The gastrointestinal tract of the horseshoe bat, *Rhinolophus hildebrandti* (Peters), was studied macroscopically, with the light microscope and with the scanning electron microscope. Macroscopically, the stomach was of the simple type and the intestine was a short convoluted tube with an almost uniform diameter. A caecum, an appendix and a colon were absent, and the only portion of the large intestine observed was a short rectum which had a distinctly greater diameter than the rest of the intestine. The proximal part of the intestine showed a brief 'honeycomb' segment preceding the ridge-like transverse villi that occupied the rest of the foregut. In the region immediately proximal to the rectum the villi joined in a geometrical pattern to form chambers resembling 'reticular cells' of the ruminant stomach. The villi were covered with a prominent columnar epithelium occasionally interrupted by goblet cells. Generally, the intestine of *Rhinolophus* resembles that of the other bats which have been studied, but showed structural details suggestive of an increased surface area.

Le tractus intestinal du Rhinolophe, *Rhinolophus hildebrandti* (Peters) a été étudié au moyen d'un microscope simple et d'un microscope électronique. Macroscopiquement, l'estomac est de type simple, et l'intestin est un tube court enroulé d'un diamètre presque constant. Il n'y a ni caecum, ni appendice, ni colon, et la seule portion de gros intestin observée était un rectum court d'un diamètre nettement plus grand que le reste de l'intestin. La partie proximale de l'intestin présente un court segment en "nid d'abeille" qui précède le reste de l'intestin strié transversalement. Dans la partie qui précède directement le rectum, les villosités transversales rejoignent un schéma géométrique pour former des chambres semblables aux "cellules réticulaires" de l'estomac des ruminants. Les villosités étaient couvertes d'un épithélium en colonnes très visible, interrompu çà et là par des cellules en gobelet. Globalement, l'intestin du Rhinolophe ressemble à celui des autres chauves-souris qui ont déjà été étudiées mais présente des détails de structure qui suggèrent une augmentation de la surface.

Makin, D. (1989). Age groups in the fruit bat *Rousettus aegyptiacus.* Abstract. Eigth International Bat Research Conference, Sydney, Australia, 9 - 15 July 1989.

During the procedure of "capture-mark-recapture" research conducted in Israel on the local fruit bat *R. aegyptiacus* I from 1982 through 1989, 4725 bats were marked. The age of suckling and 'of growing bats was determined by the forearm length, the stage of physical development and the bats' weight. These bats constitute the known age groups. Adults were subjectively sorted into relative age groups according to the extent of abrasion of the canines. The age of recaptured adults which had been marked first as juveniles was evaluated by adding the interval period between the captures. The recapture of adult specimens first caught as adults provided data on the rate of canine abrasion. On

the basis of these recaptures each of the relative age groups was given a range of possible values in terms of absolute age. Among the oldest bats captured most were males, probably indicating that in nature females have a shorter life span. A comparison of the average forearm lengths of the different age groups showed that in both sexes older bats were significantly larger than younger adults indicating that there is a selective pressure favoring large size.

Makin, D. (1990). Annual weight cycle in the fruit bat *Rousettus aegyptiacus*. Abstract.

In the process of a capture-mark-recapture research conducted in Israel on the local fruit bat *R. aegyptiacus*, 6000 bats were marked, during the period of 1982-1990.

The adult specimens were subjectively sorted into relative age groups according to the abrasion of the canines.

The absolute age of the relative groups were estimated on the basis of the recaptures of known-aged specimens. The recapture of adult specimens provided information to the age determination by providing data on the rate of the abrasion of canines.

The relations between body weight, month of capture, time of capture, and age were investigated. The results show that body weight in adults has a circannual cycle, a daily cycle and is influenced by age.

Marandat, B. (1994). Premier catalogue des spécimens-types paléontologiques déposés dans les collections de l'Université de Montpellier II (Sciences et techniques du Languedoc).

Plus de 400 spécimens types paléontologiques déposés dans les collections de l'Université de Montpellier II sont inventoriés dans le présent catalogue qui comprend des charophytes, végétaux du Paléozoïque, brachiopodes, mollusques, arthropodes et des vertébrés (sélaciens, amphibiens, reptiles, oiseaux et mammifères). Les vertébrés ont été traités exhaustivement dans le catalogue et on peut donc considérer que ce dernier rassemble la quasi-totalité des spécimens types déposés à l'Université de Montpellier II.

More than 400 paleontological type-specimens housed in the Montpellier University collections have been inventoried in this catalogue which includes charophytes, Paleozoic plants, brachiopodes, molluscs, arthropodes and vertebrates (selachians, amphibians, reptiles, birds and mammals). The vertebrates have been treated exhaustively in the catalogue and one can consider that it includes most of the type specimens deposited in the Montpelier II collections.

Maree, S. and W. S. Grant (1996). Description of electrophoretic loci and tissue specific gene expression in the horseshoe bat genus *Rhinolophus* (Rhinolophidae).

The number of loci encoding an enzyme system, tissue specificity of gene expression and the degree of gene expression in various tissues are often not mentioned in evolutionary studies, but could indirectly provide evidence of evolutionary relationships. Protein electrophoresis was used to study the distributions and tissue specificity of gene expression of enzymes encoded by 42 loci in *Rhinolophus clivosus* and *R. landeri*, the genetically most divergent of the ten species of southern African horseshoe bats. No differences in gene expression were found between *R. clivosus* and *R. landeri* and isozyme patterns may be compared with other bat species to derive possible phylogenetic relationships.

Marshall, A. G. (1983). Bats, flowers and fruit: evolutionary relationships in the Old World.

Old World phytophagous bats (Megachiroptera: Pteropodidae) number 173 species of which 79 % are Asian and 21 % African. Bats arose, presumably monophyletically, in the early Tertiary, the Megachiroptera soon diverging from the Microchiroptera. By the Cretaceous-Tertiary boundary the major groups of modern angiosperms were present, some of these probably being pollinated nocturnally by large insects and non-flying mammals and others with seeds dispersed by terrestrial vertebrates. Early bats were perhaps initially attracted to such flowers and fruit by the insects found around them, later finding the plants themselves nutritious. Megabats today feed upon floral resources, fruit and leaves from a total of at least 183 plant genera in 64 families. They may effect both pollination and seed-dispersal, and both bat-flower and bat-fruit syndromes are commonly recognized. Individual species are generally catholic in their feeding, favoured food varying with locality and season. Depending upon roosting habits and season, megabats may travel considerable distances each night to feed and may undertake seasonal migrations. Their feeding in orchards may sometimes require their control, but the future of certain species is more seriously threatened by slaughter for food and particularly by habitat destruction.

Marshall, A. G. (1985). Old World phytophagous bats (Megachiroptera) and their food plants: a survey.

The Megachiroptera, with a single family, 43 genera and 174 species, are confined to the Old World tropics and subtropics where they are exclusively phytophagous, feeding upon floral resources (largely nectar and pollen but also petals and bracts), fruit, leaves and water. A literature survey revealed information on the food sources for only 21 genera of bats, these feeding upon 75 genera of flowers, 145 genera of fruit and 10 genera of leaves in a total of 34 orders, 66 families and 198 genera. The bats are likely to pollinate flowers of at least 31 genera and presumably may disperse the seeds of the majority of fruits consumed. Despite our ignorance about the relationship between Megachiroptera and plants, it appears that most bats are catholic in their choice of food, and most plants are visited by a diversity of bats.

Mathias, M. da Luz (1988). An annotated list of the mammals recorded from the Madeira islands.

Twenty five species of extant mammals are cited for the Madeira Islands, including 13 species of marine mammals. Vernacular names and the world distribution for each species are given together with biological and ecological comments.

These species include five bats (Chiroptera), two carnivores (Carnivora), two seals (Pinnipedia), ten toothed whales (Cetacea, Odontoceti), one baleen whale (Cetacea, Mysticeti), one even-toed ungulate (Artiodactyla), three rodents (Rodentia) and one lagomorph (Lagomorpha).

Neste trabalho são referidas, com anotações, as 25 espécies de mamíferos actuals que ocorrem no Arquipelaqo da Madeira, incluindo as 13 espécies de mamíferos marinhos. As areas de distribuìção e os nomes vernaculos das espécies vão indicados juntamente com alquns comentários sobre a biología e ecologia das mesmas.

Mathias, M. L., M. G. Ramalhinho, M. Santos-Reis, F. Petrucci-Fonseca, R. Libois, R. Fons, G. Ferraz de Carvalho, M. M. Oom and M. Collares-Pereira (1998). Mammals from the Azores islands (Portugal): an updated overview.

Nine species of mammals arc recorded for the Azores islands: one insectivore (*Erinaceus europaeus*), two bats (*Myotis myotis, Nyctalus azoreurn*), one lagomorph (*Oryctolagus cuniculus*), three rodents (*Rattus norvegicus, R. rattus. Mus musculus domesticus*) and two carnivores (*Mustela nivalis, M. furo*). Here, notes on the origin and known distribution are given for each species, together with taxonomical and ecological comments. Except for bats all the remaining species seem to have been introduced under the influence of man's exploratory and commercial activities.

Neuf espèces de mammifères sont citées de l' Archipel des Açores: un insectivore (*Erinaceus europaeus*), deux chiroptères (*Myotis myotis, Nyctalus azoreum*), un lagornorphe (*Oryctolagus cuniculus*), trois rongeurs (*Rattus norvegicus, R. rattus, Mus musculus domesticus*) et deux carnivores (*Mustela nivalis, M. furo*). Le present travail apporte des données sur l'origine et la distribution, ainsi que certains aspects de la taxonomie et l'ecologie de chaque espèce. Exception faite des chiroptères, routes les espèces semblent avoir été introduites, suite à des activités humaines (exploration et commerce).

Matschie, P. (1897). Zur Faunistik Deutsch-Ost-Afrikas. 5. Säugethiere.

Seit dem Erscheinen meines Buches: "Die Säugethiere Deutsch- Ost-Afrikas. Dietr. Reimer, Berlin, 1895." ist unsere Kenntniss der ostafrikanischen Säugethiere erheblich gefördert worden. Nicht nur die Zahl der für das Schutzgebiet bekannten Arten hat zugenommen, sondern auch über die geographische Verbreitung der einzelnen Species und über die Unterschiede der Säugethier-Fauna in den verschiedenen Gegenden unseres Gebiets ist etwas mehr Licht verbreitet worden. Allerdings sind wir noch weit entfernt von einem ein germaassen befriedigenden Ueberblick über die Vertheilung der Sängethierwelt in Deutsch-Ost-Afrika.

Ich habe in meiner grösseren Arbeit (p. X) die Ansicht ausgesprochen, dass in Deutsch-Ost-Afrika zwei Faunen-Gebiete zusammenstossen, ein südliches und ein nördliches, und habe als Grenze für das südliche Gebiet eine Linie angegeben, die vom Kilima-Ndjaro über Umbugwe und West-Nguru nach Mpapwa verläuft. Ich glaube jetzt auf Grund neuerer Sammlungen diese Linie ergänzen zn können.

Ziemlich sicher erscheint es, dass das gesammte Küstengebiet in der Zusammensetzung seiner Fauna einen einheitlichen Charakter aufweist. Natürlich werden im Urwalde andere Arten leben als in der Steppe, und die Ebene wird uns ein anderes Bild zeigen als das Gebirge; aber die Urwald-Fauna des deutschostafrikanischen Küstengebietes wird überall da, wo im Gebiet Urwald vorhanden ist, ungefähr gleichartig sein, und ebenso wird in den Steppen allüberall dort eine ganz bestimmte Zusammensetzung der Säugethier-Fauna obwalten. Als Hinterlandsgrenze dieses Gebietes sehe ich eine Linie an, welche die Flusssysteme des Rovuma, Rufiji, Kingani, Wami, Mligasi, Msangasi und Pangani umfasst. - Sehr verschieden von diesem Gebiet ist die Massai-Steppe in der Zusammensetzung ihrer Fauna. Als drittes Untergehiet ist das übrige Hinterland von der Wembaere-Steppe nach Westen anzusehen und als viertes Untergebiet erscheint das System des Kagera im Westen des Victoria-Nyansa und der äusserste Nordzipfel von Deutsch-Ost-Afrika nördlich vom Speke-Gold im Osten des Nyanusa. Dieses letzte Gebiet zeigt unverkennbar westafrikanische Einflusse, das Massai-Gebiet solche des Nordostens, die Küste solche des Südens und das Hinterland scheint eine Mischfauna zu besitzen, in der nördliche und südliche Einflüsse bemerkbar sind. Wahrscheinlich wird die Ost- und Nordküste des Nyassa und das Kondeland ein fünftes Untergebiet bilden, in welchem die reine Zambese-Fanna vorhanden sein dürfte.

Sehr eigeuthümlich zusammengesetzt ist die Fauna des Kilima-Ndjaro. Hier finden wir sehr viele Formen, welche in der Massai Nyika ihre Südgrenze haben. Wenn man berücksichtigt, dass auf dem Kilima-Ndjaro der zum Indischen Ocean fliessende Pangani entspringt, dass aber andererseits dort die Massai-Steppe beginnt, so werden wir uns nicht wundern, hier Faunen zweier verschiedener Untergebiete neben einander zu finden.

Matschie, P. (1899b). Die Fledermäuse des Berliner Museums für Naturkunde. 1. Lieferung. Die Megachiroptera des Berliner Museums für Naturkunde.

Professor Dr. Peters, 1857 - 1883 Direktor des Berliner Zoologischen Museums, hatte beabsichtigt, unter dem Namen: Museum: Zoologicum Berolinense. Chiroptera eine Monographie der Fledermäuse herauszugeben. Während der Jahre 1865 - 1883 sind für diesen Zweck 75 lithographirtr Tafeln durch die bekannten, inzwischen verstorbenen Thiermaler Franz Wagner und Gustav Mützel hergestellt worden. Im Frühjahr 1883 starb Peters und in seinem Nachlasse fand sich keinerlei Manuskript über Fledermäuse. Die Verlagsbuchhandlung von Georg Reimer, welcher die Tafeln gehören, bemühte

sich Jahre lang vergeblich, einen Herausgeher für die werthvollen Abbildungen zu finden. Erst jetzt, 34 Jahre nach der Herstellung der ersten Tafel, erscheint der erste Theil des Werkes.

Die Verlagsbuchhandlung hat in ausserordentlich weitgehender Weise dafür gesorgt, dass die vorliegenden Tafeln soweit ergänzt werden konnten, wie der heutige Stand unserer Kenntniss der Fledermäuse es verlangt. Nicht weniger als 15 neue Tafeln sollen zu den schon vorhandenen 75 treten; 11 von ihnen wurden gezeichnet und lithographirt durch meine Frau Anna, geb. Held, und dürfen sich gleichwerthig den von Wagner und Mützel gearbeiteten an die Seite stellen. Der Tod hat meine Frau verhindert, ihr Werk zu vollenden.

Bei der Aufgabe, einen Text zu diesen Tafeln zu schreiben, habe ich darauf verzichten müssen, eine Monographie der Fledermäuse zu schaffen, weil das im Berliner Museum für Naturkunde aufbewahrte Material nicht ausreicht für die Bearbeitung dieser nicht leichten Aufgabe, und ein längerer Aufenthalt in Paris, London und Leyden zum Studium der dortigen Sammlungen mir nicht möglich war.

Ich habe mich deshalb damit begnügt, nach zoogeographischen Gesichtspunkten die Arten, welche mir vorlagen, in Gruppen zusammenzustellen, die von mir nicht untersuchten Arten nach Möglichkeit neben die am nächsten verwandten Formen einzureihen, in Bestimmungstabellen die Unterschiede anzugeben, welche ein Erkennen der einzelnen Arten erleichtern, und die im Berliner Museum vorhandenen Exemplare aufzuzählen.

Besonderen Werth habe ich auf eine genaue Feststellung der Fundorte gelegt.

Die Litteratur wurde im allgemeinen nur insoweit genannt, als sie nicht in Trouessart's und Dobson's Werken zu finden ist.

Durch die Liebenswürdigkeit des Herrn Geheimen Hofraths Dr. A. B. Meyer, Direktor des Zoologischen Museums in Dresden, ist es mir vergönnt gewesen, einen Theil des Dresdener Materials an Flughunden hier in Berlin untersuchen zu dürfen.

Mit seiner Bewilligung habe ich diese Exemplare in meiner Arbeit aufgeführt.

Ich sage hier Herrn Geh. Hofrath Dr. A. B. Meyer meinen herzlichsten Dank. Auch Herrn Dr . Jentink , Direktor des Leydener Museums, haue ich für eine freundliche Auskunft auf eine Fruge zu danken, vor allem aber meinem verehrten Herrn Chef, Geh. Regierungsrath Professor Dr. K. Möbius, welcher mich in weitgehender Weise unterstützte.

Den ersten Theil meiner "Fledermäuse des Berliner Museums für Naturkunde" lege ich hiermit vor. Er umfasst die *Megachiroptera*. In 4 Lieferungen soll der gesammte Stoff bewältigt werden. Eine allgemeine Einleitung in die Fledermauskunde werde ich der Ietzten Lieferung beigeben.

Matthews, L. H. (1937). The form of the penis in the British rhinolophid bats compared with that in some of the vespertilionid bats.

1. Although the penis of the Chiroptera is generally described as pendulous, it is directed cranially in *Rhinolophus ferrum-equinum insulanus* and *R. hipposideros minutus*.

2. In five species of British Vespertilionid bats the penis varies from the cranially directed type to the completely pendulous type.

3. The glans penis in the Rhinolophidse is large and complicated in architecture, but in the Vespertilionids it is very small and comparatively simple.

4. The form and structure of the glans penis and prepuce in *R. ferrum-equinum insulanus* and *R. hipposideros minutus* are briefly described and compared with those of five species of British Vespertilionid bats.

5. The biological correlations and taxonomic importance of the differences in the form and structure of the glans penis in the Rhinolophidae and the Vespertilionidae are indicated.

Matthews, L. H. (1941). Notes on the genitalia and reproduction of some African bats.

1. The anatomy and histo-physiology of the genitalia of nine species of African bats are described. The species are *Cœlura afra* Peters, *Taphozous* sp. indet. (Fam. Emballonuridæ); *Nycteris luteola* Thos. and *N. hispida* Schreb. (Fam. Nycteridæ); *Cardioderma cor* Peters (Fam. Megadermidæ); *Hipposideros caffer* Sund. and *Trænops afer* Peters. (Fam. Hipposideridæ); *Miniopterus minor* Peters and *M. dasythrix* Temm. (Fam. Vespertilionidæ).

2. The glans penis is large and complicated in structure in *C. cor* and *T. afer*, smaller in *N. luteola, N. hispida* and *H. caffer*, and minute in *Taphozous, M. minor* and *M. dasythrix*. The prepuce is thin and retractile in the first five; thick and glandular in the last three.

3. An os penis of complicated architecture is .present in *N. luteola, C. cor* and *T. afer*. It is of simple form, in *N. hispida, Taphozous* and *H. caffer*. It is comparatively large in the first four species and extends into the penis proximal to the glans. In the last two it is minute and confined to the glans. There is no os penis in *M. minor* and *M. dasythrix*.

4. Accessory erectile bodies, in addition to the corpora cavernosa and corpus spongiosum, are present in all species. They are "particularly conspicuous in *N. luteola* and *C. cor*. The corpora cavernosa are fused for the whole or part of their length in all species ; in some they are separated by a septum of tunica albuginea, in others they are completely fused.

5. The scrotum is post-anal, the testes are oval and the epididymides have long tails in *M. minor* and *M. dasythrix*. The testes and epididymides are similar but lie beneath the integument of the base of the penis in immature specimens of *Taphozous*. The scrotum is pre-arial, the testes are subglobular and the. epididymides do not have greatly elongated tails in *N. luteola* and *C. cor*. The testes and epididymides are similar in form in *N. hispida* and *H. caffer*, but in *T. afer*, though the testes are subglobular, the tails of the epididymides are long. In the first species they lie in the inguinal canals at the sides of the base of the penis; in the last two cranial to the base of the penis. In all three free spermatozoa are present in the genital tract. It is possible that the testes have been withdrawn from pre-anal scrotal pouches, though no structural evidence for this was found.

6. Vesiculæ seminales are present in *T. afer* and *Taphozous*. They are large glandular bodies, whose ducts open into the urethra near the openings of the vasa efferentia in *T. afer*, and unite with the vasa efferentia near their openings in *Taphozous*. Vesiculæ seminales are absent in the other species.

7. The ampullæ of Henle are represented by a slight convolution of the vas deferens in *T. afer* and by small glandular swellings in *Taphozous*. In all the other species they are large glandular swellings of the ends of the vasa deferentia and are comparable in structure with the vesiculæ seminales in the two species where those bodies occur. In *H. caffer* they are divided into two unequal lobes.

8. The prostate is a large glandular mass below the neck of the bladder. It surrounds the urethra, having large anterior and posterior lobes, in all species except *N. luteola* and *N. hispida*. In the latter two species it is confined to the posterior surface of the urethra. In several species the ampullæ of Henle are partly embedded in the prostate.

9. The urethral gland is large in *C. cor* and *H. caffer*, small in *T. afer, M. minor* and *M. dasythrix*. It is absent in *Taphozous, N. luteola* and *N. hispida*.

10. A utriculus prostaticus is present in *Taphozous, N. luteola. H. caffer* and *C. cor*. It is comparatively large in *Taphozous* and ends in a number of diverticula; it is small and simple in the other three. No sign of a utriculus prostaticus was found in *N. hispida, T. afer, M. minor* or *M. dasythrix*.

11. Cowper's glands are comparatively large in all species.

12. The vulvar opening is transverse in all species. The clitorideal pad is large in *C. cor* and *T. afer*, less developed in *C. afra, N. luteola* and *N. hispida*, and small in *Taphozous, M. minor* and *M. dasythrix*.

13. Pubic teats, unconnected with a mammary gland, are present in *C. cor* and *T. afer*. In both species they contain canals which are identical in histological appearance with true milk-ducts. The canals end blindly at the base of the teats. No pubic teats occur in the other species. Rudimentary pubic teats are present in the males of *C. cor*.

14. The uterine cornua are approximately equal in size in *C. afra*. One cornu is slightly larger, on the right side in *Taphozous* and *N. hispida*, and on the right or left side in *N. luteola* and *T. afer*. It is considerably larger on the right side in *M. minor* and *M. dasythrix*. A pregnancy was present, or had occurred, on the right side in *C. afra* (one specimen), *N. hispidia* (three),*M. minor* (thirteen), and *M. dasythrix* (six). In *N. luteola* occurrences were right side, six; left side, seven. In *T. afer* and *C. cor* the pregnancy fills the cornua of both sides, together with the body of the uterus which are thrown into one large cavity. Assuming that the pregnancy started on the side to which the placenta is attached, it started in the left side in two specimens of *T. afer* and once each on the left and right in *C. cor*.

15. There is no internal uterine body in *N. luteola* and *N. hispida*, where each cornu communicates with its own cervical canal which opens separately into the vagina. There is a completely divided septate uterine body communicating with a- single cervical canal in *Taphozous*. The undivided uterine body is very short in *T. afer, M. minor* and *M. dasyihrix*, and short and wide in *C. afra*.

16. The epithelium of the vagina, is thrown into high longitudinal ridges in *N. luleola, N. hispida, C. cor* and *T. afer*, and into comparatively low ones in the other species. The epithelium becomes strongly cornified at oestrus. In one pregnant specimen of *C. afra* the urinogenital canal was strongly constricted and its lumen nearly occluded by cornified epithelium.

17. The urethra is asymmetrical, being displaced to the right of the vagina, in the females of *C. afra, N. luteola* and *T. afer*. In all the other species it is symmetrical.

18. A "female prostate" is well developed in *C. afra, Taphozous, N. luteola* and *C. cor*, less conspicous in *M. minor*, and absent in *N. hispida, T. afer* and *M. dasythrix*.

19. One corpus luteum was present in each ovary of two pregnant *C. cor* which were near full term. One was present in the ovary of the side of pregnancy in a *C. afra* containing an early pregnancy. One was present in .the ovary of the opposite side from the pregnancy in six *M. dasythrix* containing unattached blastocysts in the enlarged right cornu. No corpora lutea were present in either ovary of pregnant' examples of *N. luteola* (nine) or *T. afer* (two).

20. A post partum œstrus occurs in *N. luteola*. All the nine pregnant specimens were.also in full lactation.

21. In the localities of provenance birth occurs approximately at the following times: - in early December, *N. hispida* and *M. minor*; in early January, *C. cor* and *T. afer*; late in January, *C. afra*; in November and again late in January, *N. luteola*, where one pregnancy immediately follows another.

22. In all species the mammary gland fills the axilla and extends well on to the back over m. serratus magnus. The nipples are thoracic in position and lie towards the median border of the gland.

Mayoux, A., E.-R. Brygoo and J.-R. Simond (1971). Bilan d'une année d'étude de *Pteropus rufus* à Madagascar son rôle comme réservoir de virus d'entérobactéries.

Le rôle de réservoir de virus pour les entérobactéries pathogènes pour l'homme, de la roussette de la côte est de Madagascar est maintenant bien démontré avec l'isolement de 45 souches de *Salmonella typhi*, d'une souche *S. typhimurium* et d'une *Salmonella* nouvelle en même temps que de 16 souches de *Shigella flexneri* et de 5 souches d'*Escherichia coli* pathogènes. Ces souches ont été obtenues par l'examen de 438 animaux. Le bacille d'Eberth appartient au lysotype E_{Ia}, le plus fréquemment rencontré en pathologie humaine.

Les rapports de la chauve-souris et de *S. typhi* doivent encore être précisés. La salmonelle se comporte comme un germe de sortie, n'apparaissant le plus souvent, dans le sang, et surtout dans les selles, que chez des animaux soumis à des agressions.

McBee, K., J. W. Bickham, S. Yehbutra, J. Nabhitabhata and D. A. Schlitter (1986). Standard karyology of nine species of Vespertilionid Bats (Chiroptera: Vespertilionidae) from Thailand.

Karyotypes of nine species of vespertilionid bats from Thailand are described. *Pipistrellus mimus* (2n = 34, FN = 46), *Tylonycteris robustula* (2n = 32, FN = 50), *Murina leucogaster* (2n = 44, FN = 50), and *Miniopterus schreibersi* (2n = 46, FN = 52) have karyotypes essentially identical to ones previously reported from other regions. *Pipistrellus pulveratus* (2n = 32, FN = 50) is reported for the first time and differs by six Robertsonian fission/fusion events from the primitive *Myotis*-like karyotype. Karyotypes for *Hesperoptenus tickelli* (2n = 32, FN = 50) and *H. blanfordi* (2n = 34, FN = 60) are reported for the first time and parallel the extreme morphological differences between the two species. *Harpiocephalus mordax* (2n = 40, FN = 62) is very distinct from other members of the subfamily Murininae but is apparently derived from a *Murina*-like ancestor. *Kerivoula papillosa* (2n = 38, FN = 52) though considered little differentiated from primitive vespertilionines has a relatively highly derived karyotype similar to *Vespertilio*.

McBee, K., D. A. Schlitter and R. L. Robbins (1987). Systematics of African bats of the genus *Eptesicus* (Mammalia: Vespertilionidae). 2. Karyotypes of African species and their generic relationships.

Bats of the genus *Eptesicus* are characterized by extreme consistency in karyotypes. All species of *Eptesicus* for which karyotypes have been reported have 2n = 50, FN = 48 (Baker and Patton, 1967; Williams, 1978; Bickham, 1979a) except the African *E. capensis*, which has 2n = 32, FN = 50 (Peterson and Nagorsen, 1975). We report standard karyotypes for four more species of African *Eptesicus*, none of which possess the 2n = 50 karyotype considered typical of the genus. *Eptesicus rendalli* (2n = 38), *E. brunneus* (2n = 36), *E. tenuipinnis* (2n = 34), and *E. somalicus* (2n = 26) all apparently have experienced numerous Robertsonian events and do not mirror the karyotypic conservatism of their New World and Palearctic relatives. These data are discussed as they apply to the currently recognized systematics of the genus *Eptesicus* and the proposed primitive karyotype of the family Vespertilionidae.

McDonald, J. T., I. L. Rautenbach and J. A. J. Nel (1990a). Foraging ecology of bats observed at De Hoop Provincial Nature Reserve, southern Cape Province.

Prey preferences, foraging strategies, foraging zones, activity regimes and habitat selections of the five species of insectivorous bats at the Guano Cave on the De Hoop Provincial Nature Reserve, were investigated. It is evident that the cave is used on a seasonal basis by the different species. A measure of temporal and spatial separation of resources between species could be demonstrated, particularly of airspace and prey, and this differentiation correlates with differences in specific wing morphology and echolocation attributes. It would appear that bats do not feed extensively over nearby wheat fields, and available evidence suggests that the potentially deleterious effect of insecticide poisoning does not presently seem to be a major threat to the bat populations.

Prooivoorkeure, jagstrategiee, jagsones, aktiwiteitsritmes en habitatvoorkeure van die vyf insekvretende vlermuisspesies in die gwanogrot gelee in die De Hoop Provinsiale Natuurreservaat, is ondersoek. Dit is duidelik dat die grot seisoenaal deur die onderskeie spesies benut word. 'n Mate van ruimtelike en temporele skeiding van bronne tussen spesies is demonstreerbaar, veral van die lugruim en van prooi, en hierdie differensiasie korreleer met verskille in vlerkmorfologie en egolokasie-kenmerke tussen spesies. Dit blyk dat vlermuise nie ekstensief oor nabygelee graanlande jagmaak

nie, en beskikbare gegewens dui daarop dat die vermeende nadelige gevolge van insekdoder-vergiftiging dus nie huidig 'n bedreiging vir die vlermuisbevolkings inhou nie.

McDonald, J. T., I. L. Rautenbach and J. A. J. Nel (1990b). Roosting requirements and behaviour of five bat species at De Hoop Guano Cave, southern Cape Province of South Africa.

The roosting requirements and behaviour of five obligatory cave-dwelling bats occurring in the De Hoop Guano Cave, is reported. A measure of interspecific temporal and spatial partitioning of this resource is demonstrable. The cave is characterized by structural and thermal complexity, and was found to be an important breeding site for two species during summer, whereas it served as winter residence for the other three. *M. schreibersii* was by far the most abundant species, and predominated in the warmest sections of the cave, where it further modified temperatures towards optimal levels.

Die skuilplek-behoeftes en -gewoontes van vyf grotvlermuise wat in die De Hoop Gwanogrot voorkom, word gerapporteer. Ons bevindinge dui op 'n mate van interspesifiese ruimtelike en temporale be nutting van hierdie bron. Die grot word gekenmerk deur strukturele en termo-kompleksiteit, en is daarom 'n belangrike aanteelplek vir twee spesies gedurende die somer, terwyl dit dien as oorwinterings-verblyfplek vir die ander drie. *M. schreibersii* was verreweg die getalsterkste spesies, en het hoofsaaklik in die warmste dele van die grot gekonsentreer, waar hul ook temperature aangepas het na optimale vlakke.

McFarland, D. C. (1998). Forest vertebrate fauna study for a comprehensive regional assessment in south-east Queensland. Stage IA: Data audit and gap assessment.

This report has been prepared for the joint Commonwealth/State Steering Committee which oversees the Comprehensive Regional Assessment (CRA) of forests in the South East Queensland CRA region.

The Comprehensive Regional Assessment provides the scientific basis on which the State and Commonwealth governments will sign a Regional Forest Agreement (RFA) for the forests of the South East Queensland CRA region. This agreement will determine the future of the region's forests, providing a balance between conservation and ecologically sustainable use of forest resources.

This report was undertaken to a) collate existing fauna information concerning the distribution (and where possible habitat use, abundance and breeding activity) of freshwater and terrestrial vertebrates and selected invertebrates for the South-east Queensland Comprehensive Regional Assessment region, and b) identify significant gaps in the dataset.

A total of 306,269 records was collected for 586 native and 44 feral forest using taxa known from the region. The number of records per species ranged from 1 to 7,496.

Across the entire region, major taxonomic gaps are apparent for threatened insects, freshwater fish, reptiles and bats. At a finer spatial scale, data are limited for most animal groups in conservation (National Park) and forestry (State Forest/Timber Reserve) areas in those environmental provinces outside the south-east corner (Provinces 5, 6, 7, 8, 10 and 16). The deficiencies in most provinces are real and not simply a reflection of the spatial extent of various tenures and habitat types. On the environmental scale, there are fauna in particular vegetation types which would benefit from a greater spatial coverage (distribution of species in the extensive dry forests of Spotted Gum and ironbark). In addition several rainforest, wet sclerophyll forest and non-eucalypt dominated types, despite relatively intense work, may still yield new fauna species with more survey effort.

The audit of the historical data reinforces the need for an extensive systematic survey of terrestrial vertebrates in the region to address deficiencies and provide more recent information on the abundance and distribution of forest-dwelling species.

McLellan, L. J. (1986). Notes on bats of Sudan.

Based upon recent collections ofbats from Bahr-el-Ghazal and Equatoria provinces in southern Sudan, *Epomophorus minor* is added to the list of species known from that country, and the geographic ranges of *Micropteropus pusillus, Eptesicus capensis, Eptesicus somalicus*, and *Chaerephon major* are extended within Sudan. Examples of species poorly represented in museum collections were also collected, including *Nycteris thebaica, Chalinolobus variegates*, and *Scotoecus hirundo*. Ecological notes were recorded; embryos and parasites were collected and preserved. Seventy-one species of bats are now known to occur in Sudan.

McWilliam, A. N. (1987a). Territorial and pair behaviour of the African false vampire bat, *Cardioderma cor* (Chiroptera: Megadermatidae), in coastal Kenya.

Cardioderma hangs from habitual perches to wait for mainly terrestrial prey. Their broad wings provide the lift at low speeds necessary to capture such prey from the ground. Male-female pairs were found in the long dry season, a period when reduced insect availability led to lower body weights and males used song to delineate their feeding territories. Males moved between perches more frequently during the first half-hour of nightly singing. An enlargement of foraging area was associated with earlier singing, as well as an increase in song rate, movement between perches and pair contact-vocalizations. Females are larger than males and the sex ratio favoured the latter. There was evidence of long-term territories and breeding throughout the year. These results are discussed in relation to pair-bonding and environmental seasonality

---

McWilliam, A. N. (1988a). Social organisation of the bat *Tadarida (Chaerephon) pumila* (Chiroptera: Molossidae) in Ghana, West Africa.

The social organisation of the polyoestrous bat, *Tadarida pumila*, was studied in northern Ghana (W. Africa). Although this small (8.5 g) free-tailed bat is not sexually dimorphic in size, adult males develop an odorous inter-aural crest of long hairs. A social system based on female defense polygyny was found which, however, also involved elements of resource defense. Harems, each generally established in the roof space of separate dwelling houses with restricted access, consisted of an adult male and up to 21 females, with their young, and the larger harems were held by heavier males. Harem composition was stable and both harem males and females showed high site fidelity over the study span of 16 months. Some female young were recruited to their natal harems, at a sufficient rate to replace the annual loss of harem females. However, most young, which were born in three successive cohorts during the rainy season, apparently dispersed over the dry season, following early sexual maturation. The potential causes and benefits of female associations are discussed.

McWilliam, A. N. (1988b). The reproductive cycle of male tomb bats, *Taphozous hildegardeae* (Chiroptera: Emballonuridae), in a seasonal environment of the African tropics.

Two cave populations of Hildegarde's tomb bat had a reproductive cycle that corresponded closely to the rainfall-induced seasonality of coastal Kenya (4s). Males had pronounced bimodal cycles of body weight due to the deposition of fat during periods of relative food abundance in both rainy seasons, and fat depletion during competitive mating and the dry seasons, when numbers of moths were lowest. The main period of sexual regeneration coincided with the increase in body weight experienced during the 'long rains' [April-June) and led to mating. A secondary peak in the weights of male sexual glands, associated with the increase in body weight that occurred in the 'short rains' (October-December), did not result in reproduction. It is suggested that this latter period of sexual activity was related to the maintenance of year-round harems, and may represent the male response to a vestigial, bimodally polyoestrous, reproductive cycle.

Meester, J. A. J. (1962). Some mammals from the Namib Desert.

The following is an account of the mammal specimens collected on the Bernard Carp expedition to the Namib desert during May 1959. It is a pleasure to acknowledge the generous sponsorship of Mr Bernard Carp, of Cape Town, which made this expedition possible. Sincere thanks are also due to the following: Dr C. K. Brain, of Salisbury, for collecting some of the specimens, and kindly placing at my disposal his habitat notes on these specimens; the late Dr W. Heesch, of Okahandja, for material collected by him in the course of the expedition, as well as some specimens from his private collection; Mr O. P. M. Prozesky, of Pretoria, for also assisting in collecting, and for supplying useful information regarding collecting localities; and the Transvaal Museum skinner, Samson Maseko, for his part in collecting, preparing and caring for the collections.

Meester, J. (A. J.) (1965). The origins of the southern African mammal fauna.

Southern Africa can be geographically subdivided into different biotic zones, differing from each other climatically and vegetationally, and also in respect of the animal species occurring in them. The purpose of the present paper is to consider the nature of the mammal faunas associated with these biotic zones, and to speculate about their origins.

Mein, P. and Y. Tupinier (1977). Formule dentaire et position systématique du Minioptère (Mammalia, Chiroptera).

La présence constante d'une prémolaire vestigiale antérieure au maxillaire supérieur des *Miniopterus* amène les auteurs à discuter des affinités de cette forme et à proposer pour elle la création d'une nouvelle famille (Miniopteridae).

Miniopterus is shown to possess a supplementary vestigial tooth between upper canine and the first premolar. The authors think this form does not belong to the Vespertilionidae and suggest to create a new family called Miniopteridae and include this genus into it.

Meirte, D. (1981). New data on *Casinycteris argynnis* Thomas, 1910 (Megachiroptera - Pteropodidae). Abstract.

The cranial and external measurements of the thirteen specimens of *Casinycteris argynnis* in the possession of the Koninklijk Museum voor Midden-Afrika, Tervuren (Belgium), are presented.

A comparison with published data on three other records is made, remeasurements of the type in the British Museum (Natural History) are included.

Females are clearly larger than males: forearm-length is highly discriminative: adult males 50.4 - 54.2 mm, adult females 56.1 - 61.6 mm. One juvenile specimen with the wing dimensions of an adult male is concluded to be a female.

