (Anderson and de Winton, 1902; Kinnear, 1916; Bianchi, 1917; Cheesman and Hinton, 1924; Ognev, 1928); *O. cinerea* Satunin, 1909 (Bobrinskoy, 1925; Noack, 1887; Kuzyakin, 1950, 1965; Strelkov, 1963; Strelkov *et al.*, 1978). Ellerman and Morrison-Scott (1951) synonymised all recognised forms within *Otonycteris* into a single species *O. hemprichii*, with tree subspecies (*hemprichii, cinerea, jin*), but marked this combination with a question mark. Kock (1969a: 183) did not recognise any subspecies within *O. hemprichii*. Although Corbet (1978: 59) recognised five valid subspecies (*hemprichii, jin, petersi, leucophaeus, cinerea*, he noted that "it seems likely that variation will prove to be continuous throughout the range". While Nader and Kock (1983c) stated that pelage coloration was inadequate for subspecies definition, Horáček (1991) and Horáček *et al.* (2000: 133) carried out a partial analysis of geographic variation where they found that the differences in pelage coloration and size was clinal, and did not support the recognition of separate subspecies. Benda *et al.* (2006) performed a simple comparison of a set of *Otonycteris* specimens from North Africa and the Middle East, which showed clear morphotypes that confirmed categorial variation recognising two subspecies (*hemprichii, cinerea*). In the past, five subspecies have been recognized (Atallah, 1977; Ellerman and Morrison-Scott, 1951; Harrison and Bates, 1991; Gharaibeh and Qumsiyeh, 1995; Koopman, 1993a) - the nominotypical form *O. h. hemprichii* Peters, 1859, *O. h. leucophaeus* (Severcov, 1873); *O. h. cinerea* Satunin, 1909; *O. h. petersi* Anderson, 1902; and *O. h. jin* Cheesman and Hinton, 1924.

Benda and Gvoždík (2010), examining both morphological and molecular data, concluded that one of the previously recognized subspecies, *O. h. leucophaeus* (Severcov, 1873), should be elevated to full species rank *O. leucophaea* (Severcov, 1873), from central Asia. In *Otonycteris hemprichii*, they recognized three distinct subspecies: *O. h. hemprichii* Peters, 1859 from North Africa, Levant and Mesopotamia; *O. h. cinerea* Satunin, 1909, from the mountainous areas of eastern Arabia and Iran; and *O. h. jin* Cheesman and Hinton, 1924, from the lowland deserts of eastern Arabia and southeasternmost Iran.

CONSERVATION STATUS:
Global Justification
This is a relatively common species in desert and sub-desert habitats of the SW Palaearctic. It has a presumed large population, but the current trend is unknown. However, if it is in decline, it is unlikely to be at a rate which would qualify it for inclusion in the threatened categories. There are no major threats to the species, although it may

be affected by pesticides in some parts of its range. Therefore, it is listed as Least Concern (LC ver 3.1 (2001)) (Benda *et al.*, 2008c; IUCN, 2009; Monadjem *et al.*, 2017b).

Assessment History
Global
2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2017b). 2008: LC ver 3.1 (2001) (Benda *et al.*, 2008c; IUCN, 2009). 1996: LR/lc [as *Otonycteris hemprichi*].

Regional
None known.

MAJOR THREATS:
Although not a major threat this species is affected by pesticides (Benda *et al.*, 2008c; IUCN, 2009; Monadjem *et al.*, 2017b). Sherwin *et al.* (2012: 174), furthermore, list the small distribution range, water stress and the aerial hawking feeding style to be the risk factors related to climatic change. Bilgin *et al.* (2012: 434) predict that climatic change will result in a major range contraction for *O. hemprichii*.

CONSERVATION ACTIONS:
Benda *et al.* (2008c) [in IUCN (2009)] and Monadjem *et al.* (2017b) report that the species presumably occurs in some protected areas across its range. No other specific measures are known, although it will be protected under national legislation in some of the range states. A study on the impacts of pesticides is required, especially ways in which the impact might be minimised.

GENERAL DISTRIBUTION:
Otonycteris hemprichii occurs in the southern desert and sub-desert belt of Western and Central Palaearctic from Morocco and Niger as far east as north-west India. It is possibly present in the whole of the desert area in the north of Africa where there is suitable habitat. In the Mediterranean region it is recorded from Morocco, Algeria, Tunisia, Libya, Niger, northern Sudan and Egypt. In the Middle East it is found in Israel, Palestine, Jordan, Lebanon, Syria and a single locality from southeastern Turkey. It has an area of occupancy of >20,000 km^2 and occupies an altitude of up to 2,400 m (in Pakistan).

Albayrak and Aşan (1999: 65) mention one specimen from a locality in southern Turkey.

Benda and Gvoždík (2010: 95) allocate specimens previously referred to *O. hemprichii* from Central Asian should be rather referred to *Otonycteris leucophaea* (Severcov, 1873).

Native: Afghanistan; Algeria; Egypt; Iran, Islamic Republic of; Israel; Jordan; Kazakhstan; Libyan Arab Jamahiriya; Morocco (Benda *et al.*, 2010a: 158; El Ibrahimi and Rguibi Idrissi, 2015: 363; Dbiba *et al.*, 2025: 7); Niger; Oman; Qatar; Saudi Arabia; Sudan; Syrian Arab Republic; Tajikistan; Tunisia (Dalhoumi *et al.*, 2016b: 867; 2023: 4); Turkey; Turkmenistan; United Arab Emirates (Anonymus, 2008: 38); Uzbekistan.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:
In their study on the reversibility of the mandibular symphyseal fusion, Scott *et al.* (2012: 2943) mention that this symphysis is fully fused in *O. hemprichii*.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987), and Benda and Gvoždík (2010: 93). Benda and Gvoždík (2010: 87) found that the bacula from different parts of the distribution range were very similar in shape. The bones are simple, dorso-ventrally flattened, crescent-shaped sticks. The baculum length were 2.47 - 3.31 mm long. Slightly differing specimens, originating in northeastern Iran and Kirghizstan, possessed larger bacula (length= 3.02 - 3.31 mm), relatively narrower and in most cases also slightly less curved than bacula from other parts of the range (baculum length = 2.47 - 2.96 mm) (Benda and Gvoždík, 2010: 87).

FUNCTIONAL MORPHOLOGY:
In Israel, Marom *et al.* (2006: 954) found that the physiological responses of *O. hemprichii* to a range of ambient temperatures (both by night and by day) are characteristic of a mammal adapted to arid environments.

SEXUAL DIMORPHISM:
Bogdanowicz and Owen (1996: 494) found that females are approximately 4.4 % larger than males.

ECHOLOCATION:
Holderied *et al.* (2010: 425) indicate that *Otonycteris hemprichii* is a whispering bat (approx. 80 dB peSPL), with short, multiharmonic calls. The two dominant harmonics sweep from 39 to 22 kHz, and from 77 to 43 kHz, with average peak frequencies respectively 29.96 ± 5.3 kHz and 54.45 ± 5.5 kHz. The pulse duration is 2.46 ± 1.1 ms, the pulse interval 131.6 ± 82.0 ms.

In Jordan, Benda *et al.* (2010b: 204) recorded the following parameters for 66 calls: F_{start}: 46.8 ± 8.6 (34.2 - 68.3) kHz, F_{end}: 20.4 ± 3.0 (15.0 - 25.6)

kHz, F_{peak}: 26.8 ± 3.2 (19.4 - 31.8) kHz, duration: 7.2 ± 2.4 (2.9 - 11.9) ms, and interpulse interval: 142.7 ± 52.9 (72.0 - 302.0) ms.

For Iran, Benda *et al.* (2012a: 183) provide two series of data: **1**: F_{start}: 38.8 ± 2.1 (28.6 - 32.8) kHz, F_{end}: 22.1 ± 0.2 (21.9 - 22.3) kHz, F_{peak}: 22.9 ± 6.1 (16.9 - 29.9) kHz, duration: 3.7 ± 0.3 (3.4 - 4.1) ms, interpulse interval: 157.9 ± 22.1 (143.0 - 190.1) ms; **2** (hand released in a close room): F_{start}: 35.0 ± 2.2 (30.5 - 38.6) kHz, F_{end}: 20.1 ± 0.7 (19.0 - 21.2) kHz, F_{peak}: 26.2 ± 2.6 (23.5 - 32.3) kHz, duration: 2.6 ± 0.5 (1.7 - 3.6) ms, interpulse interval: 44.4 ± 19.3 (26.8 - 80.5) ms.

From Israel, the following values were obtained by Hackett *et al.* (2016: 223) from 68 calls: Pulse duration: 5.19 ± 3.52 ms, F_{start}: 36.86 ± 2.95 (25.3 - 46.3) kHz, F_{end}: 20.94 ± 2.16 (18 - 25.3) kHz, F_{peak}: 24.45 ± 2.73 (20.5 - 34.1) kHz.

Disca *et al.* (2014: 226) indicate that the type of call is FM multi H for specimens from Morocco, with the following parameters: F_{start}: 42.4 ± 1.6 kHz, F_{end}: 17.0 ± 0.6 kHz, F_{peak}: 25.3 ± 1.0 kHz, $F_{max\ first\ harmonic}$: 45.3 ± 1.7 kHz, bandwidth: 25.3 ± 1.9 kHz, duration: 5.2 ± 0.3 ms.

Tunisian bats were reported to have F_{start}: 46.68 ± 6.35 (30.7 - 55.9) kHz, F_{end}: 17.72 ± 1.40 (15.7 - 18.9) kHz, F_{max}: 22.97 ± 2.80 (18.9 - 27.7) kHz, duration: 6.49 ± 1.54 (4.0 - 8.4) ms and Interpulse interval: 200.92 ± 61.65 (112.2 - 313.9) ms (Dalhoumi *et al.*, 2023: 5).

Luo *et al.* (2019a: Supp.) reported the following data (Free flying bats): F_{peak}: 24.45 kHz, F_{start}: 36.86 kHz, F_{end}: 20.94 kHz, Band width: 15.92 kHz, and duration: 5.19 ms.

In the United Arab Emirates, Davis (2007: 7) reports the ending frequency to be around 18 kHz.

Holderied *et al.* (2010: 425) also suggest that this bat is probably a passive gleaner, listening to noises generated by their prey. In a test environment, moving scorpions were found within 5 to 58 seconds, whereas non-moving or dead scorpions were not found at all.

Hackett *et al.* (2014: 3028), however, found that *O. hemprichii* switches between being a passive gleaner and an aerial hawker. Aerial hawking seems to occur when their usual prey becomes scarcer (e.g., desert scorpions - *Scorpio maurus palmatus* - at the end of a hot, dry summer) or less active (e.g., common yellow scorpions - *Buthus occitanus israelis* (Hackett *et al.*, 2014: 3031). The bats also switch from low-amplitude echolocation calls during ground gleaning to high-call amplitude when flying in the open, suggesting that the cost of the shorter detection distance of low-amplitude calls is too high during aerial hawking. (de Framond *et al.*, 2023: 1).

Molecular Biology:

Karyotype

Arslan and Zima (2014: 14) mention 2*n* = 28, FNa = 46, FN = 50, and a medium-sized submetacentric X. No data were available for the Y chromosome. The autosomal complement contains seven large metacentrics, two large submetacentrics, one small metacentric and three acrocentric pairs (of which one is dot-like). They also indicate that the karyotype with 2*n* = 30, FN = 48, BA = 20, a submetacentric X chromosome and a dot-like Y chromosome for specimens reported by Zima *et al.* (1992b) from Kyrgystan is actually for *O. leucophaea*.

Genetics

See Hoofer and Van Den Bussche (2003), Mayer *et al.* (2007), and Benda and Gvoždík (2010: 88).

Habits:

Horáček (1991) reported that *O. hemprichii* foraged in two different ways; very close to the ground (40 - 80 cm) or at a height of some 4 - 8 meters above the ground. Holderied *et al.* (2010: 429) reported a flight height of 2.19 ± 1.0 m above the ground while searching for prey at Park Sapir, Israel, and a flight speed of 3.52 ± 1.3 m/s.

Hackett *et al.* (2014: 3030) found that *O. hemprichii* specimens flew slower during aerial hawking than during their passive gleaning foraging flights.

Roost:

Daniel *et al.* (2010: 295) found that during pregnancy, female bats roosted either alone, or in small groups of two to five individuals. While during lactation, female bats roosted without males in groups of two to five individuals. Korine *et al.* (2013: 131) reported that, in Israel, female bats roosted primarily in cracks during reproduction, and most of these were facing the morning sun. They also indicated that during pregnancy horizontal cracks were used, whereas vertical cracks were used by lactating females. Some of these roosts were used year after year.

Diet:

Studies from different parts of its range indicate that its prey includes mainly large ground arthropods (Coleoptera, Blattodae, Othoptera, Solpugida, Heteroptera, Hymenoptera, and Scorpionidae) (Horáček, 1991; Whitaker *et al.*, 1994: 75; Arlettaz *et al.*, 1995; Fenton *et al.*,

1999; Benda *et al.*, 2001, 2006, 2010: 83, 2012a: 469; Conenna and Korine, 2024: 115).

Andreas (2010: 265) mentions that it is suggested that *O. hemprichii* is a potential carnivore. However, there is no proof for this. Furthermore, no perch feeding was observed for this species and this type of tactics is generally used when consuming relatively larger preys.

Holderied *et al.* (2010: 425) indicate that 70 % of the droppings can contain scorpion fragments. They also observed that while capturing the scorpions, the bats were frequently stung, even in their faces, without any indication of poisoning, and the scorpions' poison glands and stinger were eaten too. Page and Bernal (2019: "3") indicated that the toxicity of the scorpions did not influence their selection as prey.

Benda *et al.* (2014c: 100) analysed 14 faecal pellets from one individual and found robust crickets (Ensifera; 97.1 % by volume), complemented by a small proportion of moth remnants (Lepidoptera; 2.9 %).

POPULATION:
Structure and Density
Mostly solitary animals, female colonies up to 18 individuals (Benda *et al.*, 2008c; IUCN, 2009; Monadjem *et al.*, 2017b).

Trend
2016: Unknown (Monadjem *et al.*, 2017b). 2008: Unknown (Benda *et al.*, 2008c; IUCN, 2009). *O. hemprichii* populations within the Asia Minor and Levant region are unknown population trend, under predictive climate change scenarios (Bilgin *et al.*, 2012: 433).

ACTIVITY AND BEHAVIOUR:
Daniel *et al.* (2010: 296) showed that *O. hemprichii* delayed their foraging emergence time as gestation progressed from the first to the second trimester, while during nursing the bats' emergence time to forage did not change. Emergence time of female bats from their roosts during pregnancy was delayed from an average of 18h33 (about 40 min after sunset) in the first trimester of pregnancy (late March and beginning of April) to an average of 20h00 (about 1 h and 50 min after sunset) during the second trimester of pregnancy (Daniel *et al.*, 2010: 295). Contrary to the situation during pregnancy, emergence time of bats from their day roosts during nursing did not change with the sunset times, and was almost always between 20h00 and 21h00 (Daniel *et al.*, 2010: 295). Pregnant bats did not emerge to forage more than four times per night; the average was two bouts per night, whereas lactating bats made up to six foraging bouts per night (Daniel *et al.*, 2010: 296).

Daniel *et al.* (2010: 297) observed that female bats often used both deep and shallow daily torpor during the first two trimesters of pregnancy, with skin temperature frequently dropping as low as 15° C, while pregnant females used only shallow torpor during the last trimester of pregnancy and nursing.

Korine *et al.* (2015: 5) point out that the activity of *O. hemprichii* could be underestimated because of the whispering nature of their echolocation calls.

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) report this species as being polytocous (more than one young per litter).

Daniel *et al.* (2010: 295) estimated that pregnancy began by the end of March, and that parturition took place around the first week in June. Body mass of pregnant bats increased by over 50% from the beginning to the end of pregnancy (22 - 35 g).

In the United Arab Emirates, Davis (2007: 7) thinks the females are pregnant in May-June.

PARASITES:
The tick *Argas vespertilionis* (Latreille, 1802) was reported from Jordan by Benda *et al.* (2010b: 294), who also indicate that the only two other ectoparasites found in the Middle East are *Argas hermanni* Audouin, 1827 in Egypt, and the flea *Araeopsylla wassifi* Traub, 1954 in Turkey.

Sándor *et al.* (2021a: 4) reported the presence of the argasid ticks *Chiropterargas boueti* (Roubaud and Colas-Belcour, 1933) and *Chiropterargas confusus* (Hoogstraal, 1955).

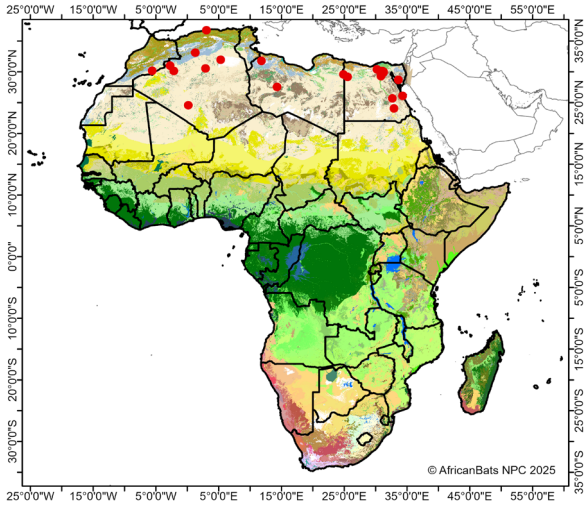

Figure 348. Distribution of *Otonycteris hemprichii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: "Africa", Algeria, Egypt, Libya, Morocco, Niger, Sudan.

Genus ***Plecotus*** E. Geoffroy St.-Hilaire, 1818

1816. *Macrotus* Leach, Cat. Mamm. Birds B.M, p 5. - Comments: Type species: *Macrotus europaeus* Leach, 1816 [= *Vespertilio auritus* Linnaeus, 1758]. Preoccupied by *Macropus* Gray, 1842, *Nomen nudum* by Pavlinov *et al.* (1995: 103).. - Etymology: From the Greek "*μακρός*", meaning large and "*ούς*" or "*ώτός*", meaning ear, referring to very large ears (see Palmer, 1904: 395).

*1818. *Plecotus* E. Geoffroy Saint-Hilaire, Description des Mammifères qui se trouve en Egypte, 2: 112, pl 2, No 3. Publication date: 1818. - Comments: Type species: *Vespertilio auritus* Linnaeus, 1758. - Etymology: From the Greek "*pleko*" meaning folded or twisted and "*otis*" meaning ear (see Jones, 1977a: 3; Álvarez-Castañeda and Álvarez Solórzano, 1996: 43). Gardner (2005: 184) considers this to be masculine (*Plec* = twisted + *ot* = ear(ed) + *us* (Latin second declension ending)). (Current Combination).