Color and color patterns are very homogeneous throughout the series. The variation in palatal ridges is described.

Principal component analysis could not detect significant allometrical relations, the width of the skull is clearly a size independent variate. There is a slight indication that the western (Cameroon) specimens are more heavily built than the eastern ones.

This poor known forest species is so far only found in the central African forest bloc and is thought to be locally quite abundant.

Meirte, D. (1983). New data on *Casinycteris argyinnis* Thomas 1910 (Megachiroptera, Pteropidae).

The external morphology and the external and cranial morphometries of the *Casinycteris argynnis* specimens in the possession of the Koninklijk Museum voor Midden-Afrika, Tervuren, Belgium, were studied. Of thirteen specimens eleven are new records which add seven new localities for this poor-known species. Variation in color, teeth and palatal ridges was studied. Morphometrical data reveal significant sexual dimorpbism; especially in forearm length females are larger than males. Apparently also decrease in size from west to east is present. The species remains restricted to the central forest block in Africa.

Menu, H. (1984). Révision du statut de *Pipistrellus subflavus* (F. Cuvier, 1832). Proposition d'un taxon generique nouveau: *Perimyotis* nov. gen.

L'examen de la denture de *P. subflavus*, effectué dans le cadre d'une étude cornparative des rangées dentaires des Vespertilioninés, permet de mettre en évidence des structures qui justifient le retrait de cette espèce du genre *Pipistrellus*. En outre, certains caractères odontologiques s'avèrent être communs à *subflavus* et aux Myotini: ils témoignent d'une ascendance commune. Concurremment, quelques points de la morphologie dentaire sont particuliers; ils résultent d'une évolution indépendante et différenciatrice. Par ailleurs, des arguments ostéologiques ont été recherchés; ils apparaissent, par exemple, aux niveaux de l'articulation distale de l'humérus et de l'os pénien. Ces considérations justifient la création d'un taxon générique nouveau (*Perimyotis* nov. gen.), concrétisant l'appartenance de *subflavus* à la tribu des Myotini.

Within a comparative study of the tooth rows of vespertilionine bats, the *subflavus* species let appear structures which justify the removal of this species from the genus *Pipistrellus*. Moreover sorne features shared by *subflavus* and the Myotini tribe give evidence of a common ancestry of both. Concurrently, a few peculiar characters of the *subflavus* dental rnorphologv appear the result of subsequent differential evolution.

Skeletal features have also been investigated. Sorne arguments can be obtained from the elbow articulation of the humerus and from the penian bone.

These facts justify the erection of a generic taxon, *Perimyotis* nov. gen., making allowance for the relationships between it and the Myotini group.

Menu, H. (1985). Morphotypes dentaires actuels et fossiles des chiropteres vespertilionines. I Partie: Etude des morphologies dentaires.

Les classifications des vespertilioninés actuels étaient bâties sans qu'il soit tenu compte de la morphologie dentaire, ce qui restreignait les possibilités de comparaisons avec les fossiles connus. L'utilisation des formules dentaires était abusive: cette pratique a notablement contribué à l'admission de genres artificiels. Ces conditions ont retardé la valorisation de caractères susceptibles de structurer les bases d'une phylogénie de la sous-famille.

Dans la première partie du travail, les morphologies dentaires sont décrites et analysées. Des types morphologiques de référence sont établis pour chaque dent des rangées supérieure et inférieure; ils sont destinés à faciliter l'élaboration de critères de différenciation. Les réponses des espèces à ces critères permettent de les regrouper en genres homogènes, et d'appréhender le degré de parenté que ces derniers ont entre eux.

La seconde partie du travail (à paraître) commentera les implications systématiques des observations et proposera les bases d'une approche phylogénique.

The classifications of the recent vespertilionine bats were made without taking in account the teeth morphology; this resulted in a reduction of the possibilities of comparison with the available fossils. The generalized use of dental formulae was abusive: this contributed to the admission of artificial genera. These conditions have long delayed the consideration of characters able to frame the phylogeny of the sub-family.

In the first part of the study, the teeth morphologies are described and analysed. Morphological reference types are established for cach upper and lower tooth: they should make an easier elaboration of criteria for the ditterenciation at generic level. The position of the species in view of these criteria allows one to group them in to homogeneous genera, and to appreciate the degree of relationship that the latter have between them.

The second part of the study (next publication) will develop inferences dealing with systematics and phylogeny.

Menu, H. (1987). Morphotypes dentaires actuels et fossiles des chiroptères vespertilioninés. 2eme partie: Implications systematiques et phylogeniques.

La première partie de cette étude était consacrée à la description et à l'analyse des morphologies dentaires des vespertilioninés; elle conduit à une tentative synthétique de reconsidération des affinités et de la systématique.

Les résultats s'ordonnent par rapport à trois objectifs distincts mais intimement liés: 1 - l'apurement des contenus génériques pour tendre à faire des genres des taxons homogènes susceptibles de représenter les aboutissants de lignées évolutives; 2 - la recherche du degré de parenté entre les genres actuels afin d'en déduire les possibilités d'origines communes; 3 - en fonction des éléments précités, mais aussi des tendances évolutives constatées, l'élaboration d'une hypothèse phylogénique modeste et prudente.

De nombreux contenus génériques ont été apurés: le sous-genre *Leuconoe* prend rang de genre, et *Myotis* devient sous-genre du premier; les espèces myotodontes sont retirées du genre *Pipistrellus; Glischropus* et *Scotozous* tombent en synonymie de *Pipistrellus; Hypsugo* est élevé au niveau générique; des espèces provenant du genre *Pipistrellus*, constituant un ensemble hétérogène, sont provisoirement rassemblées en un Groupe Collectif: *Attalepharca* nov.; le genre *Eptesicus* est démembré, les espèces exclues constituent le genre *Nycterikaupius* gen. nov.; la tribu des Nycticeini est redéfinie après le retrait des genres *Otonycteris, Scotoecus, Scotophilus* et l'adjonction du genre *Hesperoptenus; la io* et *Pipistrellus tasmaniensis* sont mutées dans le genre *Eptesicus* (n. s.); *Pipistrellus dormeri* est rattaché au genre *Scotoecus*.

La considération des divers modes évolutifs de I1/, principalement, soutient la notion de regroupements de genres en des ensembles dont la valeur est souvent corroborée par la proximité morphologique d'autres dents. Cette tentative est à la base de la distinction des radiations majeures survenues dans l'histoire du groupe.

La schématisation proposée à la fin de ce travail met en évidence la parenté odontologique qui existe entre les genres actuels, et représente l'infrastructure d'une phylogénie présumable. Deux points prépondérants sont à souligner : l'isolement précoce du rameau leuconoïde, les accessions successives à la myotodontie par les formes issues du courant nyctaloïde. Les éléments paléontologiques connus d'après la littérature sont intégrés ponctuellement dans cette trame évolutive, à titre hypothétique.

The first part of this study was devoted to a descriptive analysis of teeth morphologies among the vespertilionine bats. This leads now to a tentative synthesis, providing views on the systematics of the

group. The results could be seen according to three distinct but closely related purposes: 1 - the sorting of the genera contents in order to conform the genera units to homogeneous taxa that could represent natural issues of evolutionary lineages; 2 - the investigation of relationships between extant genera in order to infer the possibilities of common origin; 3 - according to the preceeding items and to the observed evolutionary trends, a tentative phylogeny, modest and cautious.

The contents of many genera are sorted: *Leuconoe* is removed from subgeneric to generic position, whereas *Myotis* becomes a subgenus of it; the myotodont species are cleared away from the *Pipistrellus* genus; *Glischropus* and *Scotozous* are synonymized within *Pipistrellus ; Hypsugo* is raised to the generic level; some species previously ranged within *Pipistrellus* will form provisionally a collective group, *Attalepharca* nov.; the *Eptesicus* genus is broken up, the excluded species being grouped within *Nycterikaupius* gen. nov.; the Nycticeini tribe is defined again after exclusion of *Otonycteris, Scotoecus, Scotophilus*, and addition of *Hesperoptenus*; the species *la io* and *Pipistrellus tasmaniensis* are removed to *Eptesicus* (n.s.) and *Pipistrellus dormeri* to *Scotoecus*.

Groupings of genera are stated according to the main evolutionary trends of I1/. The relevance of these is often warranted by close morphologic similarities of other teeth. This leads to a recognition of the major evolutionary radiations which occurred in the group.

The filiations schematized at the end of the work show the dental relationships observed between the extant gênera, and could represent a phylogenic framework. Two major facts are to be underlined: 1 - the early divergence of leuconoids; 2 - the successives crossings to myotodonty from the nyctaloid flow.

Fossil data from the literature are punctually and tentatively incorporated within phylogenic sketches.

Menzies, J. I. (1973). A study of Leaf-nosed Bats (*Hipposideros caffer* and *Rhinolophus landeri*) in a cave in northern Nigeria.

Two species of leaf-nosed bats were netted as they emerged from their roosting cave at dusk. Collecting was repeated four times in 1966 and twice in 1967. Color of pelage, age, and reproductive condition of the bats were noted. From these data I conclude that the bats copulate late in the year, undergo a brief period of delayed implantation, give birth about April, and molt between May and July. The natural hair color of the adult is gray but quickly changes to reddish gold. Association between the breeding cycle and climate of the region is suggested.

Mertens, R. (1925). Verzeichnis der Säugetier-Typen des Seckenbergischen Museums.

Im vorliegenden Verzeichnis sind 136 Typen von Säugetiereh angeführt, die sich im Besitze des Senckenbergischen Museums in Frankfurt a. M. befinden. Für viele Formen, deren Originalbeschreibung auf Grund von 2 oder mehr Exemplaren erfolgt ist, von denen aber vom Autor kein bestirnmtes Stück als Typus bezeichnet wurde, habe ich stets eine nachträgliche Typen-Fixierung vorgenommen ("Lektotypus").

Mit Ausnahme des Typus von *Meriones melanurus* RÜPPELL (Mus. Senck. III, S. 95, Taf. VII. Fig 3; 1845), der im Britischen Museum ist (vgl. THOMAS, Ann. Mag. Nat. Hist. 9. III. S, 264; 1919), befinden sich alle Typen aus den wertvollen Sammlungen RÜPPELL's im Senckenbergischen Museurn. Bei der Durcharbeitung der Fledermaus-Sammlung des Landesgeologen Dr. C. KOCH, die nach seinem Tode in den Besitz des Senckenbergischen Museurns übergegangen ist, habe ich zu folgenden 4 Formen keine Belegstücke gefunden, die als Lektotypen betrachtet•werden könnten: *Rhinolophus ferrum-eauinun* var. *italicus* KOCH (Jahrb. Ver. Naturk. Herzogth. Nassau XVIII, S, 523; 1863), *Rhinolophus hipposideros* var. *alpinus* KOCH (a. a. O. S, 530), *Rhinolophus hipposideros* var. *pallidus* KOCH (a. a. O. S. 531) und *Cateorus serotinus* var *pallidus* KOCH (a. a. O. S, 467). Auch der Typus von *Herpestes ornatus rufescens* LORENZ-LIBURNAU (Abh. Senck. Nat. Ges. XXI, S. 462; 1898) ist nicht in unserem Museum.

Zu den Literatur-Zitaten ist zu bemarken daß RÜPPELL's "Atlas zu der Reise im nördlichen Afrika" lieferungsweise in einzelnen Heften herausgegeben worden ist. Mit freundlicher Hülfe von Herrn P. CAHN, der ein teilweise mit Lieferungsumschlägen versehenes Exemplar becsitst, konnte ich für den von CRETZSCHMAR bearbeiteten Säugetier-Teil die Erscheinungsjahre der einzelnen Lieferungen feststellen: im Jahre 1826 ist Lieferung 1 - 2 (mit Taf. I - VII). im Jahre 1827 Lieferung 3 - 6 (mit Taf. VIII - XV), im Jahre 1828 Lieferung 7 - 8 und 11 (mit Taf. XVI - XXVI) und im Jahre 1830 Lieferung 18 - 19 (mit Taf. XXVII - XXX) erschienen. Auch die Herausgabe des zweiten Hauptwerkes von RÜPPELL "Neue Wirbelthiere zu der Fauna von Abyssinien gehörig", von dem sich ein vollständiges Exemplar mit Original-Lieferungsumschlägen in der Bücherei des Herrn P. CAHN befinced, erfolte in einzelnen Lieferungen; und zwar ist vom Säugethier-Teil im Jahre 1835 Bogen 1 - 4 (mit Taf. I - VI), im Jahre 1936 Bogen 5 - 9 (mit Taf. VII - XII), im Jahre 1838 Taf. XIII - XIV (ohne text) und im Jahre 1840 Bogen 10 (ohne Tafeln) erschienen.

Für freundlihe Hülfe und Auskunft in verschiedenen Fragen bin ich den Herren P. CAHN in Frankfurt a. M., Prof. P. MATSCHIE in Berlin und Dr E. SCHWARZ in Frankfurt a. M., der auch für einige Namen verantwortlich ist, zu großem Danke verpflichtet.

Metselaar, D., M. C. Williams, D. I. H. Simpson, R. West and F. A. Mutere (1969). Mount elgon bat virus: A hitherto undescribed virus from Rhinolophus hildebrandtii eloquens K. Anderson.

A hitherto undescribed virus was isolated from salivary glands of fruitbat of the species *Rhinolophus hildebrandtii eloquens* (K. Andersen). Some of its properties are discussed. Of the viruses, isolated from organs of bats only and not from other sources, this virus is the first of which multiplication in mosquitoes - *Aedes aegypti* - was demonstrated.

Transmission to infant mice or to a blood reservoir through a batwing membrane was not achieved. The implications of the finding are discussed. The name Mount Elgon Bat virus (MEB) is proposed for the isolate.

Michelmore, A. J., D. J. Keegan and B. Kramer (1998). Immunoctochemical identification of endocrine cells in the pancreas of the fruit bat, *Rousettus aegyptiacus*.

The fruit bat, *Rousettus aegyptiacus*, is able to absorb large amounts of glucose in very short periods of time. This ability is partly reflected by the structure of the gastrointestinal tract and pancreas. The aim of this study was to confirm preliminary histochemical studies of the bat pancreas and to identify and quantitate endocrine cells by immunocytochemical techniques in order to understand the ability of the bat to absorb these large amounts of glucose. Endocrine cells were distributed in islets throughout the gland and also occurred as discrete cells in the exocrine ducts. Three-dimensional reconstruction and quantitation showed that the endocrine component of the pancreas occupied 9.1 % of the total volume. This is far more than that reported in any other species. Four endocrine cell types were demonstrated. Insulin (ß) cells (51.4 %) were located throughout the islet and extended between the glucagon (a) cells (30.6 %). Somatotostatin (`d) cells (8.8 %) and pancreatic polypeptide (PP) cells (17.1 %) were irregularly scattered throughout the islets. While the percentage of a, b, and d cells was similar to that in other species, the percentage of PP cells was higher. The high percentage of endocrine tissue found in the pancreas of the fruit bat may reflect metabolic adaptations involved in the absorption of the high carbohydrate diet of this animal.

Middleton, G. J. (1998). Lava caves of the republic of Mauritius, Indian Ocean.

In their *Underground Atlas*, Middleton & Waltham (1986) dismissed Mauritius as: "very old volcanic islands with no speleological interest". Recent investigations indicate this judgement as inaccurate; there are over 50 significant caves, including lava tube caves up to 687 m long (one 665 m long was surveyed as early as 1769) and 35 m wide. Plaine des Roches contains the most extensive system of lava tube caves with underground drainage rising at the seashore.

Notable fauna includes an insectivorous bat and a cave swiftlet (*Collocadia francica*), the nests of which are unfortunately prized for "soup". The caves are generally not valued by the people and are frequently used for rubbish disposal or filled in for agricultural development.

Bien que les îles Maurice ne soient pas connues pour leur intéret spéléologique, de récentes recherches indiquent qu'il ya plus de cinquante cavernes importantes, comprenant des tunnes de lave allant jusqu'à de 687 m de long et 35 m de large, l'un d'entre eux, de 665 m de long a été découverte dès 1769.

La Plaine des Roches contient le système le plus étendu de tunnels de lave avec un écoulement souterrain qui s'élève au niveau du rivage. La faune importante de ces caves comprends de chauves-souris insectivores et de petites hirondelles (*Callocalia francica*), les nids desquelles sont malheureusement recherchés pour soupes de gourmets. Les caves ne sont généralement pas appréciées par les habitants qui trop fréquemment s'en servent comme dépôts d'ordures ou d'entrepôts agricoles.

Miller, G. S. , Jr. (1897). Revision of the North American bats of the family Vespertilionidae.

Writers on American bats have published a large mass of facts concerning the distribution and comparative anatomy of members of the family *Vespertilionidæ*: Unfortunately, however, no work has yet appeared in which the numerous species by which this group is now known to be represented in North America are treated from the standpoint of the systematic zoologist. In other words it has hitherto been impossible for anyone not thoroughly acquainted with the extensive and scattered literature of North American bats to identify specimens correctly. The present paper has been prepared with special reference to the long-felt want of a ready means to accomplish this object.

Miller, G. S. , Jr. (1900). A collection of small mammals from Mount Coffee, Liberia.

In 1897 Mr. R. P. Currie spent about fourteen weeks, February 1 to May 10, as the guest of the New York State Colonization Society, at Mount Coffee, Liberia, where he made extensive collections in the interest of the United States National Museum. Though principally occupied with entomology, he secured a collection of small mammals, which proves to be of particular interest. Only twenty-eight species are represented, but nine of these are additions to the known fauna of Liberia, and seven are new to science. That so large a proportion of forms new to the region should be included in the collection is especially remarkable, in view of the fact that Mount Coffee, situated on the St. Paul River, about twenty-five miles from Monrovia, is within the area covered by the explorations of Büttikofer, Sala, and Stampfli; who obtained no less than ninety species of mammals.

The country in which the Currie collection was made calls for no detailed description. Mount Coffee lies in a damp, densely forested region, and its elevation above sea level is only 400 or 500 feet.

A few of the specimens were obtained by Professor O. F. Cook, but when no collector's name is mentioned it is to be understood that were taken by Mr. Currie, who is, in all cases, responsible for the native names and, unless the contrary is stated, for the measurements of the total length, tail vertebræ, and hind foot. I am much indebted to Mr. Wm. E. de Winton for aid in determining many of the rodents, and also for identification of most of the Cameroon material on which comparisons are based. Dr. F. A. Jentink has kindly compared a specimen of *Pipistrellus minusculus* with the type of *P. stampflii* in the Leyden Museum. This paper is published here by permission of the Secretary of the Smithsonian Institution.

Miller, G. S. , Jr. (1905). A new bat from German East Africa.

Two bats of the genus *Lavia* collected by Dr. W. L. Abbott at Taveta, German East Africa, in 1889, prove to differ too considerably from the West African *Lavia frons* to be regarded as the same species.

Miller, G. S. , Jr. (1907). The families and genera of bats.

In 1758, Linnæus knew seven bats, all or which he placed in *Vespertilio*, the fourth and last genus of the order Primates. The work of the next fifty years, as recorded by Tiedemann in 1808, though it had resulted in the recognition of the order Chiroptera, had not increased the species beyond 14, while the number of genera, even with the addition of the flying lemur, was still only seven. The first subdivision of the order into families appears to be due to Goldfuss, who, in 1820, arranged the genera in four groups, one of which still comprised the flying lemur. To each group he definitely applied the name "Familie." The real foundation for the current classification was, however, not laid by Goldfuss, but by Gray, who published the first of his many papers on bats in 1821. Gray excluded the flying lemur, recognized the two main subdivisions of the order, and applied to the names of families the system of nomenclature now in use. According to this scheme there were two suborders, the Fructivoræ and Insectivoræ, the former containing the families Pteropidæ and Cephalotidæ, the latter the Noctilionidæ and Vespcrtilionidæ. Though Gray's system was not followed very closely during the succeeding fifty years, it was finally given definite form by Gill in 1872 and Dobson in 1875, and since then has been almost universally adopted. The new classification now presented is, in fact, little more than an amplification of that founded by Gray. The increase in our knowledge of the Chiroptera since 1821 has been, however, very great. As we have seen, Linnæus recognized only one genus of bats; Gray placed the number comprised in his four families at about 14. In 1865 Peters divided the group into 10 families and subfamilies, containing, in all, 59 genera. When Dobson published his Catalogue of the Chiroptera in the British Museum, in 1878, he described 401 species, 80 genera, and 14 families and subfamilies. As might have been anticipated, this work, the only complete special monograph of the order, was such a stimulus to the study of bats that since it appeared these animals have received more attention than ever before. In 1904 Trouessart recorded no less than 851 species, 122 genera, and 18 families and subfamilies. It appears, however, that even these numbers are much too small. Detailed study of the skeleton, particularly of the wing and shoulder girdle and of the structure of the tooth cusps, leads me to the conclusion that among the known species at least 173 genera and 36 families and subfamilies should be recoguized. With regard to the species, recent work shows that an enormous increase is to be expected as the characters on which distinctions are based come to be better understood. It seems highly probable that the total number of recognized bats will eventually exceed 2,000 named forms.

Miltgen, F., I. Landau and J. Bradbury (1980). *Hepatocystis* d'*Hypsignathus monstrosus* (Pteropinae) au Gabon. II. Description d'*Hepatocystis carpenteri* n. sp.

Hepatocystis carpenteri n. sp. parasite d'*Hypsignathus monstrosus* au Gabon se différencie d'*Hepatocystis epomophori* et d'*Hepatocystis brosseti*, parasites d'autres Megachiroptères africains par la morphologie et la taille de ses schizontes intrahépatiques: *H. carpenteri* a une taille beaucoup plus grande et possède une paroi d'aspect spongieux qui n'a jamais été rencontrée chez d'autres *Hepatocystis*.

Hepatocystis of *Hypsignathus monstrosus* (Pteropinae) in Gabon. II. Description of *Hepatocystis carpenteri* n. sp.

Hepatocystis carpenteri n. sp. parasite of *Hypsignathus monstrosus* in Gabon is different from *Hepatocystis epomophori* and *Hepatocystis brosseti*, parasitic in other African Megachiroptera. *H. carpenteri* has bigger intrahepatic schizonts and a wall with a spongy appearance which has not been seen in other *Hepatocystis*.

Miltgen, F., I. Landau, G. Rosin and C. Erard (1977). *Hepatocystis brosseti* n. sp., Haemoproteidae, parasite d'*Epomops franqueti*, Pteropinae, au Gabon.

L'examen sanguin et histologique des *Epomops franqueti* (Pteropinae) capturés aux alentours de Makokou (Gabon) a montré que ces chauves-souris sont fréquemment parasitées par un Hépatocyste que nous nommons *Hepatocystis brosseti*. Le foie est l'organe de prédilection des schizontes, qui, à maturité, sont extracellulaires, polylobés, de taille modérée (250 µ) et pourvus d'une abondante colloïde en flaques. Un seul schizonte a été trouvé dans la rate.

Hepatocrstis brosseti n. sp., Haemoproteidae, parasite of *Epomops franqueti*, Pteropinae, in Gabon.

Epomops franqueti (Pteropinae) trapped around Makokou (Gabon) are frequently infected with *Hepatocystis brosseti* n. sp. Blood smears and tissue sections were made; all schizonts were found in the liver except a single one in the spleen. In liver, near maturity the schizonts are extracellular, convoluted, medium sized (250 µ) and filled with abundant colloidal substance.

Monadjem, A. (1998b). Distributional patterns and conservation status of mammals of Swaziland, southern Africa.

Distributional patterns (mapped at the quarter-degree square scale) of species richness of 121 species of mammal recorded from Swaziland were examined in relation to the distribution of protected areas (reserves), privately-owned ranches and six vegetation types. The richness of mammal species was highest in the NE and NW, and lowest in the SW areas of Swaziland. Total mammal species richness was positively and highly significantly correlated with the presence of reserves. Similar patterns were shown by artiodactyls, rodents and carnivores. Total mammal species richness, as well as for most mammalian orders, was positively correlated with moist grassveld and moist savanna vegetation types but negatively correlated with dry grassveld. Mammal species richness. especially for the larger species, was very low on Swazi Nation Land, which covers about 60 % of the country. The mammalian fauna of the high-lying areas (Highveld) was distinct from that of the low-lying areas (Lowveld). The Middleveld region supported elements of both Highveld and Lowveld species. A large proportion (87.6 %) of Swaziland's mammal species have been recorded from reserves. Two species (*Alcelaphus lichtensteini* and *Lycaon pictus*) no longer occur in Swaziland. For effective conservation of Swaziland's mammals, the issue of how to maintain viable populaions on Swazi Nation Land will have to be addressed.

Monard, A. (1935). Contribution à la mammalogie d'Angola et prodrome d'une faune d'Angola.

La Mammologie d'Angola est relativement peu connue; tandis qu'en Ornithologie, l'ouvrage capital de BARBOZA DU BOCAGE paru en 1877-1881 donnait déjà un tableau bien complet de cette partie de l'Histoire naturelle, auquel relativement peu de choses ont pu être ajoutées, la Mammologie ne faisait l'objet que d'un mémoire beaucoup moins étendu, paru en 1889-1891. Quelques traités spéciaux sur les Damans, les Rats-Taupes, les Antilopes ont complété sur ces points les données primitives de BOCAGE. Depuis lors les principaux auteurs ont été SEABRA qui s'occupe des Chiroptères, THOMAS, WROUGHTON, DE WINTON, HINTON, BLAINE, STATHAM, FRADE, qui étudient des collections des sujets spéciaux particuliers, en général peu étendues, on se placent au point de vue du chasseur. Aucun ouvrage d'ensemble, aucune faune générale n'a été entreprise depuis l'essai de BOCAGE.

Or, les difficultés d'identification des Mammifères sont grandes; leurs espèces ont été considérablement multipliées depuis une trentaine d'années, passant pour le total des formes actuelles de 3500 environ, à 13.000; des modifications incessantes de nomenclature ont contribué, dans une recherche souvent vaine de la priorité, à compliquer la besogne, si bien que certaines espèces ont changé trois ou quatre fois de genres depuis le *Catalogus Mammalium*: de TROUESSART (ex: *Herpestes*, devenu *Mungos, Ichneumon, Atilax, Myonax* ou *Ichneumia*); les anciens grands genres ont été divisés en nombreux sous-genres, puis ceux-ci élevés au rang supérieur et engendrant à leur tour de nouveaux genres et sous--genres (ex: *Mus*); les monographies de genres et familles sont pour certains groupes, et surtout les plus difficiles, ou périmées, ou inexistantes; l'analyse des caractères a été poussée à un tel degré qu'on a distingué dans les anciennes espèces des quantités de formes;

des espèces nouvelles, basées uniquement sur les mensurations des crânes, bases à notre avis bien chancelantes, ont fait leur apparition; en sens contraire INGOLDBY réunit en une seule les 45 formes de l'écureuil *Heliosciurus*, envisageant ses nombreuses espèces et variétés comme des phases climatiques d'un seul type; ajoutons à ces difficultés d'ordre scientifique celles qui résultent d'une extrême dispersion des mémoires originaux qui ne sont souvent que de simples notes éparpillées, la nécessité absolue de posséder le *Zoological Record* qui donne les références indispensables et une vaste bibliothèque scientifique - et l'on comprendra qu'il est vain de vouloir faire de la Mammologie précise sur le terrain et de chercher, pour un profane, un colon ou un missionnaire, à identifier là-bas les espèces recueillies.

C'est pourquoi, à la demande de quelques uns de nos amis d'Angola, nous nous sommes décidés à donner à ce mémoire une forme plus pratique et plus étendue qu'une simple liste additionnelle de noms avec localités. Nous avons cherché à en faire, non pas une "Faune d'Angola" ce qui serait prématuré et d'une trop grande envergure, mais le "Prodrome d'une faune". Cela nous permettra de développer inégalement les parties de ce mémoire, de nos attarder plus longuement aux espèces sujettes à discussion, ou d'homologation difficile (en l'espèce surtout les petits Marnmifères) et de passer plus rapidement ou d'énumérer simplement les espèces d'identification facile. Les collections importantes, recueillies dans nos deux voyages restent à la base de notre étude, qui sera donc une contribution à la Mammologie de ce pays; mais nous avons traité les espèces découvertes par nos devanciers de façon a donner un aperçu aussi complet que possible de la faune d'Angola. Nous ne nous dissimulons nullement les imperfections de ce travail; elles proviennent de l'impossibilité dans laquelle nous sommes d'examiner les types originaux et les collections des autres musées puis des oublis et des erreurs presque inévitables dans une oeuvre si compliquée et de si vaste envergure. Mais nous pensons néaumoins que l'essai devait être tenté et que notre oeuvre sera utile à beaucoup, qu'elle contribuera dans la population cultivée d'Angola à la connaissance de l'histoire naturelle, qu'elle encouragera l'étude zoologique du pays.

Pour chaque espèce nous donnons dans la règle une description originale ou tirée d'une monographie classique (DOBSON, pour les Chiroptères, ou SCLATER, *Fauna of South Africa*, etc.], sa distribution connue en Angola, le nom indigène en une ou plusieurs langues, des détails sur son habitat ou ses moeurs. Pour faciliter les recherches nous avons disposé des tableaux dichotomiques d'un usage aussi facile que possible; les synonymes des auteurs qui ont écrit sur l'Angola ont seuls été cités de manière à pouvoir se rapporter facilement à leurs oeuvres. Enfin nous avons donné souvent des mensurations crâniennes qui contribuent à la connaissance scientifique de l'espèce. Toutefois, le souci de ne pas allonger trop ce mémoire nous a fait supprimer les détails de moeurs donnés par les grands traités tels que celui de BREHM.

Monard, A. (1939). Résultats de la mission scientifique du Dr. Monard en Guinée Portugaise 1937-38. III. Chiroptères.

Nous connaissons très peu de choses concernant les Chiroptères de la Guinée portugaise, et l'étude que nous présentons ici est certainement la plus complète qui ait été écrite, Et cependant, elle ne contient qu'un tableau bien imparfait de la riche faune de Chauves-souris que possède cette colonie. Chaque soir, en saison sèche comme en hivernage, on voit évoluer ces animaux en nombre; leur variété n'est pas moins grande que leur fréquence. Mais on sait combien la chasse de ces animaux est difficile; si on n'a pas la chance de découvrir leurs retraites, leur capture est presque impossible. C'est en s'adressant aux Noirs qu'on a plus de facilité à s'en procurer,

Dans une liste de Vertébrés de la Guinée portugaise, BARBOZA DU BOCAGE (Jorn. Sc. Math. phys. nat. 2, 1890, p. 179) ne cite que deux espèces de Chiroptères: *Epomophorus gambianus* et *Nycteris hispida*. En outre, il avait cru devoir faire d'un exernplaire de la première espèce le type d'une forme nouvelle, *Epomophorus guineensis* qui n'a pas été conservé par les auteurs modernes. On trouve aussi, par ci par là, la mention de la Guinée portugaise dans les ouvrages généraux consacrés à ces animaux. C'est en cela que se bornent les connaissances actuelles sur la faune des Chiroptères de ce pays.

Montfort, A. (1992). Première liste commentée des mammifères du Rwanda.

A preliminary checklist is presented for the marnrnals of Rwanda based on the literature and our own observations. For several important groups as such bats in Nyungwe or small carnivores, data are certainly incornplete and details of large collections of rodents obtained by W.N. Verheyen and colleagues have yet to be published. Under such circumstances, this paper can not present more than a first provisional list of the rnammals of Rwanda.

Cet article fait l'état des connaissances sur les espèces et le statut des rnammifères sur l'ensemble du Rwanda à partir de la litérature existante et des observauons de l'auteur. Certains groupes n'ont pas encore fait l'object d'études importantes (petits carnivores) ou n'ont été que peu étudiés dans certains habitats (chauves-souris à Nyungwe par ex.) et. les détails des irnportantes collections de rongeurs réalisées par W. Verheyen et ses collègues ne sont pas encore publiés. Compte tenu de ces restricuons, la liste qui suit doit être considérée comme une première tentative d'inventorier les marnrnifères du Rwanda.

Morales, J. C., S. W. Ballinger, J. W. Bickham, I. F. Greenbaum and D. A. Schlitter (1991). Genetic relationships among eight species of *Eptesicus* and *Pipistrellus* (Chiroptera: Vespertilionidae).

Genetic relationships among eight species of *Eptesicus* and *Pipistrellus* were analyzed by use of horizontal starch-gel electrophoresis. It has been suggested that a 2n = 50 and FN = 48 karyotype defines the genus *Eptesicus*, and that related forms of differing karyotype should be placed in the genus *Pipistrellus*. Three species of *Eptesicus* with 2n = 50 and FN = 48, three species with lower diploid numbers, and two species of *Pipistrellus* were assayed in this study. The results show that the species of *Eptesicus* with 2n = 50 and FN = 48 form a homogeneous group with high similarity values, despite the included taxa coming from two continents. Species with lower diploid number show a lesser degree of similarity.

Morales Agacino, E. (1933). Datos y observaciones sobre algunos mamiferos marroquies.

Durante una excursión entomológica organizada por esta SOCIEDAD bajo los auspicios de la Dirección General de Marruecos y Colonias, en la que acompañé al Sr. Martínez de la Escalera (D. Fernando), en el mes de agosto de 1932, por la zona de Protectorado español en Marruecos, he podido tomar algunos datos sobre unas cuantas especies de mamíferos, muy pocas y muy vulgares, pero que el ser principalmente casi todas de la región del Rif - región tan poco conocida zoológicamente - hace me incline a redactar esta pequeña nota, pues tal vez pueda contribuir al mejor conocimiento de la fauna mastozoológica marroquí.

Morales Agacino, E. (1943). Algunos datos y observaciones sobre mamiferos marroquies.

En el transcurso de la- pasada excursión entomológica que en compañía de los buenos amigos los señores Dr. Werner Harten y D. Anselmo Pardo realizamos por distintos puntos del Marruecos español, recogimos una serie de datos de tipo mastozoológico que creemos muy conveniente publicar, ya que las novedades que encierran son una aportación más que añadimos a nuestros conocimientos sobre la fauna de este territorio.

Morel, P.-C. and J. Mouchet (1965). Les tiques du Cameroun (Ixodidae et Argasidae) (2e note).

Ce texte est un complément à notre note de 1958. Il comporte essentiellement une étude du genre *Ixodes*, qui n'avait pas été envisagée dans le travail précédent, car sa systématique était alors en cours de révision. A l'heure actuelle l'abondant matériel dont nous disposons (surtout du Cameroun et de

Côte-d'Ivoire) permet d'effectuer les diagnoses de tous les stades. Il a donc été possible d'étudier les collections du Cameroun et d'en obtenir d'importants renseignements quant à la distribution de ce genre dans les diverses zones de végétation.

Nous apportons également des renseignements complémentaires sur la systématique, la terminologie et la répartition, notamment dans le nord du pays, des espèces précédemment citées (une partie de ceux-ci avait d'ailleurs été publiée dans un travail sur les tiques des animaux domestiques de la région du lac Tchad)

Morrison-Scott, T. C. S. (1939). Some Arabian mammals collected by Mr. H.StJ.B. Philby, C.I.E.

Arabian mammals were first discussed systematically by Cretzschmar (1826), Lichtenstein (1827-34) and Hemprich & Ehrenberg (1828-33). Since then little was written till Thomas (1894B) wrote on the mammals of Oman. This was quickly followed by discussions of the Aden mammals by Yerbury & Thomas (1895) and Thomas (1900). Since that time there have been many papers (see Appendix I) on individual forms, notably by Thomas, but only three papers dealing with any considerable collections: Cheesman & Hinton (1924) on mammals collected by Cheesman between Riyadh and the east coast, Dollman (in B. Thomas 1932) on collections by Bertram Thomas in the south-east and Pocock (1935A) on Thomas's specimens once more and on a collection from various parts of Arabia presented to this museum by Philby.

Now Philby has sent home another fine collection, the results of his recent journey to the Hub al Khali (Philby 1938), and it is with these specimens that this paper is principally concerned though the earlier material has been reexamined.

Apart from the fact that Arabia is still relatively unknown zoologically, natural history collections from that country are of the greatest interest from the zoogeographical point of view. Arabia lies between the Ethiopian, Palaearctic and Indian regions and the extent to which each region has contributed to the fauna has been a matter of speculation ever since 1866 when Murray wrote on the geographical distribution of mammals.

The Red Sea is almost certainly a rift valley and the land connexion between Aden and Somaliland does not appear to have been broken until late in the Tertiary period. Pilgrim (1919. PI. I: 1925A, p. 73; 1925B, p. 202) shows that the land bridge across the Straits of Hormuz between Oman and Persia lasted at all events until the end of the Pliocene and probably till the late Pleistocene.

In view of the above it might be expected that south-eastern Arabia should show faunistic affinities with Africa and that Oman should have Persian and Indian relationships, and this is in fact the case. The Arabian Tahr (*Hemitragus jayakari* Thos.), a goat-like animal living in the mountains of Oman, is an interesting case. It is a close relative of the Tahr which is found on the southern slopes of the Himalaya and the one in the hill ranges of southern India. It is essentially a mountain animal and there do not appear to have been mountains along the land route which the Tahr would have had to have followed if there had been no bridge across the Straits of Hormuz. Oman has not been explored from the mammal point of view since Dr. Jayakar's time, and it would be interesting to find out if there are any Oriental forms there; that is, truly Oriental as opposed to Indian.

Some elements of the fauna are common to India and Africa. Philby's latest collection includes some gerbils of the genus *Tatera* (a new record for Arabia) which ranges as far as Ceylon on the one hand and S. Africa on the other, but the connexion between these two extremes may be independent of land bridges across the south end of the Red Sea and the Persian Gulf, as the genus has been recorded from the top end of the Persian Gulf.

The largest of the Arabian foxes (*Vulpes vulpes* L.) is common to N. Africa, Arabia and N.W. India, but it is not to be regarded as a true Ethiopian or Indian form, but as a Palaearctic intruder.

Lastly there are some Arabian mammals such as the hyrax (*Procavia*) which are found elsewhere only in Africa, Palestine and Syria.

The Arabian fauna, therefore, is of mixed origin and offers many interesting problems. More specimens are needed to solve these, apart from the entirely philosophical object of finding out what mammals live in Arabia, and any specimens sent to the British Museum will be gratefully acknowledged.