1829. *Plecautus:* F. Cuvier. - Comments: Lapsus: see Cabrera (1914). (Lapsus).

? *Plecotus sp.:*

TAXONOMY:
A key to the genus was published by Jones (1977a: 1). Mediterranean and Atlantic islands forms reviewed by Juste *et al.* (2004a).

Benda *et al.* (2006) indicated that Benda *et al.* (2004c) and Spitzenberger *et al.* (2006) performed combined genetic and morphological analyses of Mediterranean plecotine bats with very similar results but with a slightly different interpretation. The difference is in the taxonomic evaluation of the *kolombatovici* clade of the *austriacus* group (in the sense of Juste *et al.* (2004a). This clade consists of a mosaic of morphotypes with a relatively very shallow genetic divergence. Benda *et al.* (2004c) coidentified this group with one species *P. teneriffae*, containing three to four more or less distinct forms living in allopatry (*teneriffae*, *kolombatovici*, *gaisleri*, and a possible fourth form in the Maghreb, but preliminary included into *gaisleri*). Spitzenberger *et al.* (2006) distinguished two species in the clade, the monotypic *P. teneriffae* and *P. kolombatovici* with three forms, *kolombatovici*, *gaisleri*, and the unnamed Maghrebian form. A third possible interpretation, considering three species within the clade (which well confirm with the morphological evidence) was recently suggested by Mayer *et al.* (2007). Since all three analyses used almost the same types of character sets, their interpretations are alternatives arising from almost identical results. Thus, contrary to Benda *et al.* (2006) who suggest to follow the 'intermediate' designation *P.* (*teneriffae*) *gaisleri* for the populations of the Maghreb and Cyrenaica, the IUCN evaluated *P. kolombatovici* including these North African populations. Spitzenberger (2021: 19) mentioned that *P. kolombatovici* occurs in the Maghreb (Morocco, Algeria, Tunisia), Tripolitania and Cyrenaica (Libya) in the south, and Anatolia, Greece, Albania, Croatia, and Italy in the north of the Mediterranean region, but she also indicates that the systematics of *P. kolombatovici* should still be subjected to a thorough study using nuclear markers, especially to assess its relation to P. teneriffae.

Currently (Simmons and Cirranello, 2023b) recognized species of the genus *Plecotus*: *auritus* (Linnaeus, 1758) – Norway, Ireland and Spain to Sakhalin Isl (Russia), Korea, Japan, northern China, Nepal, India (Simmons, 2005: 482); *austriacus* (J.B. Fischer, 1829) – England and Spain to Mongolia and western China (Simmons,

2005: 482); ***balensis*** Kruskop and Lavrenchenko, 2000; ***christii*** Gray, 1838; *gobiensis* Dolch, Stubbe, Gärtner, Thiele, Ariunbold, Batsaikhan, Lkhagvasuren, Stubbe and Steinhauser, 2021 – Mongolia; *homochrous* Hodgson, 1847 – Nepal, Pakistan, India; *kolombatovici* Dulic, 1980 – Croatia and nearby islands in the Adriatic Sea (Simmons, 2005: 483); ***koslovi*** Bobrinskii, 1926 – S Mongolia, N China; *macrobullaris* Kusjakin, 1965 – from the Caucasus and Asia Minor (Russia, Georgia, Armenia, Azerbaijan, Iran, Turkey), the Alps (France, Switzerland, Liechtenstein, Austria) and the Balkans (Croatia, Serbia, Albania, Montenegro, Macedonia, Greece), the Pyrenees (Andorra, France, Spain), Crete, Syria; *ognevi* Kishida, 1927 – Taiga and southern Siberian mountains, Sakhalin, Kurilles, N Mongolia, Korea, China, Kazakhstan, Mongolia, Russia; *sacrimontis* G.M. Allen, 1908 – Asia from Altai Mts through C Siberia and Tranbaicalia to Far East and Japan; *sardus* Mucedda, Kiefer, Pidinchedda and Veith, 2002; *strelkovi* Spitzenberger, 2006 – Afghanistan, China, Iran, Kazakhstan, Kyrgyzstan, Mongolia, Tadjikistan; *taivanus* Yoshiyuki, 1991 – Taiwan (Simmons, 2005: 483); ***teneriffae*** Barrett-Hamilton, 1907; *turkmenicus* Strelkov, 1988 – Turkmenistan, Usturt, Mangyashlak, Kazakhstan (possibly Iran), Mongolia; *wardi* Thomas, 1911 – Caucasus, Transcaucasia, Pamiro-Altain, Tian-Shan, Kazakhstan, Tarbatatai, Karakorum, Hindukush, Himalaya, ? Iran, ? Turkey, Pakistan, India, and Nepal.

COMMON NAMES:
Czech: praví ušani, ušanové, srostlouchové, pletušanové, vrásničové. English: Long-eared bats, Old World Big-eared Bats, Big-eared Bats, Old World Long-eared Bats. French: Oreillards, Chauves-souris à grandes oreilles. German: Langohrfledermäuse, Langohren. Ukrainian: Вухань [= Vukhan'].

PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
González-Dionis *et al.* (2021: 12) indicate that the genus *Plecotus* was split up into the "*austriacus*" group (Europe and north Africa) and the "*auritus*" group (Middle East and Europe), which occurred during the Miocene/Pleistocene boundary at about 5 mya.

GENERAL DISTRIBUTION:
Dorst and de Naurois (1966: 292) report on *Plecotus austriacus* specimens collected on the Cape Verdian islands of Maio and Santiago. Borloti *et al.* (2020: 3), however, indicate that it is still unknown whether the Cape Verdian bats belong to *P. austriacus (sensus strictu)* or *P. teneriffae/P. kolombatovici*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Canary Islands (Spain), Cape Verde.

Plecotus balensis Kruskop & Lavrenchenko, 2000

*2000. *Plecotus balensis* Kruskop and Lavrenchenko, Myotis, 38: 6, figs 1, 5, 6, 7. Publication date: December 2000. Type locality: Ethiopia: Southern Ethiopia, Bale Mountains National Park: Harenna Forest [06 45 N 39 44 E, 2 760 m]. [Goto Description]. Holotype: ZMMU S-164904: ad ♂, skin and skull. Collected by: Sergey V. Kruskop; collection date: 29 December 1995. - Etymology: In reference to the Bale mountains, the area from where the type specimen originated (see Kruskop and Lavrenchenko, 2000: 8). (Current Combination).

TAXONOMY:
See Simmons (2005).

COMMON NAMES:
Czech: ušan habešský. English: Bale Big-eared Bat, Bale Long-eared Bat, Ethiopian Big-eared Bat, Ethiopian Long-eared Bat. French: Oreillard d'Ethiopie. German: Bale-Langohr.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status. The species has only been recently described, and there remains very little information on the distribution of the species. While it is currently known from fewer than five locations, it seems plausible that the species ranges more widely than this and does not therefore qualify for a threatened category (Lavrenchenko *et al.*, 2008; IUCN, 2009; Lavrenchenko *et al.*, 2019).

Using machine learning techniques, Wieringa (2022: 535) predicted this species to be threatened.

Assessment History
Global
2018: DD ver 3.1 (2001) (Lavrenchenko *et al.*, 2019). 2008: DD ver 3.1 (2001) (Lavrenchenko *et al.*, 2008; IUCN, 2009). 2004: VU D2 ver 3.1 (2001) (Lavrenchenko *et al.*, 2004a; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
This species is threatened by the rapid destruction of montane forest, presumably through extraction of timber and firewood, and the conversion of land to agricultural use (Lavrenchenko *et al.*, 2008; IUCN, 2009; Lavrenchenko *et al.*, 2019, Razgour *et al.*, 2020).

CONSERVATION ACTIONS:
Lavrenchenko *et al.* (2008) [in IUCN (2009)] and Lavrenchenko *et al.* (2019) report that this species has been recorded within the Bale Mountains National Park. Additional management of the area is needed to prevent further deforestation of the Harenna Forest. There is a need for further field surveys to better determine the range of this species.

GENERAL DISTRIBUTION:
Plecotus balensis is endemic to the Ethiopian highlands were it is currently known only with certainty from the upper belts of the Harenna Forest in the Bale Mountains National Park and from Abune Yosef (Kruskop and Lavrenchenko, 2000; Juste *et al.*, 2004a; Benda *et al.*, 2004c). There is an early record from "Shoa" (= Shewa), which probably came from the uplands north or northwest of Addis Ababa (Kruskop and Lavrenchenko, 2000). It is possible that the species occurs in similar areas of montane forest, but it has not been recorded during surveys in either the Beletta Forest or the Sheko Forest (Kruskop and Lavrenchenko, 2000). The species is found at elevations of 2,500 to 3,000 m asl, which is confirmed by new records reported by Ahmed *et al.* (2024: 179).

There are a number of poorly documented museum specimens that may have come from additional sites within Ethiopia, or possibly from adjacent Eritrea (although this may refer to a specimen of *Plecotus christii*) (Kruskop and Lavrenchenko, 2000).

Benda *et al.* (2011b: 44) tentatively assign *Plecotus* specimens from Yemen to this taxon as *Plecotus* cf. *balensis*.

Native: Ethiopia (Kruskop and Lavrenchenko, 2000; Juste *et al.*, 2004a; Benda *et al.*, 2004c).

Presence uncertain: Eritrea (Kruskop and Lavrenchenko, 2000).

DETAILED MORPHOLOGY:
Baculum
See Kruskop and Lavrenchenko (2000), Benda *et al.* (2004c).

MOLECULAR BIOLOGY:
Genetics
See Benda *et al.* (2004c), Juste *et al.* (2004c).

HABITAT:
All of the females and subadults caught by Razgour *et al.* (2020: 798) were found in *Juniperus procera* or *Erica arborea* forests, whereas they only caught adult males at the higher altitude Afroalpine moorlands.

Chakravarty *et al.* (2024: 7) assigned this species to the group of "highland dwelling species."

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 76 minutes, and the digestibility rate about 80.1 %.

POPULATION:
Structure and Density
Kruskop and Lavrenchenko (2000) mention that this bat appears to be relatively common within its limited distribution.

Trend
2018: Unknown (Lavrenchenko *et al.*, 2019).
2008: Unknown (Lavrenchenko *et al.*, 2008; IUCN, 2009).

PARASITES:
ARACHNIDAE
Argasidae
Ševčík *et al.* (2024: 6) reported *Secretargas transgariepinus* from *Plecotus balensis* in Ethiopia.

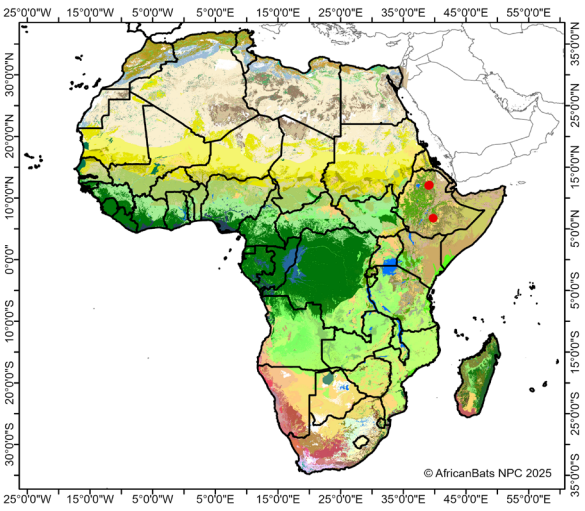

Figure 349. Distribution of *Plecotus balensis*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Ethiopia.

Plecotus christii J. E. Gray, 1838

1829. *[Vespertilio auritus] ß aegyptius* J.B. Fischer, Synopsis Mamm, 117. Publication date: 1829 [Goto Description]. - Comments: Junior homonym of *Vespertilio pipistrellus var aegyptius*: see Qumsiyeh (1985: 65). Allen (1939a: 96) mentioned this form to be based on the description by E. Geoffroy, 1818: Description de l'Egypte, 2: 119.

*1838. *Plecotus christii* J. E. Gray, Mag. Zool. Bot., Edinburgh, 2 (12): 495. Publication date: 1 February 1838. Type locality: Egypt: southern Egypt: Nile valley between Qena and Aswan. Lectotype: NHMUK 1866.a: skin only. Collected by: Major (Dr.) Turnbell Christie. Skin in poor condition. Sometimes also mentioned as "NHMUK GMC M66a". - Comments: Type locality originally North Africa but restricted by Qumsiyeh (1985: 65, 67) to southern Egypt, Nile valley between Qena and Aswan. Between 16° 10' N, 32° 43' E and 24° 05' N, 32° 53' E: see Benda *et al.* (2008f: 70). - Etymology: In honour of Dr. Turnbull Christie, the collector of the type specimen (see Gray, 1838: 495).

1866. *Plecotus æthiopicus* Heuglin, in: Fitzinger and Heuglin, Sber. k. Akad. Wiss. Wien, math. naturw. Kl., 54 (1) 10: 546. Publication date: 1866. Type locality: Sudan: Bahr-el-Abiad [ca. 14 00 N 33 00 E]. - Comments: Nomen nudum. Mentioned by Allen (1939a: 96) as a synonym of *Plecotus auritus aegyptiacus* Geoffroy.

1878. *Plecotus ægyptiacus* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, p 178. Publication date: 15 June 1878. Type locality: Egypt. Topotype: MCZ 32976: ♂, alcoholic (skull not removed). Collected by: Dr. John Anderson. - Comments: Allen (1939a: 96) mentioned "I. Geoffroy, Mag. de Zool., 2: cl. 1, p. 2 of description of pl. 2-3, 1832, who repeats characters given by E. Geoffroy, in Description de l'Egypte, 2: 119, 1818. Egypt". Kock (1969a: 179) also mentions "I. Geoffr.", buf refers to Fitzinger (in Heuglin and Fitzinger, 1866: 545) as first reference, who reported it from Egypt, Abyssinia and Shoa. Pavlinov *et al.* (1995) mentioned Dobson, 1878 as author.

1911. *Plecotus christiei:* Thomas, Proc. zool. Soc. Lond., 1911, I: 160. - Comments: Unjustified emendation (Benda *et al.*, 2006). (Emendation).

1964. *Plecotus austriacus christiei:* - Comments: Unjustified emendation (see Thomas, 1911; Benda *et al.*, 2006). (Name Combination, Lapsus).

2002. *Plecotus cristiei:* Kiefer and Veith, Myotis, 39: 12. (Lapsus).

2008. *Plecotus christii petraeus* Benda, in: Benda, Dietz, Andreas, Hotový, Lučan, Maltby, Meakin, Truscott and Vallo, Acta Soc. Zool. Bohem., 72: 1, 71, fig 68. Type locality: Egypt: Sinai: Janub Sina Governate: Wadi Feiran: western edge of Feiran Oasis [28 43 N 33 37 E, 595 m]. Holotype: NMP 90496: ad ♂, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 8 September 2005; original number: pb2858. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: NHMUK 1903.12.8.5: ad ♀, skull and alcoholic. Collected by: Dr. John Anderson. Tor [= El Tur], Sinai [Egypt]. Paratype: NMP 90497: sad ♀, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 9 September 2005; original number: pb2859. El Milga, Sinai, Egypt. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: NMP 90499: ad ♂, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 10 September 2005; original number: pb2861. Feiran, Sinai, Egypt. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: NMP 90518: ad ♀, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 10 September 2005; original number: pb2880. El Tur, Hammam Musa, Sinai, Egypt. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: NMP 90519: ad ♂, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 10 September 2005; original number: pb2881. El Tur, Hammam Musa, Sinai, Egypt. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: NMP 90523: ad ♂, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 15 September 2005; original number: pb2885. Ain Hudra, Sinai, Egypt. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: NMP 90533: ad ♀, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Josef Hotový and Radek K. Lučan; collection date: 18 September 2005; original number: pb2895. Ain Sudr, Sinai. See Benda in Mlíkovský *et al.* (2011: 138). Paratype: TAU M.7160: ad ♂, skin and skull. Collection date: 01 December 1977. Hashiba [= Umm Khisheib], Sinai [Egypt]. See Benda *et al.* (2008f: 71).

? *Plecotus auritus aegyptiacus:*

? *Plecotus austriacus christei:* (Lapsus).

? *Plecotus austriacus christii:* (Name Combination).

TAXONOMY:
Generally considered to be a subspecies of *austriacus* but see Benda *et al.* (2004c: 23), who raised it to species rank.

Since *Plecotus austriacus* is a strictly European species (Juste *et al.*, 2004a; Mayer *et al.*, 2007). Therefore, this species is removed from the list of African species. All the African records of *P. austriacus* in fact belong to *P. christii*, *P.* (*teneriffae*) *gaisleri* or to *P. balensis*.

COMMON NAMES:
Arabian: Khaffash. Czech: ušan egyptský. Dutch: Egyptische grootoorvleermuis. English: Christie's Long-eared Bat. French: Oreillard d'Egypte. German: Christis Graues Langohr. Hebrew: אוזן, Oznan.

CONSERVATION STATUS:
Global Justification
Probably a small population, suitable habitat might be fragmented, but needs more research to be properly assessed (Aulagnier and Benda, 2008; IUCN, 2009; Aulagnier and Benda, 2019).

Assessment History
Global
2018: DD ver 3.1 (2001) (Aulagnier and Benda, 2019). 2008: DD ver 3.1 (2001) (Aulagnier and Benda, 2008; IUCN, 2009). 2006: DD ver 3.1 (2001) (Aulagnier and Benda, 2004b; IUCN,

2006). 2004: DD ver 3.1 (2001) [assessed as *Plecotus christiei*] (Aulagnier and Benda, 2004b; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
Affected by human disturbance (Aulagnier and Benda, 2008; IUCN, 2009; Aulagnier and Benda, 2019).

CONSERVATION ACTIONS:
Aulagnier and Benda (2008) [in IUCN (2009)] and Aulagnier and Benda (2019) report that no conservation measures are in place. Further research on population is needed in order to make an assessment.

GENERAL DISTRIBUTION:
Plecotus christii is known only from a few localities in NE Africa, including eastern Libya (S. Aulagnier *pers. comm.*, 2007 in Aulagnier and Benda, 2008 [in IUCN, 2009]), Egypt including Sinai and Sudan. Benda *et al.* (2004c: 26) restricted its confirmed distribution to the north-eastern African desert region, Mayer *et al.* (2007) suggested its occurrence also in the Jordan desert.

A specimen from Eritrea may belong to this species or to *P. balensis* (Kruskop and Lavrenchenko, 2000).