Throughout this paper the use of parentheses for the names of authors of species which have been moved to another genus has been discontinued for reasons given by Dr. Osgood (1939). *Science*, **89**: 9. Conventions used with regard to certain measurements have been explained in Appendix II and a list of the co-ordinates of those Arabian Iocalities which are hard to find in maps has been giyen in Appendix Ill.

I should like to take this opportunity of thanking my colleagues in the Mammal Room for their various suggestions and help, especially Mr. R. I. Pocock. F.R.S.

Müller, J. (1858). Eine neue Fledermausart aus Nordafrika.

Wir erhielten aus einer Partie Fledermäuse, die, der Präparateur des kais. Hofnaturalienkabinets, der glückliche und eben so unermüdliche, als umsichtige Sammler Hr. Zelebor aus Aegypten mitgebracht und dem Prof. Dr. Kolenati ebenfalls mitgetheilt hatte, eine sehr kleine Fledermaus, welche bei sorgfältiger Untersuchung und Vergleichung mit *Vesperugo macuanus* Peters, mit *V. Rüppelii* Fischer, mit *V. nanus* Peters, mit *V. platycephalus* Smuts, mit *V. minutus* Temmink, mit *V. Kuhlii* Natterer, mit *V. ursula* Wagner - mit keiner der angeführten Arten die Charaktere gemein halle, von jeder viel mehr in mehreren wesentlichen Merkmalen differirte, wie wir diess weiter unten, im Anhange darthun werden. Wir konnten daher um so beruhigter zur Aufstellung dieser ausgezeichneten Art schreiten, als wir bei dem kritischen Chiropterologen Prof. BIasius (in der Fauna der Wirbelthiere Deutschlands I. S. 63) bei *Vesperugo Kuhlii* Natterer die schon entschiedenen Synonyme: *V. vispistrellus* Bonaparte, *Alcythoe* Bonaparte, *marginatus* Cretschmar in Rüppel, und *albolimbatus* Küster fanden, als wir ferner bei dem eben so scharfsinnigen als im Geiste der vorschreitenden Neuzeit die Chiroptern bearbeitenden Naturforscher, Prof. Kolenati, alle Tafeln zu dessen grossartigem neuen Werke über Chiropterologie direct nach der Natur gezeichnet haben. Wir fanden in einem Schreiben des Herrn Zelebor an Dr. Kolenati, vom 6. October 1856 datirt, die Bemerkung, ob nicht dieser Art der Name "Kolenatia" gegeben werden dürfte, und in der Antwort des Dr. Kolenati an Hrn. Zelebor vom 15. October 1856 die widerstrebende Bemerknng, dass diese Art erst die .vergleiche mit den obengenanuten Afrikanischen bestehen müsste. Wir nehmen gegenwärtig um so weniger Anstand, sie im Geiste des Finders nach unserem Chiropterologen, der uns schon, wie allbekannt, so viele schlagend neue Beiträge zur Naturgeschichte der Handflügler geliefert hatte und noch immer siefert, zu benennen, und nach dem Muster seiner nunmehr unübertrefflichen Diagnosen zu beschreiben.

Mutere, F. A. (1967). The breeding biology of equatorial vertebrates; reproduction in the fruit bat *E. helvum*, at latitude 0º20'N.

The African fruit bat, *Eidolon helvum* Kerr, is known to occur only south of the Sahara where its distribution is localized. At 0°20' N, this bat exhibits seasonal and synchronized breeding the rhythm of which appears to correspond with the two rainfall peaks typical of Uganda. Quite unexpectedly and unprecedently, this bat exhibits delayed implantation lasting about three months. Evidence for this phenomenon comes from the histological examination of the adult female genital tracts which indicate that mating occurs only in April-June, but implanted embryos are only in evidence in October-November. The male sexual cycle corresponds to such a rhythm and shows a maximum testicular weight at the mating time. Births take place in February-March thus giving a gestation period of about four months. Only one young is born at a time and births occur just before the onset of the higher of the two rainfall peaks, presumably creating favourable conditions for the maximum survival of the young bats when weaned.

Mutere, F. A. (1970). Bat studies in Uganda.

The author reviews the results of recent studies of the hahitat, breeding and feeding habits, viruses, and flight behaviour of the rich bat fauna of Uganda. Some bats breed seasonally (either once or twice a year) whereas others breed aseasonally throughout the year. Fruit bats fulfill the role of both pollination and seed dispersal. Some of the bats of Uganda act as hosts to viruses, and, as such, are important from the aspect of public health studies.

Mutere, F. A. (1973a). A comparative study of reproduction in the populations of the insectivorous bats, *Otomops martiensseni*, at latitudes 1° 5' S and 2° 30' S.

The insectivorous bat under review, *Otomops martiensseni* (Matschie) is essentially an African bat with a distribution from down south to as far north as Kenya. It is cave-dwelling and does not appear to occur in West Africa. In this study, reproduction of two populations, one at Suswa in the Rift Valley, latitude 1° 5' S and the other at Ithundu in the Chyulu Hills, latitude 2° 30' S was investigated and compared. Regular monthly samples from both populations were collected commencing in March 1970 and running on to February 1972. The bats were processed in the laboratory for pregnancies, weights of testes and foetuses and other measurements and observations. Seasonality in the occurrence of pregnancies was observed in both populations, that is, from October to January only. Also the adult males realized a peak in their mean testicular weight in August, a short period just before the onset of pregnancies thus indicating the most likely time of mating. The female sexual cycle at Ithundu appears to be geared to the rainfall regime as measured at Makindu Meteorological Station about 10 krn away. The male sexual cycle, on the other hand, shows a peak in the very dry months suggesting that such a dry spell may be more important than the rain. Molossid bats exhibit variation in their breeding cycles.

Mutere, F. A. (1973b). Reproduction in two species of equatorial free-tailed bats (Molossidae).

(1) The insectivorous bat *T. pumila* living at Entebbe latitude 0°6' N breeds throughout the year. However, it exhibits peaks in its breeding cycle which appear to coincide with the two rainfall peaks which occur at Entebbe and in Uganda generally; a low one in October-November and a higher one in April-May.

(2) The other insectivorous bat *T. condylura* living at Bukalasa latitude 0°43' N exhibits a bimodal breeding rhythm also closely correlated with the rainfall pattern at Bukalasa which is similar to that at Entebbe.

(3) Rain may therefore be an important proximate factor in the breeding of these bats while food (insects) may play an important ultimate role.

(4) One young per bat is the rule and implantation which always takes place in the right horn of the bicornuate uterus of both species is unilateral.

(5) The gestation period in *T. condylura* is about 2 months and in *T. pumila*, it may be shorter than this.

(6) Both species develop and mature rapidly and as they are often found living together, the difference in their breeding patterns is advantageous in that it helps to reduce competition between them.

Myers, P. (1978). Sexual dimorphism in size of vespertilionid bats.

Sexual dimorphism in body size of mammals is usually explained in terms of competition among members of one sex for members of the other or as a means of reducing intraspecific competition for resources such as food. Sexual dimorphism in vespertilionid bats, often characterized by females exceeding males in body size, does not seem to fit either explanation. A third hypothesis that female body size is influenced by the need to fly with and nourish large fetuses (and occasionally young), is probably unique to bats. If true, it should follow that the greatest degree of sexual dimorphism would occur in those species the greatest fetal or neonatal weight. Examination or data concerning size (skull

and lengths) and reproduction for vespertilionid bats reveals that the total weight and modal number of young born per pregnancy per species are strongly, positively correlated with the degree of sexual dimorphism in wing size. Further, covariance analysis shows that the wings of females of several species of vespertilionids are larger than those of males even after statistical adjustment of the data to make the body size of each sex the same. These observations suggest that sexual dimorphism in size of vespertilionid bats is influenced by the demands of large fetuses.

Nadachowski, A., J. Smielowski, B. Rzebik-Kowalska and A. Daoud (1990). Mammals from the Near East in Polish collections.

Mammals from Turkey, Syria, Lebanon, Israel, Cyprus and Iraq stored in Polish collections are described. Additional records of 47 taxa of mammals are given from the Near East.

Nader, I. A. (1975). On the bats (Chiroptera) of the kingdom of Saudi Arabia.

As part of a study of the mammalian fauna of the kingdom of Saudi Arabia, a number of interesting bat specimens have been collected. The Egyptian fruit-eating bat, *Rousettus aegyptiacus*, and the Greater mouse-tailed bat, *Rhinopoma microphyllum*, are recorded for the first time from the country. Distributional notes and comments on the biology of these two and on five other species of bats from Saudi Arabia are mentioned. Previous distributional records of the other eight species known from the country are summarized. A map showing collecting localities is included.

Nader, I. A. (1982). New distributional records of bats from the kingdom of Saudi Arabia (Mammalia: Chiroptera).

Hipposideros caffer (Sundevall, 1846) and *Miniopterus schreibersi* (Kuhl, 1819) are recorded for the first time from Saudi Arabia. Additional information and second records in addition to measurements are reported form six other bats: *Rhinopoma m. microphyllum, Taphozous n. nudiventris, Rhinolophus clivosus, Rhinolophus hipposideros minimus, Tadarida midas* and *Eptesicus nasutus*. Distribution maps of *Rhinolophus clivosus* and *Eptesicus nasutus* are included.

Nader, I. A. (1985). First record of *Eidolon helvum sabaeum* (K. Andersen, 1907) for the kingdom of Saudi Arabia (Chiroptera: Pteropodidae).

The chiropteran fauna of the Arabian peninsula was reviewed by Harrison (1964, 1972) who recorded thirteen species of bats from the kingdom of Saudi Arabia. Additional information and new records of bats for the kingdom were given by Nader (1975, 1982), Nader and Kock (1980, 1983 a and b) and Jennings (1979) bringing the number of bat species recorded from the kingdom to nineteen. The present record brings the total of Saudi Arabian bats to twenty species. Further collecting most likely will add new species to the chiropteran fauna of the kingdom.

Nader, I. A. and D. Kock (1980). First record of *Tadarida nigeriae* (Thomas 1913) from the Arabian peninsula (Mammalia: Chiroptera: Molossidae).

Tadarida nigeriae (Thomas 1913) is recorded for the first time from the Arabian peninsula; measurements, zoogeographical notes and a key to the Arabian molossid bats are given.

Nader, I. A. and D. Kock (1983a). A new slit-faced bat from central Saudi Arabia (Mammalia: Chiroptera: Nycteridae).

Nycteris thebaica najdiya n. subsp. is an extremely pale coloured population in central Saudi Ambia, extending species range by 920 km from nearest known localities. Zoogeographical relations are discussed.

Nader, I. A. and D. Kock (1983b). *Rhinopoma microphyllum asirensis* n. subsp. from southwestern Saudi Arabia (Mammalia: Chiroptera: Rhinopomatidae).

Rhinopoma microphyllum asirensis n. subsp. is described from the Asir region, SW-Saudi Arabia. It differs from neighbouring conspecific populations by smaller size and in skull characters.

Nader, I. A. and D. Kock (1987). First record of *Miniopterus schreibersi* (Kuhl 1819) (Mammalia: Chiroptera) from North Yemen with zoogeographical relationship evidenced by wing mites (Acarina: Spinturnicidae).

Miniopterus schreibersi is recorded for rhe first time from North Yemen. Because of slightly smaller measurements and geographical proximity we identifiy the SW Arabian population as *M. s. arenarius*, described from E-Africa. - For the first time Spinturnicidae are recorded from Saudi Arabia: parasitic wing mites from *M. schreibersi* are identified as *Spinturnix semilunaris*. This is an Aethiopian faunal element, replaced by *S. psi* on *M. s. pallidus* in the Near East. This finding supports our classification of the SW-Arabian host population with the E-African subspecies, *M. s. arenarius*.

Nader, I. A. and D. Kock (1990). *Eptesicus* (*Eptesicus*) *bottae* (Peters, 1869) in Saudi Arabia with notes on its subspecies and distribution.

Eptesicus bottae is een additional species to the bat fauna of Saudi Araibai and data for the nominate subspecies are given for the first time since its original description. Additional measurements and notes are given for recognition of the known subspecies *innesi, hingstoni, anatolicus* (new material) *taftanimontis*, and *ognevi* (new materialà; lists of synonyms are attempted for these subspecies and their distribution is mapped. Data on reproductive activity are included. - *E. hingstoni* collected at Shanna/SE-Arabia actually represents *E. nasutus*; *E. nilssoni* recorded for Iraq had been re-identified as *E. bottae*.

Nel, J. A. J. and J. J. L. Pretorius (1971). Note on the smaller mammals of the Mountain Zebra National Park.

Collecting in April 1971 yielded 74 specimens of 16 species. Of these, seven species (*Elephantulus rupestris, Lepus saxatilis, Pronolagus crassicaudatus, Graphiurus murinus, Aethomys namaquensis, Desmodillus auricularis* and *Gerbillurus paeba*) are new records for the park. Distribution in habitat-types for each species known to occur are described.

Niort, P. L. (1970). Contribution à la connaissance des chiroptères du Burundi (Afrique Centrale).

La présente communication concerne les Chiroptères du Burundi, Ordre de Mammifères qui n'a jamais été étudié précédemment sur le territoire de ce jeune Etat. Cet exposé a pour but de présenter les études entreprises par le Laboratoire de Zoologie e Biologie Animale de la Faculté de Sciences de l'Université de Bujumbura, en mettant en évidence l'intérêt actuel de ces études, et faire connaître les

résultats obtenus durant la première phase de ces recherches. Dans le domaine de la faunistique, 18 espèces de Chauves-souris - dont 15 non encore signalisées dans cette partie de l'Afrique - ont été observées et enregistrées. D'autre part, 35 stations où furent faites des observations, sont notées avec précision et localisées sur la carte. Ces résultats ne doivent être considérés que comme le début d'une série de travaux qui porteront sur la physiologie, le comportement et l'écologie de ces animaux.

The present paper deals with the Bats of Burundi (Central Africa), a country whose Mammals have been very little studied up to this day. It is first showing the research which has begon in the Biological Laboratory of the University of Bujumbura, and the ecological and social interest of this work.

Then we give a list of the records, with some remarks about the circumstances of the captures and the behaviour of the animals concerned. We presently know in Burundi at least seven families, fifteen genus or subgenus and eighteen species of Chiroptera, a great number of them have been observed and nearly 250 specimens are kept in our collections. Some mistakes about Burundi which had been written in precedent works have here been corrected.

But, in spite of great difficulties following the lack of laboratory material and scientific workers, this research must be continued during the next years, we will certainly identify many other species. Inquiries of physiology, ecology and behaviour which have been undertaken about these Bats will be continued;

Noack, Th. (1887). Beiträge zur Kenntnis der Säugethier-Fauna von Ost- und Central-Afrika. Nach Sammlungen und Aufzeichnungen des verstorbenen Dr. Richard Böhm.

Durch die Güte des Herrn Dr., ANTON REICHENOW in Berlin erhielt ich zur Bearbeitung eine Kollektion von Säugethierbälgen und Schädeln, welche von dem leider schon im Anfange einer voraussichtlich glänzenden zoologischen Laufbahn zu Katapäna in Urua (Central-Afrika) verstorbenen Dr. RICHARD BÖHM auf der Reise von Sansibar bis über den Tanganika-See hinaus gesammelt und von Herrn PAUL REICHARD, dem einzigen Ueberlebenden der Expedition, nach Berlin gebracht wurden. Die aus zwei Antilopen, 1 Carnivoren, 2 Insectivoren, 11 Nagern, 19 Chiropteren und 3 Affen bestehende Kollektion, zu welcher. noch 2 schon von Herrn Dr. REICHENOW im "Zoologischen Anzeiger" beschriebene Thiere, *Sciurus böhmi* und *Rhynhocyon reichardi*, gehören, ist freilich nur ein geringer Rest der umfangreichen, leider zu Grunde gegangenen Sammlungen BÖHM's; aber er gewinnt erheblich durch 2 erhaltene, mir gleichfalls durch Herrn Dr. REICHENOW zur Verfügung gestellte Aufzeichnungen desselben Reisenden, ein zoologisches Notizbuch und eine für den unterdessen auch verstorbenen Professor Dr. PETERS in Berlin bestimmte systematische Arbeit über die Säugethier-Fauna von Ost- und Central-Afrika, sowie durch eine reichhaltige Sammlung vortrefflicher Farbenskizzen, deren Einsicht und Benutzung mir Frau Geheimrath BÖHM in Berlin gütigst gestattete. Durch Verarbeituug und Kombinirung dieses Materials lässt sich eine genügende Uebersicht über die Säugethier-Fauna in den von den Herren REICHARD, BÖHM und KAISER durchzogenen Gebieten gewinnen.

Die Bestimmung der Säugethiere, unter welchen sich manche neue Arten befinden, wurde mir hauptsächlich durch die Güte des Herrn Professor Dr. PAGENSTECHER in Hamburg ermöglicht, welcher mir in Iiberalster Weise die Benutzung. Der Hamburger Sammlung gestattete und dem ich für seine sehr freundliche Unterstützing in jeder Beziehung hierdurch meinen herzlichsten Dank ausspreche.

Indem ich im Folgenden eine Uebersich über die von Dr. BÖHM in Ost- und Central-Afrika gefudenen Säugethiere gebe, lege ich seine eigene Arbeit zu Grunde, welche sich allerdings nur auf das Gebiet Zwischen Sansibar und dem Tanganika-See bezieht, dieselbe durch seine Notizen über das Gebiet im Westen des Tanganika und durch meine bearbeitung der mir übergebenen Thiere vervollständigend. Ich werde dabei BÖHM's eigene Worte jedesmal durch Anführungszeichen hervorheben. Wenn die Arbeit eine Ungleichmässigkeit zeigt, indem manche Partien rein biologisch, andere rein anatomisch und physiologisch sind, und wenn viele Arten nach kurzen Notizen BÖHM's von mir nicht bestimmt werden konnten, ohne dass ich in werthlose Konjekturen verfallen wäre, so liegt das in der Art der Entstehung.

Das faunistische Gebiet, welches von BÖHM erforscht wurde, zieht sich von Sansibar dem 6.° S. B. folgend nach Westen durch den Besits der deutsch-ostatrikanischen Gesellschaft bis Usagara, geht dann durch Ugogo nach Ugunda und Kawende bis an den Tanganika-See und schweift nördlich von Ugogo in Unyamnesi bis zum 4.° S. B. nach Norden. Jenseit des Tanganika-Sees erstreckt es sich nach Südwesten durch Marungu, woher die meisten von mir untersuchten Thiere stammen, über den Lualaba nach Urna, bis zu den Kongo-quellflüssen, dem Lufire und Likulve, etwa bis zum 10.° 0 S. B. reichend. Es bildet also in Unyamuesi ungefähr einen rechten Winkol und reicht von Ost-Afrika bis in das zoologisch noch fast jungfräuliche Gebiet des oberen Kongo. (Vergl. Die Karte von Central-Ostafrika von Dr. ENGELARDT u, J. v. WENSIERSKY Berl. 1886 und für Marungu und die westlich vom Tanganika gelegenen Gegenden die Kartenskizze von REICHARD in: Mittheil. Der afrikanischen Gesellschaft, Bd. VI, Taf. 10, 1886.) Das Hochland um den fast 90 deutsche Meilen langen, 814 m hoch gelegenen Tanganika bildet die grosse Wasserscheide zwischen den 3 Seiten Afrikas, zwischen Nil, Kongo und Sambesi. Daraus erklärt sich, dass die Säugethiere, deren Verbreitung besonders durch die Flüsse (Nager, Antilopen, Dickhäuter) bedingt wird, hier Formen aufweisen, welche ebensowhl der durch TEMMINCK von Guinea wie der durch HEUGLIN aus den Nilländern und durch PETERS aus Mosambique bekannt gewordenen Fauna verwandt sind. Bedingt wird diese Fauna ferner durch die Gestaltung des Landes: es ist ein wasserreiches, mehrere Tausend Fuss hohes, von höheren Gebirgen durchzogenes Plateau, bedeckt in der Höhe von lichtem Buschwald, sowie an den Flüssen und Gewässern von dichtem Urwald, in der Ebene von hohen Grassavannen mit vereinzelten Bäumen (östlich vom Tanganika boga, westlich buga genannt), dazwischen hier und da Kulturen der Eingeborenen.

Unyarmuesi, die Wasserscheide zwischen Tanganika und Ukerewe, ist, wie Dr. BÖHM in siener zu Gonda (Norden von Ugunda, südlich von Unyamuesi und Ubyaniembe) verfassten Uebersicht bemerkt, abgesehen von Hufthieren, ausserordentlich arm an Säugethieren, woran wohl die Dürftigkeit und Einförmigkeit des "pori", des liecten Waldes, der das Land, Ebene wie Gebirge, fast durchaus bedeckt, und dem es an Dickichten, Wiesengründen selbst üppig belaubten Baumgipfeln ganz gehricht, die Hauptschuld tragen mag. Besonders auffallen muss die Artenarmuth an Sciuriden, Herpestiden und Affen. Aermer noch erscheint die Säugethier-Fauna, weil eine grosse Zahl ihrer Glieder wegen ihrer nächtlichen Lebensweise nur äusserst selten zu sehen oder aber wirklich selten ist. Dagegen ergiebt sich aus BÖHM's Notizen, dass die Säugethier-Fauna um den Tanganika-See, besonders auch im Westen desselben nach den Kongoquellflüssen hin, ausserordentlich an Artenreichthum zunimmt. Auf dem Wege von Sansibar bis Ugogo und Ugunda ist die Fauna schon erheblich durch den Einfluss des Menschen gemindert worden, während sich um den Tanganika und jenseit mehr der Urzustand der Dinge erhalten hat.

Noack, Th. (1889). Beiträge zur Kenntnis der Säugethierfauna von Süd- und Südwest-Afrika.

Von zwei Afrikareisenden, Herrn Dr. HANS SCHINZ in Riesbach bei Zürich und Herrn P. HESSE, jetzt in Venedig, resp, dem Senckenbergischen Museum in Frankfurt a, M., in dessen Besitz die Sammlungen des letzteren Herrn übergegangen sind, wurde mir die Bestimmung und Bearbeitung einer Anzahl von Säugethieren übertragen. Die von Herrn Dr. SCHINZ gesammelten Specimina stammen aus Damara- und Ovamboland und der Kalahari-Wüste, welche Gebiete derselbe auf einer 2 1/2 jährigen, besonders botanischen Studien gewidmeten Forschungsreise bis zum Kunene und Ngamisee durchzog (vergl. Seinen Bericht in: Verhandl. Gesellsch. Erdkunde, Berlin, Bd.14, 7, p. 322-334). Herr HESSE erwarb seine umfangreichere Sammlung im Gebiete des unteren Kongo, wo derselbe mehrere Jahre Beamter der Nieuwe Africaansche Vernootschap war. Sein Bezirk deckt sich im Grossen mit dem von der deutschen Loango-Expedition 1873-76 erforschten Gebiete, reicht aber über Boma nach Stanleypool aufwärts, und seine Funde ergänzen besonders in Bezug auf die Chiroptera wesentlich die von Dr. PECHUEL-LOESCHE: (Deutsche Loango-Expedition, Bd. 3, Cap. 4) gegebene Uebersicht. Die mir übergebenen Objecte bestanden theils in Körpertheilen, Schädeln und vollständigen oder unvollständigen Bälgen, theils und besonders zahlreich von Herrn HESSE gesammelt, in vollständigen Spiritus-Exemplaren.

Die beiden Sammlungen gehören wesentlich der ostafrikanischen Subregion von SCLATER-WALLACE an, und zwar die des Herrn HESSE der nordwestlichen Grenze desselben, welche nach WALLACE gerade mit dem unteren Laufe des Kongo abschneidet, während die des Herrn Dr. SCHINZ in den Norden der südafrikanischen Subregion eingreift, deren Grenze von der Walfischbai in östlicher

Richtung durch die Kalahari- Wüste bis zum Limpopo zieht und von da landeinwärts von der Ostküste bis nach Mosambique verläuft (vergl, die Karte bei WALLACE, Die geographische Verbreitung der Thiere , deutsch von A. B. MEYER, p. 294). Da das untere Kongo-Gebiet nicht mehr wesentlich in das der westafrikanischen Hyläa hinüberreicht, anderseits Ovamboland und der Ngami-See , bis wohin Dr. SCHINZ vorgedrungen ist, noch dem Süden der ostafrikanischen Sub egion angehören, so wird es sich empfehlen, die Besprechung der beiden Collectionen zu vereinigen. Für die specielle Characterisirung des von Herrn HESSE zoologisch erforschten Gebietes verweise ich auf die classischen Schilderungen von PECHUEL-LOESCHE, besonders im 3. und 4. Cap. des 3. Bandes der deutschen Loango-Expedition , sowie auf die grosse Uebersichtskarte von LANGE, Bd, 1 und die Karte des Kuïlu-Gebietes von PECHUEL-LOESCHE, Bd. 3. Der letztere bestätigt ebenfalls Bd, 3, p. 124 die von SCLATER-WALLACE bestimmte Nordgrenze durch die Bemerkung, dass die letzten grossen Wälder der westafrikanischen Subregion in dem breiten Mündungsgebiete des Kongo gedeihen und südlich davon die Gegend den Oharacter der Savanne und Campine trägt, in welcher der Busch vorherrscht, vereinzelt zum Buschwalde, an den Flüssen zu dem von Dr. SCHWEINFURTH so malerisch geschilderten Galeriewalde, ja zum wirklichen Hochwalde sich potenzirt. Dem widerspricht nicht, dass nach den Berichten von FRANÇOIS, KUND und TAPPENBECK das zoologisch noch der Erforschung harrende Gebiet der grossen südlichen Kongozutlüsse, des Kassai und Sankuru, vielfach wieder den Character der Hyläa trägt. In dem von Herrn HESSE besonders erforschten Küstenstrich ist noch der Mangrove-Sumpf, welcher manchen Säugethieren, selbst Atlen zum gelegentlichen Aufenthalte dient, eine besonders characteristiscbe Erscheinung. Das von Dr. SCHLNZ durchzogene Gebiet, in welchem die die südafrikanische Subregion so gut characterisirenden Proteaceen gar nicht mehr vorkommen, während die Euphorbien sich auch in der ganzen ostafrikanischen Region finden, wurde vor ein paar Jahren ebenfalls von Dr. PECHUEL-LOESCHE im Westen der Walfischbai besucht, und seine 1885 auf dem 5. Geographentage in Harnburg ausgestellten Aquarelle . . .

Norberg, U. M. (1972). Functional osteology and myology of the wing of the dog-faced bat *Rousettus aegyptiacus* (É. Geoffroy) (Mammalia Chiroptera).

The muscles moving, directly or indirectly, the anterior extremity, the action of the muscles, and the skeletal elements on which these muscles attach are described in *Rousettus aegyptiacus* (É. Geoffrey) (Pteropodidae). On the whole the morphological pattern and action of the muscles are the same as in microchiropteran bats, though there are some differences. The description, high-speed films, and flash photographs are made the basis of functional aspects.

1. *Rousettus aegyptiacus* has a very low midventral sternal ridge. The sternum also has three keels, on which a median ligamentous sheet attaches. This ligament and the keels form an enlarged area of attachment for the pectoralis muscle without any appreciable increase in weight.

2. The cross sections of the digits are described. The digits are shaped in such a way as to have their largest diameters in those planes where the bending forces are largest, thereby keeping low the weight while still possessing rigidity in the important directions. However, this flattening of the digits in certain planes is less pronounced in *Rousettus aegyptiacus* than in many micro chiropteran species.

3. The metacarpals are short in relation to the entire digits, as compared with many microchiropteran species. This permits the bat to get a potentially high camber of the wing during the downstroke. During the later part of the upstroke the digits are highly flexed, folding the hand wing, to reduce the drag. A relatively short metacarpal contributes to giving a small area of the hand wing meeting the airstream during the upstroke.

4. The rigid unit formed by the second and third digits is very broad in megachiropteran bats. Musculus palmaris longus is very powerful in *Rousettus aegyptiacus* in comparison with most microchiropteran bats so far investigated. These features contribute to giving high camber of the wing.

5. *Rousettus aegyptiacus* has a powerful flexor muscle of the radius, Musculus brachio-radialis, which is unusual in microchiropteran bats.

6. Megachiropteran bats, so far investigated, possess more powerful membrane muscles than do the small microchiropteran bats.

Flight characteristics: The wing loading for females is ca. 21 Nm^{-2}, for males ca. 30 Nm^{-2}, the aspect ratio ca. 5.8, and the stroke frequency ca. 8 per sec in slow level flight, ca. 3.3 m per sec.

Novacek, M. J. (1987). Auditory features and Affinities of the Eocene Bats *Icaronycteris* and *Palaeochiropteryx* (Microchiroptera, incertae sedis).

The earliest known bats are skeletons of *Icaronycteris index* from the early Eocene of western Wyoming and a few less well-represented species from the early Eocene of France. Also known are *Palaeochiropteryx tupaiodon* and several other species from the middle Eocene of western Germany. These taxa have been regarded as primitive forms, either "ancestral" to echolocating microchiropterans or "ancestral" to both micro- and megachiropterans. Details of basicranial structure suggest that these Eocene forms were, however, specialized echolocators comparable to Recent microchiropterans. Moreover, quantitative analysis reveals that the Eocene bats have a more pronounced expansion of the cochlea than many Recent microchiropteran species. There is clear justification for reference of *Icaronycteris* and *Palaeochiropteryx* to the Microchiroptera. Conversely, there is no reason to recognize a "primitive ancestral" group, Eochiroptera, that is excluded from Microchiroptera or Megachiroptera. The relationships of *Icaronycteris* and *Palaeochiropteryx* within Microchiroptera remain uncertain. Association of these taxa and several other Eocene forms within the microchiropteran superfamily Palaeochiropterygoidea fails to clarify these relationships. Palaeochiropterygoidea has not been defined by derived characters, and *Icaronycteris* and *Palaeochiropteryx* are more accurately designated Microchiroptera incertae sedis. Several primitive features shown by *Icaronycteris* suggest that the development of a sophisticated system for echolocation within Microchiroptera occurred earlier than certain modifications of the postcranial skeleton.

Oelofsen, M. J. and M. S. Smith (1993). Rabies and bats in a rabies-endemic area of southern Africa: application of two commercial test kits for antigen and antibody detection.

In southern Africa, isolates of rabies-related viruses (Le, Duvenhage virus and Lagos bat virus) have been made from insectivorous and frugivorous bats. As no recent formal bat virus survey has been reported in southern Africa, a survey of bats in rabies-endemic areas was undertaken. Five hundred and fortyseven bats (13 species) were collected from 21 localities in the Orange Free State, Lesotho and the northern Cape Province. None of the 190 bat sera tested using the "Trousse Platelia Rage" ELISA kit (Diagnostic Pasteur), had antibodies to rabies virus glycoprotein G. Rabies virus nucleocapsid antigen was also sought for in the brains of 530 bats (13 species) by means of the "Rapid rabies enzyme irnrnunodiagnosis" (RREID) test (Diagnostics Pasteur). No positive results were obtained. These results show that bats are unlikely to play an important role as hosts of rabies in these parts of Africa, although a low rate of infection cannot be excluded.

Ogen-Odoi, A. A. (1981). The influence of seasonality of food and rainfall on some aspects of the ecology of bats on Entebbe Penninsular, Uganda.

The influence of availability of food (fruits and insects) and rainfall on some aspects of the ecology of Chiropteran fauna on Entebbe Peninsular was investigated in a twelve month intensive study, and the data presented are discussed in relation to survival, competition and adaption of the bats in the area. The bats were sampled, regularly using Nylon Mist Nets.

Observations and records were made of the fruiting phenology of the most abundant fruit plants within the Peninsular through the study and aerial insect count data were noted of the insects caught using light traps.

Epomophorus anurus (Hegluin) and Tadarida species showed the highest incidence and widest spatial distribution amongst the frugivorous and insectivorous bats respectively.

The numbers, spatial dispersion and activities of the bats were strongly correlated with rainfall patterns and the subsequent food availability. Numbers of individual bat species progressively decreased, but species diversity increased after the high rainfall peaks, when food become abundant. The activities of the fruit bats were randomly distributed at various levels above ground during seasons of food scarcity, but became restricted to higher levels during food abundance. Flight patterns of the insectivorous bats were however not affected by changes in seasons and food availability.

During the peaks of high rainfall and low food supply,
flight and foraging activities started early in the evening (1800 hrs local time) and ended some two hours after mid-night, before the characteristic early morning heavy rains. In addition, their activities were secondarily influenced by the intensity of moon light causing the bats to disappear.

The abundance of insects and fruits coincided with similar bimodal peaks. There was no sex difference in activity patterns in all the bats, although there was a marked female dominance in numbers over males. Over all, more fruit bats were caught in the mist nets than insectivorous bats.

Ogen-Odoi, A. A. (1983). The influence of seaonality of food and rainfall on some aspects of ecology of bats in Entebbe Peninsula, Uganda.

Studies showing correlations between various environmental factors, e.g. rainfall, temperature, photo and others with seasonal fluctuation of various parameters of populations of different living organisms, have been conducted in different parts of the world. In particular, how these factors influence reproductive and breeding cycles and activity patterns have been reported in bats (Marshall, 1947; Mutere, 1967 + 1968; Wimsatt & Trapido, 1952; Okia, 1973; Gaisler, 1973).

Previous work involving mist-netting of bats in the Entebbe Peninsula (Mutere, 1967; Ogen-Odoi, pers. observ.), revealed interesting fluctuations in number of catch and species of bats with seasons. Detailed investigations to determine the nature of the patterns and possible factors involved have not been made. This paper reports the findings of research whose major aim was to understand the possible influences of rainfall and seasonality of food on patterns of foraging and flight activities, spatial dispersion and distribution and species composition of bats in Entebbe Peninsula.

Ognev, S. I. (1927). A synopsis of the Russian bats.

The Russian Chiroptera hitherto have not been well known. Our knowledge has not only been deficient concerning the biology of these interesting mammals, but also as to the number of species found in Russia and their distnbution. K. A. Satunin in his "Conspectus Mammalium Imperii Rossicae" (1914) enumerates thirty-nine species and subspecies of Chiroptera which are found in this country. Nevertheless in Satunin's list it is doubtful whether some of the bats can be regarded even as weak subspecies, for example *Rhinolophus ferrum-equinum colchicus* Satun. and *R. euryale nordmanni* Satun.; the systematic relations of different species of *Barbastella*, etc., are also not clear. If we take into consideration an this the list of bats in Satunin's book must be shortened to thirty-five species and subspecies.

In the interesting little paper by W. L. Bianchi (Notes preliminaires sur les chauve-souris ou Chiroptera de la Russie, Annuaire du Musée Zoologique de l'Académie des Sciences, Petrograd, vol, 21, 1916, pp. lxxiii-lxxxii) thirty-eight species and subspecies of Russian bats are enumerated. If we delete from this list the wrongly included *Otonycteris cinereus* Satunin and *Barbastella walteri* Bianchi, the synopsis contains only thirty-six forms.

Having examined a very considerable collection of bats, I estimate that in Russia (considering the borders as they were at the time of the past Russian Empire) we meet with forty-nine species and subspecies. It is very possible that new investigations will essentially complete this sufficiently long list, in which I have included some quite new species and subspecies.

Three families of these animals are found in Russia, as follows: Rhinolophidae, Vespertilionidae, and Molossidae, the distinctive peculiarities of which are well known.

Okafor, F. C. (1988). *Oochoristica agamae* Baylis, 1919 (Eucestoda, Linstowiidae) in one reptile and two bat species from Nsukka (Anambra State, Nigeria).

The same cestode parasite was recovered from the small intestines of different insectivorous hosts: a lizard *Agama agama*, two bats *Tadarida chaeraphon nigeriae* (Thomas, 1913) and *Hipposideros caffer tephrus* (Cabrera, 1906) at Nsukka. Various measurements and observations on gross anatomy (eg. number and arrangement of the ovary, dimensions of the cirrus sac, etc.) show that all specimens of the parasites belong to the same species. The different hosts feed on a common intermediate host in the same environment which may account for this phenomenon. The prevalence of the worms and the intensity of infection in the three hosts are also presented. There is a significantly high prevalence in the males, but no explanation for this trend is given.

Okia, N. O. (1974a). The breeding pattern of the Eastern Epauletted bat, *Epomophorus anurus* Heuglin, in Uganda.

Continuous monthly observations of the reproductive organs of the Eastern epauletted bat, *Epomophorus anurus*, has revealed its breeding to be cyclic with two distinct breeding seasons separated by about a month. Gestation appeared to last between 5 to 6 months, and occurred from April to September and October to March. Testes were heaviest from February to April and from September to December, and a majority of young bats were caught in late March and early October during the short intervals between breeding. This study supports the findings of earlier workers showing that breeding in tropical fruit bats is seasonal and closely related to rainfall. It further supports an earlier suggestion that this fruit bat is polyoestrous and breeds continuously.

O'Shea, T. J. (1980). Roosting, Social organization and the annual cycle in a Kenya population of the bat *Pipistrellus nanus*.

The tiny (3.1 - 3.8 g) vespertilionid bat *Pipistrellus nanus* was studied in Kenya palm thatched roofs from May 1973 to July 1974. Roosting social organization and related activities and behavior are described. MM held diurnal roosting territories where FF gathered in small and compositionally labile groups, attracted to the most vocal MM. Annual variation in population-wide aspects of social organization follows predictable seasonal changes in climate and predator abundance. Variability between individuals follows a common mamrnalian pattern: high male competition for FF, variance in presumed male reproductive success, and a mating system resembling one based on resource defense polygyny. Social organization in this population contrasts with that known from studies of other *P. nanus* populations.

O'Shea, T. J. and T. A. Vaughan (1980). Ecological observations on an East African bat community.

L'etude de Ia faune de chauves-souris du centre-sud du Kenya a été entreprise de mai 1973 à julllet 1974: vingt-cinq espèces de chauves-souris appartenant à 7 familles ont été collectées; 24 d'entre elles étaient insectivores. Cette faune est pauvre quand on Ia compare aux régions subtropicales en raison de l'absence de non-insectivores. Le nornbre d'espèces et de familles de chauves-souris insectivores, cependant, est presque identique a celui de Costa-Rica où un climat semblable est réparti de manière comparable.

La région subit une saison sèche prolongée de mai à la fin d'octobre, deux saisons des pluies en novembre et en mars-avril, et une saison sèche courte et moins sévère de decembre à fevrier. La

moitié seulement des espèces ont été trouvées au cours de la longue saison sèche et beaucoup entre elles paraissent avoir de faibles densités. On pense que des migrations saisonnières vers des régions où il y a des pluies supplementaires peuvent expliquer ces différences. Toutes les espèces sauf une se reproduisent avec les pluies les plus constantes de novembre, quelques-unes mettent bas au cours de la saison des pluies de mars-avril, mais aucune ne se reprodutt pendant la longue saison sèche. La plupart des résidents annuels se reproduisent seulement en novembre et la plupart de ces espèces qui mettent bas en mars-avril sont probablement migratrices. Celles qu'on croit migratrices ont tendance à donner des portées plus petites.

The bat fauna of a south-central Kenya study area was monitored from May 1973 to July. Twenty-five species of bats in seven families were collected: 24 of these were Insectivores. This fauna is depauperate compared to neotropical areas due to a lack of non-insectivores. The number of species and families of insect eating bats, however, is nearly identical to that found at a Costa Rican site with a similar clirnate sampled in a comparable manner (Laval and Fitch 1977).

The area had a pronounced dry season from May to late-October, two rainy seasons in November and March-April, and a short and less severe dry season from December through February. The maximum number of species was detected from November to May. Only about half of these species were found during the long dry season, and many oft.hose present seemed to occur in lower densities. Seasonal migration to areas with complementary rainfall patterns is suggested to account for these differences. All but one species reproduced with the more predictable November rains, a few also gave birth in the March-April rainy season, but none bred in the long dry season. The annnual residents bred only in November and most of those species which gave birth in March-April were suspected to be migratory. Suspected migrants tended towards smaller litter sizes.

Several foraging-related characters were examined as indicators of food resource partitioning. Aspect ratio was significantly correlated with estlmates of foraging height. It is suggested that all the common non-molossid insectivorous bat species could coexist on the basis of differences in pursuit strategy, prey size, orientation pulses or feeding heights. A greater proportion of migrating species overlap in size during the period from November-May than during the long dry season. This may indicate a greater degree of selective feeding when insect abundance is high, greater partitioning on the basis of size when abundance is low.

Oustalet, E. (1894). Les mammifères et les oiseaux d'Obock et du pays des çomalis, (Première partie).

J'espérais pouvoir apporter aujourd'hui un exposé complet de nos connaissances relatives à la faune des Mammifères et des Oiseaux de la portion de l'Afrique orientale qui comprend le pays des Danakil, notre colonie d'Obock et le pays des Çomalis; mais, comme cela arrive souvent en pareil cas, j'ai reconnu, en rassemblant les éléments de cette étude, que les matériaux à réunir étaient plus nombreux et plus épars que je ne le supposais, que la faune des Vertébrés du Çomal était plus riche que je ne le croyais et que, par conséquent, je n'aurais pas le temps nécessaire pour terminer à la date fixée mon travail dont l'étendue aurait dépassé d'ailleurs les limites qui me sont tracées. Je me bornerai donc aujourd'hui à donner la première partie de mes recherches, celle qui est relative aux Mammifères d'Obock.

Cette colonie a été visitée en 1893 par notre collègue M. le Dr Jousseaume et par M. Maurice Maindron. Le premier de ces voyageurs, tout en s'adonnant de préférence à la recherche des Mollusques, a recueilli pour le Muséum des nids et des oeufs de Balbuzard, de Tisserin, de Fauvette, et M. Maindron a rapporté un assez grand nombre de dépouilles de Mammifères et d'Oiseaux, ainsi que des nids et des oeufs de Tisserin, de Guépier et de Ganga. C'est à l'aide de ces matériaux que j'ai pu dresser les listes suivantes:

Overal, W. L. and L. R. Wingate (1976). The biology of the batbug *Stricticimex antennatus* (Hemiptera: Cimicidae) in South Africa.

A colony of *Stricticimex antennatus* Ferris & Usinger from a bat-roost near Pietermaritzburg. Natal, was estimated to contain more than 50 000 individuals. The bat bugs were observed to feed on *Myotis tricolor, Rhinolophus simulator, R. clivosus, Nycteris thebacia*, and *Hipposideros caffer*. People entering the bat-roost were bitten, and several developed skin sensitivity to the bites. In the laboratory batbugs were ted on rabbits and rats, and round to undergo five nymphal instars. Moulting did not take place in unfed individuals. The aggregating and orientation behaviour of the batbugs in response to simple stimuli is described.

Owen, R. D. and M. B. Qumsiyeh (1987). The subspecies in the Trident leaf-nosed bat, *Asellia tridens*: homomorphism in widely separated populations.

Examined univariate and multivariate morphometric variation in populations of a desert bat, *Asellia tridens*, from most of its range in Africa and Asia. Morphometric and color variation in this species suggest that two distinct taxonomic groups exist. One of these represents at least two widely disjunct populations with a large intervening region occupied by the other morphologically distinct group. The existence of widely separated homomorphic populations may prove to be more common than previously believed in mammalian species with large ranges, and may cause difficulty in recognizing subspecies based on classical taxonomic criteria.

Pagenstecher, H. A. (1885b). Die von Dr. G.A. Fischer auf der in Auftrage des geographischen Gesellschaft in Hamburg unternommenen Reise in das Massai-Land gesammelten Säugethiere.

Die von Herrn Dr. *G. A. Fischer* auf seiner im Auftrage der geographischen Gesellschaft zu Hamhurg im Jahre 1883 in das Massailand ausgeführten Reise gesammelten Thiere und Mineralien sind von der gedachten Gesellschaft als ein höchst dankenswerthes Geschenk dem Naturhistorischen Museum überwiesen worden.

Die Bearbeitung der Reptilien, Amphibien und Fische durch Herrn Dr. *J. G. Fischer* und die der Käfer in der Hauptsache durch Herrn Professor Dr. *Gerstücker* wurden in 1884 bereits so zeitig fertig, dass diese Arbeiten als Beilagen zum Jahresberichte des Museums für 1883 im Jahrbuche der Hamburgischen wissenschaftlichen Anstalten I. Jahrgang erscheinen konnten.

Eine Uebersicht der Vögel hat Herr Dr. *G. A. Fischer* seitdem selbst in der Zeitung für die gesammte Ornithologie 1884 (Budapest) gegeben.

Ueber die Säugethiere soll hier Bericht erstattet werden. Wie mehrfach zu den Vögeln früher gesammelte Stücke, so hat zu den Säugern Herr Dr. *Fischer* den auf Zanzibar erlegten Colobus Kirkii als sein Geschenk beigelegt. Eine annähernd volle Vertretung der Fauna des durchwanderten Gebietes liegt nicht vor. In seiner Reiseskizze hat Dr. *Fischer*" von Säugern als beobachtet noch angeführt Elenantilope, Giraffe, Zebra, gestreiftes Gnu, Warzenschwein, Büffel, Nilpferd, Rhinoceros, Hyaena crocuta, Löwe, Cynocephalus babuin, Hase: als von den Massai zum Mantel benutzt Cercopithecus pygerythrus. Hyrax, "Wildkatze"; (unzweifelhaft Lynx sp.), Leopard: von der Jagd und den Spuren des Elephanten ist die Rede.

Das grosse Wild war besonders reich in den lichten Waldungen und dem Graslande bei Klein-Aruscha, aber die reichste Fauna gab der dichte Wald bei Gross-Aruscha am Maeruberge.

Palmeirim, J. M. (1991). A morphometric assessment of the systematic position of the *Nyctalus* from Azores and Madeira.

The Atlantic archipelagoes of Madeira and Azores both have populations of small *Nyctalus*, which have been described as separate species. But their systematic situation remains unclear because of the difficulty in assigning a taxonomic status to geographically isolated forms, and to the lack of a comprehensive study of the genus. In this paper a comparative craniometric study of all the widely

recognized species of *Nyctalus* is done, and in this context the taxonomic status of *verrucosus* and *azoreum* is assessed. It is concluded that *N. azoreum* from the Azores should be regarded as a separate species, and the Madeiran form, *verrucosus*, as a subspecies of *N. leisleri*.

Les petites noctules-des archipels de Madère et des Acores ont été décrites cornme des espèces différentes. Leur position systématique reste douteuse en raison de la difficulte de classement de formes géographiques isolées et aussi a cause de l'étude insuffisante du genre. Notre étude craniométrique comparative de toutes les espèces qui ont été rapportées au genre *Nyctalus* conduit à la conclusion que la forme *azoreum* des Acores doit être considerée comme une espèce, *N. azoreum*, et que la forme *verrucosus* de Madère peut être considerée comme une sous-espèce de *N. leisleri*.

Panouse, J. B. (1951). Les Chauves-souris du Maroc.

Au Maroc, pays ouvert à l'investigation scientifique organisée depuis un demi-siècle à peine, nos connaissanccs faunistiques comportent de nombreuses et larges lacunes. L'inventaire des formes animales vivant sur le territoire de l'Empire Chérifien et dans les mers qui le bordent, a été entrepris par l'Institut Scientifique Chérifien dès la fondation de ce dernier en 1920. Malgré l'aide apportée par les Services qui, à un titre ou à un autre, s'occupent au Maroc de la vie animale, malgré les recherches effectuécs par les naturalistes sur le matériel récolté, cet inventaire est loin d'être complet. Aussi les zoologistes spécialistes, certains de voir dans un avenir prochain le catalogue des animaux étudiés par eux s'enrichir de formes non encore rencontrées au Maroc ou même entièrement nouvelles pour la Science, sont-ils peu enclins à punlier des mises au point de quelque importance sur leur groupe de prédilection. Le nombre des svstématiciens est très réduit et de tous côtés on leur envoie du matériel: aussi est-il difficile de les blâmer lorsqu'ils hésitent à entreprendre une révision qui s'avérera sûrement incomplète et périmée au bout d'un temps très court.

Il me semble cependant indispensable de présenter dès à présent des mises au point sur les groupes les mieux connus. Combien de fois m'a-t-on posé la question: "Pouvez-vous m'indiquer un travail d'ensemble sur tel ou tel groupe animal existant au Maroc"? Lorsqu'il ne s'agissait pas des serpents ou des poissons d'eau douce, force m'était de répondre par la négative. C'est pourquoi je crois nécessaire la parution de notes destinées à permettre l'identification des principaux représentants de la faune marocaine, notamment des Vertébrés. Pour pouvoir être utilisés par tous ceux qu'intéresse la Nature, ces travaux, ébauche d'une Faune du Maroc, doivent présenter certaines caractéristiques. Les termes techniques utilisés ne doivent pas être trop nombreux: il convient cependant de ne pas tomber dans un excès inverse, car le langage scientifique est seul capable de désigner avec précision et sans ambiguïté certaines structures et certains fails. Les tableuux de détermination doivent être aussi clairs que possible: les caractères qu'ils utilisent doivent pouvoir être facilement appréciés et permettre un choix sans équivoque. Ils doivent être conçus non pour des spécialistes disposant d'une collection de comparaison, mais pour des naturalistes qui désirent simplement nommer un animal rencontré peut-être par hasard. Cela implique une illustration abondante, car une figure décrit souvent mieux et plus qu'un long texte. Toutes ces exigences sont difficiles à réaliser ou même à concilier, mais elles doivent constituer un idéal à satisfaire dans la plus grande mesure possible. Le présent travail sur les Chauves-souris du Maroc est une première tentative dans ce sens.

Je suis heureux de remercier ici tous ceux dont l'aide m'a été précieuse. M. NEMETH s'est chargé de mesurer les Chiroptères des collections de l'I.S.C. M. le Professeur BERLIOZ, Directeur du Laboratoire de Mammalogie du Muséum National d'Histoire Naturelle de Paris a bien voulu me confier des échantillons de la plupart des espèces qui manquent dans les collections de Rahat, M. le Professeur HEIM DE BALSAC, le spécialiste certainement le plus éminent en ce qui concerne les Mammifères d'Afrique du Nord, à bien voulu examiner le manuscrit.

L'illustration est en partie originale, en partie tirée des travaux de CABRERA, MILLER, DIDIER ET RODE et RODE. La plupart des figures ont été dessinées par M. de BRETTES, dessinateur de l'Institut Scientifique Chérifien et la représentation du Grand Rhinolophe est due à M^{me}• Luce de CHAMPRIS.

Panouse, J. B. (1953). Observations sur les chauves-souris du Maroc et addition d'une nouvelle espèce *Myotis mystacinus* (Kuhl 1819) à la faune marocaine.

Depuis la parution, en 1951, de mon travail sur les Chauves-Souris du Maroc, j'ai pu, avec l'aide de correspondants dévoués, recueillir un certain nombre de renseignements nouveaux qui permettent de préciser la répartition de quelques espèces, de confirmer la présence de l'Oreillard par la capture de deux spécimens et enfin d'enrichir la faune du Maroc et même de l'Afrique d'une forme connue jusqu'ici d'Europe et d'Asie. La publication de ces données récentes constitue le but de cette note.

Panouse, J. B. (1958). Présence au Maroc de *Nycteris thebaica*.

Récemment le Docteur BLANC, Directeur de l'Institut Pasteur du Maroc m'a communiqué une chauve-souris qu'il venait de capturer en compagnie de son adjoint, M. ASCIONE. Un bref examen de l'animal me permit de constater qu'il s'agissait d'un *Nycteridae* dont plusieurs autres examplaires furent pris ultérieurement.

Une étude plus précise de ces chiroptères et leur comparaison avec des exemplaires du Museum de Paris m'amènent à considérer qu'il s'agit de *Nycteris thebaica* E. Geoffroy 1813, espèce décrite d'Egypte et fréquente en Afrique noire mais jusqu'ici inconnue en Afrique du Nord, comme d'ailleurs tous les autres *Nycteridae*.

Cette forme est suffisamment connue des spécialistes pour que sans doute une nouvelle description soit pour eux superflue. Mais l'accès aux documents originaux n'est pas toujours facile aux naturalistes amateurs qui lisent ce Bulletin, aussi je crois bien faire en donnant de cette espèce une description sur le type de celles publiées dans mon travail de 1951.

Park, K. J., J. D. Altringham and G. Jones (1996). Assortative roosting in the two phonic types of *Pipistrellus pipistrellus* during the mating season.

The European pipistrelle, *Pipistrellus pipistrellus*, consists of two phonic types that echolocate with frequencies of maximum energy (*FMAXE*) averaging 46 kHz and 55 kHz (named the 45 kHz and 55 kHz phonic types for simplicity). These two phonic types occur in sympatry over much of Britain. Between 1993 and 1995 mating groups of *P. pipistrellus* were located in bat boxes between August and October, the main mating period for these bats. Mating groups comprised a single male and up to three females. Broadband, time-expanded recordings of search-phase echolocation calls were made from bats immediately after release. The average *FMAXE* of each bat was calculated: bats with an *FMAXE* less than 49 kHz were classed as 45 kHz phonic types and bats with an *FMAXE* greater than 52 kHz were classed as 55 kHz phonic types. A total of 16, 45 kHz groups and ten 55 kHz groups were located. No mating group ever contained more than one phonic type, although both types were known to be present at several of the study sites. Males emitted calls of higher frequency than females for both phonic types. The study suggests that the two phonic types are reproductively isolated and supports the hypothesis that *P. pipistrellus* should be considered as two cryptic sibling species.

Parsons, S., C. W. Thorpe and S. M. Dawson (1997). Echolocation calls of the Long-tailed bat: A quantitative analysis of types of calls.

The echolocation calls of long-tailed bats (*Chalinolobus tuberculatus*) were recorded in the Eglinton Valley, Fiordland, New Zealand, and digitized for analysis with signal-processing software. Univariate and multivariate analyses of measured features facilitated a quantitative classification of the calls. Cluster analysis was used to categorize calls into two groups equating to search and terminal-buzz calls described qualitatively for other species. When moving from search to terminal phases, the calls decrease in bandwidth, maximum and minimum frequency of call, and duration. Search calls begin with a steep-downward FM sweep followed by a short, less-modulated component. Buzz calls are FM sweeps. Although not found quantitatively, a broadband pre-buzz group of calls also was identified.

Ambiguity analysis of calls from the three groups shows that search-phase calls are well suited to resolving the velocity of targets, and hence, identifying moving targets in stationary clutter. Pre-buzz and buzz calls are better suited to resolving range, a feature that may aid the bats in capture of evasive prey after it has been identified.

Pedersen, S. C. (1998). Morphometric analysis of the chiropteran skull with regard to mode of echolocation.

I compared simple morphometric data with cephalometric data on the angular arrangements of the facial and neural components of the skull of bats. The morphological dichotomy between oral and nasal emission of the echolocation pulse in the Microchiroptera is presumably under strong selective pressure to provide an acoustical horn for efficient emission of the echolocative call. Cephalometric and morphometric data compliment each other in the distinction between oral and nasal *baupläne*. However, fine taxonomic resolution provided by morphometric data is subject to the otherwise plastic functional matrix of the head conforming to the acoustical axis of the skull.

Perret, J. L. and V. Aellen (1956). Mammifères du Cameroun de la collection J.L. Perret.

Les Mammifères qui font l'objet de cette étude ont été recueillis par l'un de nous (J.-L. P.) dans le sud du Cameroun Français, principalement aux environs de Sangmelima, durant la période 1953 - 1955. Ils sont représentés par 405 spécimens et 91 espèces. Toute la collection est déposée au Muséum d'Histoire naturelle de Genève.

Leur préparation, leur détermination provisoire et les mesures sur le terrain, ainsi que les noms vernaculaires et les indications biologiques sont l'oeuvre de J.-L. P.

La détermination définitive, les mesures craniennes et les discussions taxinomiques sont le travail de V. A.

Cette riche collection apporte peu de formes nouvelles pour le Cameroun, mais son étude permet d'utiles précisions biogéographiques et systématiques. Quelques espèces rares ou peu connues, telles que *Casinycteris argynnis, Miniopterus i. inflatus, Epixerus wilsoni*, etc. y sont représentées.

Sont nouveaux pour le Cameroun Français:
Graphiurus surdus Dollm., *Mus m. musculus* L., *Rhinolophus alcyone* Temm. et *Pipistrellus c. culex* Thom.

Perrin, M. R. (1982). Prey specificity of the barn owl, *Tyto alba*, in the Great Fish River valley of the Eastern Cape Province.

The responses of barn owls preying on a community of small mammals in the Great Fish River valley of the Eastern Cape have been determined by pellet analysis. The species composition of the prey was compared with the results of intensive trapping in adjacent habitat. Differences were apparent and their probable causes are discussed. The age-structure of several prey species found in the pellets was recorded following the establishment of relative age classes based on tooth wear, and interpreted in relation to the theory of prudent predation. There was no common pattern of age specific mortality. It was concluded that prudent and non-prudent behaviour may occur irregularly in space and time in these polyphagous barn owls, since the prey species varied in size and density, and were characterized by different reproductive strategies and survivorship patterns.

Die reaksies van nonnetjie-uile wat jag maak op 'n gemeenskap van klein soogdierspesies in die Groot-Visriviervallei van die oostelike Kaapprovinsie is vasgestel deur ontleding van hul pilvormige onverteerde kosrestes. Die spesiesamestelling van die prooi is vergelyk met die opbrengs van

omvattende valstrikvangste in die naburige habitat. Daar was duidelike verskille en die waarskynlike oorsake daarvan word bespreek. Die ouderdomstruktuur van verskeie prooispesies wat in die uilklonte aangetref is, is na vasstelling van die betreklike ouderdomsklasse volgens tandslytasie aangeteken, en met inagneming van die teorie van selektiewe buitmaak geïnterpreteer. Geen algemene patroon van ouderdomspesifieke sterflikheid is opgemerk nie. Daar is tot die gevolgtrekking gekom dat selektiewe en nie-selektiewe gedrag dalk onder hierdie polifage nonnetjie-uile tegelyk voorkom, aangesien die prooispesies volgens grootte en bevolkingsdigtheid verskil het en gekenmerk is deur verskillende voortplantingstrategiee en oorlewingspatrone.

Peters, W. C. H. (1869a). Ueber neue oder weniger bekannte Flederthiere, besonders des Pariser Museums.

Die Osterferien während des Aprilmonats d. J. habe ich zu einer Reise nach Paris verwandt, um die berühmen reicher Sammlungen des Jardin des plantes zu untersuchen. In Be.ag auf die Säugethiere und Vögel wurde mir mit der größten Liberalität und Gastlichkeit Alles von unserem Mitgliede Herr H. Milne-Edwards zur Dispositions gestellt und hatte ich mich dabei der besonderen Unterstützung des bereits rühmlich bekannten Hrn. A. Milne-Edwards zu erfreuen, während Hr. A. Duméril mir mit der ihm eigenen Liebenwürdigkeit hin..ich der Untersuchung der Amphibien un Fische entgegenkam. Bei der nur kurz zugemessenen Zeit habe ich vielen ununterzucht lassen müssen, nur die Flederthiere, mit deren Monographie ich seit Jahren beschäftigt bin, habe ich vollständig durgehen können, was besonders wegen der dort beßudlichen typischen Exemplare, welche den Publication von Geoffroy St. Hilaire, Fr. Cuvier, Gervais, H. de Saussure u. A. zu Grunde liegen und die z. Th. Noch nicht den neueren Anforderungen entsprechend untersucht worden sind, von Wichtigkeit war. Ich erlaube mir daher hierüber einei meine früheren Mittheilungen über diesen Gegenstand ergänzende Zusätze vorzulegen.

Peters, W. C. H. (1876). Ueber die von dem verstorbenen Professor Dr. Reinhold Buchholz in Westafrika gesammelten Säugethiere.

Indem ich der übernommenen Verpflichtung nachkommen über die von dem Professor Dr. Buchholz gesammelten Säugethiere der Akademie Nachricht zu geben, kann ich dieses nicht thun, ohne das lebhafteste Bedauern über den unerwarteten frühen Tod des rastlos thätigen und ausgezeichneten Forschers zu wiederholen. Obgleich dieser Theil der Zoologie nicht in solchem Maße sein Interesse in Anspruch nahm, wie die Gliederthiere, zeigen doch sowohl seine Sammlungen, wie die brieflich an mich gerichteten Mittheilungen, dass er auch in diesem Zweige mit beschränkten Kräften und Mitteln Bermerkenswerthes geleistet had. Es ist mir daher eine angenehme Pflicht, mit voller Berechtigung hervorheben zu können, dass die dem Verstorbenen bewiesene thätige Theilnahme von Seiten der Akademie un die ihm von dem Curatorium der Humboldt-Stiftung gewährte Unterstützung eine wohlbegründete und wohlverdiente ware. Wen auch die Mehrzahl der in der folgenden Übersiche enthaltenen Arten bereits bekannt waren, haben doch die genauen Nachrichten über ihr Vorkommen in bis dahin wenig oder noch gar nicht erforschten Gegenden ein beseonderes Interesse.

Peters, W. C. H. (1879). Ueber die von Hrn J.M. Hildebrandt während seiner letzten ostafrikanischen Reise gesammelten Säugethiere und Amphibien.

Die meisten der von Hrn. Hildebrandt mitgebrachten Gegenstände stammen von dem Festlande und sind hauptsächlich in den Districten von Taita und Ukamba auf einer Tour von Mombassa nach dem Kenia, der jedoch selbst nicht erreicht wurde, gesammelt.

Peterson, R. L. (1965). A review of the flat-headed bats of the family Molossidae from South America and Africa.

Among the molossid bats. three genera have become adapted for living in the thin crevices of rocks or similar situations and each reflects this adaptation in an extreme tlattening of the skull. To date all three have been quite rare in collections and our knowledge of them quite meagre. *Platymops* is known to occur in the thin crevices between rocks in east Africa. *Sauromys* has been discovered in south Africa underneath stones where scorpions were being sought. The first *Neoplatymops* discovered in British Guiana was also found underneath a stone out in the savannahs. The three genera are rather widely separated geographically and each has fundamentally distinct morphological characteristics which indicate that although related, the relationships among them are not particularly close. The closest affinities with other genera seem to be exhibited by *Sauromys* which cranially resembles a *Tadarida* with an extremely flattened skull, and externally resembles *Mormopterus*. Both *Sauromys* and *Platymops* of Africa share with *Mormopterus* a wide separation of the ears. Which differs from *Tadarida*, but show a relationship with *Tadarida* in the conformation of the palate (both fore and aft). *Platymops* differs in (1) the development of the wart-like granulations on the forearm; (2) the development of gular glands; (3) an extreme antorbital expansion of the lachrymal ridges. a modification undoubtedly associated with the great flattening of the skull; and (4) a reduction of the hypocones of M^1 and M^2. These latter four characteristics are shared with *Neoplatymops* but the South American genus is more distinct from the *Tadarida* line in the conformation of the palate (both fore and aft). The fusion of the premaxillary bones to form a solid palate in *Neoplatymops* appears to represent an intermediate condition between *Tadarida* on the one hand and the *Molossops-Cynomops* complex on the other. While the palate is complete in all *Neoplatymops* known (both juvenile and adult) the spacing between the upper canines would suggest that fusion of the anterior portion of the palate represents a transitional condition moving toward the *Molossops-Cynomops* line. *Neoplatymops* shows other affinities with that line in the shape of the upper incisors which are strongly hooked forward. The conformation of the posterior margin of the palate as well as other details of the skull suggest that *Molossops* could be derived from *Neoplatymops* by the loss of the anterior premolar and one of the lower incisors or that *Cynomops* could be similarly derived by the loss of the anterior premolar and the third commissure of the last upper molar and a corresponding reduction of the posterior lobe of M_3. In each case, however, a deepening of the skull and an expansion of the hypocone of M^1 and M^2 would have to accompany the reduction in dentition along with the loss of the wart-like granulations on the forearm.

The flat-headed rnolossid bats may thus be regarded as three distinct genera with the following forms known at present. The geographic races of *S. petrophilus* are listed provisionally pending a critical review of the species.

Peterson, R. L. (1967). A new record for the African molossid bat *Tadarida aloysiisabaudiae*.

A specimen of *Tadarida aloysiisabaudiae* from Western Uganda, Africa, appears to represent the third known example of this species since its original discovery in 1907 and the first specimen to be collected since 1913. External and cranial measurements agree closely with the type specimen. It is compared with *Tadarida bivitata* and confirmed as a distinctively different species. The lateral view of the lower jaw and anterior aspect of the upper and lower canines and incisors are illustrated for the first time.

Peterson, R. L. (1969). Further notes on the African molossid bat *Tadarida aloysiisabaudiae*.

Four additional specimens of *Tadarida aloysiisabaudiae* are recorded. bringing the total known number to seven. Two are fully adult males, the first known. Sexual dimorphism is described and illustrated in the relative sizes of the anterior premolars. The conformations of the basisphenoidal pits are described and their taxonomic value discussed. *Tadarida russata* is shown to be the closest known living relative, differing primarily in relative size (shorter skull and forearm length), and its only known locality is mapped along with those of *T. aloysiisabaudiae*.

Peterson, R. L. (1971a). The African molossid bat *Tadarida russata*.

Five specimens of *Tadarida russata* obtained from Cameroun, West Africa, appear to be the first collected since the original series was obtained in 1910 from near Medje, Congo. Both the new and the original specimens were taken along the junction of the so-called "high forest" and "Guinea forest" zones but some 1200 miles apart. The Cameroun specimens were compared with the original type series and additional morphological data provided as well as the illustrations of facial and cranial features. *T. bivittata*, of similar size, is shown not to be closely allied with *T. russata* nor any member of the subgenus *Chaerephon*. *T. russata* is closely related to *T. aloysiisabaudiae* but differs in size, skull proportions. and details of the basisphenoid pits.

Peterson, R. L. (1971b). Notes on the African long-eared bats of the genus *Laephotis* (family Vespertilionidae).

The third known specimen of *Laephotis wintoni* is compared with the other two known examples, and morphological details are analyzed and compared with examples of *Laephotis angolensis*. Details of the face and ear of *L. wintoni* are illustrated, and photographs of the skulls of both species are provided for the first time.

Peterson, R. L. (1971c). The systematic status of the African molossid bats *Tadarida bemmeleni* and *Tadarida cistura*.

Twenty-four specimens of *Tadarida bemmeleni*, collected in Cameroun in 1970, to be the first taken since the holotype was collected in 1875 from Liberia. Morphological comparisons with *T. cistura* from East Africa indicate that the two taxa are subspecies of the same species. Systematic relations, and sexual variation, as well as ecological notes, are provided. The facial feautures, caudal glands, ridges, and cranial details are illustrated for the first time.

Vingt-quatre spécimens de *Tadarida bemmeleni* recueillis au Cameroun en 1970 semblend être les premiers qui aient été pris depuis que l'holotype a été recueilli au Liberia en 1875. Des comparaisons morphologique avec *T. cistura* de l'Afrique de l'Est indiquent que les deux taxa sont des sous-cspcccs de la même espèce. Les relations systématiques, la variation sexuelle ainsi que des notes écologiques sont données. Les traits faciaux, les glandes caudales, les rides palatales et certains détails du crâne sont illustrés pour la première fois.

Peterson, R. L. (1972). Systematic status of the African molossid bats *Tadarida congica*, *T. niangarae* and *T. trevori*.

A series of *Tadarida congica*, including the first known males, is the first to be reported since the species was originally described from Medje, Congo (now Zaire) by J. A. Allen in 1917 and extends the known range of the species in Africa from Uganda to Cameroun. *T. niangarae* is considered to be a synonym of *T. trevori*, and an earlier report of *T. trevori* from Garamba Park, Congo (Zaire), is shown to be erroneous and to be of *T. aloysiisabaudiae*. Morphometric data from *T. congica* and *T. trevori* are analyzed and compared by sex and age, and the taxa are shown to be distinct but related species. Sexual dimorphism and variation with age are analyzed in both species. The relationships of *Tadarida congica* and *T. trevori* with *T. aloysiisabaudiae, T. anchietae, T. brunnea*, and *T. midas* are discussed, and distinguishing characters are provided for each taxon. Facial characters, the upper right third molar, postpalatal features, and the arrangements of the ridges of the soft palate are illustrated for the first time.

Une série de *Tadarida congica*, comprenant les premiers mâles connus, se trouve actuellement dans le Musée Royal de l'Ontario. Elle est la première à être signalée depuis que l'espèce fut decouverte à Medje au Congo (maintenant Zaire) et fut décrite par J. A. Allen en 1917. L'aire connue de cette espèce s'étend maintenant en Afrique de l'Uganda au Cameroun. *T. niangarae* est considéré comme

synonyme de *T. trevori*. Dans une rapport précédent une espèce trouvee au Parc Garamba, Congo (Zaire) fut identifiée par erreur comme *T. trevori* alors qu'elle était en fait *T. aloysiisabaudiae*. Les données morphométriques de *T. congica* et *T. trevori* sont analysées et sont comparées par le sexe et par l'âge, et on demontre que les taxa sont les espèces distinctes mais apparentées. Le dimorphisme sexuel et la variation de l'âge sont analysées dans les deux espèces. Les parentés de *T. congica* and *T. trevori* avec *T. aloysiisabaudiae, T. anchietae, T. brunnea* et *T. midas* sont déliberés et des caractères distinctifs sont donnés pour chaque taxon. Les physionomies, les molaires troisièrnes supérieures à droite, les traits postpalatales, et les disposition des crêtes du voile du palais sont illustrées pour la première fois.

Peterson, R. L. (1973). The first known female of the African long-eared bat *Laephotis wintoni* (Vespertilionidae: Chiroptera).

A subadult *Laephotis wintoni* Thomas taken west of Mount Kenya in Kenya on 22 June, 1972, represents the fourth specimen and the first known female of that taxon. Measurements are compared with those of three males, and systematic relations within the genus are discussed. The soft palate is illustrated for the first time.

On a capturé un *Laephotis wintoni* Thomas subadulte, a l'ouest du Mont Kenia, au Kenia, Ie 22 juin 1972; ceci représente Ie quatrièrne spécimen et la première femelle connue de cette espèce. On en compare les mensurations avec celles des trois mâles et on discute des relations systématiques au sein de ce genre. On donne ici, pour la première fois, une illustration du voile du palais chez cette espèce.

Peterson, R. L. (1974). Variation in the African bat, *Tadarida lobata*, with notes on habitat and habits (Chiroptera: Molossidae).

Known specimens of *Tadarida lobata* are increased from three to 23 with the addition of a specimen from the Kapenguria area about 80 km SSW of the type locality in northwestern Kenya, and a series of 19 specimens from Maungu Hill in southeastern Kenya. Statistical comparisons of adults of the latter series showed sexual dimorphism in 14 of 23 cranial characters but none in external features. The white interscapular spot is shown to be characteristic of *T. lobata* and may be associated with a glandular area of the skin that is best developed in adults. The palatal ridges number six, the last ridge extending posterior to the level of M^2. Field observations indicate that *T. lobata* emerge late and are most active around midnight. They are fast, solitary flyers and apparently feed high above the ground.

Peterson, R. L. (1982). A new species of *Glauconycteris* from the east coast of Kenya (Chiroptera: Vespertilionidae).

A unique specimen of *Glauconycteris* differs from any known species of bat in colour. facial markings. and cranial characteristics and is diagnosed as a new species.

Un spécimen unique de *Glauconycteris* diffère de toutes les espèces connues de chauves-souris par sa coloration, les marques de sa face et ses caractéristiques crâniennes; on y reconnait une nouvelle espèce.

Peterson, R. L. (1987). Notes on systematic variation in the *nanus* group of African *Pipistrellus*.

The *nanus* group shares the following characters; a distinctive "hatchet" shaped tragus; a more-or-less elevated frontal: I1 usually weakly bifid; I2 relatively long; anterior upper premolar moderate in size; C

and P4 usually separated by a space, mensural data have been subjected to various multivariate statistical analysis programs in an attempt to clarify the taxonomic status of the taxa that are allied in this group. *Pipistrellus nanus* (Peters, 1852) is widespread across central Africa. *P. minusculus* (Miller, 1900) includes *P. fouriei* (Thomas, 1926) and *P. culex* (Thomas, 1911). *P. helios* (Heller, 1912) is widespread. *P. musiculus* (Thomas, 1913) appears valid but is known only by the type series from Cameroun. *P. n. australis* (Roberts, 1913) is an invalid name but is a valid taxon which we propose to rename as a distinct species that is occasionally sympatric with *P. nanus*.

Peterson, R. L., J. L. Eger and L. Mitchell (1995). Faune de Madagascar: Chiroptères.

Notre connaissance de la faune des Chauves-Souris malgaches ne s'est développée qu'assez lentement depuis que E. Geoffroy a décrit le *Pteropus rufus* en 1803.

Quelque soixante-cinq ans plus tard, on ne connaissait encore guère que six espèces de la région, une ou deux d'entre elles n'étant même citées que de la Réunion. Ces espèces étaient énumérées par Pollen et van Dam (1868) à l'occasion d'une étude sur divers Mammifères et Oiseaux de Madagascar: il s'agissait de:
Pteropus dupreanus (= *Eidolon dupreanum*), pp. 13, 164, 172.
Pteropus edwardsi (= *P. rufus*), pp. 25, 164, 172.
Taphozous leucopterus (= *T. mauritianus*), p. 26.
Dysopes (= *Mormopterus*), pp. 26, 164 (la Réunion), 172.
Vespertilio ? (la Réunion), p. 164.
Rhinolophus commersonii (= *Hipposideros c.*), p. 172.

La plupart de ces espèces et de celles qui ont été découvertes, par la suite, de Madagascar, proviennent de petites collections occasionelles, ne permettant pas d'étudier leurs véritables relations avec des taxa semblables d'autres provenances. L'examen des principales collections mondiales confirme la rareté des spécimens de Chauves-Souris d'origine malgache possédant une provenance précise. La plupart d'entre eux ont été réunis à l'occasion de recherches faunistiques de caractère général ou à la suite de la rencontre accidentelle d'individus isolés. La plus importante et la plus complète des collections de Chauves-Souris malgaches existant avant nos recherches personnelles, était sans doute celle de G. Grandidier, qui vécut plusieurs années à Madagascar. Sa collection, acquise par le Musée de Zoologie comparée de Harvard, vers 1957, n'a été disponible pour l'étude que vers 1979. G. Grandidier, qui a décrit *Triaenops aurita* (1912), *Rousettus madagascariensis* (1929) et *Nycteris madagascariensis* (1937), était le fils du célèbre explorateur et naturaliste A. Grandidier qui travailla longtemps à Madagascar et décrivit, pour sa part, *Mops miarensis* (1870) et, avec A. Milne-Edwards, *Myzopoda aurita* (1878).

La révision la plus récente de la faune malgache de Chiroptères est due à J. Dorst (1947) qui a publié aussi une révision du genre *Triaenops* (1948b) et a décrit *Otomops madagascariensis* (1953).

En 1967, le premier auteur du présent ouvrage eut la chance de pouvoir mener une courte étude, intensive, de la faune malgache, avec la généreuse coopération des autorités malgaches et des responsables du Centre O.R.S.T.O.M. de Tananarive. Avec le concours compétent de MM. John Williams d'Oakharn, Leics., Angleterre et Robert Glen, de Nairobi, et de Madame Noreen Curry, à l'époque de Winnipeg, Manitoba, Canada (actuellement en Californie), nous avons pu récolter assez d'exemplaires de plusieurs taxa pour être en mesure d'entreprendre une étude précise de leurs rapports systématiques.

Mais, une fois cette étude engagée, il apparut que la position systématique des taxa les plus proches, se retrouvant ailleurs, était, elle aussi, peu ou mal comprise ou même inconnue. Il devint, par suite, nécessaire d'étendre nos recherches bien au-delà des limites de Madagascar pour éclairer les affinites systématiques et zoogéographiques complexes, surprenantes, hautement intéressantes, de plusieurs formes.

Dans un certain nombre de cas, c'est le taxon malgache qui a fourni la clef des affinités existant entre taxa vivant en Afrique, en Asie ou ailleurs.

Plusieurs taxa malgaches restent encore insuffisamment connus et il faudra attendre qu'un matériel et une information plus riches soient réunis avant de pouvoir en entreprendre une étude satisfaisante. Le présent travail s'efforce de rassembler toute l'information disponible pour fournir la base des travaux futurs.

On sait, depuis longtemps, que la faune des Chiroptères malgaches est constituée par un mélange de formes à affinités zoogéographiques et systématiques différentes, avec des éléments endêmiques et d'autres liés aux faunes africaines, asiatiques ou pacifiques. Nous essaierons de préciser ces affinites, là où le matériel s'a vèrera suffisant.