Native: Egypt [Sinai] (Horáček *et al.*, 2000: 135); Libyan Arab Jamahiriya (Horáček *et al.*, 2000: 135); Saudi Arabia; Sudan (Horáček *et al.*, 2000: 135).

Presence uncertain: Eritrea.

DETAILED MORPHOLOGY:
Baculum
See Benda *et al.* (2004c).

ECHOLOCATION:
In Jordan, Benda *et al.* (2010b: 204) recorded the following parameters for 42 calls: Start frequency: 44.2 ± 2.8 (34.5 - 49.0) kHz, End frequency: 25.0 ± 1.0 (22.6 - 26.7) kHz, Peak frequency: 30.5 ± 1.7 (28.6 - 34.2) kHz, Pulse duration: 2.3 ± 0.5 (1.4 - 3.5) ms, and Inter-pulse duration: 57.6 ± 18.9 (18.0 - 89.0) ms.

Hackett *et al.* (2016: 223) reported on 25 calls from Israel: Pulse duration: 3.05 ± 0.98 ms, F_{start}: 37.22 ± 3.43 kHz, F_{end}: 23.85 ± 2.45 kHz, F_{peak}: 28.47 ± 2.74 kHz.

MOLECULAR BIOLOGY:
Genetics
See Benda *et al.* (2004c), Juste *et al.* (2004c), Spitzenberger *et al.* (2006, Mayer *et al.* (2007).

POPULATION:
Structure and Density
Probably very small population, only scattered and isolated records (Aulagnier and Benda, 2008; IUCN, 2009; Aulagnier and Benda, 2019).

Trend
2018: Unknown (Aulagnier and Benda, 2019).
2008: Unknown (Aulagnier and Benda, 2008; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
Korine *et al.* (2015: 5) indicate that the activity of *P. christii* could be underestimated because of the whispering nature of their echolocation calls.

PARASITES:
Argasidae
Sándor *et al.* (2021a: 4) reported the presence of *Secretargas transgariepinus* (White, 1846) and *Carios vespertilionis* Latreille, 1802. In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following tick: Argasidae: *Carios vespertilionis* Latreille, 1802.

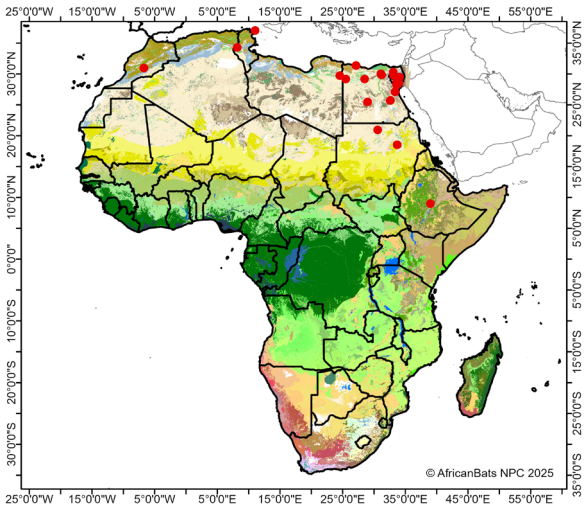

Figure 350. Distribution of *Plecotus christii*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Egypt, Ethiopia, Libya, Morocco, Sudan, Tunisia.

Plecotus gaisleri Benda, Kiefer, Hanak & Veith, 2004

*2004. *Plecotus teneriffae gaisleri* Benda, Kiefer, Hanák and Veith, Folia Zool., 53 (Monogr 1): 28. Type locality: Libya: Cyrenaica: Al Jabal Al Akhdar district: 8 km SW Massah,: Wadi al Kuf (Jabal Akhdar Mts) [32 42 N 21 35

E, ca. 330 m]. [Goto Description]. Holotype: NMP 49911: ad ♀, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002. Paratypes: 4 MM + 2 FF; see Benda *et al.* (2004c: 29). Paratype: NMP 49905: ad ♂, skull and alcoholic. Collected by: Michal Andreas, Petr Benda, Vladimír Hanák, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2153. See Benda *et al.* (2004c: 29), Benda in Mlíkovský *et al.* (2011: 137). Paratype: NMP 49906: ad ♂, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2154. See Benda *et al.* (2004c: 29), Benda in Mlíkovský *et al.* (2011: 137). Paratype: NMP 49907: ad ♂, skull and alcoholic. Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2155. See Benda *et al.* (2004c: 29), Benda in Mlíkovský *et al.* (2011: 137). Paratype: NMP 49908: ad ♂, alcoholic (skull not removed). Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2156. See Benda *et al.* (2004c: 29), Benda in Mlíkovský *et al.* (2011: 137). Paratype: NMP 49909: ad ♀, alcoholic (skull not removed). Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2157. See Benda *et al.* (2004c: 29), Benda in Mlíkovský *et al.* (2011: 137). Paratype: NMP 49910: ad ♀, alcoholic (skull not removed). Collected by: Petr Benda, Vladimír Hanák, Michal Andreas, Antonin Reiter and Marcel Uhrin; collection date: 20 May 2002; original number: pb2158. See Benda *et al.* (2004c: 29), Benda in Mlíkovský *et al.* (2011: 137). - Comments: Considered a valid species by Mayer *et al.* (2007: Additional file 1) based on mitochondrial DNA analyses. - Etymology: In honour of professor Jiri Gaisler (Brno, Czech Republic) who significantly contributed to the knowledge of the North Afrian bat fauna (see Benda *et al.*, 2004c: 29).

2006. *P. kolombatovici gaisleri:* Spitzenberger, Strelkov, Winkler and Haring, Zool. Scr., 35 (3): 221. (Name Combination).

2020. *Plecotus cf. gaisleri* Ancillotto, Bosso, Smeraldo, Mori, Mazza, Herkt, Galimberti, Ramazzotti and Russo, Ecol. Evol., 10 (12): 5791. Publication date: 29 April 2020.

? *Plecotus gaisleri:* (Name Combination, Current Combination).

Taxonomy:

See under *Plecotus* above. Formerly considered as *P. auritus* or *P. austriacus*, for details see Benda *et al.* (2004c). Spitzenberger *et al.* (2006) include it in *P. kolombatovici*.

See Mayer *et al.* (2007) and Mayer *et al.* (2007: Additional material).

Ancillotto *et al.* (2020: 9) indicate that Maghrebian bats from Morocco show molecular and morphological differences and identified these tentatively as "*Plecotus* cf. *gaisleri*", although they might represent a yet undescribed species (p. 12).

Common Names:

Czech: ušan berberský. Dutch: Gaislers grootoorvleermuis. English: Gaisler's Long-eared Bat, The North African long-eared bat. French: Oreillard du Gaisler, Oreillard du Maghreb. German: Gaislers Langohrfledermaus, Libysches Langohr. Italian: Orecchione di Gaisler.

Conservation status:

Assessment History

Global

VU (Baillie and Groombridge, 1996); DD ver 3.1 (2001) (IUCN, 2004; Juste *et al.*, 2004a) as *P. teneriffae*.

General distribution:

Northern Cyrenaica (Libya); north-west Africa [Maghreb: Morocco (Benda *et al.*, 2010a: 158; El Ibrahimi and Rguibi Idrissi, 2015: 364 [as "*Plecotus teneriffae = (P. austriacus, P. gaisleri)*"]; Dbiba *et al.*, 2025: 7), Algeria, Tunisia (Dalhoumi *et al.*, 2014: 53; 2016b: 867; 2019b: 26; 2023: 4); Pantelleria island (Italy) and Malta (Batsleer *et al.*, 2019: 172; Ancillotto *et al.*, 2020: 1). In Lybia it is found in two areas, Tripolitania in the northwest and Cyrenaica in the northeast (Razgour, 2023: 658).

Echolocation:

Benda *et al.* (2010a: 163) are the first to provide echolocation data for this species, based on 58 Moroccan specimens. They report a F_{start}: 41.7 ± 1.7 (37.2 - 44.5) kHz, F_{max}: 31.9 ± 2.0 (28.3 - 37.0) kHz, F_{end}: 21.7 ± 2.3 (16.1 - 26.5), with a duration of 1.4 ± 0.3 (0.9 - 1.9) ms, and an inter-pulse interval of 40.9 ± 23.5 (12.9 - 95.7) ms.

Also from Morocco, Disca *et al.* (2014: 226) report the following: call type FM multi H, F_{start}: 51.4 ± 1.1 kHz, F_{end}: 22.0 ± 0.7 kHz, $F_{max\ all\ harmonics}$: 29.7 ± 1.0 kHz, bandwidth: 29.3 ± 1.0 kHz, duration: 2.6 ± 0.2 ms.

From Tunisia, Dalhoumi *et al.* (2023: 5) reported F_{start}: 43.00 ± 4.27 (38.1 - 48.3) kHz, F_{end}: 20.06 ± 3.46 (15.7 - 24.3) kHz, F_{max}: 28.10 ± 1.20 (26.4 - 29.7) kHz, duration: 3.44 ± 0.66 (2.3 - 4.0) ms and Interpulse interval: 135.30 ± 42.12 (85.6 - 186.2) ms.

Habitat:

Plecotus gaisleri is found in Mediterranean woodland habitats and sub-Mediterranean dry steppes, but also in desert habitats up to a few hundred kilometers from the coast (Razgour, 2020: 24). In Morocco, it occurs in the Atlas mountains up to an elevation of 2,630 m, whereas in Tunisian open pine forests, it occurs up to 950 m, where it was found flying over river beds and wadis (Razgour, 2023: 660). In Lybia, it

has been caught in oases, large caves, lakes surrounded by dense riparian vegetation, quarries, fortress ruins, under bridges, and in wadis with open shrubby vegetation (Benda *et al.*, 2014c: 104).

ROOST:
Benda *et al.* (2014c: 103) found a roost (probably the remainder of a maternity colony) in deep holes and crevices of the ceiling of an ancient ruin covered by carob trees. Further specimens were also recovered from ruins, indicating that *P. gaisleri* is probably a petrophilous species, which seems to select its roosts solely in underground spaces rather open to daylight and in rock fissures

Razgour (2020: 25) [referring to Benda and Aulagnier (2013b) and Benda *et al.* (2014b)] mentions summer roosts in rock crevices, caves, mosque towers, ancient ruins, caverns, old houses, cistern, and an underground aqueduct, whereas winter roosts include caves, mines, attics, wells and tree holes.

DIET:
Benda *et al.* (2014c: 108) examined eight sample sets of the diet and found large amounts of moths (Lepidoptera), most with wingspans between 30 and 35 mm. From other areas in Libya, orthopterans (Ensifera) or cockroaches (Blattoidea) formed the major part of the diet.

Based on three fecal samples, Gonçalves *et al.* (2024: 4) reported the diet for "*Pipistrellus austriacus*" on Madeira to consist mainly of Lepidoptera (80 %), followed by Coleoptera (20 %). In the Lepidoptera, the Noctuidae were the most common family (70 %), followed by Cerambycidae (20 %), and Geometridae (10 %). At species level, *Arhopalus ferus* (Mulsant, 1839) (Cerambycidae) and *Mythimna unipuncta* (Haworth, 1809) (Noctuidae) were the most common items (both 20 %). Of the 6 prey species, at least 50% referred to known agriculture pests.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

REPRODUCTION AND ONTOGENY:
Two pregnant females, both with one foetus, were collected in the central part of Wadi Al Kuf (Libya) on 19 May, whereas lactating females were found between 9 May and 4 August (Benda *et al.*, 2014c: 105).

PARASITES:
Benda *et al.* (2014c: 109) reported one egg with praelarvae of a mite belonging to the superorder Acariformes.

From Algeria, Bendjeddou *et al.* (2017: 15) and Khelfaoui *et al.* (2018: 67) reported the following ectoparasites: Nycteribiidae: *Nycteribia (Nycteribia) latreillii* (Leach, 1817) and Arachnida: *Spinturnix myoti* (Kolenati, 1856), *Eyndhovenia euryalis* (Canestrini, 1884) and *Argas vespertilionis* (Latreille, 1802).

In their checklist of arthropod parasites of North African bats, Bendjeddou *et al.* (2023: 4 - 7) mention the following species: Argasidae: *Carios vespertilionis* Latreille, 1802; Ischnopsyllidae: *Rhinolophopsylla unipectinata arabs* Jordan and Rothschild, 1921; Nycteribiidae: *Nycteribia schmidlii schmidlii* Schiner, 1853; and Spinturnicidae: *Eyndhovenia euryalis euryalis* (Canestrini, 1884), *Spinturnix plecotinus* (Koch, 1839).

Razgour (2020: 25) also mentioned the mite *Eyndhovenia euryalis* (Canestrini, 1884), the flea *Nycteridopsylla pentactena* (Kolenati, 1856) and the tick *Carios boueti* Roubaud and Colas-Belcour, 1933.

VIRUSES:
Coronaviridae
Zeghbib *et al.* (2025: 22) mention that the first Coronavirus that was described from Algerian bats was more related to *Rhinolophus* viruses from Kenya and Guinea than Algeria.

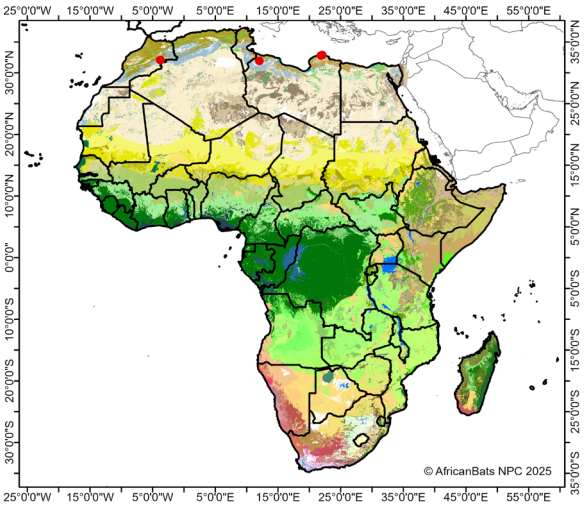

Figure 351. Distribution of *Plecotus gaisleri*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Libya, Morocco.

Plecotus kolombatovici Dulic, 1980

*1980. *Plecotus austriacus kolombatovici* Dulic, 5th Internat. Bat Res. Conf., (D.E. Wilson and A.L. Gardner, eds), Texas Tech Press, 159. Type locality: Croatia: Dalmatia: 2.5 km NW Zrnovo: Korčula Isl [42??N 17??E, 276m]. Holotype: UZ 3007: ad ♀, skin and skull. Collected by: B. Dulic and O. Seple; collection date: 21 July 1969. See Spitzenberger *et al.* (2002: 3), Spitzenberger *et al.* (2006: 220). - Etymology: Dedicated to Juraj Kolombatovič, the investigator of the vertebrate fauna of Dalmatia.

2001. *Plecotus kolombatovici:* Spitzenberger, Strelkov and Haring, 50 (3): 162. - Comments: This species rank was errouneously attributed to a genetic clade that subsequently emerged to pertain to *P. macrobullaris* (Spitzenberger *et al.*, 2003).

TAXONOMY:
Synonymized with *P. austriacus* by Corbet (1978); but Mayer and von Helversen (2001) reported a high sequence divergence between a specimen from Germany and individuals caught in Croatia and Greece that could represent two separate species. This status was supported by Spitzenberger *et al.* (2001) and subsequent studies. Juste *et al.* (2004c: 10) suggest *teneriffae* is closely related with *kolombatovici*.

Fukui *et al.* (2020: 73) consider *P. kolombatovici* to be a valid species occurring in Morocco and Libya.

COMMON NAMES:
Croatian: Kolombatovićev dugoušan. Czech: ušan balkánský. Dutch: Balkangrootoorvleermuis. English: Kolombatovic's Big-eared Bat, Balkan long-eared bat, Kolombatovic's Long-eared Bat, Mediterranean Long-eared Bat. French: Oreillard Des Balkans. German: Balkan-Langohr. Italian: Orecchione di Kolombatovic.

CONSERVATION STATUS:
Global Justification
Assessed as Least Concern (LC ver 3.1 (2001)), as this species range is wide and uses a variety of habitats. Population trend has not been quantified, but it does not appear to be declining at a fast rate in North Africa (Hutson *et al.*, 2008d; IUCN, 2009).

Assessment History
Global
2008: LC ver 3.1 (2001) (Hutson *et al.*, 2008d; IUCN, 2009).

Regional
None known.

MAJOR THREATS:
Pesticides and roost disturbance have a negative impact on the species but are not thought to be causing significant population declines at the global level. However, in Europe, where this species is largely restricted to coastal areas, disturbance of roost sites by tourists may be a major threat (Hutson *et al.*, 2008d; IUCN, 2009).

The small distribution range and the aerial hawking feeding style are identified by Sherwin *et al.* (2012: 174) as the risk factors linked with climatic change

CONSERVATION ACTIONS:
Hutson *et al.* (2008d) [in IUCN (2009)] report that it is protected by national legislation in most range states. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention in those parts of the range where these apply. It is included in Annex IV of EU Habitats and Species Directive, and there is some habitat protection through Natura 2000. Recommended actions include monitoring population trends and minimising or preventing disturbance to roost sites in Europe.

GENERAL DISTRIBUTION:
Plecotus kolombatovici is a Mediterranean endemic with its distribution fragmented into three parts: southern regions of the Balkans and Asia Minor (Cyprus, Turkey, Syria, Lebanon and probably into Israel, Palestine and Jordan), northeast Libya (Cyrenaica) and northwest Africa from Morocco to northwest Libya, it was found in Malta and Pantellaria (Spitzenberger *et al.*, 2006). It occurs from sea level to higher altitudes in the Rif and Atlas mountains.

Native: Albania; Algeria; Croatia; Cyprus; Greece [Kriti]; Italy; Lebanon; Libyan Arab Jamahiriya Fukui *et al.*, 2020: 73); Malta; Morocco (Fukui *et al.*, 2020: 73); Serbia; Tunisia; Turkey.

Presence uncertain: Bosnia and Herzegovina; Israel; Montenegro; Palestinian Territory, Occupied; Syrian Arab Republic.

DETAILED MORPHOLOGY:
Baculum
See Đulić (1980), Benda *et al.* (2004c).

MOLECULAR BIOLOGY:
Karyotype
Đulić (1980) reported 2n = 32, X = metacentric, Y = acrocentric, differing from *P. austriacus* by biarmed small autosomes of pair 14.

Genetics
See Mayer and von Helversen (2001), Benda *et al.* (2004c), Juste *et al.* (2004c), Spitzenberger *et al.* (2006), Mayer *et al.* (2007).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 76 minutes, and the digestibility rate about 80.1 %.