Dans ce travail, nous essayons de combiner les résultats fournis par notre expérience personnelle, l'examen d'exemplaires vivants, la préparation et la récolte de spécimens destinés à la recherche, la description systématique traditionnelle et une étude statistique faisant appel à l'ordinateur et en utilisant des programmes de regroupement.

Peterson, R. L. and D. L. Harrison (1970). The second and third known specimens of the African molossid bat, *Tadarida lobata*.

A specimen of *Tadarida lobata* (Family Molossidae) from Salisbury, Rhodesia, in the David L. Harrison Collection and one recently taken on the Oxford University Expedition to the Cherangani Hills, Kenya, 1969, represent the second and third known examples of this species, originally described in 1891 from Turkwell, Suk, northwestern Kenya. The species is illustrated, and its pelage colour described for the first time. Photographs of the skin and skull are provided. Comparative measurements and discussion of taxonomic characteristics and systematic relationships are included.

Peterson, R. L. and D. W. Nagorsen (1975). Chromosomes of fifteen species of bats (Chiroptera) from Kenya and Rhodesia.

Karyotypes of 15 species of African Chiroptera (*Epomops franqueti, Epomophorus crypturus, E. gambianus, E. wahlbergi, Nycteris thebaica, Hipposideros caffer, Rhinolophus hildebrandti, R. darlingi, R. denti, Pipistrellus nanus, Eptesicus hottentotus, E, capensis, Scotophilus nigrita, Tadarida bivittata*, and *T. fulminans*) were studied. An XO male sex chromosome system was discovered in *E. crypturus* and *E. gambianus*. Distinctive marker chromosomes occurred in 14 species.

Peterson, R. L. and D. A. Smith (1973). A new species of *Glauconycteris* (Vesptertilionidae, Chiroptera).

In a systematic study of the African genus *Glauconycteris* Dobson, we have found a series of white-winged specimens that represent a new species that has not been previously described. The genera (or subgenera) *Chalinolobus* Peters of the *Australasian* region and *Glauconycteris* from Africa are closely related as discussed by Dobson (1875, 1878), Miller (1907), Ryan (1966), Hayman (1967), Hayman and Hill (1971), and Koopman (1971). Arguments have been advanced that all species belong to one genus (*Chalinolobus*), that the two should be considered subgenera, or that generic distinction should be retained for the two taxa, an option that has been widely followed in recent years. We tentatively recognize *Glauconycteris* as a genus pending the results of our own analysis of variation within each of the African species, now in progress.

We have compared the new taxon with all previously described species of *Glauconycteris*, but in our opinion, it needs critical comparison only with *G. argentata* (Dobson) and *G. variegata* (Tomes) as it differs so distinctly either in size or in pelage and wing coloration (or both) from all other known species. We are pleased to name this new species after Mr. Robert Glen, Nairobi, Kenya, who collected the holotype, assisted in the collection of the Uganda series of the new species, and who has been a field companion *extraordinaire*.

Pettigrew, J. D. (1991a). Wings or Brains? Convergent Evolution in the Origins of bats.

On the Monopophyly of bats .....

Pettigrew, J. D. and J. A. W. Kirsch (1998). Base-compositional biases and the bat problem. I. DNA-hybridization melting curves based on AT- and GC-enriched tracers.

We explored the interordinal relationships of mammals using DNA - DNA hybridization, with particular reference to the much-debated problem of whether the megabats and microbats are more closely related to each other than the megabats are to primates. To try to improve resolution when taxa are distantly related and the melting points of hybrids are low and difficult to distinguish, we increased the GC content of DNA by a fractionation method that used the same melting-point apparatus used in the hybridization studies. When we used GC-rich DNA as the tracer to make hybrids, the melting point of the self-hybrid shifted to a higher temperature as expected, but the behaviour of heterologous hybrids varied with the taxa being compared. When the melting point of the heterologous hybrid also shifted to a higher temperature so that the two compared taxa maintained the same or proportional distance, we called this 'following behaviour', because the heterologous hybrid made with GC-rich tracer 'followed' the GC-rich self-hybrid to higher temperatures, We also commonly saw anomalous behaviour, where the melting point of the heterologous hybrid shifted to a lower temperature when compared with an AT-rich hybrid. In these anomalous cases, the distance measured between the taxa increased markedly as a result of GC-enrichment, indicating that an underestimate of distance may have resulted from AT bias in DNA. This inference was supported by the finding that it was rare to observe a decrease in measured distance between taxa using GC-rich DNA, but very common to find an increase as would he expected from the generally higher AT contenls of eutherian DNAs. Moreover, the most extreme cases, where distances changed most using GC-rich DNA, were usually those involving comparisons between taxa known to have the most extreme AT-biases arnong mammals, such as the megabats and rhinolophoid (including megadermatid) microbats. Our results show consistent underestimates of measured differences between eutherian taxa with extreme AT-biases.

Pienaar, U. de V. (1964). The small mammals of the Kruger National Park - A systematic list and zoogeography.

The Kruger National Park, covering some 7,340 square miles in the north-eastern Transvaal Lowveld between 22° 25' to 25° 32' latitude south and 30° 50' to 32° 2' longitude east, forms an integral part of the southern savanna subregion of the great Aethiopian geographical region south of the Sahara (Darlington '57).

The secondary subdivision by Roberts (1951) of the primary biotic zones in Southern Africa into a number of secondary zoogeographical sub-zones acquires significance in an analysis of the distribution patterns of small mammals in the Kruger National Park and elsewhere. The area under consideration lies in what is designated by Roberts as the Eastern Low Country, with its inherently distinctive fauna and flora.

Although the Lebombo mountain range, forming the eastern boundary of the Park can not be regarded as a faunal barrier in the true sense of the word, it does exclude from the Transvaal Lowveld faunistically as well as florislically, a number of species which are essentially endemic to the eastern tropical littoral. At two points among the boundary line, however, an encroaching sandveld plateau from Moçambique carries with it a number of inhabitants of this zone into the extreme eastern sections of the Park (Pienaar, 1963).

Similarly, marginal encroachment of other typical inhabitants of the Natal and south-eastern Transvaal midlands, as well as the Eastern Transvaal forested area on the eastern side of the Drakensberg escarpment, is evident in the south-western portion of the Park.

As a broad basis for understanding the diversified faunal patterns of the Transvaal Lowveld, these subdivisions of biotic zones are important, but an interpretation of the individual distribution pattern of each small mamrnal species in the precincts of the area under discussion, and within the primary biotic zone, can only be sought in their specific habitat preferences.

Pienaar, U. de V. (1972). A new bat record for the Kruger National Park.

The first record of the Midas bat, *Tadarida (Mops) midas midas* (Sundevall), a large, tropical species of free-tailed bat, is noted from the vicinity of Skukuza, and it is also the first specimen of this species for South Africa.

Pierquin, L. (1960). Note complémentaire sur les tiques du Congo belge et du Ruanda Urundi.

L'auteur a examiné un lot de tiques provenant de diverses régions du Congo belge et du Ruanda-Urundi. Dans la présente note, il commente les acquisitions récentes dans la littérature, met à jour le répertoire qui comporte, sur un total de 67 espèces, 62 au Congo belge et 29 au Ruanda-Urundi, soit 24 communes aux deux pays; il termine par une liste des localisations nouvelles, en y incorporant ses propres identifications.

Pierquin, L. and K. Niemegeers (1957). Répertoire et distribution géographique des tiques au Congo belge et au Ruanda-Urundi.

Les auteurs ont dressé le répertoire des différentes espèces de tiques signalées pour le Congo belge et le Ruanda-Urundi, la distribution géographique de chacune d'elles, et la bibliographie complète des travaux les concernant.

Les auteurs se sont abstenus de prendre parti en faisant cette synthèse des publications sur la distribution géographique des tiques. Une étude critique dépasserait le but qu'ils se sont fixé, notamment de faire le point des connaissances actuelles, base de départ pour des travaux futurs.

Sur les 128 publications citées dans la bibliographie, 91 ont été consultées par les auteurs. Parmi les 37 publications non consultées, 24 sont antérieures à 1931, les renseignements qui s'y trouvent sont donc repris dans le "Synopsis" de BEQUAERT 1931. Quant aux 13 publications postérieures à 1931 et non consultées, elles concernent souvent des points litigieux repris par H. HOOGSTRAAL ou G. THEILER.

Il est remarquable qu'en reportant tous les lieux de récolte de tiques, renseignés dans la littérature, sur une carte du Congo belge et du Ruanda-Urundi, on arrive à couvrir la presque totalité de ces territoires.

Que les régions du Bas-Congo et du Kivu aient été plus fréquemment prospectées que la province de l'Équateur et que le Nord du Kasai, est fort compréhensible. Dans l'ensemble cependant, si l'on tient compte du fait que les premiers chercheurs récoltaient tout ce qu'ils trouvaient, sans viser plus spécialement une espèce plutôt qu'une autre, on peut admettre que nous avons une vue assez précise de la fréquence des espèces.

En ce qui concerne la distribution géographique, les espèces qui sont en nombre suffisant et bien localisées ont été reprises sur les cartes 1, 2 et 3. Pour d'autres espèces, le nombre de spécimens trouvés est trop peu élevé pour qu'il puisse être tiré des conclusions. Enfin, certaines espèces sont réparties sur l'entièreté des territoires.

Le présent travail ne se prête pas à être autrement résumé, et le lecteur interessé est invité à se référer au texte original.

De schrijvers hebben een tabel opgemaakt waarin de verschillende soorten teken opgesomd worden die in Belgisch-Congo en Ruanda- Urundi gevonden werden; tevens wordt de geografische verspreiding gegeven en een volledige bibliografie over de teken.

Zij geven een objektieve samenvatting van de publicaties handelend over de geografische verspreiding van de teken zonder echter zelf stelling te nemen. Het lag niet in hun bedoeling hier over een kritische studie te maken maar wel al wat tot nu toe hierover gekend is samen te brengen als basis voor latere opzoekingen.

De bibliografie citeert 128 publikaties, daarvan hebben de schrijvers er 91 bestudeerd. Onder de 37 niet geconsulteerde werken, zijn er 24 die dateren van voor 1931 en waarvan derhalve de gegevens te vinden zijn in de "Synopsis" van BEQUAERT (1931, 5). De 13 publikaties van na 1931 die niet geraadpleegd werden, handelen meestal over twistvragen die uitvoerig behandeld werden door H. HOOGSTRAAL en G. THEILLER.

Het is merkwaardig dat wanneer men alle vindplaatsen van teken, zoals zij opgegeven zijn in de litteratuur op een kaart van Belgisch Congo en Ruanda-Urundi aantekent, bijna alle gewesten aangestipt worden.

Dat de streken van Neder-Kongo en Kivu veelvuldiger geprospekteerd werden dan de Evenaarsprovincie en het noorden van Kasai is zeer begrijpelijk. Maar als men rekening houdt met het feit dar de eerste onderzoekers alles noteerden wat zij vonden, zonder voorkeur voor een bijzondere soort, dan mag men aannemen dat wij aldus ook een vrij nauwkeurig overzicht hebben van de frekwentie van de soorten.

Wat de geografische verspreiding aangaat werden de soorten, die een voldoende aantal malen gevonden werden en waarvan de vindplaars nauwkeurig opgetekend werd, weergegeven op de kaarten.

Voor andere soorten kan men wegens het te kleine aantal gevonden specimen geen besluit nemen. Tenslotte zijn bepaalde soorten over het gehele gebied verspreid.

Pine, R. H. (1993). A new species of *Thyroptera* Spix (Mammalia: Chiroptera: Thyropteridae) from the Amazon basin of northeastern Perú.

A new and large species of disk-winged bat of the genus *Thyroptera* Spix, sympatric with *Thyroptera tricolor* Spix, is named and described from the Departamento de Loreto, Peru. Morphological characters separating the new species from currently recognized species of *Thyroptera* are presented and characters which have been previously used to characterize these latter species are discussed and evaluated.

Une nouvelle et grande espèce de chauve-souris du genre *Thyroptera* Spix, sympatrique de *Thyroptera tricolor* Spix, est nommée et décrite du departernent de Loreto, Perou. Les caractères morphologiques qui separent la nouvelle espèce des espèces de *Thyroptera* actuellement reconnues sont présentés et les caractères qui étaient utilisés pour caractériser les espèces de ce genre sont discutés et evalués.

Poché, R. M. (1975). The bats of the National Park W, Niger, Africa.

Quinze espèces de Chiroptères ont été collectées dans Ie Parc National du W au Niger. Elles appartiennent à une famille de Mégachiroptères (1 espèce) et à sept familles (10 genres) de Mlcrochiroptères. Pour chacune l'auteur donne des précisions portant sur la reproduction, la répartition géographique et d'autres aspects de la biologie, ainsi que les mesures corporelles et crâniennes comparées à celles de spécimens de régions voisines.

This paper documents the first chiropterans collected from Niger's National Park W. A total of 15 species representing one family of Megachiroptera (1 species) and seven families (10 genera) of Microchiroptera was netted. Reproduction, geographic distribution and other aspects of the biology of each species are noted. Body and cranial measurements are recorded and compared with representatives from neighboring countries.

Pocock, R. I. (1935). The mammals collected in S.E. Arabia by Mr. Bertram Thomas and Mr. H. St. J. Philby.

Provisionally nominal lists of the mammals forming the subject-matter of this paper were published by my colleague, Capt. J. G. Dollman, in Mr. Bertram Thomas's 'Arabia Felix,' pp. 339 - 341, 1932, and in Mr. H. St. J. Philby's ' The Empty Quarter,' p. 394, 1933. But more detailed examination of the material and closer comparison of it with the skins and skulls of the same species already preserved in the British Museum, from Arabia and the adjoining countries of Asia, brought to light a number of unrecorded facts, showing that both the collections were instrumental in adding very considerably to our knowledge of the mammal fauna of south-western Asia.

Although Mr. Bertram Thomas secured a larger number of species and the representatives of all the new forms described, Mr. Philby's series is particularly valuable for the careful preparation of the skins, with a complete record of their flesh-measurements, localities, and dates. Only those who have had actual experience in the field can appreciate the time and labour expended over these processes. All the flesh measurements quoted were taken from his labels.

Poll, M. (1939). Mammifères de la région de Rutshuru recoltés par M.J. Ghesquière.

Dans deux articles successifs, le Dr. H. SCHOUTEDEN a eu l'occasion, dans cete Revue (*Rev. Zool. Bot. Afr.*, XXV, 3, 1934. et XXVI, 2, 1935) de décrire une première liste de Mammifères connus du Secteur méridional (Volcans) et du Secteur septentrional (plaines du lac Edouard) de la région située entre les lacs Kivu et Edouard et notamment du Parc National Albert.

Ces listes, déjà longues, donnaiend 65 espèces pour le Secteur méridional (où le Dr. SCHOUTEDEN lui-même fit des récoltes au cours d'un bref séjour en 1926) et 49 espèces pour le Secteur septentrional: soit au total 95 noms différents.

Pendant son séjour au Parc Albert, en 1933-35, M. DE WITTE a pu y réunir une collection de Mammifères à laquelle M. S. FRECHKOP a recemment consacré une étude dans laquelle 85 espèces sont signalées comme probables pour le Parc (*Institut des Parc Nationaux du Congo Belge. Exploration du Parc National Albert*, mission G. F. DE WITTE (1933, 1935). Fasc. 10. Mammifères. Bruxelles 1938.

Ainsi qu'en témoigne la série de Mammifères que M. J. GHESQUIERE a bien voulu envoyer au Musée du Congo Belge durant les années 1937 - 1938, il est encore possible d'allonger la liste des Mammifères de la région. Sur un total de 45 espèces réunies pare lui en région de Rutshuru, 8 espèces ne sont pas mentionnées dans les listes publiées par M. SCHOUTEDEN, et 10 ne figurent pas dans celle de M. FRECHKOP.

La région d'où proviennent les Mammifères envoyés par M. GHESQUIERE; c'est-à-dire la région de Rutshuru doit évidemment se rattacher en son ensemble au point de vue faunistique au Secteur septentrional du Parc Albert: M. SCHOUTEDEN l'a déjà indiqué, en signalant toutefois ainsi que je dis également le faire, que certaines localités ou zones se rattachen au contraire au fascies du Secteur méridional, montagneux.

Il m'a paru intéressant de donner l'inventaire complet de la collection de M. GHESQUIERE. Elle apporte, en effet, une contribution importante à la faune de la région. On notera cependant que M. GHESQUIERE s'est moins intéressé à la récolte des grands Mammifères, plus fréquemment rapportés, ainsi que

précisément le note M. SCHOUTEDEN. C'est ainsi que sa collection ne renferme qu'une seule Antilope et qu'il n'a pas rapporté des types fréquemment vus, tes les Topi, le Waterbuck, etc. De même le Lion, fréquemment noté par lui, notamment à 8 kms. de Rutshuru et en direction de Ngoma ne figure pas dans la liste des espèces récoltées, pas plus que l'Hyène, vue à deux reprises à Rutshuru même, le Léopard, noté entre Rutshuru et Ngoma, la Loutre à gorge tachetée, *Lutra maculicollis* commune à 17 kms. de Rutshuru et à 18 kms. vers l'intérieur à l'est de la route de Rutshuru à Ngoma, ni enfin la Phacochère, vu à 20 kms. au nord de Rutshuru.

Poulet, A. R. (1970). Les Rhinopomatidae de Mauritanie.

Des chauves-souris de la famille des Rhinopomatidae ont été capturées à Akjoujt (Mauritanie).

L'étude des mensurations corporelles a permis d'identifier *Rhinopoma microphyllum* Brunnich et *Rhinopoma hardwickei* Gray.

Les deux espèces vivent ensemble dans des grottes et des galeries de mines désaffectées.

R. microphyllum est déjà connue de l'Adrar mauritanien. *R. hardwickei*, signalée dans l'Air, est une espèce nouvelle pour la Mauritanie

Bats of the family Rhinopomatidae were captured at Akjoujt, Mauritania. *Rhinopoma microphyllum* Brünnich and *Rhinopoma hardwickei* Gray were identified by their body measurements. These two species live side by side in caves or in released mine galleries. *R. microphyllum* is already known from Adrar; *R. hardwickei*, previously reported from Aïr, is a new species for Mauritania.

Poulet, A. R. (1972). Recherches écologiques sur une savane sahelienne du Ferlo Septentrional, Senegal: Les mammifères.

Twenty eight species of wild mammals have been observed in the 100 km^2 area surrounding the 1 Km^2 reference quadral of Fété-Olé. Six other species have been found in similar habitats in the immediate vicinity and their occasional occurrence in the study area is theefore probable. During the last century most of the wild ungulates (and one large carnivore, the lion) have disappeared from the Ferlo and have been replaced by the cattle herds of nomadic Fulani tribesmen.

Taterillus pygargus is the commonest terrestrial rodent in the area. After a short period of juvenile nomadism (dispersion phase of the population) adults settle for life on very small home ranges. That of an adult female averages 300 m^2, and that of an adult male 1100 m^2. The home-range of an adult male overlaps those of several adult females. Gestation lasts 3 weeks and the most frequent litter size is 4 young. A female may have a litter every 6 weeks changing its burrow each time. However births only take place after the rains, from November to March. The population turnover is high, mortality rate among adults averaging 25 % per month. Data are given on population fluctuations over two consecutive years. Reproduction in a given year is strongly influenced by the importance of the previous rains. On quadrat QR, production (fresh weight was 392.8 g/ha in 1969-70 after "normal" rains, and only 12.1 g/ha in 1970-71 after sub-normal rains. On quadrat QF, the respective figures were 599.0 g/ha in 1969-70 and 63.6 g/ha in 1970-71. A first estimation of seeds is made: out of the 60 Kg/ha produced, 2.1 to 6.6 Km/ha are consumed by this species alone.

Püscher, H. (1972). Über die Schultertaschen von *Epomophorus* (Epomophorini, Pteropodidae, Megachiroptera, Mammalia).

Die Präparation der Kopf-Hals-Gegend mehrerer Vertreter der Tribus Epomophorini, Pteropodidae, ergab, daß eine spezielle Muskulatur vorhanden ist, die auf die Beweglichkeit der Tasche Einfluß nimmt. Ein Teil dieser Muskulatur leitet sich vermutlich von den Muskeln des Propatagiums ab.

Die histologische Untersuchung der Schultertaschen zeigte, daß sie keine speziellen Hautdrüsen enthalten und daher die Bezeichnung "Drüsentasche" nicht zutreffend ist.

Summary

Studies on the Shoulder Pouches in some Epaulet Bats

The region of the Shoulder pouches has been dissected in some epaulet bats. There are special muscles which can move the dermal pouch. It is supposed that these muscles may be derived from the musculature of the propatagium.

The skin of the shoulder pouch has been studied histologically, but no special cutaneous glands have been found, whereas a reduction of the sabaceous glands can be seen.

Pye, J. D. (1972). Bimodal distribution of constant frequencies in some hipposiderid bats (Mammalia: Hipposideridae).

Constant frequency echolocation signals of the Rhinolophidae and Hipposideridae have generally been found to occupy narrow bands, at least within single populations. Examination of three species of Hipposideridae from a cave in Kenya shows a wide spread of frequencies in each case. In *Hipposideros commersoni* the pulses occur in two bands at 56 and 66 kHz with a silent interval of 8 kHz. Single individuals in isolation use only one of these frequencies and this is correlated with their forearm length. It may be that two forms of subspecific rank were cohabiting, but it may be significant that the width of the silent band is just wide enough to prevent interference from band-spreading due to reflection from beating wings when several bats are flying together. In *Triaenops afer* and *Hipposideros caffer* there is a suggestion that the bats leave silent bands when in groups but use more varied individual frequencies when isolated. This impression might be due to sampling error and the position is little clarified by examining other populations. A group of *Asellia tridens* from Egypt occupied a single, fairly narrow band of frequencies. Further examination of these and other constant frequency species with a simple detector would be of interest in resolving the position.

Qumsiyeh, M. B. (1985). The bats of Egypt.

Egypt occupies the northeastern portion of Africa and provides the major connection between the land masses of Africa and Asia. As such, this area is an important connection between the Palearctic and Ethiopian faunas and a study of the composition of this fauna can prove very important.

This report reviews the systematics, zoogeography, and ecology of the bats of Egypt (including Sinai) based on the examination of available museum specimens, original field work, and literature review. The Medical Zoology Department of the U.S. Naval Medical Research Unit Number Three (NAMRU-3) in Egypt collected much of this material as part of other collections made on parasites and their mammalian hosts in Egypt. Most of the bat material collected by NAMRU-3 was preserved in alcohol and is deposited in the U.S. National Museum, Washington, D.C., and the Field Museum of Natural History, Chicago. Collectors for NAMRU-3 included H. Hoogstraal, Ibrahim Helmy, Sobhy Gaber, Sayed Metwally, Hassan Touhamy, W. H. Wells, G. M. Malakalis and various local field assistants particularly from the village of Abu Bawash. The land mammals observed or collected by NAMRU-3 were studied by Osborn and Helmy (1980). The present paper is intended to complement that study by focusing on the bats.

Numerous old reports exist dealing either in part or in total with the bats of Egypt. Several species of bats have been described by E. Geoffroy Saint-Hillaire in 1810, 1813, and in the monumental "Description de la Egypte" of 1818. Many of Geoffrey's original descriptions were augmented with figures and most of his names are still used. Later reports on bats of northeast Africa include those of Riippel (1842) and Heuglin (1861, 1877). Dobson's (1878) Catalogue of the Chiroptera at the British Museum includes many specimens from Egypt and presents an update of the taxonomic work at that

time. The earliest and most exhaustive treatment of the bats of Egypt is Anderson's (1902) Zoology of Egypt: Mammalia. This work also covered much of what is now the Sudan and treated specimens obtained by Anderson himself and the growing collection of the British Museum (Natural History) from the Nile Valley made by R. H. Brown, A. L. Butler, W. E. de Winton, S. S. Flower, W. Innes, J. Rogers, N. C. Rothschild, and others.

In 1932, S. S. Flower updated and reviewed Anderson's work, but restricted his discussion to Egypt in the modern sense (without Sudan). The section on Chiroptera in Flower's work was based on additional specimens acquired by the British Museum (Natural History) mainly through the efforts of the previously mentioned collectors, and those of L. W. Bough, M. Mackilligin, M. J. Nicoll, and W. H. Witherby, among others.

Professor Kamal Wassif of Ain Shams University in Cairo made extensive collections of mammals in Egypt and published several reports dealing with bats (1949, 1953, 1959a, b, 1962). Contributions to the morphology of Egyptian bats were made by Madkour (1961, 1975, 1976a-e, 1977c, d, 1978, 1982), Wassif (1969) and Wassif and Madkour (1963, 1969, 1971, 1972a, b, c, 1973, 1974). The collections made by NAMRU-3 were studied by Setzer (1952) for the Nile Delta region and later by Hoogstraal (1962). In addition, Sanborn and Hoogstraal (1955) presented a key to the identification of Egyptian bats. The most recent report is that of Gaisler, Madkour, and Pelikan (1972) who listed 21 species of bats for Egypt, including Sinai.

The taxonomy of Egyptian bats has been included in larger regional works such as Alien (1939), Ellerman and Morrison-Scott (1951), Hayman (1967), Hayman and Hill (1971), and Corbet (1978). Special reference must also be made to Kock's (1969) "Die Fledermaus-Fauna des Sudan" and Koopman's (1975) "Bats of the Sudan." Both of these excellent works extend their taxonomic and zoogeographical discussions to bats occurring in the Nile Valley.

The material examined is the largest collection of Egyptian bats available for a single review, and most of it has been little examined in the previous works. Though the present work is not intended to be a final answer to even some of the basic questions of chiropteran taxonomy in Egypt, it seems timely to review the available knowledge and to summarize previous contributions. Egyptian bats do not seem to play a role in the transmission of rabies (El Sabban et al., 1967) or any other human disease (Dr. Harry Hoogstraal, personal communication). Only one species, *Rousettus aegyptiacus*, is suspected of becoming an economic menace (Madkour, 1977a). Inasmuch as all Egyptian bats but this one are insectivorous, it would be ecologically and economically harmful to apply such control measures as fumigating caves and ruins. In Israel, this kind of treatment resulted in the almost complete extinction of many useful insectivorous bats and the target species, *Rousettus*, still survives in large numbers. Much field work remains to be done, especially from an ecological perspective, and it is hoped that the present review at least would spark an interest in this fastdeveloping country, especially in nature protection and management.

Qumsiyeh, M. B., Z. S. Amr and R. M. Al-Oran (1998). Further records of bats from Jordan and a synopsis.

Recent records along with a synopsis of the known bats of Jordan are given. Twenty-four species of bats are reported from Jordan, including two additional records, *Rhinolophus mehelyi* and *Asellia tridens*. Five other bat species are suspected to occur.

Qumsiyeh, M. B., A. M. Disi and Z. S. Amr (1992). Systematics and distribution of the bats (Mammalia: Chiroptera) of Jordan.

The order Chiroptera (bats) represent the second (second only to the rodents) most diverse group of mammals, with some 950 species known. Most species of bats belong to the suborder Mlcrochiroptera or insect-eating bats. In Jordan, there is only one species of fruit-eating bat (suborder Megachiroptera); the Egyptian fruit-eating bat, *Rousettus aegyptiacus*. The extent of damage this species causes to certain crops in Jordan is unknown, and ecological studies are needed. On the other hand, this species

Is known to help pollinate many of the fruit trees on which it feeds. Thus, all but perhaps one species of bats in Jordan are highly beneficial. Their role in controlling agricultural pests and as an Integral part of the balanced ecosystem cannot be overemphasised. Yet, there is continuous habitat destruction accompanying development in Jordan. Many bat caves are visited frequently or used by humans, which results In the loss of the bat populations inhabiting these caves. Conservation efforts in Jordan by concerned citizens under the guidance of the Royal Society for the Conservation of Nature (RSCN) would benefit significantly by the presence of baseline data on the distribution and status of bats in Jordan.

There are very few studies of bats in Jordan, and our knowledge of the bat fauna Is still preliminary. Recent field work in Jordan yielded significant new records and distributional data. We are presenting these data here as well as reviewing our knowledge of the bat fauna of this region. Keys to the species of bats occurring or potentially occurring in the region can be found in previous publications.

Qumsiyeh, M. B., R. D. Owen and R. K. Chesser (1988). Differential rates of genic and chromosomal evolution in bats of the family Rhinolophidae.

Data for nondifferentially stained chromosomes from 10 species of *Rhinolophus* (Chiroptera: Rhinolophidae) suggest a conserved chromosomal evolution. G-banded chromosomes for three well differentiated species (*Rhinolophus hipposideros, Rhinolophus blasii*, and *Rhinolophus acuminatus*) corroborate a low level of gross chromosomal rearrangements. Additionally, a comparison between G-banded chromosomes of *Rhinolophus* (Rhinolophidae) and *Hipposideros* (Hipposideridae) suggests extreme conservatism in chromosomal arms between these two distantly related groups. On the other hand, we report extensive genic divergence as assayed by starch gel electrophoresis among these 10 species, and between *Rhinolophus* and two hipposiderid genera (*Hipposideros* and *Aselliscus*). The present chromosomal data are not sufficient for phylogenetic analysis. Phylogenies based on electrophoretic data are in many aspects discordant with those based on the classical morphological criteria. Different (and as yet not clearly understood) evolutionary forces affecting chromosomal, morphologic, and electrophoretic variation may be the reason for the apparent lack of concordance in these independent data sets.

Des données sur la coloration non-différentielle des chromosomes de 10 espèces de *Rhinolophus* (Chiroptera: Rhinolophidae) suggèrent une évolution conservatrice des chromosomes. Les bandes G des chromosomes de trois espèces bien differenciées (*Rhinolophus hipposideros, Rhinolophus blasii* et *Rhinolophus acuminatus*) corroborent l'existence d'un faible niveau de réarrangements palpables des chromosomes. De plus, une comparaison entre les bandes G des chromosomes de *Rhinolophus* (Rhinolophidae) et d'*Hipposideros* (Hipposideridae) suggère un conservatisme extrême des bras chromosomiques entre ces deux groupes relativement distants. D'autre part, des électrophorèses sur gel d'amidon permettent de rapporter l'existence de differences géniques extensives entre ces 10 especes, ainsi qu'entre *Rhinolophus* et deux genres d'Hipposideridae: *Hipposideros* et *Aselliscus*. Les présentes données chromosomiques sont insuffisantes pour les fins d'analyses phylogénetiques. Les phylogénies basées sur les données obtenues par electrophorèse basées sur les critères morphologiques. Ce manque apparent de concordance entre groupes de données independants pourrait bien relever de forces évolutives différentes, qui affectent la variation chromosomique, morphologique et électrophoretique.

Qumsiyeh, M. B. and D. A. Schlitter (1981). Bat records from Mauritania, Africa (Mammalia: Chiroptera).

The occurrence of seven species of bats previously unknown in Mauritania are documented, making a total of 11 species of bats recorded from the country. The new records include *Taphozous perforatus, Nycteris hispida, Hipposideros caffer, Asellia tridens, Pipistrellus rueppelli, Scotophilus leucogaster*, and *Tadarida condylura*. Additional information is provided on three species of bats (*Rhinopoma hardwickei, R. microphyllum*, and *Nycticeius schlieffeni*) already known to occur in Mauritania.

Qumsiyeh, M. B. and D. A. Schlitter (1982). The bat fauna of Jabal Al Akhdar, Northeast Libya.

Fifty nine specimens of bats representing eight species in three families are reported from the region of Jabal Al Akhdar in northeastern Libya. *Nyctalus lasiopterus* is reported for the first time from Africa, while *Pipistrellus pipistrellus, Miniopterus schreibersii* and *Tadarida teniotis* are new additions to the fauna of Libya. *Rhinolophus clivosus, R. mehelyi, Pipistrellus kuhlii*, and *Plecotus austriacus* are additional distributional records from Libya. Taxonomic comments are given. Although distinctive, the bat fauna of Jabal Al Akhdar is considered of Mediterranean origin and includes taxa seemingly closely associated with those from southcentral Europe rather than the Eastern Mediterranean and Maghreb regions.

Qumsiyeh, M. B., D. A. Schlitter and A. M. Disi (1986). New records and karyotypes of small mammals from Jordan.

Presented new distributional records for 14 species of mammals in Jordan. Of these, two species of bats are new to the fauna of the country, *Myotis capaccinii* and *M. emarginatus*. Karyotypic data are presented for 11 species that have not been previously studied from Jordan. The diploid number in *Rhinolophus hipposideros* from Jordan is different from that reported for European specimens. The rare *Gerbillus nanus* is confirmed in Jordan by karyotypic data. *Acomys lewisi* has the same chromosome number as *A. russatus*, a fact which is compatible with the idea that these two forms are conspecific.

Rahm, U. (1965). Distribution et écologie de quelques mammifères de l'est du Congo.

Si on mettait sur carte la répartition de tous les mammifères existants au Congo, on remarquerait une grande lacune dans la partie est de ce pays, entre le fleuve Congo et le Graben Centre-Africain. Grâce au matériel récolté jadis par Lang et Chapin et par Christy dans le nord-est du Congo, nous connaissons assez bien les mammifères de cette région. Le Ruwenzori et les volcans au nord du lac Kivu ont été explorés par plusieurs missions scientifiques. Nous nous sommes efforcés depuis 1958, d'explorer au moins une partie de la région forestière de l'est du Congo afin de connaître les mammifères y existants. Nous avons particulièrement prêté notre attention à la région située entre le premier et le quatrième parallèle sud et délimitée par le fleuve Congo et le Graben Centre-Africain. Politiquement, cette région du Congo comprend une grande partie de la Province du Kivu ct au point de vue botanique elle se compose de forêt équatoriale, de forêt de montagne et de prairies de montagnes (carte 1).

La forêt équatoriale (ou forêt dense humide) de notre région explorée est du même type que celle au nord-est du Congo. Nous y avons récolté jusqu'à présent 86 espèces de mammifères, les crocidures non comprises. Notre recensement a démontré que la faune de la forêt équatoriale de l'est du Congo ne diffère guère de celle connue de la forêt de l'Ituri au nord-est du Congo. Par contre le fleuve Congo représente une barrière zoogéographique importante vers l'ouest et de nombreuses espèces de mammifères n'existent pas sur la rive gauche de ce fleuve. Parmi ceux-ci nous ne citons que quelques-uns: *Cercocebus albigena, Gorilla gorilla, Pan troglodytes, Cercopithecus hamlyni, Cercopithecus l'hoesti, Galago inustus, Rhynchocyon stuhlmanni, Genetta victoriae, Osbornictis piscivora, Hylarnus harrisoni, Funisciurus pyrrhopus, Tamiscus alexandri, Idiurus, Anomalurus pusillus, Deomys ferrugineus*.

La forêt de montagne à l'ouest du lac Kivu est semblable à celle qu'on trouve tout le long du Graben. *Lophuromys woosnami, Thamnomys kempi, Aethosciurus ruwenzorii, Funisciurus carruthersi* et *Chlorotalpa stuhlmanni* sont des représentants typiques de ces montagnes. La forêt équatoriale et la forêt de montagne ont plusieurs espèces en commun, d'autres ne se trouvent qu'en forêt équatoriale et font défaut en forêt de montagne (voir graphiques et cartes).

Nous donnons ci-après des notes et cartes sur la répartition de quelques mammifères qui sont d'un intérêt particulier.

Rahm, U. (1966). Les mammifères de la forêt équatoriale de l'est du Congo.

Le but de cette publication est de donner un aperçu des mammifères de la forêt équatoriale de l'Est du Congo. Le Nord et le Nord-Est du Congo ont été explorés par plusieurs naturalistes, notamment par LANG et CHAPIN, et par CHRISTY, mais nous avons très peu de données concernant les mammifères de la région forestière de l'Est du Congo. La région explorée est située, grosso modo, entre le Graben Centre Africain et le fleuve Lualaba-Congo d'une part, et entre les fleuves Lowa-Oso et Elila (à peu près entre 1° S et 30° 30' S) d'autre part.

Nous avons effectué un voyage le long de la Lowa en 1960 et M. CHRISTIAENSEN a parcouru la région de Shabunda en 1959. La plus grande partie de notre étude a été faite dans la région d'Irangi et dans les alentours de Niamiringi, où nous avons séjourné plusieurs fois depuis 1959. A Niamiringi, nous avons joui de l'hospitalité de M. et M^{me} Ch. CORDIER qui y séjournèrent jusqu'en 1960; à Irangi, l'IRSAC possède un gîte bien aménagé.

Après avoir étudié les mammifères de la région occidentale du lac Kivu (RAHM et CHRISTIAENSEN, 1963), nous souhaitions comparer la faune de la forêt de montagne de la dorsale du Kivu avec celle de la forêt équatoriale à l'Ouest du Graben Centre Africain. Un aperçu général de l'écologie et de la répartition de quelques mammifères a été publié ailleurs (RAHM, 1965).

Au point de vue botanique la région explorée se compose de forêt équatoriale à *Macrolobium* et de forêt équatoriale non caractérisée (carte 2). La plupart des villages sont situés le long des routes. Près des villages habités ou abandonnés, il y a généralement de la forêt secondaire, des champs indigènes ou de la brousse à *Pennisetum*. Dans la région d'Irangi et de Niamiringi, les bananeraies sont particulièrement nombreuses.

Rahm, U. and A. Christiaensen (1966). Les mammifères de l'île Idjwi (Lac Kivu, Congo).

Dans le cadre d'une étude sur les mammifères de l'Est du Congo et du Graben Centre Africain, un recensement des mammifères existant sur l'île Idjwi a été effectué par intermittence en 1959 et 1960. Idjwi est de loin la plus grande île du lac Kivu dont elle occupe l'axe Nord-Sud. Elle a une longueur d'un peu plus de 40 km et une largeur maximale de 10 km. Idjwi est extrêmement montagneuse, le plus haut sommet dépassant 2.200 m d'altitude, alors que le niveau du lac Kivu est de 1.463 m. La moitié Nord de l'île est de moindre altitude que le centre et le Sud.