POPULATION:
Structure and Density
Little is known about population size and trends in this species, although it is regarded as relatively common in North Africa. In Europe, the total population is estimated at fewer than 10,000 mature individuals, and it is suspected that the population may be declining. Summer colonies usually number 10 - 30 females, although a breeding colony of 120 females was found in a building in Croatia (F. Spitzenberger *pers. comm.,* 2006). Winter clusters are smaller (10 individuals), and the species is often solitary at this time of year (S. Aulagnier *pers. comm.,* 2007). It was thought that European, African and southwest Asian populations were isolated from each other, but range extensions as a result of recent records indicate that they might not be as isolated as was previously thought (Hutson *et al.*, 2008d; IUCN, 2009).

Trend
Decreasing (Hutson *et al.*, 2008d; IUCN, 2009).

Plecotus teneriffae Barrett-Hamilton, 1907

*1907. *Plecotus teneriffae* Barrett-Hamilton, Ann. Mag. nat. Hist., ser 7, 20 (120): 520. Publication date: 1 December 1907. Type locality: Canary Islands (Spain): Tenerife island: Orotava [28 23 N 16 31 W]. [Goto Description]. Holotype: NHMUK 1887.4.18.1: ad, skin and skull. Collected by: Ramon Gómez; collection date: 3 April 1887. See Benda *et al.* (2004c: 39). - Comments: Barrett-Hamilton (1907: 520) mentions that the type specimen has no skull. - Etymology: Referring to the island where the type specimen was collected. (Current Combination).
1939. *Plecotus auritus teneriffae:* G.M. Allen, Bull. Mus. comp. Zool., 83: 96. Publication date: February 1939. (Name Combination).
1971. *Plecotus austriacus teneriffae:* Hayman and Hill, Order Chiroptera. In Meester, J. & H.W. Setzer [Eds]: The mammals of Africa. An Identification manual. Part 2, 35. (Name Combination).
1978. *Plecotus austriacus austriacus:* Corbet, The mammals of the Palaearctic region: a taxonomic review, 61. - Comments: Not of J.B. Fischer, 1829. (Name Combination).
2021. *P[lecotus]. cf. teneriffae:* Kruskop, Artyushin, Yuzefovich, Undrakhbayar, Speranskya, Lisenkova, Bannikova and Lebedev, Acta Chiropt., 22 (2): Suppl. Publication date: 4 March 2021. (Name Combination).
? *Plecotus austriacus:* (Name Combination).

TAXONOMY:
Synonymized with *P. austriacus* by Corbet (1978); but see Ibáñez and Fernández (1985b). Genetic studies clearly show that *teneriffae* is more closely related with *kolombatovici*, while Pestano *et al.* (2003a: 306) suggested the North African to be the closest relative.

COMMON NAMES:
Albanian: Lakuriq nate veshgjatë i Teneriffae-ve. Armenian: Կանարյան կամ Տենեռիֆյան ականջեղ. Azerbaijani: Kanar palazqulağı. Basque: Belarrihandi kanariar. Belarusian: Вушан канарскі. PALAEONTOLOGICAL OR ARCHAEOLOGICAL RECORDS:
González-Dionis *et al.* (2021: 13) reported on fossil remains of *P. teneriffae* on El Hierro and found these to differ from other European and north African species, specifically in the height of the paracone and metacone of M3 and in the cingulid of p4 and the lower molars.

CONSERVATION STATUS:
Global Justification
Juste and Alcaldé (2016b) justification for the global listing as Vulnerable (VU B1ab(iii,v)) due to this species has an EOO of < 20,000 km^2 and it is found on three, or possibly four, of the Canary Islands, which are each considered to be a single location based on the threat of habitat decline. It is linked to forest habitats that are shrinking, and recent declines have been recorded in the largest known breeding colony.

Assessment History
Global
2016: Vulnerable B1ab(iii,v) ver 3.1 (2001) (Juste and Alcaldé, 2016b). 2004: DD ver 3.1 (2001) (IUCN, 2004; Juste *et al.*, 2004a). 1996: VU (Baillie and Groombridge, 1996).

Legal Status
It is protected by national legislation in Spain. There are also international legal obligations for its protection through the Bonn Convention (Eurobats) and Bern Convention. It is included in Annex IV of EU Habitats & Species Directive.

MAJOR THREATS:
The population declined in the 1950s after aerial fumigation for pest control. Current threats include disturbance of colonies in their roosts, use of pesticides on agricultural land near to the forests, loss of woodland habitat, restoration of buildings and the destruction of roost sites (Trujillo, 2002). The recent decline of the La Palma maternity colony has been attributed to disturbance, and it is known that at least one individual from this colony has been taken by private collectors (Trujillo, 2002).

Sagot and Chaverri (2015: 1670) mention roost loss or disturbance, and habitat degradation or loss as major threats for this species.

CONSERVATION ACTIONS:
A bat protection programme aimed at protecting caves used as roost sites from human disturbance was instigated in 1993 (Benzal and Fajardo 1999). Protection of the species' woodland foraging habitat is also recommended (Trujillo 2002).

GENERAL DISTRIBUTION:
Plecotus teneriffae is endemic to the Canary Islands (Tenerife, La Palma, El Hiero) (Spain) (Benda *et al.*, 2004c: 28; Razgour, 2023: 661), where it occurs on altitudes between 100 and 2,300 m.

DETAILED MORPHOLOGY:
Baculum
See Ibáñez and Fernández (1985b), Benda *et al.* (2004c).

MOLECULAR BIOLOGY:
Genetics
See Pestano *et al.* (2003a), Benda *et al.* (2004c), Juste *et al.* (2004a), Spitzenberger *et al.* (2006), Mayer *et al.* (2007).

HABITAT:
On Madeira, Ferreira *et al.* (2022a: 1) reported that the activity of "*Plecotus austriacus*" was negatively influenced by cropland cover and that also altitude had a negative effect on its activity.

Ibáñez and Fernández (1985b: 148) report it to be primarily associated with *Pinus canariensis* forests and the transition zones with laurel forests.

ROOST:
Plecotus teneriffae is a crevice dwelling bat that mainly roosts in volcanic tubes, caves, water mines, and abandoned buildings (Razgour, 2020: 28, 2020: 663). In caves, these bats roost individually or in small clusters.

MIGRATION:
Razgour (2020: 28) mention that this species is very sedentary, not moving more that 10 km between roosts.

DIET:
Trujillo (1992: 80 - 83) report that the diet of *Plecotus teneriffae* mainly consists of Lepidoptera, and to a lesser extent Coleoptera. Within the Lepidoptera, the majority of the species belonged to the Noctuidae and the Geometridae.

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 80 minutes, and the digestibility rate about 79.5 %.

POPULATION:
Structure and Density
Juste and Alcaldé (2016b) report that summer colonies usually consist of 10-30 females (the maximum number recorded is 61). Winter clusters are usually small (c.10 animals), and the species often roosts solitarily at this time of year. There are only two known breeding colonies (on La Palma and Tenerife respectively). The larger of these two (the La Palma colony) has declined in number in recent years (Trujillo, 2002).

Trend
2016: Decreasing (Juste and Alcaldé, 2016b).

REPRODUCTION AND ONTOGENY:
Razgour (2020: 28) mention that young are born in July, and lactating females were found between mid-July and the end of August/begin.of September.

PARASITES:
Estrada-Peña and Sanchez (1988: 309) described the mite *Steatonyssus (Steatonyssus) teidae* from a *P. teneriffae* specimen from La Caldera, Tenerife, Canary Islands.

Trujillo (1992: 83) and Razgour (2020: 28) mention the presence of *Steatonyssus (Steatonyssus) balcellsi* Estrada-Pena and Sanchez, 1988, *Steatonyssus (Steatonyssus) teidae* Estrada-Pena and Sanchez, 1988 and *Spinturnix plecotinus* (Koch, 1839).

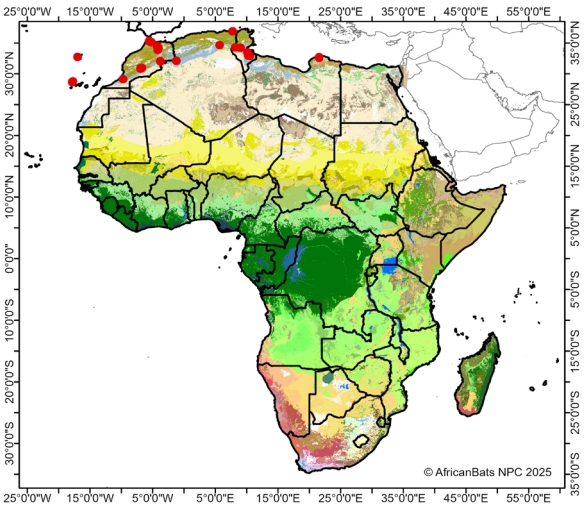

Figure 352. Distribution of *Plecotus teneriffae*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Algeria, Canary Islands (Spain), Libya, Madeira (Portugal), Malta, Morocco, Tunisia.

TRIBE Vespertilionini J. E. Gray, 1821

*1821. *Vespertilionini* J. E. Gray, London Med. Repos., 15 (1): 299. Publication date: 1 April 1821.

GENERAL COMMENTS:
Based on karyological data (the presence of three derived Robertsonian fusion chromosomes, 7/11, 8/9, and 10/12,), Volleth *et al.* (2023c: 35) created a new subtribe - Laephotina - containing the genera *Laephotis, Neoromicia, Afronycteris*, and *Pseudoromicia*. The close relationship of these genera is also supported by their penis and bacular morphology. Within the Laephotina, *Laephotis* and *Neoromicia* are the closest relatives, but Volleth *et al.* (2023c: 46)'s data were unable to support a close relationship between *Afronycteris* and *Pseudoromicia*.

TAXONOMY:
Baird *et al.* (2025: 6) state that the relationship between *Afronycteris+Pseudoromicia* and *Neoromica* and *Laephotis* is still not well resolved. However, based on four independent nuclear introns, Demos *et al.* (2025: 143) found strong support for the subtribe Laephotina, containing the genera *Afronycteris, Laephotis, Neoromicia* and *Pseudoromicia*. They also found a sister relation between *Laephotis* and *Neoromicia*, but the relation between *Afronycteris* and *Pseudoromicia* remains unclear. *Nycticeinops* + *Afropipistrellus* are considered to be sister to the Laephotina, and the differences between the two in nuclear introns, dentition and bacula support their recognition as separate genera.

Genus ***Afronycteris*** Monadjem, Patterson and Demos, 2020

1852. *Vespertilio:* Peters, Reise nach Mossambique, 61.
1860. *Hypsugo:* Kolenati, Monographie der Europäischen Chiroptern, 20. - Comments: In part. Not of Kolenati, 1856 (see Monadjem *et al.*, 2020a: 1127, 1138).
1878. *Vesperugo:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 183. Publication date: 15 June 1878. - Comments: In part. Not of Keyserling and Blasius, 1839 (see Monadjem *et al.*, 2020a: 1127, 1138).

1900. *Pipistrellus:* Miller, Proc. Wash. Acad. Sci., 2: 647. Publication date: 28 December 1900. - Comments: In part. Not of Kaup, 1829 (see Monadjem *et al.*, 2020a: 1138).
1907. *Myotis:* Matschie, Liste der von Herrn V.B. Schillings gesammelten Säugetier-Arten, 534. - Comments: In part. Not of Kaup, 1829 (see Monadjem *et al.*, 2020a: 1138).
1934. *Neoromicia:* Shortridge, The mammals of South West Africa, 59. - Comments: In part. Not of Kaup, 1829 (see Monadjem *et al.*, 2020a: 1138).
1951. *Eptesicops:* Roberts, The mammals of South Africa, 84. - Comments: In part. Not of Roberts, 1926 (see Monadjem *et al.*, 2020a: 1138).
*2020. *Afronycteris* Monadjem, Patterson and Demos, in: Monadjem et al., Zool. J. Linn. Soc., 191 (4): 1120, 1138. Publication date: 10 September 2020. - Etymology: From the Greek word νυχτερίδα, meaning bat, and the prefix Afro- referring to the African continent (see Monadjem *et al.*, 2020a: 1138).

TAXONOMY:
Currently (Simmons and Cirranello, 2024a) recognized species in the genus *Afronycteris*: ***helios*** (Heller, 1912); ***nanus*** (Peters, 1852).

Afronycteris helios (Heller, 1912)

*1912. *Pipistrellus helios* Heller, Smiths. Misc. Coll., 60 (12): 3. Publication date: 4 November 1912. Type locality: Kenya: 30 mi (48 km) S Mount Marsabit: Merelle Water [01 23 S 37 44 E]. [Goto Description]. Holotype: USNM 181813: ad ♂, skin and skull. Collected by: Edmund Heller; collection date: 22 July 1911; original number: 3065. - Etymology: From the masculine Greek substantive "*ἥλιος*" (hèlios), meaning "sun", referring to the ochraceous-buff colour of the dorsal fur (see Lanza *et al.*, 2015: 407).
1951. *Pipiestrellus helios:* Watson, Uganda J., 15 (1): xx. - Comments: Lapsus. . (Lapsus).
1968. *Pipistrellus nanus helios:* Funaioli and Lanza, Mon. Zool. ital., (NS) 2 (Suppl): 199. (Name Combination).
1987. *Pipistrellus (Hypsugo) helios:* Hill and Harrison, Bull. Br. Mus. (nat. Hist.) Zool., 52 (7): 281. (Name Combination).
1994. *P[ipistrellus (Pipistrellus)] a[fricanus] helios:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 113. (Name Combination).
2002. *Hypsugo helios:* Kruskop, Plecotus et al., pars spec: 21. (Name Combination).
2006. *Neoromicia helios:* Van Cakenberghe, Kearney and Seamark, African Chiroptera Project, Pretoria, 134. (Name Combination).
2019. *L[aephotis] helios:* M. Taylor, Bats: An illustrated guide to all species, 283. Publication date: 11 April 2019. (Name Combination).
2020. *Afronycteris helios:* Monadjem, Demos, Dalton, Webala, Musila, Kerbis Peterhans and Patterson, Zool. J. Linn. Soc., 191 (4): 1138. Publication date: 10 September 2020. (Name Combination).

TAXONOMY:
Hayman and Hill (1971) indicated that the shape of the baculum supports the separation of *helios* from *Afronycteris nana*, which is confirmed by Kock (pers. Comm.). See discussion in Simmons (2005).

Simmons and Cirranello (2020) included *helios* in the genus *Laephotis*, but Monadjem *et al.* (2020a: 1138) include it (together with nana) in the newly erected genus *Afronycteris*.

COMMON NAMES:
Chinese: 桑布鲁伏. Czech: netopýr slunečný. English: Samburu Pipistrelle Bat, Helios Pipistrelle Bat, Heller's Pipistrelle Bat, Heller's Pipistrelle. French: Pipistrelle soleil. German: Samburu-Zwergfledermaus, Samburu-Pipistrelle. Italian: Pipistrèllo di Hèller.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of the absence of sufficient information on its extent of occurrence, natural history, threats and conservation status (Jacobs *et al.*, 2008t; IUCN, 2009; Jacobs *et al.*, 2014b).

Assessment History
Global
2014: DD ver 3.1 (2001) [assessed as "*Neoromicia helios*"] (R). 2008: DD ver 3.1 (2001) [assessed as "*Pipistrellus helios*"] (Jacobs *et al.*, 2008t; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004z; IUCN, 2004).

Regional
None known.

MAJOR THREATS:
The threats to this species are not known (Jacobs *et al.*, 2008t; IUCN, 2009; Jacobs *et al.*, 2014b).

CONSERVATION ACTIONS:
Jacobs *et al.* (2014b) repeats what stated by Jacobs *et al.* (2008t) [in IUCN (2009)] who report that it is not known if the species is present in any protected area. There is a need for studies into the distribution, abundance, natural history and possible threats to this species.

GENERAL DISTRIBUTION:
Afronycteris helios is an East African species, which has been recorded from Djibouti, southern Somalia, southern Sudan, northeastern Uganda, Kenya and northern Tanzania. It may be more widely distributed (Peterson, 1987; Simmons, 2005).

Native: Djibouti; Kenya; Somalia; Sudan; Tanzania; Uganda.

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

HABITS:
Keeley and Keeley (2004: 116) [referring to O'Shea (1980) and Happold and Happold (1996)] mention that male "*Pipistrellus nanus*" roosting in palm-thatched roofs show territoriality and aggressive competition for spacious roosts, whereas males in populations roosting in banana leaves appear not to defend territories aggressively, and indicate that this difference might be based on the availability of preferred roosts. However, the more likely explanation being that these differences are due to these two groups belonging to different species, as the thatched roof inhabiting form is most likely *A. helios*.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 52 minutes, and the digestibility rate about 84.4 %.

POPULATION:
Structure and Density
Little information is available on the population abundance or size of this species (Jacobs *et al.*, 2008t; IUCN, 2009; Jacobs *et al.*, 2014b).

Trend
2014: Unknown (Jacobs *et al.*, 2014b). 2008: Unknown (Jacobs *et al.*, 2008t; IUCN, 2009).

PARASITES:
DIPTERA
Nycteribiidae
Basilia ansifera Theodor, 1956 - mainly a West African species reaching Lake Victoria in the east and Lake Nyasa in the south - nearly all localities lie between 15° latitude north and south (Haeselbarth *et al.*, 1966: 110; Dick *et al.*, 2023: 73).

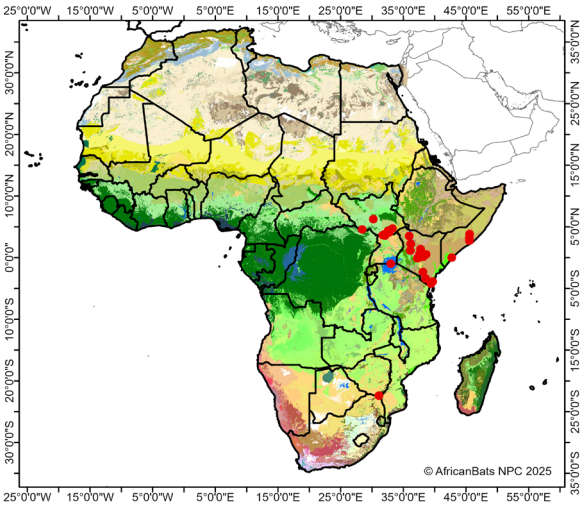

Figure 353. Distribution of *Afronycteris helios*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Kenya, Somalia, South Africa, South Sudan, Tanzania, Uganda.

*1852. *Vespertilio nanus* Peters, Naturwissenschaftliche Reise nach Mossambique, Zoologie, Säugethiere, 63, pl 16, fig 2. Publication date: 1852. Type locality: Mozambique: Inhambane [24 00 S 35 28 E]. [Goto Description]. Syntype: NHMUK 1907.1.1.421: ad, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters. See Turni and Kock (2008). Syntype: NHMUK 1907.1.1.422: ad ♀, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters. Syntype: NHMUK 1907.1.4.421: ad, skin and skull. Collected by: Prof. Wilhelm Carl Hartwig Peters. Syntype: NHMUK 1907.1.4.422: ad ♀, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters. Syntype: NMW 19644: ad ♂, alcoholic (skull not removed). Collected by: Prof. Wilhelm Carl Hartwig Peters. See Turni and Kock (2008). Syntype: ZMB 588a: ad ♀, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008). Syntype: ZMB 588b: ad ♀, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008). Syntype: ZMB 588c: ad ♂, skull and alcoholic. Collected by: Prof. Wilhelm Carl Hartwig Peters; collection date: between 1843 and 1847. See Turni and Kock (2008). - Etymology: From the Latin "*nanus*" meaning dwarf (see Lausen and Barclay, 2005: 5).

1855. *Vespertilio (Vesperugo) nanus:* Wagner, in: Schreber, Die Säugethiere in Abbildungen nach der Natur mit Beschreibungen, Suppl 5: 746. (Name Combination).

1860. *Hypsugo nanus:* Kolenati, Monographie der Europäischen Chiroptern, 18. (Name Combination).

1870. *Vesperugo pusillulus* Peters, J. Sci. mat. phys. nat., ser 1, 3 (10): 124. Publication date: December 1870. Type locality: Angola: Cabinda: Loango [ca. 04 52 S 12 52 E]. [Goto Description]. Syntype: ZMB 3975: ♂, alcoholic (skull missing). Collected by: José Vicente Barboza du Bocage. See Turni and Kock (2008). - Comments: The type locality (Loango) was originally located in Angola, but see Kock et al. (in prep).
1875. *Vesperugo nanus:* Dobson, Proc. zool. Soc. Lond., 1875, III: 472. (Name Combination).
1878. *Vesperugo (Vesperugo) nanus:* Dobson, Catalogue of the Chiroptera of the collection of the British Museum, 237. Publication date: 15 June 1878. (Name Combination).
1888. *Vesperugo stampflii* Jentink, Notes Leyden Mus., 10: 54 (for 1887). Publication date: April 1888. Type locality: Liberia: Farmington River [06 08 N 10 22 W]. [Goto Description]. Holotype: RMNH MAM.17836: ad ♂, skull and alcoholic. Collected by: F.X. Stampfli; collection date: 1 July 1887. The RMNH catalog mentions two numbers: 17836.a (skull + loose bones) and 17836.b (wet specimen).
1889. *Vesperugo pagenstecheri* Noack, Zool. Jb. Syst., 4: 220, pl 2, fig 3, pl 5, fig 64 - 65. Publication date: 28 February 1889. Type locality: Congo (Democratic Republic of the): Bas Congo province: near mouth of Congo river, Banana Creek: Netonna [05 58 S 12 27 E]. [Goto Description]. Lectotype: SMF 2524: ad ♀, skull only. Collected by: P. Hesse; collection date: 1887. See Mertens (1925: 22). Paralectotype: SMF 2525: ad ♀, skull only. Collected by: P. Hesse. See Mertens (1925: 22). Noack (1889: 220) refers to two female specimens, both in alcohol and collected by P. Hesse.
1889. *Vesperus pusillus* Noack, Zool. Jb. Syst., 4: 216, pl 2, fig 3, pl 5, fig 60, 61. Publication date: 28 February 1889. Type locality: Congo (Democratic Republic of the): Congo River: Boma [05 50 S 13 03 E, 30 m]. [Goto Description]. Holotype: SMF 2523: juv ♂, skull only. Collected by: P. Hesse; collection date: 1887.
1897. *Vesperugo (Vesperugo) Pagenstecheri:* Trouessart, Catalogus Mammalium tam viventium quam fossilium, fasc I: 112.
1900. *Pipistrellus minusculus* Miller, Proc. Wash. Acad. Sci., 2: 647, fig 43. Publication date: 28 December 1900. Type locality: Liberia: Mount Coffee [06 34 N 10 33 W]. [Goto Description]. Holotype: USNM 84500: ad ♀, skull and alcoholic. Collected by: Orator Fuller Cook Jr. Collection date: May 1894. Catalogued: 11 April 1898.
1900. *Pipistrellus stampflii:* Miller, Proc. Wash. Acad. Sci., 2: 647. Publication date: 28 December 1900.
1901. *Vespertilio (Pipistrellus) nanus:* Sclater, Mammals of South Africa, 123, 126. (Name Combination).
1903. *Pipistrellus nanus:* Cabrera, Mem. Soc. espan. Hist. nat., 1: 22. (Name Combination).
1906. *Vespertilio (Vesperugo) stampflii:* Johnston, Liberia, Volume II: 692. (Name Combination).
1907. *Myotis nanus:* Matschie, Liste der von Herrn V.B. Schillings gesammelten Säugetier-Arten, 534. (Name Combination).
1908. *Vespertilio (Glischropus) nanus:* Lönnberg, Sjöstedts Kilimanjaro-Meru Expedition, 2: 11. (Name Combination).
1911. *Pipistrellus culex* Thomas, Ann. Mag. nat. Hist., ser 8, 7 (41): 458. Publication date: 29 April 1911. Type locality: Nigeria: Northern Nigeria, Bauchi plateau: Kabwir [09 24 N 09 34 E, 2 700 ft]. [Goto Description]. Holotype: NHMUK 1911.3.24.4: ad ♀, skin and skull. Collected by: Rév. G.J. Fox; collection date: 15 May 1910; original number: 100.
1913. *Pipistrellus nanus australis* Roberts, Ann. Transv. Mus., 4: 67. Publication date: 20 October 1913. Type locality: South Africa: Transkei, Western Pondoland: Port St. Johns district: "Port St. Johns district" [ca. 31 27 S 29 33 E, 200 ft]. Holotype: TM 1076: ad ♀, skin and skull. Collected by: H.H. Swinny; collection date: 20 April 1908. Holotype for both *Pipistrellus africanus meesteri* and *Pipistrellus nanus australis*. - Comments: Replaced by *P. africanus meesteri* by Kock (2001a: 129). (Name Combination).
1917. *Pipistrellus abaensis* J.A. Allen, Bull. Am. Mus. Nat. Hist., 37 (18): 442. Publication date: 29 September 1917. Type locality: Congo (Democratic Republic of the): Oriental province: Uele district: Aba [03 53 N 30 17 E]. [Goto Description]. Holotype: AMNH 48979: ad ♀, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition; collection date: 18 December 1910; original number: 1825. Topotype: AMNH 48980: ♀, skin only. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition. Topotype: AMNH 48981: ♂, skin and skull. Collected by: Herbert Lang, James Paul Chapin and The American Museum Congo Expedition.
1925. *Pipistrellus pagenstecheri:* Mertens, Senckenb. biol., 7 (1/2): 22.
1926. *Pipistrellus fouriei* Thomas, Proc. zool. Soc. Lond., 1926, I: 288. Publication date: 29 April 1926. Type locality: Namibia: NW Ovamboland: 32 mi NW of Rehoboth Mission Station: Ukualukasi [17 32 S 14 37 E, 3 400 ft]. [Goto Description]. Holotype: NHMUK 1925.12.4.20: ad ♀, skin and skull. Collected by: Captain Guy Chester Shortridge; collection date: 7 October 1924; original number: 1390.
1934. *Neoromicia pusilla pusilla:* Shortridge, Mammals of South West Africa, 59.
1939. *Pipistrellus nanus nanus:* G.M. Allen, Bull. Mus. comp. Zool., 83: 95. (Name Combination).
1951. *Eptesicops fouriei:* Roberts, Mammals of South Africa, 84.
1951. *Pipistrellus (Pipistrellus) nanus nanus:* Swynnerton and Hayman, J. East Afr. Nat. Hist. Soc., 20 (6-7) (90): 293 (for 1950). (Name Combination).
1953. *Pipistrellus (Pipistrellus) culex culex:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 78.
1953. *Pipistrellus (Pipistrellus) culex fouriei:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 78.
1953. *Pipistrellus (Pipistrellus) culex:* Ellerman, Morrison-Scott and Hayman, Southern African mammals 1758 to 1951, 78.

? *Pipistrellus africanus nanus:* (Name Combination).

TAXONOMY:

Figure 354. *Afronycteris nana* caught in the Ubombo Mtns-NR, northern KwaZulu Natal, South Africa.

The oldest name for this species is (possibly) *africana*; see Koopman (1975: 400), but most authors still remained using the name *nana* (or *nanus*), until Koopman (1994: 112) and Simmons (2005), who mention this species under the name *Pipistrellus africanus*. In Opinion 2120 (Anonymus, 2005), however, the ICZN ruled that the name *Pipistrellus nanus* (currently *Afronycteris nana*) should be given precedence over *africana*, whenever the two are considered to be synonyms.

Bronner *et al.* (2003) state that Volleth *et al.* (2001) and Kearney *et al.* (2002) provided karyotypic evidence for the inclusion of the banana bat (*"Pipistrellus" nanus*) in *Neoromicia*.

Ansell and Dowsett (1988) and Koopman (1966) point out that *africanus* Ruppell, 1842 antedates *nanus* (Peters, 1852) as the valid name for this species. However, they continue to use the better-known name *nanus*, as topotypical *africanus* is restricted to Ethiopia (and is thus unlikely to be conspecific with *nanus*) and Happold (2003) has applied to the International Commission on Zoological Nomenclature for conservation of this specific epithet on the grounds of nomenclatural stability.

Grubb *et al.* (1998: 85) include it - as *nanus* - in the subgenus *Hypsugo*. Kearney *et al.* (2002: 68) states that *nanus* belongs to the genus *Neoromicia*.

Hoofer and Van Den Bussche (2003: 38) include this taxon as "*(Hypsugo) nanus*" in a separate, unnamed genus.

The generic alliance of *nanus* is certainly not clear at this stage. Most authors mention this species in the genus *Pipistrellus*, but as pointed out in the previous paragraphs, present taxonomical investigations seem to indicate that it should be included in *Neoromicia*. However, the assignement to *Hypsugo* or even a new genus is not yet excluded. Further research is needed to fix its generic assignment.

Recently, Meri Happold (pers. comm.) reported that unlike all other pipistrelles placed in *Neoromicia* by Simmons (2005) and also unlike all African species placed in *Hypsugo* (ibid.), "*P. nanus*" has nyctalodont lower molars (as have all African species in *Pipistrellus*). The taxonomic implications need further investigation.

Happold (ibid) also reported that the following subspecies of "*P. nanus*" (as "*Pipistrellus africanus*") were recognized by Koopman (1994) and/or Kock (2001a), but their status and geographic ranges are uncertain:
P. n. stampflii. Sierra Leone to Côte d'Ivoire.
P. n. culex. Nigeria, Ghana.
P. n. africanus. Zaire to Ethiopia, mostly in highlands.
P. n. nanus. Zaire, Kenya and Tanzania to South Africa, also Cameroon (Rosevear 1965).
P. n. fouriei. S Angola, W Zambia, N Namibia.
P. n. meesteri. Transkei, South Africa.
P. n. minusculus. Liberia.

Helbig *et al.* (2010: 168) suggest that *nanus* needs to be transferred to a genus that needs to be newly created or resurrected from the current synonymy.

Simmons and Cirranello (2020) included *nanus* in the genus *Laephotis*, but based on analyses of mitochondrial cytochrome b sequences, Monadjem *et al.* (2020a: 1120) concluded that this species (together with *helios*) should be assigned to a separate sister genus: *Afronycteris*.

Common Names:

Afrikaans: Piesangvlermuis. Arabian: Khouchaf al matoussat. Azande (DRC): Fulo. Castilian (Spain): Pipistrelo Enano. Chewa (Malawi): Ndemia. Chinese: 香蕉伏翼. Czech: netopýr banánový, netopýr šplhavý. English: Banana Pipistrelle Bat, Banana Bat, Banana Pipistrelle. French: Pipistrelle naine, Pipistrelle naine aux ailes brunes. German: Bananen Zwergfledermaus, Bananen-Fledermaus, Bananen-Pipistrelle, Mozambique Dämmerungsfledermaus, Zwerg-Hausfledermaus. Italian: Pipistrèllo di Pèters, Pipistrèllo nàno déi banàni. Kiluba (DRC): Kasusu. Kiswahili: Popomgomba. Malawian: Mnalimpsimpsi, Namsinsi, Ndemia. Manganja (Malawi): Chuchu. Misuku (Malawi): Kashusha. Portuguese: Morcego das bananeiras, Morcego-das-bananas. Tshokwe (Angola): Kateta. Yao (Malawi): Liputiputi (applied to all small bats).

Etymology of Common Name:

Characteristically this species roosts during the day in the rolled-up, sprouting terminal leaves of banana plants and has become associated with them in particular (Taylor, 2005).

Conservation Status:

Global Justification

Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, tolerance of a degree of habitat modification, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Hutson *et al.*, 2008g; IUCN, 2009; Monadjem *et al.*, 2017bk).

Assessment History

Global

2016: LC ver 3.1 (2001) [assessed as *Neoromicia nana*] (Monadjem *et al.*, 2017bk). 2008: LC ver 3.1 (2001) [assessed as *Pipistrellus nanus* (Hutson *et al.*, 2008g; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessed as "*Neoromicia nanus*"] (Jacobs, 2004d; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional

South Africa: 2016: LC ver 3.1 (2001) (Monadjem *et al.*, 2016m). 2004: LC ver 3.1 (2001) [assessed as "*Neoromicia nanus*"] (Friedmann and Daly, 2004).

MAJOR THREATS:
There appear to be no major threats to this widespread and seemingly adaptable species (Hutson *et al.*, 2008g; IUCN, 2009; Monadjem *et al.*, 2017bk), although Aronson *et al.* (2013: 9) report a fatality due to wind turbines in South Africa.

CONSERVATION ACTIONS:
Hutson *et al.* (2008g) [in IUCN (2009)] and Monadjem *et al.* (2017bk) report that in view of the species wide range it is likely that it is present in many protected areas. Further research is needed into the taxonomy of this species.

GENERAL DISTRIBUTION:
Afronycteris nanus is widely distributed throughout most of sub-Saharan Africa. It ranges from Senegal in the west, through West and Central Africa, to Eritrea, Ethiopia and Somalia in the east; from here it is found southwards to southeastern South Africa. The species has been recorded from Madagascar, where it has only been reported from the Kirindy CFPF forest in western Madagascar, and from Zombitse (Rasolozaka, 1994), although Goodman *et al.* (2015a: 1012) reject the occurrence of the species on Madagascar. It has also been recorded from the Tanzanian islands of Pemba, Unguja [= Zanzibar], and Mafia (O'Brien, 2011: 290).

It appears to be absent, or largely absent, from northern Kenya, Namibia, southern Botswana, western Zimbabwe, northern Mozambique, Lesotho and much of South Africa. It is possible that the species ranges more widely in these areas than is currently known, and further field studies are needed to investigate the distribution of the species.

For southern Africa, Cooper-Bohannon *et al.* (2016: Table S2) calculated a potential distribution area of 1,165,508 km^2. In South Africa, its distribution is mainly affected by the minimum temperature of the coldest month (Babiker Salata, 2012: 49).

Besides "*N. nana*", Taylor *et al.* (2018b: 63) also mentioned "*Neoromicia* cf. *nana*", whose echolocation calls do not match any known species.

Bates *et al.* (2006) recommend that the identity of the specimens from Madagascar need to be reviewed.

Native: Angola (Crawford-Cabral, 1989; Monadjem *et al.*, 2010d: 568; Taylor *et al.*, 2018b: 63); Benin (Capo-Chichi *et al.*, 2004: 163); Botswana (Archer, 1975; Monadjem *et al.*, 2010d: 568); Burkina Faso (Kangoyé *et al.*, 2015a: 620); Burundi; Cameroon; Central African Republic; Chad; Congo (Bates *et al.*, 2013: 337); Congo (The Democratic Republic of the) (Schouteden, 1944; Hayman *et al.*, 1966; Van Cakenberghe *et al.*, 1999; Dowsett *et al.*, 1991: 259; Monadjem *et al.*, 2010d: 568); Côte d'Ivoire; Djibouti (Pearch *et al.*, 2001: 388); Equatorial Guinea; Eritrea; Eswatini (Monadjem *et al.*, 2010d: 569, Monadjem *et al.*, 2021: 5); Ethiopia; Gabon; Gambia (Emms and Barnett, 2005: 50); Ghana (Decher and Fahr, 2007: 18); Guinea (Ziegler *et al.*, 2002: 78; Fahr *et al.*, 2006a: 73); Guinea-Bissau (Veiga-Ferreira, 1949; Lopes and Crawford-Cabral, 1992; Rainho and Ranco, 2001:60); Kenya; Liberia (Monadjem and Fahr, 2007: 50 [as *Neoromicia nanus*]); Malawi (Happold *et al.*, 1988; Ansell and Dowsett, 1988: 41; Monadjem *et al.*, 2010d: 568); Mali; Mozambique (Smithers and Lobão Tello, 1976; Monadjem *et al.*, 2010d: 568; Monadjem *et al.*, 2010c: 384); Namibia (Monadjem *et al.*, 2010d: 569); Niger; Nigeria; Rwanda; Senegal; Sierra Leone; Somalia; South Africa (De Graaf, 1960; Monadjem *et al.*, 2010d: 569); Sudan; Tanzania (Stanley and Goodman, 2011: 47); Togo; Uganda (Kityo and Kerbis, 1996: 61); Zambia (Ansell, 1978; Monadjem *et al.*, 2010d: 569); Zimbabwe (Monadjem *et al.*, 2010d: 569).

Presence uncertain: Lesotho, Madagascar.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Tragus: Monadjem *et al.* (2013c: 204) contains a line drawing of the tragus of specimen DNSM 12594 from Mount Nimba, Liberia.

From western Uganda, Monadjem *et al.* (2011: 30) reported the following data for 5 specimens: Fa: 31.60 ± 0.758 mm, mass: 3.6 ± 0.89 g, wing loading: 4.2 ± 0.59 N/m^2, aspect ratio: 6.2 ± 0.14.

DENTAL FORMULA:
Dorst (1949: 47) indicates that the milk dentition of "*Pipistrellus nanus*" is very similar to that of *Pipistrellus kuhlii*. He also indicated that the milk teeth form a clearly separated arcade outside the permanent tooth series.

DETAILED MORPHOLOGY:
Penis
Fasel *et al.* (2020: 1394) indicated that this bat's glans penis is slightly globular and that long hairs covering the prepuce are radiating from it. There is also a light protuberance at the distal extremity of the penis.