D'après la carte géologique du Kivu par BOUTAKOFF (1939) le Sud-Ouest d'Idjwi est recouvert de laves basaltiques anciennes, tandis que le restant de l'île est formé de roches du système de la Ruzizi, ainsi que de granites. Les terrains alluvionnaires récents sont d'étendue très limitée (voir carte). Le lac Kivu occupe une cuvette du Graben Centre Africain, formée par des épanchements de lave qui ferment le lac au Nord et au Sud; au Nord, issus des volcans récents des Virunga et au Sud, issus des monts Biega, Kahuzi et autres centres volcaniques datant de lafin de l'ère tertiaire. L'âge de ce lac, et donc l'âge d'Idjwi en tant qu'île séparée de la terre ferme, doit être de l'ordre de 10.000 à 15.000 ans.

Les pluies sont abondantes sur Idjwi (environ 1.500 mm par an) et interrompues par une saison sèche, de sévérité variable suivant les années, durant les mois de juin, juillet et août et une partie des mois de mai et septembre. Une petite saison sèche, d'une durée d'une quinzaine de jours, s'intercale parfois au sein de la période pluvieuse, vers le mois de décembre ou janvier. La majeure partie de l'île Idjwi est déboisée, bien qu'un très beau massif de forêt de montagne en occupe la partie centrale qui est, en même temps, le point le plus élevé. La composition de cette forêt est identique à celle des forêts de montagne de la dorsale Ouest du Graben il altitude égale (fig. 2). Quelques parcelles de forêt de faible étendue subsistent au bord du lac, surtout dans le Nord de l'île. L'arbre dominant y est *Newtonia buchanani*, qu'accompagnent quelques *Schrebera alata*. On y rencontre comme végétal épiphyte fréquent la très belle et très grande orchidée *Ansellia africana*, sous les touffes desquelles s'abritent

souvent des petites colonies de chauves-souris. Les collines sont couvertes, sur de larges étendues, de savanes plus ou moins arborées, parmi lesquelles notons: *Albizzia gummifera, Erythrina abyssinica, Putada abyssinica, Millettia dura, Bridelia micrantha, Fourea* sp., divers *Ficus, Sapium ellipticum*, etc., toujours chargés de nombreuses plantes grimpantes. La graminée *Hyparhenia cymbaria* domine dans les savanes nues au niveau du lac (fig. 3). On trouve également des massifs de *Pennisetum purpureum* et des collines entières couvertes de *Pteridium aquilinum*. Quelques plantations industrielles de caféiers se rencontrent au Sud-Ouest et à l'extrémité Nord de l'île. Un grand boisement d'*Eucalyptus* couvre la presqu'île de Mamvu.

L'île est habitée par l'ethnie des Bahavu, qui peuple la plupart des îles du lac Kivu, ainsi que la partie centrale de la côte Ouest. L'occupation humaine est surtout très dense au Sud du massif forestier central. Cette région est très cultivée et on y remarque d'immenses bananeraies servant principalement à la fabrication de bière. Les principales cultures vivrières sont les haricots, le sorgho et le manioc (*Manihot utilissima*). On rencontre partout des petits troupeaux de grand et de petit bétail. Au dire des autochtones, le gros bétail serait en régression par suite du recul des pâturages, causé tant par l'extension des cultures vivrières que par la diminution de fréquence des feux de brousse contre lesquels oeuvre ou oeuvrait l'Administration; ce qui a permis par ailleurs un reboisement et une pullulation progressive des broussailles en savane.

Feux de brousse, déboisement, reboisement et broussailles ont vraisemblablement eu une influence sur la faune de l'île, spécialement sur les mammifères.

A cause des événements politiques de 1960, nous n'avons pu malheureusement explorer l'extrême Sud-Est de l'île.

Antérieurement à notre prospection, quelques récoltes avaient déjà été faites par ALLEN et LOVERIDGE (1942) (voir "Conclusions").

La méthode de travail fut celle que nous avons utilisée lors de nos enquêtes précédentes. Les piégeages ont été effectués avec des "clapettes à rats" et lies "Oxford Longworth".
L'indicatif "L" et les numéros mentionnés au paragraphe "Collection" se réfèrent à la collection qui se trouve à l'IRSAC-Lwiro.

Rand, A. L. (1935). On the habits of some Madagascar mammals.

The following notes were made during the period 1929 - 1931, while I was collecting birds and mammals as member of the Mission Zoologique Franco-Anglo-Américaine à Madagascar. General accounts of the work of this expedition have been published by Jean Delacour (1930) and myself (1932).

A partial list of the mammals secures has been published by Delacour (1932), but the collection as a whole has not been critically studied. The present paper consists of field observations, made by myself unless otherwise stated.

Rautenbach, I. L. (1985). A new technique for the efficient use of Macro-mistnets.

A cheap and simple method of adapting yacht masts to allow quick and efficient stringing and versatile manipulation of a 6,0 * 30,0 meter macro-mistnet, is described

Rautenbach, I. L. (1986). Karyotypical variation in Southern African Rhinolophidae (Chiroptera and non-geographic morphometric variation in *Rhinolophus denti* Thomas, 1904.

Karyotypical properties of all ten species of Southern African *Rhinolophus* are evaluated as a parameter for clarifying species identities. No interspecific variation in diploid numbers, minor variation in fundamental numbers and a greater degree of variation in sex chromosomes render this technique of limited value concerning rhe confirmation of species identities. A series of 104 specimens of *R. denti* from the northern Cape Province, South Africa, is analysed for nongeographic variation. Significant variation is recorded betwen sexes in five mensural characters.

Rautenbach, I. L., G. N. Bronner and D. A. Schlitter (1993). Karyotypic data and attendant systematic implications for the bats of southern Africa.

The standard karyotypic properties of 60 of the 73 species of bats known to occur in southern Africa, are reviewed. The karyotypes of 23 microchiropteran species are described for the first time; our results on a further 14 species are compared with earlier reports for those taxa. The previously published chromosomal information pertaining to 23 species for which we had no information, are cited. Systematic implications of observed patterns of karyotypic variation are briefly discussed. In particular, we conclude that the taxon *Cistugo* (currently recognised as a subgenus of *Myotis*) should be afforded full generic rank; hypothesise that the karyotypes of the two species - *M. (C) seabrai* and *M. (C) lesueuri* - in *Cistugo* are probably ancestral for all vespertilionids; and question the wisdom of redefining the taxonomic limits of the genera *Eptesicus* and *Pipistrellus* until molecular data are available to resolve the dilemma posed by conflicting morphological and cytogenetic data suites.

Rautenbach, I. L., G. De Graaff and U. de V. Pienaar (1979a). Records of seven small mammal species (Insectivora, Chiroptera) new to the Kruger National Park.

On a recent collecting expedition in the Kruger National Park the occurrence of seven species of small mammals (one shrew and six bats) within the confines of this sanctuary was confirmed for the first time. One species (*Pipistrellus rusticus*) is reported for the first time from within the borders of the Transvaal, whereas another species (*Myotis bocagei*) is reported for the first time for the Republic of South Africa. The seven
species are briefly discussed and the collections where the specimens have been accesioned are indicated.

Rautenbach, I. L., N. J. Dippenaar, J. Meester and D. A. Wolhuter (1981a). The status of Southern African mammal taxonomy. Abstract.

A generally accepted belief persists within the ranks of zoologists that the 'taxonomy' of southern African small mammals are adequately documented; that the classificatory frameworks are near finite; that nomenclatural problems are resolved in the greatest majority of taxa; and that infraspecific variation is so well understood as to render further collecting and taxonomic study superfluous or of trivial importance.

Meester (1954), followed by Ansell (1958), Meester, Davis and Coetzee (1964), as well as Meester and Eloff (1973) reviewed the status of the taxonomy of the small mammals of this subcontinent, whereupon all stressed the need for continued and more detailed taxonomic work. Regardless of this circumscribed need, little was being done at that time. Since then some powerfull taxonomic procedures (*viz.* multivariate morphometric analyses, cytotaxonomy) were incorporated in local taxonomic research endeavours. In the light of such powerful but demanding taxonomic procedures, we have re-examined the status of southern African small mammal taxonomy.

We conclude that in southern Africa, not only does the progress in taxonomic research fail to keep up with contemporary work on European and North American mammals, but is in fact falling progressively further behind. A discussion on possible causes for this situation is offered. It is our belief that in southern Africa in particular and Africa in general, enough important taxonomic work within the field of small mammal taxonomy remains to occupy the fulltime attention of a score of taxonomists. Concern is expressed that unless the rates and standards of taxonomic research on local small mammals are significantly increased, much time, energy, funds and manpower could be applied uneconomically and in vain in those disciplines of mammal research relying on a sound classification.

Rautenbach, I. L., M. B. Fenton and L. E. O. Braack (1985). First records of five species of insectivorous bats from the Kruger National Park.

Five: species of insectivorous bats arc reported time from the Kruger National Park. One of these, *Pipistrellus anchietai*, represents a new record for the southern African Subregion, and two *Laephotis botswanae* and *Nycteris woodi* are recorded for the first time for the Republic of South Africa. The remaining species, *Eptesicus melckorum* and *Tadarida ansorgei* are first records of occurrence for the Transvaal. The species richness of the bat fauna of the Kruger National Park, and particularly of the Pafuri area, is reviewed.

Rautenbach, I. L., M. B. Fenton, A. C. Kemp and S. J. Van Jaarsveld (1990). Home range and activity of African goshawk *Accipiter tachiro* in relation to their predation on bats.

Winter radio-tracking of three African goshawks *Accipiter tachiro* showed that they each occupied well-wooded home ranges of at least 28 hectare. They perched and roosted mainly within densely foliaged tree and an adult female changed perches on average 4,7 times per hour. No crepuscular predation of bats was recorded, in contrast to regular summer predation on colonies of little free-tailed bat *Tadarida pumila*, but winter emergence rates of these bats at dusk had dropped to <= 5 % of the previous summer. We predict that many accipiters will be regular predators of bats and that skewed sex ratio and high fecundity may be two means by which bats counter this predation.

Rautenbach, I. L., M. B. Fenton and M. J. Whiting (1996). Bats in riverine forests and woodlands: a latitudinal transect in southern Africa.

Using captures in mist nets and monitoring echolocation calls, we quantified bat distribution and activity and measured insect abundance as numbers of insects attracted to black lights at 15-min intervals. These data were collected simultaneously at pairs of sites in riverine and dry woodland savannah along a transect of ca. 350 km from north to south in the Kruger National Park, South Africa. The sites were situated in the north, central, and south of the park and data were collected in January 1993. Our study involved 18 sites, three pairs each in the areas of the Luvuvhu, Letaba, and Sabie rivers. Half of the sites were in riverine woodland, the others in dry woodland. No statistical association exists between bat captures and either bat activity or insect abundance. Bat activity, however, was related significantly to insect abundance. Although bats were significantly more abundant (captures) in riverine habitats than in dry woodland savannah, comparisons of bat diversity and evenness (rarefaction curves, species abundance curves, and Whittaker plots) showed no differences between these habitats. The data neither demonstrate a decline in bat diversity away from the equator nor suggest specific bat communities associated with riverine habitats. The data do demonstrate the important influence of insects on the activity patterns of insectivorous bats.

Nous avons utilisé des données sur la capture dans des filets japonais et des enregistrernents de cris d'écholocation pour quantifer la répartition des chauves-souris et leurs activités et nous avons également rnesuré l'abondance des insectes capturés dans des pièges aux ultra-violets a 15 min d'intervalle. Les données ont été recueillies simultanément a des paires de sites, dans un habitat riverain et une savane boisée sèche, Ie long d'un transect nord-sud d'environ 350 km dans Ie parc

national de Kruger en Afrique du Sud. Les sites étaient situés dans les parties nord, centre et sud du parc et les données ont été recueillies en janvier 1993. Nous avons choisi 18 sites, trois paires à chaque endroit, soiit dans les bassins des rivières Luvuvhu, Letaba et Sabie. La moitié des sites se trouvaient dans des milieux riverains boisés, l'autre rnoitié dans des milieux secs boisés. Aucune relation statistique n'a été trouvée entre le nombre de chauves-souris capturées et leur activité ou l'abondance des insectes. L'activite des chauves-souris était cependant en correlation significative avec l'abondance des insectes. Les chauves-souris étaient significativement plus abondantes dans les captures éffectuées en milieu riverain qu'en milieu sec, mais la comparaison entre la diversité des chauves-souris aux deux endroits et leur regularité (courbes de rarefaction, courbes d'abondance des espèces et diagrammes de Whittaker) n'a révélé aucune différence entre ces deux types d'habitats. Les données n'indiquent pas de diminution de la divérsite des chauves-souris a mesure qu'on seloigne de l'equartur et ne signalent pas non plus l'existence de communautes de chauves-souris spécifiques des habitats riverains. Les données soulignent cependant l'influence importante des insectes sur l'activité des chauves-souris insectivores.

Rautenbach, I. L., A. C. Kemp and C. H. Scholtz (1988). Fluctuations in availability of Arthropods correlated with Microchiropteran and Avian predator activities.

Aerial arthropods were sampled by driving a standard transect along the riparian forest of the Luvuvhu River, South Africa, to assess hourly and seasonal variations in available biomass. Sampling, with an air-plankton net mounted on a vehicle, was conducted hourly over 48-hour period during the fullest phase of the moon for each of eight months during 1986/87. Seasonal variation in availability of terrestrial arthropods was assessed by means of six pitfall traps set in the riparian forest. On a daily basis the available biomass of aerial arthropods was found to increase markedly at and during the two hour following sunset, with a slight peak at or in the two hours preceding dawn. Highest monthly availability was found to correspond with the warm summer rainy season, with a marked increase after the first rains. The peak for terrestrial arthropods was found to occur later in the summer than for aerial arthropods. These patterns of arthropod availability correlate well with the daily activity rhythms and seasonal reproduction of microchiropteran bats and their avian predators.

Rautenbach, I. L. and J. A. J. Nel (1978a). Coexistence on Transvaal Carnivora.

How coexisting carnivore species avoid interspecific competition is examined by consideration of their more prominent physical and behavioral characteristics. An attempt is made to explain coexistence of the 33 Transvaal carnivore species. The behavioral characteristics, which are considered here in various combinations, are daily activity regimen, food preference, habitat preference, geographical distribution, and social structure. The mean species body weight as an indicator of the size of prey on which a carnivore exists is also incorporated. Eighty-two % of the carnivores are shown to form a trend ranging from a nocturnal/solitary mode of life to an entirely diurnal/gregarious existence.

Rautenbach, I. L. and J. A. J. Nel (1978b). Three species of microchiropteran bats recorded for the first time from the south-west Cape Biotic zone.

New distribution records are reported for three species of bats. The presence of *Tadarida (Tadarida) aegyptiaca* in the South-West Cape biotic zone is confirmed. *Tadarida (Chaerephon) pumila* is recorded for the first time from the Cape Province, whereas the known range of *Laephotis wintoni* is shown to extend some 1 000 km further south than previously recorded, to within the borders of the Republic of South Africa.

Rautenbach, I. L. and J. A. J. Nel (1980). Mammal diversity and ecology in the Cedarberg wilderness area, Cape Province.

This report deals with the results of mammal surveys in the Cedarberg Wilderness Area, Cape Province, Republic of South Africa. Specimens collected by a combined Transvaal Museum/University of Pretoria (Department of Zoology) expedition during February 1978, as well as unreported material previously accrued by the Smithsonian Institute's 'African Mammal Project' field teams, are dealt with. Material and/or other records of the 50 mammal species now known to occur in the study area, are reported. Ecological aspects of some smaller mammals are discussed, such as trapping results, species diversity and relative densities, cover preference and breeding activity.

Rautenbach, I. L., J. A. J. Nel and G. A. Root (1981b). Mammals of Itala Nature Reserve, Natal.

Itala Nature Reserve is situated in rolling hills south of the Pongola river. Historically the area was in the Vryheid Republic, and bordered on South Africa's first game reserve, the Ponzola Game Reserve. Proclaimed in 1973 with an area of 8094 ha, Itala was subsequently enlarged through the acquisition of additional farmland to its present size of 26 305 ha. While parts of the present reserve are in a fairly pristine state, others have been farmed or were the sites of kraals. These are still, and will rernain so for many years to come, in a state of floristic and presumably also faunal succession. As the process of recovery from farming practices continues the species surviving at the time of proclamation, as well as those reintroduced, will in all probability resettle those areas occupied historically.

The geographical position and variation in topography, altitude, climate and vegetation types of !tala Nature Reserve present an area of great ecological and zoogeographical interest with which to compare the mammal fauna of other parts of southern Africa. The present paper documents the current state of the mammal fauna, and also lists those species known to occur in the past, but now absent.

Rautenbach, I. L., D. A. Schlitter and L. E. O. Braack (1984). New distributional records of bats for the Republic of South Africa, with special reference to the Kruger National Park.

Data on the distributions of seven species of bats in South Africa are discussed. Four species, *Hipposideros commersoni, Pipistrellus rueppellii, Tadarida ansorgei* and *T. fulminans* are reported for the first time from South Africa and all but *T. ansorgei* from the Kruger National Park. *Rhinolophus simulator* and *Kerivoula lanosa* are recorded for the first time from the Kruger National Park. The subspecies relationship of *Eptesicus hottentotus* in the eastern part of South Africa is reviewed.

Rautenbach, I. L., D. A. Schlitter and G. de Graaff (1979b). Notes on the mammal fauna of the Augrabies falls National Park, and surrounding areas, with special reference to regional zoogeographical implications.

An annotated checklist of the mammals recorded by direct or indirect means on or near the Augrabies Falls National Park, is provided. Speculations are offered as to which species have become extinct during historical times. The Orange River as a faunal dispersal corridor and barrier, is considered. A numerical analysis to determine whether the Augrabies Falls district falls within the Namib or the South West Arid biotic zone, is discussed.

Rees, A. (1964). A check list of the mammals and amphibia of Ulanga District.

The following list of animals found in Ulanga Range is submitted, not only as part of the natural history records of this District, but also as an indication of the variety of wildlife to be found in a comparatively small area of Tanganyika. Many, in fact most, of the animals listed occur in the Selous Game Reserve, and some, such as Sharpes grysbuck and Impala have not been recorded outside the Reserve.

No attempt has been made to comment on the distribution of the animals listed, as considerably more collecting and wider observation is needed.

Apart from the larger and more easily identifiable mammals only those which have been collected personally and identified by some competent authority have been listed.

Large gaps occur, notably in the *Murinae, Herpestinae* and *Soricidae*. Very few specimens have been collected from these groups. The *Chiroptera* however have been dealt with more thoroughly and members of this order which are not listed but which may occur in this range are probably rare, very locally distributed. or by their habits or habitat, solitary and difficult to collect.

The absence of *Platymops* from the records of Tanganyika mammals is, for example, probably more likely to be due to a lack of collectors than to the non-occurrence of this bat.

In this district I have managed to collect only a single specimen of *Trianops afer*, a bat which is reputed to live in caves and which should not, one would think, be so elusive.

Notes on a collection of snakes were published in the "Tanganyika Notes and Records" (Vol 54 of March 1960). Dr. Freyvogel has since done more collecting and it is hoped that he may soon be able to add to the list.

It is emphasised that the following list is far from complete and it is only offered as a basis for further collecting and study.

Little is known about the habits and food preferences of even the larger mammals, particularly in the type of country occuring in this District and through most of the Selous Game Reserve, and a study of the association of the animals with various vegetational types would be both interesting and valuable.v- and would, of course have an important and direct bearing on conservation problems.

The local migration of elephant and buffalo, the extremely local occurence of puku, the irregular and local distribution of greater kudu in the Western Selous Reserve, and the probability of certain species of grass having an important effect, when in various stages of maturity, on the movement and distribution of the animals which occur, are all phenomena which could perhaps be understood with a greater knowledge of the feeding habits of these animals.

Reuven, Y. (1991). Foraging habits, hunting and breeding success of Lanner Falcons (*Falco biarmicus*) in Israel.

The distribution of Lanner Falcons (*Falco biarmicus*) is restricted to the Mediterranean region and Africa. During 1987-89, data were collected on foraging habits and reproductive success on two breeding pairs of Lanner Falcons at Sede Boqer, in the Negev Desert highlands, Israel. Three hundred and thirty two capture attempts of birds, mammals and insects by the Lanner Falcons were observed, of which 163 (49.1 %) were successful. The falcons also pounced on 9 rodents from a perch, or walked on the ground and gathered invertebrates on 27 occasions. A male also hunted bats. Pairs hunted cooperatively during the courtship period prior to egg laying and also when young accompanied one of the parents on hunting forays. During the fledging period, the male and the female again hunted cooperatively. The overall hatching success for both pairs during the five pair-years was 95.2 % and total fledging success was 78.3 %.

Robbins, C. B. (1978b). The Dahomey gap - A reevaluation of its significance as a faunal barrier to west african High Forest Mammals.

The Dahomey Gap as a faunal barrier to high forest mammals is reevaluated. Past researchers, utilizing incorrect or incomplete data, were led to the conclusion that the Gap was the major factor influencing high forest animal distribution in West Africa. Recent data on climate, vegetation, soil type, and mammalian taxonomy, ecology, and distribution indicate that the Dahomey Gap has not influenced mammal distribution or evolutionary changes. Rather, it is the Volta and Niger rivers, which have affected mammalian distribution and speciation in West Africa.

Robbins, C. B. (1980). Small mammals of Togo and Benin. I. Chiroptera.

Liste des chauves-souris collectées par les membres du Smithsonlan African Mammal Project au Togo et anu Bénin. Trois espèces sont nouvelles pour Ie Togo. Cette liste comprent les premières mentions de la faune des chauves-souris du Bénin. L'auteur discute de problèmes taxonomiques posés par les *Scotoecus* et de problèmes de nomenclature concernant les *Scotophilus*.

Bats collected by members of the Smithsonian African Mammal Project in Togo and Benin are listed. Three species reported are new for Togo. This list includes the first account given for the bat fauna of Benin. Problems regarding taxonomic determinations in *Scotoecus* are discussed as well as nomenclatural problems concerning species of *Scolophilus*.

Robbins, C. B. (1981). A new high forest species of the bat genus *Scotophilus* (Mammalia: Vespertilionidae). Abstract.

Research on a revision of the African bat genus *Scotophilus* (with Frits De Vree - see following abstract) included examination of many specimens referable to *S. nigrita nux* Thomas, 1904. De Vree and I have found that *S. nux* is specifically distinct and distinguishable from *S. dinganii* (previously and incorrectly called *S. nigrita*).

Examination of over 80 specimens of *S. nux* revealed that six specimens (four from Ghana, one from NE Zaire, and one from Uganda) could not be referred to *S. nux* or any other described taxon in *Scotophilus*. Although they are very similar in external appearance including pelage color, their cranial and wing measurements are markedly smaller.

Two of the Ghana specimens are, in fact, sympatric with typical *S. nux*. That locality (1 mi N Nkawkaw) will be designated as the type-locality for the new species. Both *S. nux* and the new species are restricted in distribution to the West, Central, and East African high forest blocs and remnant forest areas. The formal description of the new species will be published as a part of the Proceedings of this Colloquium.

Robbins, C. (B.) (1983). A new high forest species in the African genus *Scotophilus* (Vespertilionidae).

Analysis of the systematics of the African *Scotophilus* (Robbins, De Vree & Van Cakenberghe, 1982) revealed that the subspecies *S. nigrita nux* Thomas, 1904, was instead a distinct species (*S. nux*). Statistical analyses were used to examine population and geographic variation in over 100 specimens referred to *S. nux*. Some population samples had unusually large ranges of measurements. The specimens from those localities were then examined individually. I found that there were some individuals with smaller wing and cranial measurements than typical *S. nux* from the same or nearby localities. Additional research was necessary to clarify the characters that identify *S. nux* and distinguish the smaller specimens.

Robbins, C. B. and F. De Vree (1981). Systematic revision of African *Scotophilus* (Chiroptera, Vespertilionidae). Abstract.

The systematics of the African members of the genus *Scotophilus* are very confused and controversial at several points. Apart from size and color they do not show striking morphological differences.

In the present study approximately 2000 specimens were examined, using multivariate statistical techniques, including discriminant, principal component and cluster analysis. All analyses are based on seven cranial and one wing measurement.

A total of six species are now recognized on the mainland of Africa: *S.nigrita (=gigas), S.nux, S.dinganii, S.leucogaster* and *S.viridis*. A new species will be discussed by Brian Robbins and is included in the previous abstract; it will be described in the published proceedings of the Colloquium.

The distribution of the genus on the mainland of Africa ranges from Senegal and Mauretania in the West to Ethiopia and Somalia in the East, throughout Central Africa to South Africa. *S.nux* and the new species are restricted in distribution to the high forest zone from Sierra Leone to Kenya. Our analysis shows that *S. viridis* and *S. nigritellus* are conspecific. *S. leucogaster* and *S. viridis* occur throughout the range given for the genus in Africa and are sympatric at several localities in West Africa. However south of Ethiopia they have not been found together, but are usually found with *S. dinganii*.

Robbins, C. B., F. De Vree and V. Van Cakenberghe (1983). A review of the systematics of the African bat genus *Scotophilus* (Vespertilionidae).

The systematics of the African vespertilionid genus *Scotophilus* Leach, has been confused and at times controversial. Since the description of the earliest species in this genus, *S. nigrita* (Schreber, 1774), eighteen other taxa have been described as being African species or subspecies. The number of species recognized by various authors for the African mainland ranged from two to seven, with the usual numbers being three, four or five distinct species. The taxonomic history and the taxonomy of *Scotophilus* using multivariate statistical techniques to examine morphology, plus analysis of ecology and distribution of African mainland species, are detailed by Robbins, De Vree and Van Cakenberghe, 1982, Ann.Roy.Afr.Centr., Ser. 8. We present here a review of that paper.

Adults from a total of 2094 specimens were examined from 21 museum collections in the US, Europe and Africa. Statistical analyses were made using one wing and seven cranial measurements. Multivariate analyses included discriminant function analysis and principal component analysis. Standard univariate techniques were also used.

Morphological analyses were divided by geographical regions and habitat because many previous taxonomic treatments were regional and also to facilitate taxon recognition and allow comparisons between the regions. These regions and habitants were: the West African savanna; the savanna from West to East Africa; the high forest from West to East Africa; the southern Africa savanna; and total distribution. *S. nigrita* Schreber was excluded from these analyses because its large size distinguished it from all other *Scotophilus* species.

Analysis of the West African savanna species indicated the presence of three distinct morphological species which corresponded to *S. dinganii* (A. Smith), *S. leucogaster* (Cretzschmar), and *S. nigritellus* De Winton. Combining the West African specimens with population samples from East Africa indicated that these three species remained distinct. The West to East African high forest vegetation zone was found to have two species distinguishable from those in the savanna - as *S. nux* Thomas and a new species described in these Proceedings as *S. nucella* Robbins.

It was apparant that southern Africa also had two or three distinct species. Using specimens from previous analyses (West to East Africa) plus southern Africa specimens, confirmed that the smallest species in West Africa (previously referred by other authors to *S. nigritellus*) was conspecific with and should be recognized as a part of the southern African *S. viridis*. Also, West Africa specimens of *S. leucogaster* were found to be conspecific with specimens from Namibia and Botswana. To complete the analyses, the largest West African *Scotophilus* (excluding *S. nigrita*), *S. dinganii*, was compared with and found to be conspecific with southern African specimens. Statistical analyses using specimens from throughout the range for each morphologically distinct species confirmed the presence, on the African mainland, of six distinct species of *Scotophilus*. Therefore, we recognize *S. dinganii, S. leucogaster, S. nigrita, S. nucella, S. nux* and *S. viridis*.

We also considered the possibility that specimens from the Madagascar area corresponded to those on the African mainland. Based on only a few available specimens, we found three morphologically distinct forms. The large specimens had been described as *S. robustus* Milne-Edwards and do not correspond morphologically to any African mainland specimens. Another specimen corresponded to the lectotype of *S. borbonicus* (E. Geoffroy St. Hilaire). An additional specimen has measurements which fit those of the smallest representatives of the mainland *S. viridis*. For the present and because of a lack of Madagascar material and the inadequate description and condition of the lectotype of *S. borbonicus* we reject the use of *S. borbonicus* and *S. robustus* for species or subspecies on the African mainland.

Robbins, C. B., F. De Vree and V. Van Cakenberghe (1985). A systematic revision of the African bat genus *Scotophilus* (Vespertilionidae).

The systematics of African members of the genus *Scotophilus* has been confused and at times controversial. Apart from size and pelage color, they do not show many non-mensural differences. Multivariate statistical analyses are used with seven cranial and one wing measurement on over 2000 specimens. Six species are recognized. Two species, *S. nux* and *S. nucella*, are restricted to the high forest zone in West and Central Africa. The other four species, *S. dinganii, S. leucogaster, S. nigrita*, and *S. viridis*, occur throughout sub-Saharan Africa in the savanna vegetation zones. African mainland distribution of the genus is from Senegal and Mauritania in the west to Ethiopia and Somalia in the east, and throughout Central Africa to southern Africa.

Robbins, L. W. and R. J. Baker (1978). Karyotypic data for African mammals, with a description of an *in vivo* bone marrow technique.

Basic information, which should be included in any publication on the chromosomes of mammals, is given. A field-tested bone marrow-in vivo method of karyotyping is presented. A review of the literature concerning karyotypes of African mammals was done and these karyotypic data are listed for 292 species and subspecies of African mammals.

Robbins, L. W., M. W. Haiduk and D. A. Schlitter (1981). Chromosomal banding studies and their systematic implications in African fruit bats (Chiroptera: Pteropodidae). Abstract.

Analysis of data derived from standard karyotypes can give information concerning differences between individuals, species, and genera, and similarities can be only inferred. New techniques utilizing differentially stained chromosomes (G- and C-banding) now allow a more quantitative approach for the determination of homologies as well as types and magnitude of chromosomal differences. Standard and banded karyotypes of *Epomops franqueti, Hypsignathus monstrosus*, and two species of *Epomophorus* are compared and contrasted. The chromosomal banding data are then used to place nine species and eight genera in a systematic arrangement based on the occurrence of homologous elements and shared rearrangements.

Robbins, L. W. and V. M. Sarich (1988). Evolutionary relationships in the family Emballonuridae (Chiroptera).

Protein electrophoresis and immunology were used to test hypotheses concerning phylogenetic relationships within the family Emballonuridae and the relationship of the family Rhinopomatidae to the Emballonuridae. These data indicate the presence of three major subdivisions within the family. The eight genera from the New World form one monophyletic group, the Old World genera *Taphozous* and *Saccolaimus* form the second, and *Emballonura* and *Coleura* the third. The *Emballonura-Coleura* lineage is more closely related to the New World genera than to the other Old World group. The family Rhinopomatidae was found to be distantly related to both the Emballonuridae and the Vespertilionidae.

Roberts, A. (1914). Supplementary list of African Mammals in the collection of the Transvaal Museum, with descriptions of some species.

Since the catalogue of African Mammals in the collection of the Transvaal Museum was published last year (Ann. T.M., Vol. III, part 2, pp. 65-109), some notable additions have been made by an expedition to south-eastern Rhodesia, undertaken by the Taxidermist and the writer, for the purpose of procuring specimens to replace those formerly in the mounted collection, and skeletons of some of the larger antelopes. A few specimens have also been acquired by purchase or donation, and a number of specimens of scientific value have been found in the store of flat skins in charge of the Taxidermist. In addition to these the names of a few species found amongst the exotic specimens and overlooked in my former paper are now included to complete the list of species.

Roberts, A. (1946). Descriptions of numerous new subspecies of mammals.

During the course of critically examining the collection of mammals in the Transvaal Museum, numerous undefined subspecies were found to need naming, and they are given hereunder. There can be no doubt that we have much more to learn about the forms and distribution of the mammals in South Africa, and as new material is acquired, more will have to be named. As a result of this critical examination, it is becoming more and more apparent that there are certain ecological conditions which produce somewhat similar results in the local forms of mammals, often repeated in sedentary species of birds, going to show the importance of such studies in the evolution of species, for, in some cases, isolation of the subspecies has led to specific establishment. This is most evident in those of very local habitat, while those which tend to wander and intermingle with individuals from adjacent territories seldom become specifically isolated in the modern forms. Thus in the two species of hares of the genus *Lepus*, the range of variation under extremely different conditions of environment is very wide, but links between these subspecies exist, whereas in the genus *Pronolagus* there are more species, some of which overlap in distribution, and in some of these species subspecies may be noted.

Roche, J. (1972). Recherches mammalogiques en Guinée forestière.

Une collection de Mammifères de Guinée forestière (République de Guinée) a été rassemblée dans la région de Sérédou. A côté d'une forte proportion de représentants du milieu forestier, figurent quelques espèces d'origine savanicole. Le matériel ainsi réuni est étudié par groupes zoologiques, avec des discussions concernant la systématique, la répartition géographique, éventuellement l'écologie et les rapports avec l'homme, des différentes espèces.

A collection of Mammals from the forested part of the Republic of Guinea has been made in the region of Seredou. Next to a large proportion of forest animals stand a few savanna species. This material is studied by zoological groups and discussions concern systematic, geographical distribution and eventually the ecological aspect and the relations with man, of the different species.

Rode, P. (1937). Etude d'une collection de mammifères de l'Afrique occidentale.

Au cours d'une mission en Afrique occidentale française (déc-1935-mars 1936), mission qui avait pour but essentiel de recueillir la documentation nécessaire à la mise au point d'un ouvrage sur les Primates de l'Afrique, nous avons pu récolter quelques spécimens de Mammifères, en Guinée, au Soudan et au Sénégal. Cette petite collection d'Ongulés, de Carnivores, Rongeurs, Chiroptères et Primates, présente un certain intérêt pour les collections de Zoologie des Mammifères, puisqu'elle a permis d'inscrire 51 pièces, dont un certain nombre appartiennent à six espèces ou sous-espèces qui n'existaient pas au laboratoire.

Nous avons volontairement laissé de côté l'énumération de pièces histologiques et d'organes divers destinés à des recherches dont les résultats paraîtront ultérieurement.

Rode, P. (1941). Catalogue des types de mammifères du Muséum Nationale d'Histoire Naturelle. Ordre des Chiroptères.

La présente liste de types fait suite aux deux articles précédemment publiés, le premier sur les types de Simiens, le second sur les types de Lémuriens.

La collection de Chiroptères du Laboratoire de Zoologie des Mammifères du "Muséum National d'Histoire Naturellle de Paris comprend des animaux montés, des animaux en peau et des spécimens conservés en alcool, soit 140 pièces au total.

Les types contenus dans ces trois séries ont été retirés, classés et font l'objet du présent catalogue dont le plan est le même que celui qui a été adopté dans les deux précédents 1 et 2.

Rode, P. (1947). Les mammifères de l'Afrique du Nord. 1.

Les biogéographes englobent dans la zone dite "palearctique" le Nord de l'Afrique, c'est-à-dire, en principe, la région séparée de la zone éthiopienne par le Sahara, aujourd'hui désertique.

Si l'on considère l'histoire du peuplement de cette région nord-africaine on y retrouve, d'une part, des éléments eurasiatiques et d'autre part des éléments tropicaux. Au début.du Quaternaire, le nord de l'Afrique était peuplé d'un faune d'aspect surtout tropical, le Sahara étant, à cette période, une région habitée et fertile. En raison de la présence en Afrique du Nord d'organismes d'origine très variée, mais dont les rapports sont cependant plus étroits avec la zone tropicale qu'avec la zone palearctique, nous considérons que cette région doit être plutôt incluse dans le système éthiopien, le Sahara n'étant pas encore entièrement dépeuplé, mais pourvu d'une faune mammalogique variée et intéressante.

Il y a lieu, sans, doute, de considérer l'Afrique du Nord comme un domaine de transition entre le monde paléarctique et le monde tropical: mais c'est surtout une zone du système tropical. La Berbérie, limitée au nord par la mer et au sud par les chaînes montagneuses n'est pas une région isolée, mais, en dehors de quelques formes paléarctiques, c'est un simple territoire de bordure.

L'étude des Mammifères est, à cet égard, particulièrement démonstrative. Nous allons essayer de synthétiser, en quelques courts chapitres, les éléments actuels de cette faune, en montrant du point de vue zoologique les rapports avec les types purement tropicaux et, quand il y a lieu, la présence de types paléarctiques en donnant, chaque fois que cela ser.a possible, les caractères biologiques essentiels. Mais plus encore que pour les Mammifères européens il faut reconnaître que nous n'avons pas, maigre les nombreux travaux publiés, une connaissance complète de cette faune surtout en ce qui concerne les micromammifères sahariens ou marocains et que des découvertes sont encore possibles.

Nous' serions très heureux si cette ébauche de mise au point pouvait servir de guide à des chercheurs pour préciser nos connaissances et leur donner le désir d'apporter de nouveaux documents indispensables pour nue étude complète.

Notre étude des Mammifères de l'Afrique du Nord se limitera aux territoires suivants: Maroc, Algérie et Tunisie. La zone algérienne comprendra la région admiuistrativement désignée sous le nom de Territoires du Sud. En fait, au point de vue géographique, nous mentionnerons autant que possible toutes les espèces comprises au nord du tropique du Cancer.

La faune de-l'Afrique du Nord a été particulièrement étudiée par LOCHE (1), LATASTE (2), CABRERA (3), H. HEIM DE BALSAC (4). Citons également la contribution importante et répartie dans de nombreuses notes, de O. THOMAS, JOLEAUD, MORALES AGACINO, P. LAURENT.

Les Mammifères représentés en Afrique du Nord appartiennent aux ordres suivants: Primates, Insectivores, Chiroptères, Carnivores, Rongeurs et Ongulés.

Rodgers, W. A. and K. M. Homewood (1982). Species richness and endemism in the Usambara mountains forests, Tanzania.

The East Usarnbara Mountain forests constitute what is probably one of the richest biological communities in Africa in terms of plant and animal species numbers and endemic taxa. This review presents brief accounts of the flora and of three invertebrate and four vertebrate groups and shows the percentage endemic taxa to vary from 2 % (mammals) to 95 % (millipedes) as a proportion of the true forest species.

Notes are given on the geology, soils, climate and present land use of the Usambaras. Biological richness is considered to be due to long periods of isolation and geological stability coupled with periods of species immigration during times of re-establishment of a continuous forest cover. The nature of the endemic elements is brieflv discussed.

Evidence is given to show that the forests are subject to increasing pressure from legal and illegal encroachment due to agriculture (tea, cardamon, subsistence) and forestry timber operations. Air photograph analysis shows a forest decrease of some 50 % in the vicinity of Amani from 1954 to 1976.