Baculum
Hill and Harrison (1987) and Kearney *et al.* (2002).

Skull
Using CT-microscans, Curtis and Simmons (2018: 1390) investigated the presence of mineralized elements in the rostra of bats, and found these to be present in *A. nanus*. However, the shape and size of these was different in the two specimens they examined. As both specimens were males, the differences are not sex-based.

FUNCTIONAL MORPHOLOGY:
Amador *et al.* (2019: Suppl.) [referring to Norberg and Rayner (1987)] mention a wing loading value of 8.4 Pa, aspect ratio 7.3 for a wingspan of 21 cm and a wing area of 58 cm^2 and a body mass of 5 g.

ECHOLOCATION:
See Jacobs (1996), Taylor (1999b) and Taylor *et al.* (2005).

Schoeman and Waddington (2011: 291) mention a peak frequency of 67.1 ± 1.9 kHz and duration of 4.0 ± 0.9 ms for specimens from Durban, South Africa. Naidoo *et al.* (2011: 23) report a peak frequency of 68.1 ± 1.0 kHz and a duration of 3.1 ± 0.8 ms from the same area.

At Uzungwa Scarp Forest Reserve, Tanzania, Trentin and Rovero (2011: 57) indicate that the starting frequency is very variable (mean 86.9 kHz). In about 2 ms the call decreases from its maximum to its minimum at 60.7 kHz, after which it increases slightly to 64.5 kHz. The maximum intensity occurs at 66 kHz.

Taylor *et al.* (2013b: 17) recorded the following parameters for 4 calls from Swaziland: F_{max}: 77.2 ± 3.34 (74.4 - 80.9) kHz, F_{min}: 66.2 ± 0.92 (64.9 - 67.0) kHz, F_{knee}: 68.2 ± 1.60 (66.1 - 69.9) kHz, F_{char}: 66.9 ± 0.96 (65.4 - 67.4) kHz, duration: 3.2 ± 0.59 (2.4 - 3.6) ms. Also from Swaziland, Monadjem *et al.* (2017c: 179) reported: F_{min}: 69.7 ± 2.29 (66.8 - 71.8) kHz, F_{knee}: 72.3 ± 2.08 (70.6 - 75.1) kHz, F_c: 70.2 ± 2.25 (67.5 - 72.2) kHz and duration: 2.8 ± 0.32 (2.6 - 3.2) ms. The maximum distance over which they were able to dectect the calls was 10 m (mean: 5.8 ± 1.07 m).

At Farm Welgevonden, South Africa, Taylor *et al.* (2013a: 556) report a F_{knee} value of 68 (66 - 70) kHz. In the Mapungubwe National Park, Parker and Bernard (2018: 57) recorded 20 calls with F_{char}: 68.53 ± 2.10, F_{max}: 85.09 ± 10.70 kHz, F_{min}: 67.61 ± 2.57 kHz, F_{knee}: 72.45 ± 3.38 kHz, duration: 4.24 ± 0.83 ms and 8.15 ± 3.64 calls/sec.

Moir (2020: 30) and Geoffroy Saint-Hilaire (1810a: 371) recorded 1097 calls of 47 bats from southern KwaZulu-Natal and Eastern Cape (RSA): F_{max}: 91.8 ± 11.23 (71.92 - 118.39) kHz, F_{min}: 66.97 ± 2.26 (60.34 - 71.49) kHz, F_{char}: 67.28 ± 2.27 (61.02 - 71.68) kHz, F_{knee}: 71.17 ± 2.89 (65.27 - 77.96) kHz, and duration: 2.09 ± 0.55 (1.21 - 3.63) ms.

From western Uganda, Monadjem *et al.* (2011: 32) reported the following parameters for 5 calls: F_{min}: 71.06 ± 6.019 kHz, F_{max}: 98.94 ± 4.751 kHz, F_{char}: 79.76 ± 8.196 kHz, F_{knee}: 84.89 ± 7.145 kHz, duration: 1.1 ± 0.089 ms.

Eisenring *et al.* (2016: SI 2) reported PF: 66.8 ± 2.0 (63.0 - 69.9), HF: 94.7 ± 17.5 (69.6 - 117.9), LF: 63.7 ± 2.1 (59.8 - 66.9), DT: 0.0 ± 0.0 (0.0 - 0.1), DF: 31.0 ± 16.9 (4.9 - 55.8), IPI: 0.7 ± 0.3 (0.3 - 1.5) for 27 calls from the Aberdares Range in Kenya.

Luo *et al.* (2019a: Supp.) reported the following data (Hand released bats): F_{peak}: 70 kHz and duration: 4 ms.

For 1 FM/QCF type call from Maroua, Cameroon, Manga Mongombe (2012: 79) reported: F_{max}: 106.4 kHz, F_{min}: 96.6 kHz, F_{mean}: 101.7 kHz, F_{knee}: 106.4 kHZ, F_{char}: 96.9 kHz, and duration: 0.42 ms.

From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 12 calls of a single bat: F_{peak}: 77.2 ± 3.3 (72.7 - 80.6) kHz, F_{min}: 63.4 ± 1.2 (59.9 - 64.6) kHz, F_{max}: 115.2 ± 7.6 (112.8 - 117.8) kHz, duration: 2.7 ± 0.7 (2.1 - 3.5) ms.

Two calls recorded by Adams and Kwiecinski (2018: 4) in the Kalahari Desert had the following characteristics: F_{char}: 61.5 ± 8.9 kHz, F_{max}: 74.3 ± 6.2 kHz, F_{min}: 61.1 ± 3.5 kHz, duration: 3.7 ± 0.3 ms.

17 calls from the Okavango River Basin reported by Weier *et al.* (2020: Suppl.) had the following characteristics: F_{max}: 77.85 ± 5.89 kHz, F_{min}: 67.79 ± 0.86 kHz, F_{knee}: 69.93 ± 1.59 kHz, F_{char}: 68.54 ± 1.06 kHz, slope: 22.23 ± 31.88 OPS, duration: 2.66 ± 0.67 ms.

In the Limpopo province (RSA), Weier *et al.* (2021: 7) reported the following characteristics for 99 calls of 11 bats: F_{max}: 149.97 ± 85.61 kHz, F_{min}: 77.16 ± 6.86 kHz, F_{knee}: 1 ± 0.48 kHz, F_{char}: 3.17 ± 0.8 kHz, slope: 68.52 ± 2.18 OPS, duration: 301.04 ± 214.6 ms. 15 calls recorded at

the Venatia min by Cory-Toussaint and Taylor (2022: Table S1) had a duration of 2.83 ± 0.28 ms, F_{min}: 66.95 ± 2.48 kHz, F_{max}: 77.73 ± 5.25 kHz, F_{knee}: 69.55 ± 1.86 kHz and F_{char}: 68.20 ± 1.86 kHz.

Brinkley *et al.* (2021: Table S1) mention the following parameters for 21 "*Neoromicia nana*" calls from the Kruger Park (RSA): F_{min}: 63.9 ± 2 (60.3 67.2) kHz, Duration: 3.1 ± 0.8 (2.2 4.8) ms, F_{max}: 89.0 ± 16.9 (70.0 118.5) kHz, F_{knee}: 72.8 ± 7.5 (66.1 93.3) kHz, F_{char}: 67.7 ± 3.4 (63.5 78.5) kHz.

Roemer *et al.* (2021: Suppl.) categorized the bat's call as a FMd-QCF (Frequency modulation downward - quasi-constant frequency) sonotype [as "*Neoromicia nana*"].

65 pulses from "*Neoromicia nanas*" (sic) recorded by Taylor *et al.* (2020a: 77) at Venetia Limpopo Nature Reserve and Mapungubwe National Park (RSA) had F_{min}: 64 - 67 kHz, F_{max}: 74 - 80 kHz, F_{char}: 65 - 67 kHz, F_{knee}: 66 - 70 kHz and duration 3 - 4 ms.

Along the Chobe River (Botswana/Namibia), Parker and Bernard (2023: 54) reported F_{char}: 68.53 ± 2.10 kHz, F_{max}: 85.09 ± 10.70 kHz and F_{min}: 67.61 ± 2.57 kHz.

In Zambia, Taylor-Boyd *et al.* (2025: 116) report the following values for 12 calls: Interpulse interval: 99.2 ± 56.7 (53.8 - 216.0) ms; F_{max}: 70.1 ± 3.1 (65.7 - 76.9) kHz; Start slope: -27.7 ± 5.1 (-19.1 - -37.5) kHz/ms; End slope: -8.2 ± 4.0 (-11.6 - -8.4) kHz/ms; Ledge duration: 0.6 ± 0.1 (0.4 - 0.8) ms.

Fernandes *et al.* (2025: 4) mention two sonotypes for *Afronycteris nana* in Guinea-Bissau: one with a F_{max} of 60 - 75 kHz and one with a F_{max} of 89 - 96 kHz.

Molecular Biology:

Karyotype

Both Peterson and Nagorsen (1975) and Rautenbach *et al.* (1993) reported 2*n* = 36, FN = 50, BA = 16, a metacentric X chromosome, and an acrocentric Y chromosome. GTG-bands identified three Robertsonian fusion chromosomes (7/11, 8/9, 10,12), considered as distinguishing characters for the genus *Neoromicia* Kearney *et al.* (2002).

From Senegal, Koubínová *et al.* (2013: 3) report the following karyotype for 9 ♂♂ and 7 ♀♀: 2*n* = 34, FNa = 50, FN = 54, X = Subtelocentric and Y = dot-like (probably acrocentric). They also found (p. 7) that two pairs of acrocentric autosomes were missing compared to previous findings, but contained an additional metacentric pair, which could be the result of a Robertsonian fusion. Due to these differences, they assigned their specimens to *Neoromicia* cf. *nana*.

The different diploid number of animals from southern Africa (2*n* = 36) and Senegal (2*n* = 34) led Volleth *et al.* (2023c: 50) to the conclustion that the latter animals should better be assigned to *Afronycteris* cf. *nanus*.

Tolera *et al.* (2021: 127) reported 2*n* = 36 and FN = 50 for a female from Ethiopia. The karyotype consisted of seven pairs of large metacentrics, one pair of small sub-metacentrics and 10 pairs of acrocentrics. The X chromosome is the largest acrocentric. This was identical to the configuration they found for "*Pipistrellus pipistrellus*" specimens.

Protein / allozyme

See Morales *et al.* (1991) for results from two specimens from South Africa.

Genetics

See Hoofer and Van Den Bussche (2003) for the results of a specimen from Kenya.

Habitat:

Monadjem *et al.* (2010a) found that there was no difference in use by *A. nanus* between logged and undisturbed forested areas; however, the species exhibited higher levels of activity along the wide tracks running through the two forests than either 30 m off these tracks or along the narrow forest trails. Naidoo *et al.* (2009: 30) showed that the abundance and feeding activity of *A. nanus* at sludge tank sites and at sites downstream of wastewater treatment works (WWTWs) was significantly higher than at sites upstream of these, probably due to insect abundance, specifically pollution tolerant chironomid midges. Naidoo *et al.* (2013b: 108) found that haematocrits were significantly higher in *A. nanus* foraging at WWTWs indicating that *A. nanus* may be compensating for a chronically low oxygen circulation within the body or kidney damage. They also report that hepatosomatic and renalsomatic indices were significantly higher suggesting hypertrophy of the detoxification organs. Additionally, the gonadosomatic index of the testes were also significantly larger at WWTWs, suggesting that reproductive potential of males may be compromised.

Naidoo *et al.* (2013a: 51) found that essential metals (Cu, Zn and Fe) were detected in all tissue samples from *A. nanus* foraging at upstream and wastewater-polluted sites. Non-essential metals

(Cd, Ni and Cr) were detected only in *A. nanus* foraging at wastewater-polluted sites (except one upstream occurrence of Cd). The first set of metals is essential for normal cellular processes and bodily function, the latter are considered harmful to organisms.

Significant differences for essential metals and mineral nutrients (Fe and Zn in liver; Cu and K in kidneys) were also reported by Naidoo *et al.* (2015a: 830).

The effects of WWTWs on energy stores and leptin levels was examined by Mehl *et al.* (2016), whereas Hill *et al.* (2018: 232) investigated the arsenic concentrations and acetylcholinesterase activity.

Naidoo *et al.* (2014) reported that *A. nanus* specimens captured at WWTWs also had higher DNA damage, lower antioxidant capacity, and higher haematocrits than bats from non-polluted sites.

In another study at WWTWs, Hill *et al.* (2016: 92) found that bats rely on iBrAT (interscapular brown adipose tissue) as an energy source, and that opportunistic foraging on abundant, pollutant-tolerant prey may change fatty acid profiles in their tissue, with possible effects on mitochondrial functioning, torpor and energy usage.

LaVal and LaVal (1977) [in Naidoo *et al.* (2014)] indicate that *A. nanus* has a relatively small home range of about 300 m around its roost.

In the Mount Nimba area, Monadjem *et al.* (2016y: 370) recorded this species from forested and forest edge habitats ranging from 450 to 530 m.

HABITS:
Monadjem *et al.* (2010a) found that *A. nanus* was most active in the first 5 hrs after sunset with activity declining rapidly after midnight.

Keeley and Keeley (2004: 116) [referring to O'Shea (1980) and Happold and Happold (1996)] mention that male "*Pipistrellus nanus*" roosting in palm-thatched roofs show territoriality and aggressive competition for spacious roosts, whereas males in populations roosting in banana leaves appear not to defend territories aggressively, and indicate that this difference might be based on the availability of preferred roosts. However, the more likely explanation being that these differences are due to these two groups belonging to different species, as the thatched roof inhabiting form is most likely *A. helios*.

ROOST:
During the day, *A. nanus* usually roost in furled leaves of banana plants, where the entrance diameter is between 7 and 24 cm. This makes the leaves suitable for one to three days, and makes roost-fidelity impossible. However, about half of the males have a fidelity for a small group of banana plants growing close together. This is not the case for females (Happold and Happold, 2023: 157).

DIET:
From the Umbilo River (KwaZulu Natal, RSA), Naidoo *et al.* (2011: 26) reported the following prey volume percentages: during summer: Lepidoptera (2.3 ± 1.4), Hemiptera (34.6 ± 14.1), Diptera (43.6 ± 17.4), and Trichoptera (19.6 ± 6.8); during winter: Coleoptera (36.4 ± 2.5), Coleoptera (3.2 ± 0.9), Hemiptera (19.1 ± 7.5), Diptera (29.5 ± 3.7), and Trichoptera (12 ± 7.2).

Weier *et al.* (2019c: 6) examined droppings from this species in the Levubu region (Limpopo, RSA) and found DNA sequences of: Lepidoptera: *Cryptophlebia peltastica* (Meyrick, 1921) and *Thaumatotibia batrachopa* (Meyrick, 1908); Hemiptera: *Bathycoelia distincta* Distant, 1878 and *Nezara viridula* (Linnaeus, 1758).

Faecal pellets of 33 bats from Cameroon examined by Waghiiwimbom *et al.* (2019a: 156) contained the following volume percentages: Lepidoptera (67.5 ± 3.3), Coleoptera (21.4 ± 2.4), Diptera (8.1 ± 1.2), Hemiptera (1.2 ± 0.5), Hymenoptera (0.8 ± 0.3), Isoptera (0.9 ± 0.8), and Trichoptera (0.1 ± 0.1). The frequency percentages for these insect orders were respectively: 91.2, 72.6, 44.4, 7.3, 10.6, 1.8, and 0.9.

For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 54 minutes, and the digestibility rate about 84.0 %.

PREDATORS:
Broadley (1982) [in Schätti (1984: 338)] reported the killing of a "*Pipistrellus nanus*" specimen by an opisthoglyphe treesnake (*Thelotornis capensis* A. Smith, 1849).

Nyffeler and Knörnschild (2013: 5) refer to Rosevear (1953: 267) for a dead bat being recovered by T.S. Jones from a spider's web near Kerema, Sierra Leone.

Mikula *et al.* (2016: Supplemental data) and Malan *et al.* (2022: 167) mention the Bat hawk

(*Macheiramphus alcinus* Bonaparte, 1850) as diurnal avian predator.

Based on Vaughan (1976), Gual-Suárez and Medellín (2021: Suppl.) reported "*Neoromicia nanus*" as an occasional prey of *Cardioderma cor*, and accounted for 0.5 % of the prey items of *Nycteris grandis* (according to Fenton *et al.*, 1981; 1983).

Chen *et al.* (2023: 1) report on an opportunistic predation by a giant water bug (*Lethocerus cordofanus* Mayr, 1853 (Hemiptera: Belostomatidae) in Guinea-Bissau.

POPULATION:
Structure and Density
Probably not uncommon in suitable habitats (Happold, 1987).

Trend
2016: Unknown (Monadjem *et al.*, 2017bk).
2008: Unknown (Hutson *et al.*, 2008g; IUCN, 2009).

ACTIVITY AND BEHAVIOUR:
A. nanus uses territorial calls (possibly with a courtship function) consisting of a simple syllable type in series (O'Shea, 1980 in Smotherman *et al.*, 2016: 537).

REPRODUCTION AND ONTOGENY:
Garbino *et al.* (2021: Suppl.) mention that this species has more than one young per litter.

In Malawi, young were born at the beginning of the wet season, and they were lactated for about two months (Happold and Happold, 1990b: 567).

van der Merwe and Stirnemann (2007: 53) report that *A. nanus* is a seasonal monoestrous breeder. In Mpumalanga Province (South Africa), they found that spermatogensis began in late September and spermatozoa were present in the caudae epididymides from late April throughout August. Mating started in May and ovulation and fertilization occurred from the beginning of August, when the first implantations also occurred. Parturition took place between late October and the end of November. Lactating females were found until mid-January. They also indicate that reproduction timing was about one month earlier than in Malawi, where Happold and Happold (1998a: 67) found pregnant females from late August to mid-November, and births and lactating females were observed from mid-November to the end of April.

Trentin and Rovero (2011: 51) report five lactating females, captured at the end of November 2005 at Uzungwa Scarp Forest Reserve, Tanzania.

Monadjem *et al.* (2010d) [in Weier *et al.* (2018: Suppl.)] mentioned births taking place between November and early December.

Happold (2001: 397) - referring to Bernard *et al.* (1997) - indicates that sperm storage and delayed fertilisation is used to alter the interval between copulation and parturition, and as such their chronology of reproduction.

MATING:
McCracken and Wilkinson (2000: 329) indicate that *A. nanus* mating groups consist of a single male and multiple females (polygynous), but cannot be considered as harems. Males are often visited simultaneously by several females, and some males are visited more frequently by more females than others (see also Happold and Happold, 1996).