The low conservation status of most forest reserves and the lack of detailed knowledge on the distribution, status and biology of the endemic species means present conservation efforts are poor and haphazard. This review calls for greatly increased research inputs and a complete halt to all exploitation of natural forest areas until a long term conservation land use plan can be implemented.

Rodgers, W. A., C. F. Owen and K. M. Homewood (1982). Biogeography of East African forest mammals.

This paper analyses the distribution of seventy-three mammal species in seventeen East African forest sites of differing geological history (recent volcanic, ancient block faulted and lowland alluvial). Association analysis and principal coordinate analysis indicate four groupings (West, North, South and Coast) based on species presence. The levels of similarity between these groups are used to test previous ideas on spread of forest mammals through East Africa. The western sites have the highest richness and endemism and represent the main refuge and colonization source. The North group show overall impoverishment, low endemism and high dependence on the western fauna. The South group shows higher cndcnusm, the Coast fauna is the most impoverished, and highly dependent on South group elements. These findings are discussed with respect to current interpretations of bioclimatic events and forest environments in the East African Pleistocene and are used to investigate a specific example concerning the distribution of a recently discovered rare forest primate.

Rodríguez-Durán A. (1995). Metabolic rates and thermal conductance in four species of neotropical bats roosting in hot caves.

Data are presented on metabolic rates and thermal conductance for four species of neotropical bats, *Pteronotus quadridens, Mormoops blainvillii* (Mormoopidae), *Monophyllus redmani* and *Erophylla bombifrons* (Phyllostomidae). Each of these bats predominantly or exclusively roosts in hot caves (28 - 40° C) in Puerto Rico. Basal metabolic rates (BMR) for these four species were 55 %, 48 %, 66 %, and 66 % of values expected from the Kleiber curve, respectively. Thermal conductance was 93 %, 55 %, 175 %, and 158 % of values expected from the Aschoff curve, respectively. These data indicate that, in addition to food habits, variation in BMR is highly correlated to roost microclimate. *Pteronotus* and *Mormoops*, like other insectivorous species, have low BMRs. The low BMR of the nectar/fruit eating *Monophyllus* and *Erophylla*, as well as the low termal conductance in *Mormoops*, is consistent

with their habit of roosting in hot caves, suggesting that roost microclimate is an important selective force in the physiological adaptation of these bats.

Roer, H. (1970). Zur Wasserversorgung der Microchiropteren *Eptesicus zuluensis vansoni* (Vespertilionidae) und *Sauromys petrophilus erongensis* (Molossidae) der Namibwüste.

On the central Kuiseb in the southem Namib insectivorous bats are to be found at an important density. The following species could be approved: *Eptesicus hottentotus pallidior (Vespertilionidae), Eptesicus zuluensis vansoni (Vespertilionidae), Sauromys petrophilus erongensis (Molossidae)* and *Nycteris thebaica damarensis (Nycteridae)*.

Under the extreme climatic conditions the microchiroptera find prey enough, at least during the summer months, because this dry river-bed with its trees that partially are compact like a forest, offers favourable conditions of development to insects (above all to *Coleoptera, Lepidoptera* and *Hymenoptera*). It is being examined in which way these desert bats provide for their need of water in a region where we hardly find open water places during a large period of year. Feeding experiments have shown that *Eptesicus zuluensis vansoni* and *Sauromys petrophilus erongensis* can do without having water for several months if they find enough insects. During the observation period a female of *E. zuluensis vansoni* gave birth to twins, one young of which was nourished up to the end of the lactation period.

Roer, H. (1971). Zur Lebensweise einiger Microchiropteren der Namibwüste.

Am mittleren Kuiseb in der südlichen Namibwüste kommen insektenfressende Fledermäuse in erheblicher Populationsdichte vor. Es wurden folgende Arten nachgewiesen: *Eptesicus hottentotus pallidior (Vespertilionidae), Eptesicus zuluensis vansoni (Vespertilionidae), Sauromys petrophilus erongensis (Molossidae)* und *Nycteris thebaica damarensis (Nycteridae)*. Wenn diese Microchiropteren unter den dortigen extremen Klimabedingungen zumindest währens der Sommermonate genügend Beutetiere finden, so deshalb, weil dieser Trockenfluß mit seinem teilweise galerieartigen Baumbestand Insekten (vor allem Coleopteren, Lepidopteren und Hymentopterenà günstige Entwicklungsmögelichkeiten bietet. Es wird undersuch, wie diese Wüstenfledermäuse ihren Wasserbedarf in einem Gebiet decken, das während eines großen Teils des Jahres kaum offene Wasserstellen aufweist. Füttungsversuche haben ergeben, dass *Eptesicus zuluensis vansoni* und *Sauromys petrophilus erongensis* mehrere Monate ohne Trinkwasseraufnahme leben können, wenn ihnen genügend Insektennahrung zur Verfügung steht. Ein *zuluensis vansoni*-Weibchen hat während der Versuchszeit Zwillinge geboren, von denen ein Junges bis zum Ausgang der Laktationsperiode ernährt wurde.

On the central Kuiseb in the southem Namib insectivorous bats are to be found at an important density. The following species could be approved: *Eptesicus hottentotus pallidior (Vespertilionidae), Eptesicus zuluensis vansoni (Vespertilionidae), Sauromys petrophilus erongensis (Molossidae)* and *Nycteris thebaica damarensis (Nycteridae)*. Under the extreme climatic conditions the microchiroptera find prey enough, at least during the summer months, because this dry river-bed with its trees that partially are compact like a forest, offers favourable conditions of development to insects (above all to Coleoptera, Lepidoptera and Hymenoptera). It is being examined in which way these desert bats provide for their need of water in a region where we hardly find open water places during a large period of year. Feeding experiments have shown that *Eptesicus zuluensis vansoni* and *Sauromys petrophilus erongensis* can do without having water for several months if they find enough insects. During the observation period a female of *E. zuluensis vansoni* gave birth to twins, one young of which was nourished up to the end of the lactation period.

Rosevear, D. R. (1962). A review of some African species of *Eptesicus* Rafinesque.

The confusion of nomenclature and identity existing amongst early species of *Eptesicus* and its causes are detailed. From the original measurements and other "classic" descriptions, set forth in Table 1, a proper allocation of names is deduced. In Table 2 it is shown that British Museum spirit specimens largely conform to the grouping disclosed in Table 1; but measurement of connected series available in the dried collection, summarized in Table 3, demonstrates a complete bridge between two supposed size groups, and reveals that an apparently homogeneous series is in fact divisible on cranial features as well as length of fur. Probable specific size ranges and the correct names to apply to these are shown in Table 4. *E. capensis* is regarded as a complex species widely spread over the continent, variable in size, colour and perhaps other characters at a subspecific level, possibly more in relation to climate than locality; but material at present available is insufficient to serve as a proper foundation for any permanently useful subdivision. Synonymy is indicated. Characters which now appear to separate *somalicus* from *capensis* may in time be shown not to be specific. *E. pusillus* may possibly not exist. The value of diagnostic characters used in *Eptesicus* and colour variation are both discussed.

La confusion qui règne dans Ia nomenclature et la systématique des especes anciennement decrites du genre *Eptesicus* et ses causes sont exposées. D'après les mensurations originales et les descriptions "classiques", resumées dans Ie Tableau 1, une synonymie est proposée. Dans le tableau 2, il est montré que Ies spécimens conservés en alcool au British Museum sont conformes en tous points au groupement systématique du Tableau 1; mais la mensuration d'une série correspondante de la collection de peaux, résumée dans Ie Tableau 3, traduit une série continue entre deux groupés supposés séparables par leur tail le. Il révèle, de plus, qu'une série apparemment homogène est, au fait, divisible par des caractères craniologiques ainsi que par la longueur du pelage. Les limites de variation probables des espèces et les noms applicables à celles-ci sont indiqués dans le Tableau 4. On peut considérer *E. capensis* comme une espèce polymorphe, répandue sur tout Ie continent, variable en taille, en coloration, et aussi quant à ses autres caractères, permettant de distinguer des sous-espèces peut-être plus en rapport avec Ie climat qu'avec la répartition géographique; mais Ie matériel disponible ne suffit pas a subdiviser l'espèce d'une manière utile. La synonymie est indiquée. Les caractères qui paraissent actuellement permettre de separer *somalicus* de *capensis* pourraient se révéler un jour ne pas être spécifiques. *E. pusillus* n'est peut-être pas valable. La valeur des caractères de diagnostic utilisés dans Ie genre *Eptesicus* et les variations de couleur sont discutées d'une manière critique.

Rosin, G., I. Landau and J.-P. Hugot (1978). Considérations sur le genre *Nycteria* (Haemoproteidae) parasite de Microchiroptères africains avec description de quatre espèces nouvelles.

Cinq espèces de *Nycteria* ont été étudiées en Afrique centrale (Gabon et Congo-Brazzaville). Elles se répartissent en 2 groupes distincts: les parasited de *Nycteris* ayant de gamétocytes "en cocarde": *N. medusiformis, N. houinin* n. sp. Et *N. erardi* n. sp.: les parasites de *Rhinolophus* qui ont des gamétocytes "diffus": *N. gabonensis* n. sp. Et *N. krampitzi* n. sp.

Les caractères du genre *Nycteria* et sa place parmi les autres Hémosporidies sont analysés.

5 species of *Nycteria* from Central Africa (Gabon and Congo-Brazzaville) were studied. They can be divided into two distinct groups: the parasites of *Nycteris* with gametocytes "en cocarde": *N. medusiformus, N. houini* n. sp. And *N. erardi* n. sp.; the parasites of *Rhinolophus* with gametocytes of the "diffus" type: *N. gabonensis* n. sp. And *N. krampitzi* n. sp.

The characteristics of the genus *Nycteria* and its place amongst the other Haemosporidia are analysed.

Rowe-Rowe, D. T. and P. J. Taylor (1996). Distribution patterns of terrestrial mammals in KwaZulu-Natal.

Distribution patterns, plotted by eighth-degree squares (7.5' x 7.5'), of the 162 mammal species recorded in the province of KwaZulu-Natal, South Africa were examined in relation to the combined factors of vegetation type, climate, and altitude (= bioregions); and in relation to protected areas within the nine bioregions. Highest species richness was recorded in the warmest most heterogeneous (vegetation) bioregions, and lowest in a cool montane region. Species richness was intermediate in relatively homogeneous, predominantly grassland bioregions. Mammalian biodiversity in KwaZulu-Natal is concentrated in the savanna regions in the north-east of the province, although further species-rich areas are found in the north-west and south-west for carnivores, and in the central region for many of the smaller mammals (Insectivora, Chiroptera, Rodentia). Analysis of taxonomic resemblances between bioregions distinguished taxonomically distinct 'savanna' and 'grassland' groups. Taxonomic resemblances between bioregions were generally lowest in bats (i.e. greatest bioregion specificity) and highest in carnivores (i.e. lowest specificity). In total, 92% of the mammal species occur in one or more protected areas. The percentages of species within protected areas in each of the bioregions are generally high (68 - 100%). In four of the bioregions the amount of land occupied by protected areas is adequate (6 - 96%) and protected areas are large, but in the other five bioregions the opposite holds (< 2% protected) and populations within them may not be viable.

Ruedi, M. and R. Arlettaz (1991). Biochemical systematics of the Savi's bat (*Hypsugo savii*) (Chiroptera: Vespertilionidae).

In order to assess the controversial systematic position of the Savi's bat (*Hypsugo savii*), 43 vespertilionid bats belonging to 10 species were analyzed by mean of isozyme electrophoresis. The results were interpreted in two ways: first, we found that the amount of genetic differentiation between *Hypsugo* and the true *Pipistrellus* (D = 0.719) is of the same magnitude as the mean distance which separates the other pipistrelloid genera (D = 0.738). Secondly, the cladogram based on these biochemical results confirms the splitting of these "pipistrelles ", as *Hypsugo* is more closely related to *Vesperitlio* than to any other palearctic genus. The other species analyzed in this study group themselves in a different clade, including *Pipistrellus, Eptesicus* and *Nyctalus* . This phylogenetic interpretation presents a testable hypothesis, which could be confirmed by an analysis or other loci or other allied species.

Rushton, A. R. (1970). Cytotaxonomy and chromosomal evolution of the bats (Mammalia - Chiroptera).

An extensive literature search has compiled diploid chromosome numbers for 110 species of bats. Karyotypes for 87 of these have been reported and are used as the basis for defining tentative cytological relationships within the families Pteropodidae, Rhinopomatidae, Phyllostomatidae, Desmodonlidae, Rhinolophidae, and Vespertilionidae. Before more definitive intrafamilial relationships can be established, karyotypes from more species of the order Chiroptera must be reported.

Une compilation extensive a fourni le nombre diploïde des chromosomes de 110 espèces de Chauves-Souris. A partir de 87 caryotypes connus, on s'est efforcé d'établir les relations cytologiques existant à l'intérieur des familles suivantes: Pteropodidae, Rhtnopomatidae et Vespertilonidae. Pour établir des relations interfamiliales absolument certaines, la connaissance du caryotype de nouvelles espèces est encore nécessaire.

Ruxton, A. E. (1926). On mammals collected by Captain C.R.S. Pitman, Game Warden, Entebbe, Uganda.

This collection has been made, except where otherwise stated, in the Eastern Trans-Nzoia district, the Cherangani Hills, and on the river Kerio Suk, Kenya Colony, lat. 0° 56' N, 35° 16' E.

The altitudes for all specimens except those with the word "Suk" after the collector's number, are from 6000' to 6400'; thos from the River Kerio Suk, 3500'.

The collection contains a fine series of six skins and five skulls of a new species of oribi from Lake Nakivali, Ankole, Uganda.

Rydell, J. and R. Arlettaz (1994). Low-frequency echolocation enables the bat *Tadarida teniotis* to feed on tympanate insects.

The European free-tailed bat, *Tadarida teniotis*, forages in uncluttered airspace by using intense narrowband echolocation calls with low frequency (11-12 kHz), and feeds on relatively large flying insects, mainly (90 % by volume) of the tympanate orders Lepidoptera and Neuroptera. The use of low-frequency echolocation calls without strong harmonics appears to be a specialization for long-range detection of large, tympanate insects, which are less well represented in the diet of most other aerial-hawking bats. The results provide evidence in support of the allotonic frequency hypothesis, i.e. that use of echolocation calls with frequencies above or below the best hearing of tympanate insects is an adaptation to increase the availability of these insects.

Rydell, J. and D. W. Yalden (1997). The diets of two high-flying bats from Africa.

The diets of two fast-flying, aerial-hawking bats from north-east Africa (Ethiopia) were investigated by means of faecal analysis. *Otomops martiensseni* (Molossidae; c. 35 g body mass), which is remarkably specialized morphologically with very long, narrow wings and large ears, and which uses low frequency echolocation (10 kHz), feeds almost exclusively (97 % by volume) on moths, mostly of large species. The smaller (20 g) *Taphozous perforatus* (Emballonuridae) also has long, narrow wings but short ears and is less morphologically extreme than *Otomops*. It feeds on moths (56 %), but also on many other insect groups such as Isoptera (14 %), Coleoptera (10 %), Orthoptera (8 %), as well as Hemiptera, Neuroptera, Hymenoptera and Diptera. *Otomops martiensseni*, in particular, appears to be a highly specialized moth predator.

Sabatier, M. and S. Legendre (1985). Une faune à rongeurs et chiroptères plio-pléistocènes de Madagascar.

Une faune de vertébrés fossiles, contenant principalement des mammifères, a été découverte dans le Sud-Ouest de Madagascar, près du lac Tsimanampetsotsa. Trois ordres de mammifères sont représentés: les insectivores Lipotyphla avec une espèce, les chiroptères avec cinq espèces et les rongeurs avec quatre espèces. Un âge pliocène ou pléistocène ancien est proposé pour le gisement.

A fossil vertebrate fauna, containing mainly mammals, was found in southwestern Madagascar, near the lake Tsimanampetsotsa. Three orders of mammals are represented: insectivores Lipotyphla, with one species, Chiroptera, with five species, and rodents, with four species. A Pliocene or early Pleistocene age is proposed for this locality.

Sanborn, C. C. (1936). Descriptions and records of African bats.

This paper contains a complete list of the bats collected by the Straus West African Expedition and descriptions and notes on others collected by the Conover-Everard African and Chicago Daily News Abyssinian Expeditions of Field Museum. The taking of certain forms in French Sudan and Nigeria which were known only from Belgian Congo is of special interest.

I am indebted to Mr. Gerrit S. Miller, Jr., and to Dr. H. E. Anthony for the loan of many specimens

---

Sanborn, C. C. (1939). Eight new bats of the genus *Rhinolophus*.

During recent work on a revision of the bats of the genus *Rhinolophus* eight new forms were discovered. These are described here in advance of a complete report, which will appear later.

I wish to thank Mr. M. A. C. Hinton and Mr. T. C. S. Morrison-Scott for their help while I was at the British Museum (Natural History) and for permission to describe two of these new forms. Through the generosity of Dr. H. Boshma and Dr. G. C. A. Junge of the Rijksmuseum van Natuurlijke Historie in Lieden, I am able to describe two others.

This work was done with the aid of a Fellowship from the John Simon Guggenheim Memorial Foundation and with the permission of Field Museum of Natural History, during parts of 1938 and 1939

Sanborn, C. C. (1949b). Bats of the genus *Micronycteris* and its subgenera.

The bats of the genera *Micronycteris, Glyphonycteris*, and *Xenoctenes* were originally placed in the genus *Schizostoma* Gervais 1856. This name was preoccupied by *Schizostoma* Bronn 1835, a genus of Mollusca. *Micronycteris* Gray 1866 is the next available name. The genus *Glyphonycteris* was erected by Thomas in 1893 for three of the species and *Xenoctenes* by Miller in 1907 for one of the species.

The genera *Micronycteris* and *Glyphonycteris* were revised in 1906 by Dr. Knud Andersen (1906, pp. 50-65). His material totaled 59 specimens, and he examined all but three species (*M. microtis, M. hypoleuca*, and *G. brachyotis*). The genus *Glyphonycteris* is not represented in collections in the United States. A photograph of the type skull of *G. sylvestris* is reproduced here (fig. 49). Specimens of bats closely related to these genera have recently been received from the Trinidad Zoological Expedition, 1947, of Chicago Natural History Museum; from Brother Niceforo Maria of Bogota, Colombia; and by loan from the American Museum of Natural History, New York.

When the characters of the three described genera and the characters of the three series of bats from Trinidad, Colombia, and Brazil are tabulated it may be seen that the differences consist of various combinations of characters rather than diagnostic characters that might be regarded as of generic importance. The relationship of these bats may be more clearly indicated by placing them all as subgenera of *Micronycteris*. This will combine the bats of the Subfamily Phyllostominae, in which the tail extends to the middle of the interfemoral membrane and the middle lower premolar (pm_3) is not reduced.

I wish to thank Dr. H. E. Anthony of the American Museum of Natural History, New York, for the loan of very helpful material and for permission to describe a new subgenus and species from the American Museum specimens. Thanks are due also to Brother Niceforo Maria of the Instituto de La Salle, Bogota, Colombia, for the gift of five specimens representing another new subgenus and species.

Sanborn, C. C. (1950). Chiroptera from Dundo, Lunda, North-eastern Angola.

The bats on which this report is based were collected by Dr. A. de Barros Machado in . . . Dundo, Lunda, Northeastern Angola, a region where practically no mammals have been collected. The bat fauna, while largely like that of the Belgian Congo also contains representatives from other areas. There are 18 species represented in the collection of which six are common to both Angola and the Congo; four have been recorded from the Congo but not . . . two from Angola but not the Congo; and six have not been taken in either country. Of the 18 species, 10 are here recorded from Angola for the first time (denoted by an asterisk). Another is described as new.

The collection brings the total number of bats known from Angola to 65, which about equals the number recorded from the Congo. There are now fifteen species that have been taken . . . Angola and the

Belgian Congo. Our knowledge of the distribution of African bats has greatly augmented by this material and it is hoped that further collections from the region be made.

Sanborn, C. C. (1953). Notes sur quelques mammifères de l'Afrique équatoriale française.

Une collection d'une centaine de mammifères a été réunie par H. A. BEATTY au cours des années 1951 et 1952 pendant qu'il était occupé à collecter des oiseaux pour le Chicago Natural History Museum au Gabon et dans le Moyen Congo, en l'Afrique Equatoriale Française. Outre de nombreuses espèces communes, déjà mentionnées par MALBRANT et MACLATCHY (1949), la collection contient une nouvelle espèce d'écureuil et quelques autres particulièrement intéressantes.

These notes list seven of the rarer mammals from the Gabon and Moyen Congo and contain the description of a new species of squirrel. *Rhinolophus fumigatus* is recorded for the first time from western Africa; color variations are described and measurements given for *Hipposideros gigas*; and an unusual specimen of *Glauconycteris beatrix* is listed.

Sanborn, C. C. and H. Hoogstraal (1953). Some mammals of Yemen and their ectoparasites.

Late in 1950, His Majesty Imam Ahmad bin Yahya Hamid al-din, King of Yemen, invited Captain J. J. Sapero, M.C., U.S.N., Director of the United States Naval Medical Research Unit, Cairo, Egypt, to send a group of experts to make a brief medical survey of the Yemen for His Majesty's guidance in future disease control administration. The group, which became known as the United States Naval Medical Mission to the Yemen, was composed of Commander Robert A. Mount, epidemiologist; Lieutenant Commander Kenneth L. Knight, entomologist; Lieutenant Robert E. Kuntz, parasitologist; Mr. Harry Hoogstraal, medical zoologist; Hospital Corpsman Joseph R. Baranski, bacteriological technician; and Abdel Azis Salah Effendi, general technical assistant and interpreter. The specimens collected by the Mission .were sent to Chicago Natural History Museum and were identified by the senior author.

In order to learn as much as possible about parasite-bearing mammals in the short period of six weeks, during which other professional and social duties had to be fulfilled, it was decided to specialize on the common species in or near populated areas. For this reason little or no attempt was made to secure rarities. The work began at Ta'izz, in an area representative of middle altitude flora and fauna, on January 7, 1951, and continued through January 24. The facilities and period for study in the Ta'izz region were the best encountered during the survey, and the collections from this region are probably the most broadly representative of any of those from the three altitudinal areas visited.

On January 25 and 26 the party drove down to the coastal desert lowlands (*Tihama*) and at Hodeida commenced operations which lasted till February 4. Although the Hodeida stay was short, and facilities for work were not equal to those of Ta'izz,the collections obtained in this area well represent the common fauna at this season.

On February 4 the party lest Hodeida by jeep and climbed upward, via Bajil, 'Obal, and Hammam' Ali, through rich lower middle altitude country that we heartily recommend to fture biologists who study the natural history of Yemen. On February 5 the expedition reached Ma'bar, at 7,400 feet elevation, and remained there until February 10. The rather barren Ma'bar plateau furnished some interesting material, and the fertile valleys and hills around it are of evident intereste. Tha last highland station, reached in a few hours' drive from Ma'bar, was at San'a, 7,100 feet elevation, where the party remained till February 19, when it departed by plane. The Ma'bar and San'a collections provide a useful picture of the upland fauna, though field work at San'a was seriously curtailed.

All small mammals,except as otherwise noted, were either shot and placed in a bag to be examined for ectoparasites or were live-trapped and killed as quickly as possible afterwards, so that their parasites could be collected. The party had been erroneously advised not to take firearms to the Yemen and so was unable to collect many of the larger mammals. Thanks to the Crown Prince, Seif el Islam Albadr, the expedition was furnished with a Royal Guard, who provided some game with his gun.

The work in the Yemen was done during the height of the dry season. Hunting, trapping, and parasite infestation would probably be quite different during the rainy season.

For an excellent general account of the Yemen, with emphasis on the biological features, the reader is referred to Hugh Scott's *In the High Yemen* (1942, John Murray, London). The experiences of the U. S. Naval Medical Mission to the Yemen have been presented in the National Geographic Magazine (February, 1952). Geomedical observations made by the mission have been reported by Mount (1953).

Besides the mammals mentioned below, no others were seen except baboons, which were very common around Ta'izz. The party was told that none occurred in the coastal lowlands or in the high mountains around Ma'bar and San'a, and none were seen in these places. Hedgehogs were said to be common in the lowlands where the coastal lowlands meet the foothills, and in the foothills. The African Arabic word for mongoose never elicited a response of recognition. The Yemeni insist that the giraffe and lion exist in their hinterlands. Whether they now do is of course doubtful, but we would not be surprised to learn that the lion and giraffe were there until recent times. One man in San'a insisted that a large,striped *nam'r* ("tiger"') exits in the mountains to the east; he may have seen a picture in a book!

We are indebted to Dr .T. C. S..Morrison~Scott and to Mr. R. W. Hayman of the Mammal Department, British Museum (Natural History), for comparing the types in their care with our specimens of *Meriones* and *Gerbillus* and for advice regarding the identification of the gazelles.

Sanborn, C. C. and H. Hoogstraal (1955). The identification of Egyptian bats.

Means for identifying Egyptian bats in the form of keys to their external characters and to their dentition are provided. The type locality, known distribution in Egypt, and dental, skull, and external features are described for the following bats: *Rousettus a. aegyptiacus, Rhinopoma hardwickei cystops, R. microphyllum, Taphozous p. perforatus, T. (L.) nudiventris, Nycteris t. thebaica, Rhinolophus c. clivosus, R. c. brachygnathus, R. mehelyi, R. hipposideros minimus* (from Sinai, first Egyptian specimens), *Asellia t. tridens, Plecotus auritus christiei, Otonycteris h. hemprichi, (Nycticeius s. schlieffeni), (Eptesicus isabellinus innesi), Pipistrellus k. kuhli, (P. ariel), (P. r. ruppelli); (Barbastella l. leucomelasà, Tadarida teniotis ruppelli*, and *T. a. aegyptica*. All species except those enclosed in parentheses above have been collected in Egypt by the Medical Zoology Department of U.S. Naval Medical Research Unit Number Three (Cairo).

Satunin, K. A. (1905). Neue und wenig bekannte Säugetiere aus dem Kaukasus und aus Transkaspien.

Die Poststation Gudaur der Grusinischen Heerstrasse befindet sich auf dern Südabhang dicht beim Pass Krestovy-Pereval, der hier über das Hauptgebirge führt, und ist ein sehr bequemer Ort zur Erforschung der alpinen Fuana dieses Gebirgs. Dieser Pass liegt in 2431 M. H. und die Station selbst in 2208 M. Um sie herum befinden sich alpine Wiesen, stellenweise jedoch ist der Boden steinig un hier un da treten steile Felsen zu Tage. Etwas weiter unten trifft man auf ausgedehnte Bestände von *Azalea pontica* (= *Rhodo flavum*). Bei Gudaur wurde im Jahre 1900 das interessanteste Tier des Kaukasus gefunden, die einzige im Kaukasus endemische Gattung der Vertebraten repräsentierend - *Prometheomys schaposchnikowi* SATUNIN. Vom Wunsche beseelt dieses originelle Nagetier weiter zu erforschen, reiste ich im Juni 1901 zum Krestovy- und Bursacilj-Pass. Während meines zweitägigen Aufenthalts auf der Station Gudaur erbeutete ich hier, ausser *Prometheomys*, noch folgende Säugetiere: *Crocidura güldenstaedti* PALL., *Putorius boccamela caucasicus* BARR.-HAM., *Mus sylvaticus arianus* BLANF. und *Microtus arvalis* PALL. Nachfragen ergaben, dass hier nich selten auch Wölfe und Füchse vorkommen, auf dem umgebenden Bergen kommen Ture vor *Capra cylindricornis* BLYTH. Direktor A. N. KAZNAKOV vom Kaukasischen Museum hielt sich während einer seiner Exkursionen im Juli 1908 auch in Gudaur einige Tage auf, haupsächlich gerade um Exemplare von *Prometheomys* zu erhalten, von denen bis zu der Zeit nur zwei Stück bekannt waren. Währen dieser Tage nun erbeutete er nicht nur eine ganze Familie dieses Nagers, sondern auch eine andere Tiere

un lehrte ausserdem einem Einwohner der Station das Sammeln von kleinen Säugetieren, welcher in der Folge eine bedeutende Anzahl von *Prometheomys* und verschiedene Feldmäuse erbeutete und dem Kaukasischen Museum zuschickte. Auf diese Weise erreicht die Zahl der Arten von Mikromammalia aus Gudaur schon die Ziffer 8 und dieser Ort is daher der einzige Punkt der ganzen alpinen Zone des Kaukasischen Hauptebirgs, dessen mikromammalogische Fauna schon ziemlich genau bekannt ist. Ich führe hier weiter unten die Liste von der von dort bekannten Tiere an.

XIV. Von A.M. Sugurov im Gouvernement Kutais gesammelte Säugetiere.

Was die Säugetiere anbetrifft, so repräsentiert das Gouvernement Kutais in dem allergrössten Teile seines Territoriums buchstäblich eine "Terra incognita", wesswegen auch jede Sammlung uns einen wertvollen Beitrag zur Kenntnis über die Verbreitung der Säugetiere liefert. Die Sammlung A. M. SUGUROVS, Lehrers der Naturwissenschaften am Kutaiser Gymnasium, erhält 8 Arten, von denen besonders interessant, *Vespertilio murinus* L. ist, von dem das Museum bisjetzt keine Exemplare aus dem westlichen Transkaukasien hatte.

XI. Von Satunin und Rostovtsev in Bakuriani 1908 gesammelte Säugetiere.

Währen einer meiner Dienstreisen im Sommer 1908 verbrachte ich einige Tage in Bakuriani (bei Borzom). Ich nutzte dies aus und stellte im Walde verschiedene Fallen auf, wobei ich den Studenten des Kais. Forstinstituts ROSTOVTSEV darum bat auf sie aufsupassen. In freundlichster Weise erfüllte Herr ROSTOVTSEV meine Bitte und sandte mir nach tiflis asse Erbeutete. Ich benutze hier die Gelegenheit ihm meinen herzlichsten Dank auszusprechen.

XVI. Mammalia des Kaukasus un der angrenzenden Länder aus den Sammlungen des Zoologischen Museums der Kaiserl. Akademie der Wissenschaften in St. Petersburg.

Im November 1908 hatte ich die Möglichkeit dank der Frundlichkeit des Direktors des Zoologischen Museums der Kais. Akad. Der Wissenschaften einen Einblick in die Sammlungen des Museums, speziell der *Chiroptera* und *Insectivora* zu tun. Zweck meiner Arbeit war die Durchsicht sämmtlichen Materials vom Kaukasus, welches sich hier befand. Leider war ich durch Krankheit veranfasst mit dieser Arbeit aufzuhören bevor ich mein Ziel erreichen konnte. Aber auch unter dem schon durchmusterten fand sich viel interessantes vor, viele Fundorte diverser Arten, von wo das Kaukasische Museum keine Exempare besitzt. In Anbetracht dessen, dass diese Angaben unsre Kenntnisse der geographischen Verbreitung dieser Arten sehr erweitern, auf die baldige Publikation der Kataloge des Zoologischen Museums aber gar keine Hoffnung ist, entschliesse ich mich dazu meine Resultat hier zu veröffentlichen.

Scaramella, D. (1975). I mammiferi dello Yemen (Y.A.R.) controllati al livello della sottospecie.

L'autore elenca i mammiferi presenti nel territorio della Rep. Araba dello Yemen. Di ciascun esemplare viene trattata la posizione sistematica fino al livello della sottospecie, l'area di distrìbuzione geografica ed altre notizie, in particolare sulla consistenza, e conservazione delle specie.

The author rnakes a list of the mammals wich live in the Y.A.R. He deal with each mammal, giving its position in the sistem up to t he subspecies level through distinctive characrers: together with its geographical distribution, and few notes especially on it possibilitv of surviving

---

Schätti, B. (1984). Fledermäuse als Nahrung von Schlangen.

A further record of *Nyctalus leisleri* (Kuhl, 1818) from Afghanistan is verified by a specimen from the stomach of a snake (*Coluber rhodorachis*). A study of the literature on snakes preying on bats makes

it clear that chiropterophagy seems not to be uncommon for some populations of various snake species. Most of the observations concern giant snakes and larger climbing colubrid species.

Not only caves with large bat populations attract the interest of potential predators; snakes seem to be equally successful in hunting bat species which live together in small groups and different types of roosting places. Under favorable conditions a snake's diet can largely consist of bats. According to the type of roosting place snakes use various hunting techniques and are even capable of capturing their prey in total darkness.

Schlitter, D. A. and I. R. Aggundey (1986). Systematics of African bats of the genus *Eptesicus* (Mammalia: Vespertilionidae). 1. Taxonomic status of the large serotines of Eastern and southern Africa.

The taxonomic status of large serotine bats (*Eptesicus*) from eastern and southern Africa is studied. *Eptesicus loveni* Granvik, 1924. known from Mt. Elgon, Kenya, by only the holotype, is a junior synonym of *Myotis tricolor* (Temminck, 1832). A new subspecies is proposed for *Eptesicus hottentotus* from Njorowa Gorge, Kenya. *Eptesicus hottentotus pallidior* Shortridge, 1942, from the northwestern Cape Province, South Africa, and Namibia is synonymized wilh the nominate subspecies from the Cape Province.

Schlitter, D. A., I. R. Aggundey, M. B. Qumsiyeh, K. Nelson and R. L. Honeycutt (1986). Taxonomic and distributional notes on bats from Kenya.

Taxonomic and distributional comments are given for six species in three families of bats from Kenya. Two species (Hipposideros camerunensis and Tadarida russata) are reported from Kenya for the first time.

Schlitter, D. A. and A. F. DeBlase (1974). Taxonomy and geographic distribution of *Rhinopoma microphyllum* (Chiroptera: Rhinopomatidae) in Iran, with the description of a new subspecies.

L'étude des collections de *Rhinopoma microphyllum* a permis de préciser l'aire de répartition de cette chauve-souris en Iran et de rendre compte de nombreux nouveaux spécimens provenant de nouvelles localites. Une sous-espèce nouvelle, *R. m. harrisoni* a pu être décrite du sud-ouest de l'Iran où elle se trouve souvent à proximité de *R. m. microphyllum*. Cette dernière a été collectée à des altitudes plus élevées et dans des zones plus froides que *R. m. harrisoni*.

The taxonomy and geographic distribution of *Rhinopoma microphyllum* from Iran are reviewed and numerous new specimens and localities are reported. A new subspecies of *R. microphyllum* is from southwestern Iran and is shown to exist in close proximity to the nominate subspecies.

Schlitter, D. A. and M. J. Delany (1985). Geographic areas of Africa poorly represented in mammal research collections.

Two major areas of Africa are still poorly represented by specimens in mammal research collections. These areas include the Central Sahara and Subsaharan region, especially in western Africa and the western and southern Equatorial forest block. Countries, or parts thereof included, are southern Algeria, Chad, Niger, Mali, Mauritania and the former Spanish Sahara and Gabon, Republic of Congo, western and southern Zaire and Angola, especially the northern part. Additionally, the Horn of Africa, including Somalia, Djibouti, Ethiopia and northern and eastern Kenya are poorly represented. Other smaller areas such as the mountains of southern and eastern Tanzania, the provinces of northern Mozambique, the massifs on either side of the Central African rift and southern Sudan require

additional, careful collecting. It is difficult to assess the real situation regarding representatives by each country as much unreported material exists in various museums of the world, particularly in those in North America. Because of financial restraints numerous faunal or regional studies and taxonomic revisions have not included the extant specimens available in African, European and North American museums. Large collections of mammals from West, East and South Africa are present, but unreported in North American Museums.

Schlitter, D. A. and S. B. McLaren (1981). An additional record of *Myonycteris relicta* Bergmans, 1980, from Tanzania (Mammalia: Chiroptera).

A fourth specimen of the East African relict collared fruit bat, *Myonycteris relicta* Bergmans, 1980, is reported. This specimen, from the Nguru Mountains of central Tanzania, supports the contention of a previous connection between East African mountain forests with central African counterparts. External and cranial measurements of the new specimen are compared with other reported *M. relicta* and a sample of *M. torquata*.

Schlitter, D. A., I. L. Rautenbach and D. A. Wolhuter (1980). Karyotypes and morphometrics of two species of *Scotophilus* in South Africa (Mammalia: Vespertilionidae).

Karyotypes for *Scotophilus dinganii* (A. Smith, 1833) and *S. viridis* (Peters, 1852) are presented. Based on retfrence samples from the northern Kruger National Park, individual and secondary sexual variation are analysed for each species. Discriminant function analysis was performed with these reference samples and discriminant scores were computed to assist in accurately identifying specimens of the two species in South Africa.

Schlitter, D. A., L. W. Robbins and S. A. Buchanan (1982). Bats of the Central African Republic (Mammalia: Chiroptera).

The bats of the Central African Republic are reviewed. The occurrence of 45 species is documented, with locality, habitat, reproductive data, and other natural history information given. Taxonomic notes are discussed where necessary and selected measurements are listed for the species. Twenty species are reported for the first time for the Central African Republic.

Schlitter, D. A., S. L. Williams and J. E. Hill (1983). Taxonomic review of Temminck's trident bat, *Aselliscus tricuspidatus* (Temminck, 1834) (Mammalia: Hipposideridae).

Specimens of Ternrninck's trident bat (*Aselliscus tricuspidatus*) from Australasia were analyzed for morphological variation. Univariate and multivariate analyses were used to determine individual secondary sexual, and geographic variation within the species. Individual variation was greater in females than in males although this variation generally was minor in all cases. Females were found to be significantly larger than males in four of seven measurements tested. The analysis of geographic variation revealed that four subspecies can be recognized within the species; two of these are described as new.

Schmidt, U. and G. Joermann (1983). Untersuchungen zur Echoortung um Gruppenflug bei Mausschwanzfledermäusen (*Rhinopoma microphyllum*).

Investigated were the echolocation sounds of *Rhinopoma microphyllum* during single and group flights under laboratory conditions. In a 3-m-flight-tunnel and when flying in a large room exclusively FM-sounds with 5 to 7 harmonics were registered. Each of the 6 experimental animals had an individual

frequency range of the harmonics that remained unchanged during group flights. Duration and temporal pattern of the sounds did not alter under these conditions either. The only response to the acoustic activiry of conspecifics consisted in a rise of sound intensity up to 20 dB. A similar reaction was observed when flying in the presence of noise.