PARASITES:
PROTOZOA
Tsague *et al.* (2024: Suppl.) reported the presence of *Trypanosoma* cf. *livingstonei* in Cameroonian bats, whereas Babyesiza *et al.* (2025: 4) reported *T. dionisii* and *T. vespertilionis* from bats from the CAR.

BACTERIA
Mehl *et al.* (2021: 8) compared the intestinal microbiome of "*Neoromicia nana*" occurring around Wastewater treatment works (WWTW) and non polluted control sites in KwaZulu-Natal (RSA). In both groups, bacteria belonging to the classes Actinobacteria, Chloroplast, Bacilli, Clostridia, Planctomycetia, Alphaproteobacteria, Betaproteobacteria, Epsilonproteobactaria, Gammaproteobacteria, Spirochaetes and Mollicutes were found, although there were statistically significant differences.

ACARI
Macronyssidae
Orlova *et al.* (2020c: 951) mention *Steatonyssys afer* Radovsky and Yunker, 1963 in Angola.

Sarcoptidae
Fain (1959e: 157) described *Notoedres (Metanotoedres) miniopteri* from a "*Pipistrellus nanus*" from Bukavu, DRC.

DIPTERA
Nycteribiidae
Nycteribia schmidlii Schiner, 1853 (Haeselbarth *et al.*, 1966: 108, host referred to both "*Pipistrellus nanus*" and "*Pipistrellus culex*"). *Basilia ansifera* Theodor, 1956 mainly a West

African species, reaches Lake Victoria in the east and Lake Nyasa in the south, nearly all localities lie between 15° latitude north and south (Haeselbarth *et al.*, 1966: 110, host referred to "*P. nanus*', "*P. culex*" and "*P. stampflii*"). *Basilia robusta* Theodor, 1956 (Haeselbarth *et al.*, 1966: 111).

Dick *et al.* (2023) mentioned the nycteribiid flies *Basilia (Basilia) ansifera* Theodor, 1956, *Basilia (Basilia) robusta* Theodor, 1956 and *Nycteribia schmidlii scotti* Falcoz, 1923.

HEMIPTERA
Cicimidae
Kock *et al.* (1998b: 236, 237) reported *Cacodmus villosus* (Stål, 1855) and *Aphrania* cf. *barys* Jordan and Rothschild, 1912.

ACARINA
Dermanyssidae
Zumpt and Till (1954: 49) described *Steatonyssus eos* from "*Pïpistrellus nanus*" specimens from Kenya.

NEMATODA
Durette-Desset and Chabaud (1975: 323) described *Allintoschius dunni* from a *Myotis mystacinus* specimen from Malaysia, but also indicated that this Nematode was also found in five "*Pipistrellus nanus*" specimens from Maboké (CAR).

CESTODA
Hymenolepididae
Jenzen and Howell (1983: 135) referred to Baer (1933), who described *Vampirolepsis sandgroundi* from a bat from Zimbabwe.

VIRUSES:
Astroviridae
Neither of the two Mozambican bats tested by Hoarau *et al.* (2018: 2) was positive for this group of viruses.

Coronaviridae - Coronaviruses
SARS-CoV
During February 2008 in Ghana, Pfefferle *et al.* (2009) tested negative five fecal samples for coronavirus (CoV) RNA.

None of the 11 bats examined from the two Congos by Kumakamba *et al.* (2021: 7) tested positive for coronaviruses.

Shapiro *et al.* (2021a: 423) detected a possibly new alphacoronavirus in droppings of *A. nana* from Eswatini.

Hantaviridae (formerly included in Bunyaviridae)
Mouyassué virus - MOYV (or MOUV)
Sumibcay *et al.* (2012: 2) reported hantavirus RNA from 2 out ot 12 banana pipistrelles captured near Mouyassué village, in Côte d'Ivoire. However, Gu *et al.* (2014) were unable to find any additional bats infected with this virus. Arai *et al.* (2019b: 2) and Arai and Yanagihara (2020: 7) tentatively assigned this virus to the genus *Loanvirus*).

Paramyxoviridae
Mortlock *et al.* (2015: 1841) reported that two out of seven examined South African specimens tested positive for *Paramyxovirus* sequences.

Reoviridae
Cameron *et al.* (2023: 443) found RNA of a novel orbivirus in a bat collected in the Republic of the Congo.

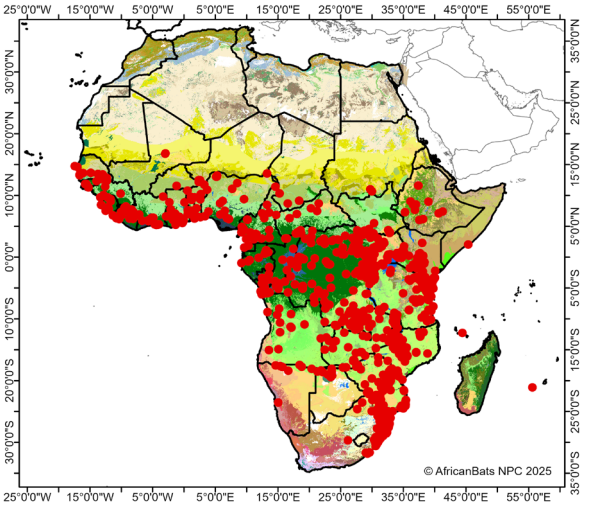

Figure 355. Distribution of *Afronycteris nanus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
"Africa", Angola, Benin, Botswana, Burkina Faso, Burundi, Cameroon, Central African Republic, Chad, Comoros, Congo, Congo (Democratic Republic of the), Côte d'Ivoire, Djibouti, Equatorial Guinea, Eswatini, Ethiopia, Gabon, Ghana, Guinea, Guinea-Bissau, Kenya, Liberia, Malawi, Mali, Mozambique, Namibia, Niger, Nigeria, Réunion, Rwanda, Senegal, Sierra Leone, Somalia, South Africa, South Sudan, Sudan, Tanzania, The Gambia, Togo, Uganda, Zambia, Zimbabwe.

Genus ***Afropipistrellus*** Thorn, Kock and Cuisin, 2007

2007. *Afropipistrellus* Thorn, Kock and Cuisin, Mammalia, 71 (1/2): 70, 75. - Etymology: From the combination of "Africa" and "Pipistrellus"; gender masculine (see Thorn *et al.*, 2007: 75).

TAXONOMY:
Based on analyses of cyt *b* sequences, Monadjem *et al.* (2020a: 1126) considered *Afropipistrellus* to be a synonym of *Nycticeinops*. However, Demos *et al.* (2025: 150) and Torrent *et al.* (2025b: 2) consider *Afropipistrellus* to be a valid taxon and raised it to genus level.

Currently recognized species in the genus *Afropipistrellus*: ***bellieri*** (De Vree, 1972), ***crassulus*** (Thomas, 1904); ***eisentrauti*** (Hill, 1968);***grandidieri*** (Dobson, 1876); ***happoldurm*** (Hutterer, Decher, Monadjem and Astrin, 2019; ***musciculus*** (Thomas, 1913).

Afropipistrellus bellieri (De Vree, 1972)

*1972. *Pipistrellus eisentrauti bellieri* De Vree, Rev. Zool. Bot. afr., 85 (3 - 4): 412. Publication date: 30 June 1972. Type locality: Côte d'Ivoire: NW of Abidjan: Adiopodoumé [05 19 N 04 08 W, 0 - 30 m]. [Goto Description]. Holotype: RMCA 35686: ad ♀, skin and skull. Collected by: Prof. Dr. Frits De Vree; collection date: 19 November 1969; original number: AX0104. Prepared and labelled in the Laboratoire d'Ecologie (L. Bellier) of the ORSTROM; see De Vree (1972). - Comments: Included in *eisentrauti* by Koopman (1993a: 221), and in *crassulus* by Simmons (2005). Considered a valid species by Fahr *et al.* (2006b: 245).
1994. *Hypsugo crassulus bellieri:* Heller, Volleth and Kock, Senckenb. biol., 74 (1/2): 1. (Name Combination).
1994. *P[ipistrellus (Pipistrellus)] e[isentrauti] bellieri:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 114.
1998. *P[ipistrellus (Hypsugo)] e[isentrauti] bellieri:* Grubb, Jones, Davies, Edberg, Starin and Hill, Mammals of Ghana, Sierra Leone and The Gambia, 84.
2003. *Nycticeinops eisentrauti:* Hoofer and Van Den Bussche, Acta Chiropt., 5 (Suppl): 38. - Comments: Although Hoofer *et al.* (2003) believed they were referring to an *eisentrauti* specimen, this was actually a *belieri* (see also the *eisentrauti bellieri* synonym by Grubb *et al.*, 1998).
2019. *Parahypsugo bellieri:* Hutterer, Decher, Monadjem and Astrin, Acta Chiropt., 21 (1): 16. Publication date: 5 October 2019. (Name Combination).
2020. *Nycticeinops bellieri:* Monadjem, Demos, Dalton, Webala, Musila, Kerbis Peterhans and Patterson, Zool. J. Linn. Soc., 191 (4): 1123. Publication date: 10 September 2020. (Name Combination).
2020. *Parahypsugo cf. eisentrauti (=bellieri):* Monadjem, Richards, Decher, Hutterer, Mamba, Guyton, Naskrecki, Markotter, Wipfler, Kropff and Dalton. Publication date: 4 September 2020. (Name Combination).
2022. *Afropipistrellus bellieri:* Benda, Uvizl, Šklíba, Mazoch and Červený, Lynx, ns 53 (1): 317. (Current Combination).

TAXONOMY:
This taxon was originally described as *Pipistrellus eisentrauti bellieri*. Heller *et al.* (1994: 3) found that the holotype was more similar in size to *Hypsugo crassulus*, and transferred the taxon to that species.

Roehrs *et al.* (2011: 26, 31) mentioned that "*eisentrauti*" belongs to the genus *Nycticeinops*, but they used a specimen from Côqte d'Ivoire which should be assigned to *crassulus bellieri*. Monadjem *et al.* (2016y: 369) and Herkt *et al.* (2017: Appendix S9) report that the ecological niches for *crassulus* and *bellieri* differ and that their geographic distributions are separated by a gap, suggesting that they might represent different species.

Penis and baculum morphology as well as cranial and dental morphometrics led Hutterer *et al.* (2019: 16) to create a new genus (*Parahypsugo*), and to raise *bellieri* to full species rank.

Based on analyses of cyt *b*, Monadjem *et al.* (2020a: 1126) considered *Parahypsugo* to be a syonym of *Nycticeinops*, and transferred *bellieri* to the latter genus. However, Torrent *et al.* (2025b: 2) fransferred it subsequently to the genus Afropipistrellus.

CONSERVATION STATUS:
Global Justification

Assessment History
Global
Not evaluated.

Regional
None known.

GENERAL DESCRIPTION OF EXTERNAL MORPHOLOGY:
Tragus: Monadjem *et al.* (2013c: 204) provide a line drawing of tragi of specimen DNSM 13222 from Mount Nimba, Liberia.

DETAILED MORPHOLOGY:
Baculum
See Hill and Harrison (1987) and Heller *et al.* (1994: 5). "*H[ypsugo] c[rassulus] bellieri*" and *P[ipistrellus] nanulus* bacula were much longer in total length than any of the *Neoromicia* species that were examined by Monadjem *et al.* (2013c). The shaft tip of "*H. c. bellieri*" was distinctly spatulate and dorsoventrally flattened baculum

shaft in both species was moderately ventrally curved, ending in a fluted base that was broader in *P. nanulus* (0.71 - 0.82 mm) than in "*H. c. bellieri*" (0.38 - 0.41 mm) (Monadjem *et al.*, 2013c: 197). Line drawing of dorsal and ventral bacula of specimen DNSM 13222 from Mount Nimba, Liberia are shown in Monadjem *et al.* (2013c: 204).

HABITAT:
Monadjem *et al.* (2016y: 369) found this species (as "*Hypsugo crassulus bellieri*") in old growth forest habitats in the Mount Nimba area.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

? *Nycticeinops cf. crassulus TD-2020*

TAXONOMY:
Mentioned in the genus *Pipistrellus* and the subgenus *Vansonia* by Koopman (1994: 116). Volleth *et al.* (2001: 27) assigned this species to the genus *Hypsugo*. Included *bellieri* but see Hutterer *et al.* (2019: 1).

Transferred to the genus *Parahypsugo* by Hutterer *et al.* (2019: 15). However, based on cyt-*b* analyses, Monadjem *et al.* (2020a: 1126) found that *Parahypsugo* should be considered a synonym of *Nycticeinops*.

Torrent *et al.* (2025b: 1) transferred *crassulus* to the genus *Afropipistrellus*.

COMMON NAMES:
Castilian (Spain): Pipistrelo. Chinese: 宽首伏翼. Czech: netopýr obtloustlý. English: Broad-headed Pipistrelle Bat, Broad-headed Pipistrelle. French: Vespère à grosse tête, Pipistrelle à grosse tête. German: Breitköpfige Zwergfledermaus, Breitköpfige Pipistrelle.

CONSERVATION STATUS:
Global Justification
Listed as Least Concern (LC ver 3.1 (2001)) in view of its wide distribution, presumed large population, and because it is unlikely to be declining fast enough to qualify for listing in a more threatened category (Fahr, 2008g; IUCN, 2009; Monadjem and Fahr, 2017d).

Assessment History
Global
2016: LC ver 3.1 (2001) [assessed as *Pipistrellus crassulus*] (Monadjem and Fahr, 2017d). 2008: LC ver 3.1 (2001) [assessed as *Pipistrellus crassulus*] (Fahr, 2008g; IUCN, 2009). 2004: LC ver 3.1 (2001) [assessed as *Hypsugo crassulus*] (Fahr, 2004o; IUCN, 2004). 1996: LR/lc [assessed as *Pipistrellus crassulus*] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
There appear to be no major threats to this widespread species as a whole (Fahr, 2008g; IUCN, 2009; Monadjem and Fahr, 2017d).

CONSERVATION ACTIONS:
Fahr (2008g) [in IUCN (2009)] and Monadjem and Fahr (2017d) report that there appear to be no direct conservation measures in place, and it is not known if the species is present within any protected areas. Further studies are needed into the taxonomy, distribution and natural history of this species.

GENERAL DISTRIBUTION:
Nycticeinops crassulus has been recorded from Guinea, Liberia and Côte d'Ivoire in the west, from Cameroon, Democratic Republic of the Congo, northern Angola, southern Sudan, Uganda and western Kenya (Kakamega Forest).

Native: Angola; Cameroon; Congo (Bates *et al.*, 2013: 325 - 1st authenticated record); Congo (The Democratic Republic of the); Côte d'Ivoire; Guinea (Decher *et al.*, 2016: 266); Kenya; Liberia; Sudan; Uganda.
Presence uncertain: Nigeria.

DETAILED MORPHOLOGY:
Vomeronasal complex
In this species, the VNC is bar-shaped in cross section (Smith *et al.*, 2024: 9).

MOLECULAR BIOLOGY:
Karyotype
Volleth *et al.* (2001) reported 2*n* = 30, FN = 56, BA = 28, a metacentric X chromosome and a metacentric Y chromosome.

GENERAL DESCRIPTION OF CRANIAL AND DENTAL MORPHOLOGY:

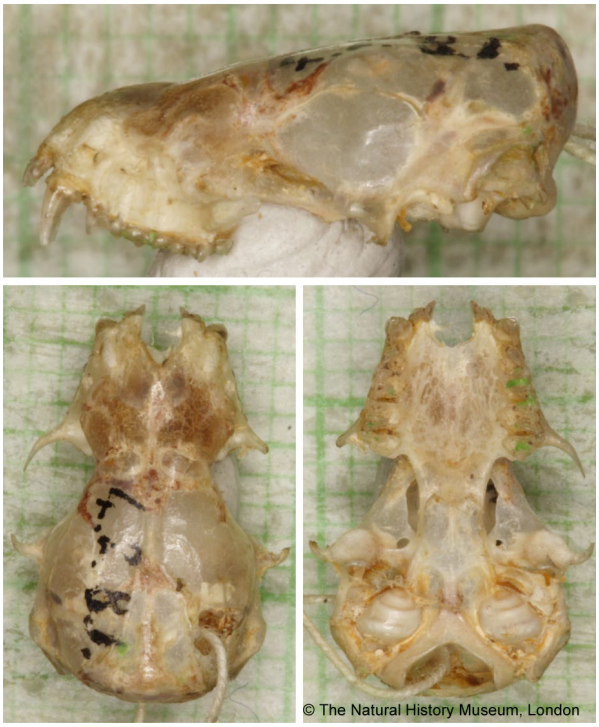

Figure 357. Clockwise from top lateral, ventral and dorsal skull images of NHMUK 1904.2.8.1, holotype of *Pipistrellus crassulus* Thomas, 1904.

DIET:
Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time for these bats to be about 68 minutes, and the digestibility rate about 81.3 %.

POPULATION:
Structure and Density
This species has rarely been recorded (Fahr, 2008g; IUCN, 2009; Monadjem and Fahr, 2017d).

Trend
2016: Unknown (Monadjem and Fahr, 2017d).
2008: Unknown (Fahr, Fahr, 2008g; IUCN, 2009).

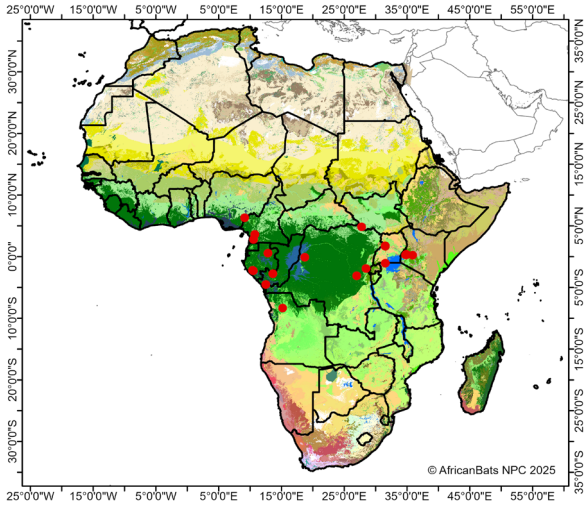

Figure 358. Distribution of *Afropipistrellus crassulus*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS: Angola, Cameroon, Congo, Congo (Democratic Republic of the), Gabon, Kenya, Nigeria, South Sudan, Tanzania, Uganda.

Afropipistrellus eisentrauti (Hill, 1968)

*1968. *Pipistrellus eisentrauti* Hill, Bonn. zool. Beitr., 19 (1/2): 45. Publication date: 10 April 1968. Type locality: Cameroon: Western province: Rumpi Highlands, Dikume-Balue: Camp V [ca. 04 13 N 09 32 E]. [Goto Description]. Holotype: ZFMK MAM-1968.0005: ad ♂, skin and skull. Collected by: Prof. Dr. Martin Eisentraut; collection date: 18 February 1957; original number: 498. See Hill (1968: 45), Thorn *et al.* (2007), Hutterer and Peters (2010: 12). Paratype: NHMUK 1967.2129: ad ♀, skin and skull. Collected by: Prof. Dr. Martin Eisentraut; collection date: 30 November 1966; original number: 198. Paratype: ZFMK MAM-1968.0006: ad ♀, skin and skull. Collected by: Prof. Dr. Martin Eisentraut; collection date: 30 November 1966; original number: 198. Lager II [=Camp II], ca. 1,100 m; Mount Kupe (see Hutterer and Peters, 2010: 12). - Comments: Thorn *et al.* (2009: 53) situate Camp V at 05 00 N 09 15 E. - Etymology: In honour of Prof. Martin Eisentraut (1902 - 1994), collector of the type specimen.

1971. *Pipistrellus [(Pipistrellus)] eisentrauti:* Hayman and Hill, Mammals of Africa: Chiroptera, 39. (Name Combination).

1972. *P[ipistrellus] e[isentrauti] eisentrauti:* De Vree, Rev. Zool. Bot. afr., 85 (3 - 4): 415. (Name Combination).

1987. *Pipistrellus (Hypsugo) eisentrauti:* Hill and Harrison, Bull. Br. Mus. (nat. Hist.) Zool., 52 (7): 274. (Name Combination).

1994. *Hypsugo eisentrauti:* Heller, Volleth and Kock, Senckenb. biol., 74 (1/2): 1. (Name Combination).

1994. *P[ipistrellus (Pipistrellus)] e[isentrauti] eisentrauti:* Koopman, in: Niethammer, Schliemann and Starck, Handbook of Zoology, volume II (Mammalia) Chiroptera, (60) 114. (Name Combination).

2019. *Parahypsugo eisentrauti:* Hutterer, Decher, Monadjem and Astrin, Acta Chiropt., 21 (1): 15. Publication date: 5 October 2019. (Name Combination).

*2020. *Nycticeinops eisentrauti:* Monadjem, Demos, Dalton, Webala, Musila, Kerbis Peterhans and Patterson, Zool. J. Linn. Soc., 191 (4): 1123. Publication date: 10 September 2020.

2025. *Afropipistrellus eisentrauti:* Torrent, Juste, Garin, Aihartza, Dalton, Mamba, Tanshi, Powell, Padidar, Garcia Mudarra, Richards and Monadjem, Zool. J. Linn. Soc., 204 (2): 4. Publication date: 13 June 2025. (Current Combination).

? *Hypsugo eisentrauti bellieri:*

TAXONOMY:
Koopman (1994: 114) mentions this species as belonging to the subgenus *Pipistrellus*. Volleth *et al.* (2001: 27) assigned this species to the genus *Hypsugo*. Koopman (1993a: 221) included *bellieri*, but see Heller *et al.* (1994), Simmons (2005). Hoofer and Van Den Bussche (2003: 38) and Roehrs *et al.* (2011: 26, 31) include *eisentrauti* in *Nycticeinops*, but they used a specimen from Côte d'Ivoire, which should be assigned to *crassulus bellieri*.

Transferred to the genus *Parahypsugo* by Hutterer *et al.* (2019: 15), but Monadjem *et al.* (2020a: 1126) found that - based on cyt-*b* analyses - *Parahypsugo* should be considered a synonym of *Nycticeinops*.

Torrent *et al.* (2025b: 4) transferred *eisentrauti* to the genus *Afropipistrellus*.

COMMON NAMES:
Czech: netopýr guinejský. English: Eisentraut's Pipistrelle Bat, Eisentraut's pipistrelle. French: Pipistrelle d'Eisentraut, Vespère d'Eisentraut. German: Eisentrauts Zwergfledermaus, Eisentrauts Pipistrelle. Italian: Pipistrèllo di Eisentràut.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient in view of continuing problems with its taxonomy as well as absence of recent information on its extent of occurrence, status, ecological requirements and threats. This species is most probably restricted to SW Cameroon. However, there are supposedly records from four other countries. Those records may all be misidentifications. If that is the case, then it is likely that this species has a very restricted range and is probably threatened (Fahr, 2008h; IUCN, 2009; Fahr, 2019c).

Using machine learning techniques, Wieringa (2022: 535) predicted this species (as *Hypsugo eisentrauti*) to be threatened.

Assessment History
Global
2018: DD ver 3.1 (2001) assessed as "*Hypsugo eisentrauti*" (Fahr, 2019c). 2008: DD ver 3.1 (2001) assessed as "*Pipistrellus eisentrauti*" (Fahr, 2008h; IUCN, 2009). 2004: DD ver 3.1 (2001) (Fahr, 2004n; IUCN, 2004). 1996: LR/lc (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The threats to this species are not well known, but in Cameroon are likely to include encroachment on montane forest by subsistence agriculture (Fahr, 2008h; IUCN, 2009; Fahr, 2019c).

CONSERVATION ACTIONS:
Fahr (2008h) [in IUCN (2009)] and Fahr (2019c) reports that it is unclear if the species is present within any protected areas. Further studies are needed into the taxonomy, distribution, and threats to this species.

GENERAL DISTRIBUTION:
Nycticeinops eisentrauti was initially described from Cameroon, where it has been recorded from localities including the Rumpi Highlands, Mount Kupe and Mount Cameroon. Although there are additional records of this species from Kenya, Somalia, Uganda and from the Democratic Republic of the Congo, these are currently assigned to *Nycticeinops macrocephalus*, or need further investigation to confirm their identity.

The specimens from Kenya were identified by V. Van Cakenberghe as belonging to *eisentrauti*.

Confirmation of the possible distribution outside of Cameroon is needed.

Native: Cameroon; Nigeria (Tanshi *et al.*, 2022a: 317).

DETAILED MORPHOLOGY:
Baculum
Hill and Harrison (1987).

MOLECULAR BIOLOGY:
Genetics
See Hoofer and Van Den Bussche (2003).

DIET:
For these bats, Cabrera-Campos *et al.* (2021: Suppl.) estimated the food transit time to be about 68 minutes, and the digestibility rate about 81.3 %.

POPULATION:
Structure and Density
The population is little known, but it may be locally common in Cameroon (Fahr, 2008h; IUCN, 2009; Fahr, 2019c).

Trend
2018: Unknown (Fahr, 2019c). 2008: Unknown (Fahr, 2008h; IUCN, 2009).

2020. *Nycticeinops grandidieri:* Monadjem, Demos, Dalton, Webala, Musila, Kerbis Peterhans and Patterson, Zool. J. Linn. Soc., 191 (4): 1123. Publication date: 10 September 2020. (Name Combination).
2022. *Afropipistrellus grandidieri:* Benda, Uvizl, Šklíba, Mazoch and Červený, Lynx, ns 43 (1): 317. (Current Combination).
? *Neoromicia grandidieri:* - Comments: . (Lapsus).
? *Pipistrellus grandidieri:* (Name Combination).

TAXONOMY:

Figure 360. *Afropipistrellus grandidieri,* Zanzibar Island.

Thorn *et al.* (2007: 73) recognize two subspecies: *P[ipistrellus] (Afropipistrellus]) g[randidieri] grandidieri* for East African specimens and *P[ipistrellus] (A[fropipistrellus]) g[randidieri] angolensis*, a slightly larger western and southern African subspecies (Angola, Malawi and Cameroon).

Monadjem *et al.* (2013c: 194) mention a specimen from Mount Nimba as "*Pipistrellus* sp. 1", which was in a later publication (Monadjem *et al.*, 2016y: 370) assigned to "*Pipistrellus* cf. *grandidieri*". The latter authors indicate that the specimen involved has very similar cranial characters as *P. grandidieri*, but that species occurs only in eastern Africa, some 2,500 km away. Pending further genetical characterisation, they tentatively named it "cf. *grandidieri*". The genetic study by Monadjem *et al.* (2020d: 550) revealed that these West-African specimens are specifically distinct from the animals from East Africa and they described these as *Pipistrellus simandouensis*.

Thorn *et al.* (2007: 70 - 71) consider "*flavescens*" to be a *nomen dubium*, since its description does

not agree with the two "syntypes" attributed to it. They indicate that one syntype (MNHN ZM-MO-1900-536) is actually a representative of *Pipistrellus* (*Afropipistrellus*) *grandidieri* Dobson, 1876.

Based on cyt *b* analyses, Monadjem *et al.* (2020a: 1126) consider *Afropipistrellus* to be a synonym of *Nycticeinops*. However, Benda *et al.* (2022: 314) indicate that as this is only based on mitochondrial DNA and the morphological traits of *Nycticeinops* are markedly distinct, they tentatively retain this species in the genus *Afropipistrellus*. Its assignment to the genus *Afropipistrellus* was confirmed by Torrent *et al.* (2025b: 5).

COMMON NAMES:
Czech: netopýr galangánský. Chinese: 黄伏翼. English: Grandidier`s Pipistrelle, Yellow Pipistrelle Bat, Yellow Serotine. French: Pipistrelle de Grandidier, Sérotine de Grandidier, Sérotine jaune, Pipistrelle jaune. German: Grandidiers Zwergfledermaus, Gelbe Zwergfledermaus, Gelbe Pipistrelle. Italian: Pipistrèllo giallàstro.

CONSERVATION STATUS:
Global Justification
Listed as Data Deficient (DD ver 3.1 (2001)) in view of continuing problems with its taxonomy as well as absence of recent information on its extent of occurrence, status, ecological requirements and threats (Jacobs *et al.*, 2008s; IUCN, 2009; Jacobs *et al.*, 2017).

Assessment History
Global
2016: DD ver 3.1 (2001) [assessed as "*Pipistrellus grandidieri*"] (Jacobs *et al.*, 2017). 2008: DD ver 3.1 (2001) [assessed as "*Pipistrellus flavescens*"] (Jacobs *et al.*, 2008s; IUCN, 2009). 2004: DD ver 3.1 (2001) (Jacobs *et al.*, 2004aa; IUCN, 2004). 1996: DD [assessed as "*Eptesicus flavescens*"] (Baillie and Groombridge, 1996).

Regional
None known.

MAJOR THREATS:
The major threats are mining, logging and wood harvesting. It is sensitive to unintentional effects on large scale like harvesting, although the species being assessed is not the target (Jacobs *et al.*, 2017).

CONSERVATION ACTIONS:
Jacobs *et al.* (2008s) [in IUCN (2009)] and Jacobs *et al.* (2017) report that there appear to be no conservation measures in place for this species. There is a need to clarify the taxonomic status of animals currently allocated to this species, and thereby better understand the distribution, natural history and potential threats.

GENERAL DISTRIBUTION:
Ethiopia to SE Democratic Republic of the Congo and Zambia, including Unguja [=Zanzibar]. Possibly Liberia (1st record, Monadjem and Fahr, 2007: 47; as "*Neoromicia* aff. *guineensis*"). Decher *et al.* (2016: 273) report "*N.* cf. *grandidieri*" specimens from Guinea. As "*Pipistrellus/Neoromicia flavescens*" recorded from Angola (type locality at Galanga), Burundi, Cameroon, Malawi (including the Shire Highlands (Happold and Happold, 1997b: 81), Mozambique, Uganda (Kampala); and Somalia (Shonto Forest).

Native: Angola (Crawford-Cabral, 1989; Thorn *et al.*, 2007; Monadjem *et al.*, 2010d: 571); Burundi; Cameroon; Congo (Democratic Republic of the) (Hayman *et al.*, 1966; Monadjem *et al.*, 2010d: 571); Malawi (Happold and Happold, 1997b: 81; Thorn *et al.*, 2007; Monadjem *et al.*, 2010d: 571); Mozambique; Somalia; Tanzania; Uganda, Zambia (Benda *et al.*, 2022: 292).

DENTAL FORMULA:
Esquivel *et al.* (2021: Supp.) reported that 17 of the 32 skulls they examined had missing teeth (oligodontia).

DETAILED MORPHOLOGY:
Baculum
Thorn *et al.* (2007).

POPULATION:
Structure and Density
There are few details available on the population status of this species (Jacobs *et al.*, 2008s; IUCN, 2009; Jacobs *et al.*, 2017).

Trend
2016: Unknown (Jacobs *et al.*, 2017). 2008: Unknown (Jacobs *et al.*, 2008s; IUCN, 2009 - as "*Pipistrellus flavescens*").

PARASITES:
Schaer *et al.* (2013a: 17416) report the presence of hemosporidian parasites of the genus *Polychromophilus* in three out of three investigated "*P.* aff. *grandidieri*" specimens from West Africa, but they indicate that the bat might represent an undescribed species. Rosskopf *et al.* (2018: Suppl.) refer to the same specimens and mention them from Guinea.

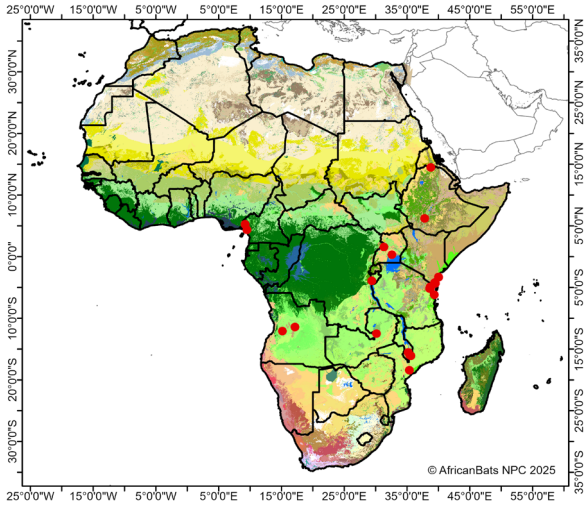

Figure 361. Distribution of *Afropipistrellus grandidieri*.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Angola, Burundi, Cameroon, Côte d'Ivoire, Ethiopia, Kenya, Malawi, Mozambique, Tanzania, Uganda, Zambia.

Afropipistrellus happoldorum (Hutterer, Decher, Monadjem and Astrin, 2019)

2013. *Neoromicia sp. 1:* Monadjem, Richards, Taylor and Stoffberg, Zool. J. Linn. Soc., 167 (1): 194. Publication date: 18 January 2013.

*2019. *Parahypsugo happoldorum* Hutterer, Decher, Monadjem and Astrin, Acta Chiropt., 21 (1): 9. Publication date: 5 October 2019. Type locality: Guinea: Macenta prefecture: Simandou Mountains: Western Spur Valley [08 33 26 N 08 55 17 W, 737 m]. Holotype: ZFMK MAM-2009.0029: ad ♂, skull and alcoholic. Collected by: Jan Decher, Blaise Kadjo and Juliane Schaer; collection date: 12 December 2008; original number: JD 700. Paratype: ZFMK MAM-2008.0295: ad ♀. Collection date: 8 March 2008. - Etymology: In honour of Meredith and David Happold in recognition of their studies on African bats, and particularly of their monumental work for the Mammals of Africa volume IV on hedgehogs, shrews, and bats (see Hutterer *et al.*, 2019: 10).

2020. *Nycticeinops happoldorum:* Monadjem, Demos, Dalton, Webala, Musila, Kerbis Peterhans and Patterson, Zool. J. Linn. Soc., 191 (4): 1123. Publication date: 10 September 2020. (Name Combination).

2022. *Afropipistrellus happoldorum:* Benda, Uvizl, Šklíba, Mazoch and Červený, Lynx, ns 53 (1): 317. (Current Combination).

? *Neoromicia sp. 1 SaSt-2013*

TAXONOMY:
Originally described in the genus *Parahypsugo*, but based on cyt-*b* sequence analyses, Monadjem *et al.* (2020a: 1126) considered *Parahypsugo* to be a synonym of *Nycticeinops*.

Torrent *et al.* (2025b: 4) transferred *happoldorum* to the genus *Afropipistrellus*.

COMMON NAMES:
English: Happolds' Pipistrelle

CONSERVATION STATUS:
Global Justification
Not assessed.

Assessment History
Global
Not assessed.

Regional
None known.

GENERAL DISTRIBUTION:
Native: Cameroon (1st record: Grunwald *et al.*, 2025: 281); Côte d'Ivoire; Guinea; Liberia.

However, Grunwald *et al.* (2025: 302) also indicate that the Cameroonian specimens have a different dental morphology and further analyses are needed to confirm their identity.

ECHOLOCATION:
From the Mbam Minkom Massif (Cameroon), Werb *et al.* (2024: 287) reported the following for 27 calls of 3 bats: F_{peak}: 46.8 ± 1.6 (43.7 - 49.4) kHz, F_{min}: 41.2 ± 1.6 (39.0 - 43.7) kHz, F_{max}: 87.4 ± 10.4 (61.5 - 100.1) kHz, duration: 2.2 ± 0.2 (2.1 - 2.6) ms.

MOLECULAR BIOLOGY:
Karyotype
Volleth *et al.* (2023c: 42) reported 2*n*=24, FNa=44 and eight large- to medium-sized meta- to submetacentric autosomal pairs and three medium-sized subtelocentric pairs. The X chromosome is a medium-sized submetacentric and the Y chromosome a small metacentric.

POPULATION:
Structure and Density
Unknown.

Trend
Not assessed.

DISTRIBUTION BASED ON VOUCHER SPECIMENS:
Côte d'Ivoire, Ghana, Guinea, Liberia.

Afropipistrellus musciculus (Thomas, 1913)

*1913. *Pipistrellus musciculus* Thomas, Ann. Mag. nat. Hist., ser 8, 11 (63): 316. Publication date: 1 March 1913. Type locality: Cameroon: Ja River: Bitye [03 13 N 12 22 E, 2 000 ft]. [Goto Description]. Holotype: NHMUK 1913.2.8.1: ad ♂, skin and skull. Collected by: George Latimer Bates Esq. Collection date: 3 September 1912; original number: 622.
1966. *Pipistrellus (Pipistrellus) musciculus:* Hayman, Misonne and Verheyen, Ann. Kon. Mus. Mid. Afr., Zool. Wetensch., (8) 154: 16. (Name Combination).
1987. *Attalepharca musciculus:* Menu, Palaeovert., 17 (3): 128. - Comments: Menu used *Attalepharca* as "groupe collectif" not as genus name. (Name Combination).
1987. *Pipistrellus (Hypsugo) musciculus:* Hill and Harrison, Bull. Br. Mus. (nat. Hist.) Zool., 52 (7): 281. (Name Combination).