Schönenberger, N. and H. C. Lane (1971). Quelques données sur le cordon nerveux digital alaire des Megachiroptères (*Rousettus aegyptiacus* et *Pteropus giganteus*).

Summary

The nerve bundle found between artery and vein on either side of the metacarpals in the bat wing are composed of fascicles. Each fascicle contains myelinated and non myelinated fibres. In these fascicles small capillaries are found.

Between the main nerve bundle and the artery and vein, interstitial tissue (collagen, fibrocytes) small blood vessels and myelinated and non myelinated nerve fibres are found. Some of these nerves react positively to an histochimical test for catecholamine.

Zusammenfassung

Der Hauptnervenstrang zwischen Flügelarterien und -venen von Megachiropteren setzt sich zusammen aus Nervenbündeln, die, neben einigen Blutkapillaren, myelinisierte und unmyelinisierte Nervenfasern enthalten.

Zwischen Hauptnervenstrang und Hauptblutgefässen finden sich neben Bindegewebe (Collagen, Fibrocyten usw.) und feinen Blutgefässen, myelinisierte und nicht myelinisierte Nervenfasern. Ein Teil dieser Fasern reagiert positiv auf histochemische Nachweismethoden fur Catecholamin.

Schutt, W. A. , Jr. and N. B. Simmons (1998). Morphology and homology of the chiropteran calcar, with comments on the phylogenetic relationships of *Archaeopteropus*.

Most researchers have considered the calcar to be a unique and homologous structure within Chiroptera (e.g., the presence of this structure and its associated musculature has been cited as a synapomorphy supporting bat monophyly). However, we report that significant morphological variation exists between Microchiroptera and Megachiroptera. In microchiropterans, a calcified or cartilaginous element articulates directly with the calcaneal tuberosity of the ankle and projects into the uropatagium. In megachiropterans, a cartilaginous structure projects from the tendon of the gastrocnemius muscle into the uropatagium and has no articulation with the calcaneal tuberosity. Considerable variation also exists in the musculature associated with these structures. Phylogenetic interpretation of hindlimb morphology of extant and fossil taxa indicates that the calcar may not be homologous in all bats. We suggest retention of the term "calcar" for the microchiropteran structure and propose a new term, "uropatagial spur," for the megachiropteran structure. The fossil bat *Archaeopteropus transiens* (Oligocene) has long been presumed to be a megachiropteran; however, this form has a microchiropteran-type calcar. Reconsideration of morphological evidence from this and previous studies indicates that *Archaeopteropus* is not a megachiropteran but, rather, a basal member of the microchiropteran lineage.

Schwann, H. (1905). A list of the mammals collected by the Hon. N.C. Rothschild, the Hon. F.R. Henley, and Mr. A.F.R. Wollaston in Egypt and the Soudan in January, February and March 1904.

Several of the species mentioned in this list - notably *Acomys witherbyi, Gerbillus pygargus, Dipodillus watersi, Lepus isabellinus*, and *Hystrix cuvieri* - have not been taken hitherto in so northern a locality, and their range must accordingly be extended.

A few notes supplied by Mr. Rothschild on some of the less-known localities, where specimens were obtained, will be a great assistance in properly understanding their geographical relationships.

Nakheila, where the battle of the Atbara was fought, is about fifty miles up the Atbara River, on the north bank.

Merowe and Kerma are both in the Dongola Province. The former is at the commencement of the fourth cataract, while the latter is the terminus of the railway from Wady Halfa to the Dongola Province.

Shereik is a railway station at the little-known Abu Haschim cataract, some fifty miles south of Abu Hammed.

Schwann, H. (1906). A list of the mammals obtained by Messrs. R.B. Woosnam and R.E. Dent in Bechuanaland.

This very interesting collection, made by Messrs. R. B. .Woosname and R. E. Dent in Bechuanaland, was obtained chiefly at two localities, viz. Kuruman and Molopo. The former is situated about 100 miles south-west of Vryburg on the Kuruman River, whose course flows parallel to the range of hills bearing the same name. The river was originally fringed with dense reeds, providing excellent shelter for game of all kinds; but in some parts clearings have bene made by the natives, and the ground drained and cultivated with corn and fruit-trees.

The Molopo River, lying considerably to the north of Kuruman, is dry most of the year, but in the rainy season may be as much as 16 feet deep. The water remains in stagnant pools till about mid-August, when it is gradually evaporated, leaving the river-bed dry until next year. The country surrounding the river is covered with dense camel-thorn forest and patches of soft sand.

The particular interest of this collection lies in its providing the British Museum with many valuable topotypes of Dr. Smith's now well-worn and rather faded specimens. His main collections, described in the 'Illustrated Zoology of South Africa,' were made at Kuruman and Old Latakoo, lying in S. lat. 27°, E. long. 24°, a place not marked on modern maps, but in his day of considerable importance. As was to be expected, the prevailing colour of the specimens is sandy and considerably lighter than that of animals inhabiting well-wooded areas. Among the species now described for the first time may be mentioned *Crocidura deserti*, a pale-coloured Shrew, probably a desert form of Sundevall's *argentata*, and *Mus woosnami*, a striking species both in colour and tooth-structure.

Setzer, H. W. (1952). Notes on mammals from the Nile Delta Region of Egypt.

From July 12, 1946, to April 9, 1947, Ens. P. Quentin Tomich collected mammals from the Nile Delta while serving with Naval Medical Research Unit No. 3. In addition to the large collection made by Ensign Tomich, Lt. S.M. Wheeler, of the United States Typhus Commission, obtained some specimens in the Cairo area. Earlier, in 1924, Miss Annie M. Alexander obtained a small collection from the Cairo area and from the Fayum. The former two collections are on deposit in the United States National Museum while the latter is on deposit at the Museum of Vertebrate Zoology of the University of California (MVZ) and has been made available for study at this time by Dr. Alden H. Miller.

Since impetus is being given study of the role wild mammals play in diseases of man, a brief diagnosis of the external characters plus comments on taxonomic problems as relating to the commoner mammals from Egypt, as based on the above-metioned material, will be useful to epidemiologists working in the Nile Delta region.

It will be noted that in certain cases names have been validated from Etienne Geoffroy St.-Hilaire, 1803. The "Catalogue des Mammifères du Muséum National d'Histoire Naturelle" meets all requirements for Linnaean names as established by the International Commission on Zoological Nomenclature. In all instances the descriptions are clearly recognizable. It is believed that the statement of Isidore Geoffroy St.-Hilaire, to the effect that his father never intended to above work for

a scientific treatise, should not be accepted, inasmuch as the work is clear, concise, and was published and circulated.

The Tomich collection is perhaps the largest and most complete single collection known from the Nile Delta region. Even so, several species that have occurred and presumably still occur in that region were not taken by the collectors on whose work this paper is based. For the sake of completeness, references to these have been extracted from the literature.

In addition there are four species which have been taken from the Delta region within historic time but have since been extirpated. They are: Wild sheep, *Ammotragus lervia*; dorcas gazelle, *Gazella dorcas*; saberhorned oryx, *Oryx algazel*; and addax, *Addax nasomaculata*.

Capitalized color terms are from Ridgway, "Color Standards and Color Nomenclature" (1912). All measurements are given in millimeters and all weight in grams.

No comments have been made in regard to habitats or habitat preference, since Tomich hopes to publish an account of the natural history of these animals and their role in epidemiology.

Setzer, H. W. (1971). New bats of the genus *Laephotis* from Africa (Mammalia: Chiroptera).

The Smithsonian Institution African Mammal Project has had field parties collecting small mammals and their ectoparasites in southern Africa since 1963.

These field teams obtained two specimens of the genus *Laephotis* from South West Africa and one specimen from northwestern Botswana. None of these individuals agree with other known taxa in the genus *Laephotis*. We have made repeated efforts to obtain additional specimens, especially from South West Africa, but have been unsuccessful. All measurements are in millimeters and capitalized color terms are from Ridgway "Color Standards and Color Nomenclature, 1912."

Owing to the degree of distinctness of these specimens two new taxa are here proposed and may be known as:

Sheil, D. (1992). Tanzanian coastal forests - unique, threatened, and overlooked.

Tanzania's remaining fragments of coastal forests support rich biological communities, but these are extremely vulnerable to exploitation and land-use pressures because of their very limited size. Until recently little attention has been paid to these areas and and it is probable that all the most important forest areas have not yet even been recognized. Conservation measures are needed urgently and while these have been incorporated into the Tanzanian Forestry Action Plan, funding has not been identified.

Shope, R. E., F. A. Murphy, A. K. Harrison, O. R. Causey, G. E. Kemp, D. I. H. Simpson and D. L. Moore (1970). Two African viruses serologically and morphologically related to rabies virus.

Lagos bat virus and an isolate from shrews (IbAn 27377), both from Nigeria, were found to be bullet-shaped and to mature intracytoplasmically in association with a distinct matrix. They were related to, but readily distinguishable from, rabies virus and each other by complement fixation and neutralization tests. The three viruses, including rabies, form a subgrouping within the rhabdoviruses.

Shortridge, G. C. (1942). 2. Field notes on the first and second expeditions of the Cape Museum's Mammal Survey of the Cape Province; and descriptions of some new subgenera and subspecies.

Expedition No. 1: Little Namaqualand (October 1936 - February 1937)

On a collection of approximately 2500 mammals from Little Namaqualand, including records of species collection between Upingon and the Aughrabies Falls in 1921.

LITTLE NAMAQUALAND is here regarded as comprrsmg the region lying between the Orange River in the north, latitude 31° in the south, longitude 19° in the east, and the Atlantic Ocean on the west. It is the most, arid part of the Cape Province. The yearly winfall at Springbok averages 7 inches, and at Port Nolloth 2 1/2 inches.

Except on the Kamiesberg there is practically no surface water. The mountains and plateaux known as the Kamiesbergen, which rise to over 5000 feet, (Welkom Kop, 5589 feet; Eselkop, 5456 feet), attract a much more adequate rainfall and have a contrastingly temperate climate. In consequence the vegetation on the higher slopes and plateaux is relatively luxuriant.

The Kamiesberg, frequeutly under cloud, forms a fertile oasis, and the mountain scenery between Garies and Leliefontein is very beautiful. Elsewhere the general aspect of Little Namaqualand during the greater part of the year is barren in the extreme: the sandy plains are sparsely clothed with dwarf desert plants, many of which are succulents. Apart from a narrow fringe along the Orange River, there are no trees of any description.

Between September and October, however, after the first light spring rains, Namaqualand changes, almost overnight, into one of the world's most magic gardens; the plains and hillsides for the short period of about six weeks become brilliantly carpeted with wild flowers, innumerable in variety and colours. On the Kamiesberg the flowering season continues until about the middle of December. Except in the extreme south, along the eastern border, and close to the coast, there are almost everywhere masses of outcrop, stony kopjes and rocky mountain ranges. Camps were made at the following places: -

1. *Witwater*: altitude: 3500 - 3800 feet, a plateau high up in the Kamiesberg almost entirely surrounded by stony hills. There are a few farms, and small plots under cultivation.

2. *Eselfontein*: altitude 4300 - 4350 feet, close to Leliefontein Hottentot Mission, the highest plateau on the Kamiesberg.

These plateaux are watered by small perennial mountain streams which disappear underground before reaching the plains. The vegetation on the higher slopes is heathy and not unlike that on the mountains of the south-western Cape. Light crops ofwheat are grown; goats and a few cattle and sheep are kept.

3. *Platbakkies*: altitude 3460 feet, about, 20 miles east of the Kamiesberg. Arid high-karooveld with occasional rocky ridges and rough stony tracts. Country quite typical of "Bushmanland."

4. *Goodhouse*: altitude: 300 feet approx., on the south bank of the lower Orange River at Raman's Drift. At this point the Orange River flows between almost unbroken chains of highly mineralized hills which rise from 500 - 1200 feet. All level country consists of heavy white sand. For the greater part of the year hardly a trace of vegetation is visible, except along the river's edge where there is a thin fringe of tree growth. In contrast to these desert surroundings is the intensely green citrus Estate of Goodhouse, irrigated by a system of canals which lead off from the river (owner, Mr. C. Weidner).

5. *Eenriet*: altitude 3300 feet approx., 7 miles north of Steinkopf. A waterhole close to rocky hills which rise between 500 and 800 feet above the surrounding level. Beyond the hills there are wide stretches of sandveld scantily clothed with low karoo scrub and intersected here and there by dry watercourses.

6. *Port Nolloth*: A camp (altitude 50 fieet approx.) was made about 15 miles inland where the white coastal sand-dune belt meets the firmer reddish-sandy country and near the first broken line of wind-swept hills which rise to about 600 feet.

7. *Kameelboom*: altitude 800 feet approx., in the bd of the dry Spoeg River, about half-way between Garies and Hondeklip Bay. Surrounding hills rise to about 1000 feet. Red and white sandy country

much broken up by rocky outcrop. Vegetation largely succulent; shrubby bushed amongst the rocks and between the hills.

During the British and Kaffrarian Museuma' Expedition to the middle Orange River in 1921, collections were made close to *Upington, Swartkop, Louisvale*, and the *Aughrabies Falls*, The Upiugton and Aughrabies camps were on the north bank of the Orange River, those near Swartkop and Louisvale on the south bank.

Out of 106 species recorded, 78 were collected; 20 are extinct, or nearly so; 4 are of doubtful occurrence. Names of species in brackets indicate that specimens were not obtained.

Contributors towards the Cape Museums' Mamrnal Survey include The Museum of Comparative Zoology (at. Harvard Uuiversity, United States of America), The South African Museum (Cape Town), The Natal Museum (Pietermaritzburg), The Albany Museum (Grahamstown), The McGregor Museum (Kimberley), The Port Elizabeth Museum, The East London Museum, The Kaffrarian Museum (King William's Town), The National Research Council, and Dr. H. Merensky.

Sidiyène, E. A. and M. Tranier (1990). Données récentes sur les Mammifères de l'Adrar des Iforas (Mali).

The Adrar des Iforas, in Mali, is zoologically a poorly known massif. Located in Southern Sahara, and with sorne 100 mm annual rainfall, it retains some elements of the ethiopian fauna. In 50 years, largest rnammals disappeared almost compterely through the combined effect of drought, gun and car. Only Barbary sheep, *Ammotragus lervia*, common gazelle, *Gazella dorcas*, and striped hyaena, *Hyaena striata*, remain there. Three bat species were recently caught: *Nycteris thebaica* (first record for Mali), *Asellia tridens* (first record for Mali), and *Nycticeius schlieffeni*. Three rodents species, too, were hand-caught: the Southern gundi *Massoutiera mzabi* (first recorded in Mali, where it was expectce, as it is known from nearby Hoggar), the Small sand gerbil, *Gerbillus gerbillus*, and the Nile rat, *Arvicanthis* sp, (northernmost capture in Mali for this genus).

Le massif de l'Adrar de, Iforas, au Mali, est zoologiquement peu connu. Situé au sud du Sahara, il retient quelques éléments de la faune éthiopienne, avec une pluviosité annuelle oscillant autour de 100 mm. La grande faune mammalienne a pratiquement disparu en 50 ans, victime de la sécheresse et de l'association du fusil et de l'auromobile; il ne subsiste que le mouflon, *Ammotragus lervia*, et la gazelle, *Gazelta dorcas*, parmi les Ongulés; la hyène rayée est le plus gros des Carnivores qui subsistent. Parmi les Chiroptères, les auteurs signalent la capture de *Nycteris thebaica* (première mention au Mali), d'*Asellia tridens* (première mention au Mali), et de *Nycticeius schlieffeni*. Parmi les Rongeurs, le goundi *Massoutiera mzabi* a été collecté pour la première fois au Mali; la présence de cet animal, connu au Hoggar proche, était attendue dans l'Adrar. *Gerbillus gerbillus* a été capturé également, ainsi qu'*Arvicanthis* sp.; un individu de ce dernier genre a été capture dans un oued: c'est la capture la plus septentrionale connue au Mali pour ce genre.

Simmons, J. A., S. A. Kick and B. D. Lawrence (1984). Echolocation and hearing in the mouse-tailed bat, *Rhinopoma hardwickei*: acousting evolution of echolocation in bats.

1. Mouse-tailed bats (*Rhinopoma hardwickei*) use short-duration, multiple-harmonic, constant-frequency (CF) or slightly frequency-modulated (FM) signals for echolocation of flying insect prey. The frequency components are 18 - 20 kHz (first harmonic), 36 - 40 kHz (second harmonic), 56 - 60kHz (third harmonic), and 75 - 80 kHz (fourth harmonic). The second harmonic is the strongest component, with the third harmonic 2 to 10 dB weaker, and the first and fourth harmonics about 10 to 20 dB weaker than the second.

2. The bat's hearing, as indicated by N 4 auditory evoked potentials, is moderately sharply tuned to the second harmonic, broadly sensitive to the first harmonic and to lower frequencies, and moderately sensitive to the third and fourth harmonics. The degree of tuning is sufficient to indicate some

specialized function for the second harmonic, perhaps in the task of detecting targets at maximum range, since this is the lowest of the strong harmonics and least affected by atmospheric attenuation. These bats probably do not perform the Doppler compensation response even though their hearing is tuned.

3. The pattern of emission of sonar sounds (repetition rate, duration) during interception of prey is similar to that observed in most other species of bats. The signals are emitted at repetition rates of 10 - 20/s during the search stage, 20 - 40/s during the approach stage, and about 100/s during the terminal stage of the pursuit process. The sonar sounds emitted during the search stage are 6 - 10 ms long, during the approach stage they are 2 - 4 ms long, and during the terminal stage they are less than 1 ms long.

4. The principal acoustic dimension of echolocation sounds that relates to perception of targets is signal bandwidth, which *Rhinopoma hardwickei* manipulates throughout the pursuit process by shortening the duration of its sonar sounds and also by slightly broadening the FM sweeps in its terminal-stage sounds. The onset-time of the long, search-stage sounds and the longer, early approach-stage sounds is more abrupt than for the shorter, late approach-stage and the short terminal-stage sounds. This apparently deliberate transient beginning broadens the signal's bandwidth at the onset relative to the narrower bandwidth prevailing for the rest of the CF harmonic structure which follows. In the shorter sounds, which are emitted during the late approach stage and terminal stage, the onset is more gradual, but the duration (the envelope) and the offset-time are now short enough that the bandwidth of the signal as a whole is increased. The bandwidth is manipulated primarily by these changes in signal envelope and secondarily by the increased FM sweep-width in the terminal stage.

5. Except for duration these signals are relatively inflexible and suggestive of a primitive kind of echolocation in which only one dimension is changed to achieve qualities which most other species of bats obtain by changing a variety of signal dimensions simultaneously. The abrupt signal onsets may be an indication that multiple-harmonic CF and FM echolocation sounds evolved from click-like echolocation sounds of the type emitted by *Rousettus* and some terrestrial mammals.

Simmons, N. B. (1994). The case for Chiropteran Monophyly.

The current controversy concerning bat monophyly centers on relationships of Microchiroptera, Megachiroptera, Primates, and several other groups of mammals. Despite claims to the contrary, studies of both molecular and morphological data strongly support bat monophyly and a single origin for powered flight in mammals. Analyses of some molecular data sets have yielded inconclusive results (e.g., rDNA restriction sites, aA-crystallin amino acid sequences, and cytochrome oxidase subunit I gene nucleotide sequences). However, analyses of most biochemical and molecular data support monophyly of bats (e.g., albumin immunological distances, DNA-DNA hybridization, a-globin + ß-globin amino acid sequences, nucleotide sequence data from the e-globin gene, interphotoreceptor retinoid binding protein gene, 12S rRNA gene, and cytochrome oxidase subunit II gene). In no instance have molecular data provided unambiguous support for bat diphyly. Morphological data show a slightly different pattern. Neural and penial characters support diphyly of bats, but other data subsets clearly support bat monophyly (e.g., characters of the cranium and postcranial skeleton, vascular system, muscles, and fetal membranes). When all of the morphological data are considered together, the combined data set strongly supports bat monophyly. Over 25 morphological synapomorphies-many of which consist of complex suites of modifications-diagnose the monophyletic order Chiroptera. The fact that these synapomorphies represent many different anatomical systems further strengthens the case for chiropteran monophyly.

Simmons, N. B. (1998). A reappraisal of interfamilial relationships of bats.

Higher-level relationships of bats remain poorly understood despite recent advances in our understanding of relationships at lower taxonomic levels. Although most bat species can be assigned easily to one of several monophyletic families, there is little agreement concerning relationships among

the latter taxa. This is not just a problem of resolution: Previous hypotheses of interfamilial relationships are largely incongruent. Lack of a well-substantiated phylogeny has hampered systematic studies at lower taxonomic levels, hindered attempts to understand patterns of morphological, karyotypic, and molecular change, and complicated interpretation of biogeographic and ecological data. In this context, the purpose of the current study is to provide a working hypothesis of interfamilial relationships of bats based upon a "total-evidence" analysis of available morphological and molecular data.

Simmons, N. B. and J. H. Geisler (1998). Phylogenetic relationships of *Icaronycteris*, *Archaeonycteris*, *Hassianycteris*, and *Palaeochiropteryx* to extant bat lineages, with comments on the evolution of echolocation and foraging strategies in Microchiroptera.

The Eocene fossil record of bats (Chiroptera) includes four genera known from relatively complete skeletons: *Icaronycteris, Archaeonycteris, Hassianycteris*, and *Palaeochiropteryx*. Phylogenetic relationships of these taxa to each other and to extant lineages of bats were investigated in a parsimony analysis of 195 morphological characters, 12 rDNA restriction site characters, and one character based on the number of R-1 tandem repeats in the mtDNA d-loop region. Results indicate that *Icaronycteris, Archaeonycteris, Hassianycteris*, and *Palaeochiropteryx* represent a series of consecutive sister-taxa to extant microchiropteran bats. This conclusion stands in contrast to previous suggestions that these fossil forms represent either a primitive grade ancestral to both Megachiroptera and Microchiroptera (e.g., Eochiroptera) or a separate clade within Microchiroptera (e.g., Palaeochiropterygoidea). A new higher-level classification is proposed to better reflect hypothesized relationships among Eocene fossil bats and extant taxa. Critical features of this classification include restriction of Microchiroptera to the smallest clade that includes all extant bats that use sophisticated echolocation (Emballonuridae + Yinochiroptera + Yangochiroptera), and formal recognition of two more inclusive clades that encompass Microchiroptera plus the four fossil genera.

Comparisons of results of separate phylogenetic analyses including and subsequently excluding the fossil taxa indicate that inclusion of the fossils changes the results in two ways: (1) altering perceived relationships among extant forms at a few poorly supported nodes; and (2) reducing perceived support for some nodes near the base of the tree. Inclusion of the fossils affects some character polarities (hence slightly changing tree topology), and also changes the levels at which transformations appear to apply (hence altering perceived support for some clades). Results of an additional phylogenetic analysis in which soft-tissue and molecular characters were excluded from consideration indicate that these characters are critical for determination of relationships among extant lineages.

Our phylogeny provides a basis for evaluating previous hypotheses on the evolution of flight, echolocation, and foraging strategies. We propose that flight evolved before echolocation, and that the first bats used vision for orientation in their arboreal/aerial environment. The evolution of flight was followed by the origin of low-duty-cycle laryngeal echolocation in early members of the microchiropteran lineage. This system was most likely simple at first, permitting orientation and obstacle detection but not detection or tracking of airborne prey. Owing to the mechanical coupling of ventilation and flight, the energy costs of echolocation to flying bats were relatively low. In contrast, the benefits of aerial insectivory were substantial, and a more sophisticated low-duty-cycle echolocation system capable of detecting, tracking, and assessing airborne prey subsequently evolved rapidly. The need for an increasingly derived auditory system, together with limits on body size imposed by the mechanics of flight, echolocation, and prey capture, may have resulted in reduction and simplification of the visual system as echolocation became increasingly important. Our analysis confirms previous suggestions that *Icaronycteris, Archaeonycteris, Hassianycteris*, and *Palaeochiropteryx* used echolocation. Foraging strategies of these forms were reconstructed based on postcranial osteology and wing form, cochlear size, and stomach contents. In the context of our phylogeny, we suggest that foraging behavior in the microchiropteran lineage evolved in a series of steps: (1) gleaning food objects during short flights from a perch using vision for orientation and obstacle detection; prey detection by passive means, including vision and/or listening for prey-generated sounds (no known examples in fossil record); (2) gleaning stationary prey from a perch using echolocation and vision for orientation and obstacle detection; prey detection by passive means (*Icaronycteris, Archaeonycteris*); (3) perch hunting for both stationary and flying prey using echolocation and vision for orientation and obstacle detection; prey detection and tracking using echolocation for flying prey and passive means for stationary prey (no known example, although

Icaronycteris and/or *Archaeonycteris* may have done this at times); (4) combined perch hunting and continuous aerial hawking using echolocation and vision for orientation and obstacle detection; prey detection and tracking using echolocation for flying prey and passive means for stationary prey; calcar-supported uropatagium used for prey capture (common ancestor of *Hassianycteris* and *Palaeochiropteryx*; retained in *Palaeochiropteryx*); (5) exclusive reliance on continuous aerial hawking using echolocation and vision for orientation and obstacle detection; prey detection and tracking using echolocation (*Hassianycteris*; common ancestor of Microchiroptera). The transition to using echolocation to detect and track prey would have been difficult in cluttered envionments owing to interference produced by multiple returning echoes. We therefore propose that this transition occurred in bats that foraged in forest gaps and along the edges of lakes and rivers in situations where potential perch sites were adjacent to relatively clutter-free open spaces. Aerial hawking using echolocation to detect, track, and evalute prey was apparently the primitive foraging strategy for Microchiroptera. This implies that gleaning, passive prey detection, and perch hunting among extant microchiropterans are secondarily derived specializations rather than retentions of primitive habits. Each of these habits has apparently evolved multiple times.

The evolution of continuous aerial hawking may have been the "key innovation" responsible for the burst of diversification in microchiropteran bats that occurred during the Eocene. Fossils referable to six major extant lineages are known from Middle-Late Eocene deposits, and reconstruction of ghost lineages leads to the conclusion that at least seven more extant lineages were minimally present by the end of the Eocene.

Simpson, D. I. H., M. C. Williams, J. P. O'Sullivan, J. C. Cunningham and F. A. Mutere (1968). Studies on arboviruses and bats (Chiroptera) in East Africa. II. Isolation and haemagglutination-inhibition studies on bats collected in Kenya and throughout Uganda.

Three previous papers have dealt with arbovirus haemagglutination-inhibition studies on sera from a variety of East African bats, with virus isolation studies from various bat tissues and also with the experimental infection of four bat species with arboviruses of African origin (Shepherd and Williams, 1964; Williams, *et al.*, 1964; Simpson and O'Sullivan, 1968). Transmission attempts with Bukalasa bat and Entebbe bat viruses, both isolated from salivary glands of *Tadarida* spp., in *Aedes (Stegomyia) aegypti* (Linnaeus) were also reported. The mechanisms of transmission of these bat viruses and the role that bats play in the epidemiology of arbovirus diseases have been discussed. Comparisons were made with the results of workers in West Africa and in the New World.

This communication reports further isolations of Group B viruses from *Tadarida* species collected throughout Uganda and also reports further haemagglutination-inhibition (III) studies on a large variety of bats collected in Kenya and Uganda over a 12-month period.

1. The isolation is described of 20 strains of group B viruses from the salivary glands of *Tadarida* species. The strains were either Bukalasa or Dakar bat viruses, according to the species of bat from which they were isolated.

2. The group B antibody results in both *Tadarida* species and in a wide variety of other bat species are compared with previous results described by other workers.

3. Mechanisms of virus transmission from bat to bat are discussed; it is thought that mosquitoes play little part in the cycle of infection.

Smith, S. A., J. W. Bickham and D. A. Schlitter (1986). Karyotypes of eleven species of Molossid bats from Africa (Mammalia: Chiroptera).

Standard karyotypic data are reported for 11 species of rnolossid bats collected from Somalia and Cameroun, Africa. Chromosomal data are reported for the first time for *Chaerephon ansorgei, C. aloysiisabaudiae, Mops midas, M. spurrelli, M. thersites, M. brachypterus, M. petersoni, M.*

demonstrator, and *M. annulus* (all were formerly members of the genus *Tadarida*). Karyotypes for two of the species we examined have been reported previously. Although our data corroborate the karyotype of *C. pumila* described by Dulic and Mutere (1973), our karyotypic analysis of *M. condylurus* differs substantially from that presented by these authors. In addition to these data, we provide a summary of the available karyotypic data for molossid bats studied to date.

Smithers, R. H. N. and V. J. Wilson (1979). Checklist and atlas of the mammals of Zimbabwe Rhodesia.

Until the publication of Roberts (1951) "*The Mammals of South Africa*", which included Rhodesia as part of the South African Subregion, with its northern limits at the Cunene - Zambezi Rivers, no attempt had been made to present a list of the species of mammals known to occur in Rhodesia.

In spite of the fact that the material available to Roberts from this territory was sparse, he was able, nevertheless, to include in this work some 109 species, as against the 190 known to occur at the present time.

Surprising omissions included such species as the antbear, *Orycteropus afer*, and the erroneous inclusion of others such as the silver fox, *Vulpes chama*. The omissions and erroneous inclusions were due to the fact that very little had been published on the mammals of Rhodesia and Roberts' personal experience of the territory was limited.

In spite of this, Roberts' work was a major factor in stimulating interest in the mammals of southern Africa and, together with an awakening interest in the future of its wildlife, led to a greatly increased and growing volume of regional study in most of the countries comprising the area, including Rhodesia.

Historically, the accounts of a number of early hunters and explorers throw interesting lights on the status of mammals in the territory.

Thomas Baines' diaries of 1869 - 1870 (Wallis, 1946), contain many interesting references, including drawings, with measurements in some cases, of mammals shot or observed by him during his wanderings.

The famous hunter F. C. Selous contributed substantial collections of mammals and accurate observational data from what is now Rhodesia. The great majority of the specimens he collected are housed in the collection of the British Museum (Nat. Hist.) in London and were catalogued by Dollman (1921), although many found their way into other Museums, including the South African Museum in Cape Town, as well as private collections.

Selous visited the western part of Rhodesia (Matabeleland) for the first time in 1872 in the search for elephant, although it was not till 1881 that, on a return expedition to the territory, he seriously devoted himself to the procuring of specimens of Rhodesian mammals for Museums and private collectors.

His interest in the territory continued over the years and in 1891 he was a member of the pioneer column which set up camp in what is today Salisbury.

In 1895 he settled temporarily on his farm in Essexvale where he pursued his interest in wildlife, collecting and sending back to the British Museum (Nat. Hist.) many smaller specimens, including a new species of spiny mouse, *Acomys selousi (A. spinosissimus)*, and a gerbil, *Tatera lobengulae (T. leucogaster)*. (de Winton, 1896; Dollman, 1921; Selous, 1908).

W. H. Brown, an American citizen, then a collector for the Smithsonian Institution, Washington, D.C., was also a member of the pioneer column and, on its arrival in Mashonaland, was detailed off to find meat for the camp. With the true instinct of a collector he recovered skins and skulls of the game animals he shot from the vicinity of what is today Salisbury, which have happily been preserved in collections of Museums in the United States, including the United States National Museum, Washington, D.C.; the Carnegie Museum, Pittsburgh, and others. He was granted a farm near Salisbury, Arlington, on which today the Salisbury Airport is situated.

When the pioneer column was disbanded he moved widely in Mashonaland collecting specimens, this collection including square-lipped rhinoceros, *Ceratotherium simum*, which later became extinct in the territory, and other species from areas where they no longer exist, for example, lion, *Panthera leo*, shot adjacent to what are today the suburbs of the City of Salisbury. Brown also made a valuable collection from Arlington, part of which the senior author had the privilege of examining in the Carnegie Museum.

Regrettably, no paper was published on this collection, but a number of his specimens, examined in Pittsburgh, are commented upon in this paper.

J. ffolliott Darling and Mr. (later Sir) Guy A. K. Marshall collected in the Mazoe district in Mashonaland in 1895 while the former was engaged in mining in the area (Thomas, 1895; de Winton, 1896). This collection consisted predominantly of rodents and is now in the British Museum (Nat. Hist.).

From 1907 till 1911, E. C. Chubb of the Rhodesia Museum (later the National Museum), Bulawayo, collected extensively and published papers on his collections and on the collections of this Museum, these being the first papers on material from the territory (Chubb, 1909).

Although a lot of Chubb's specimens found their way into the collection of the British Museum (Nat. Hist.) or the Transvaal Museum, Pretoria, such as were retained in the National Museum formed the nucleus of the research collections as they are today.

In 1908 C. F. M. Swynnerton, then living at Mt. Selinda, Melsetter, collected small mammals for the British Museum (Nat. Hist.), this being the first material available from the Eastern Districts of Rhodesia.

A further stimulus to the study of mammals came with the publication of a reclassification of the mammals of southern Africa by Ellerman, Morrison-Scott & Hayman (1953), the limits of which extended as far north as Angola, Nyasaland (Malawi) and Mocambique and, therefore, like Roberts (1951), included Rhodesia.

Child & Savory (1964), published a paper on the distribution of the larger mammal species occurring. This was based on a questionnaire, widely distributed in the territory, supplemented by their own visual observations, and was the first attempt to define the distribution of a range of 40 of the larger species, all of which were considered to be recognisable with some degree of accuracy by the range of persons to whom the questionnaire was directed.

From 1964 onwards an increasing number of papers on Rhodesian mammals have appeared annually including the results of surveys in two of Rhodesia's National Parks (Wilson, 1969; 1975) and comprehensive works on individual species (e.g, Cumming, 1974).

In spite of the fact that the National Museums of Rhodesia did not have a Keeper of Mammals until 1962, staff members had been active in collecting material from 1947 onwards and had encouraged others to assist in building up the collection. This activity has continued over the years and today the collections number some 45 000 specimens from Rhodesia alone.

It is unfortunate that it was not until 1961 that new systems were introduced at the National Museums of Rhodesia to ensure that the fullest possible data were recorded on each specimen collected. Prior to this, apart from date of collection, sex and locality, nothing was recorded on the habitat in which the specimen was taken, its reproductive status, its behaviour, or its food.

As a consequence this earlier material, while providing valuable taxonomic and distributional data, lacks sufficient information for its proper evaluation from these other points of view. In this paper such information of this type as is presented is gleaned from data available from material handled from 1961 onwards and is, therefore, limited in its scope.

With the continuation of collecting on this basis, it is hoped that, in time, it will be possible to present fuller data. In the meantime the emphasis in this work will be on the presentation of a list of species now known to occur, based predominantly on material records, with notes, where appropriate, on their taxonomy and information on their distribution. In addition, from the meagre data presently at our

disposal, we have added notes on the types of habitat in which the species occur, their habits, food and times of breeding.

We hope that by the presentation of these data in the present incomplete form we may actuate others to fill in the many gaps in the knowledge of our mammals.

Sowler, S. G. (1980). Tooth eruption in known age specimens of *Epomophorus wahlbergi*.

Descriptions of the deciduous and permanent dentition, dental development and variations in ages of eruption in 14 known age specimens of *Epomophorus wahlbergi* are presented. Tables showing the relationship between tooth eruption and age from birth to 14 weeks are given and the use of these as an age determination technique is discussed.

Beskrywings word gegee van melk- en permanente tande, dentale ontwikkeling en wisseling in ouderdomme van deurbraak van 14 eksemplare van *Epomophorus wahlbergi* waarvan die ouderdom bekend is. Tabelle wat die verhouding aantoon tussen die deurbraak van die tand en ouderdom vanaf geboorte tot 14 weke word aangegee en die gebruik hiervan as 'n tegniek om ouderdom vas te stel, word bespreek.

Speakman, J. R. and P. I. Webb (1993). Taxonomy, status and distribution of the Azorean bat (*Nyctalus azoreum*).

The taxonomic status of the Azorean bat (*Nyctalus azoreum* Thomas 1901) was assessed, by a principal components analysis of measurements of the external morphology of the bat, together with specimens of the closest related *Nyctalus* species from mainland Europe (*Nyctalus leisler*). This analysis confirms the recent suggestion, based on a similar analysis of skull morphology, that the Azorean bat represents a good species, distinguished from *N. leisleri* by its smaller size -forearm lengths for *N. azoreum* in range 35.7 - 42.0 mm (n = 14), compared with 42.0 - 45.8 mm (n = 8) for *N. leisleri*. The status and distribution of the Azorean bat was assessed by a survey conducted in the Islands in September and October 1988. We assessed the presence or absence of bats, in 62 (1' latitude x 1' longitude) plots at the west end of the island of Sao Miguel. The study area covered 6 % of the total land area of the archipelago and contained representative areas of all the major island habitat types. A less intensive survey throughout four other islands, literature review and information from other sources revealed that the bat is probably distributed throughout the entire archipelago, with the possible exception of Flores and Corvo. Bats were active both in the day and at night. At night, bats were mostly active in coastal villages where they were closely associated with street lighting. During the day, most bats were active in the inland areas near to Caldeira lakes. The maximum number of bats observed simultaneously active in the day was six whilst at dusk swarms of up to 55 (± 5) bats were observed together. At night, bats were also active over approximately 1.5 x the area they occupied in the day. By assuming the bat is found throughout the archipelago, and that our study area was representative, we estimated the maximum population to be between 1750 (from daylight activity) and 23,650 (from nocturnal activity). This latter estimate implies a population density throughout the archipelago of around 0.1 bats per hectare.

Spiewak, R., S. G. O. Johansson and B. Wüthrich (1996). Der interessante Falll. Berufsbedingtes Asthma auf Fledermäuse (Chiropteren).

Es wird ein 31-jähriger Patient mit atopischer Konstitution beschrieben, bei dem es infolge heruflicher Exposition mit Fledermäusen zur Asthmaentwicklung kam. Aufgrund der duchgeführten Untersuchungen (Hauttests und RAST mit Fledermausallergenen) konnte eine IgE-abhängige Reaktion bestätigt werden. Da der Patient, als engagierter Wissenschaftler, auf die Kontakte mit Chiropteren nicht verzichten wollte, wurde eine Desensibilisierungstherapie mit Fledermaus-

allergenextrakt unternommen. Nach einem Behandelungsjahr verspürte der Patient bei erneuten Chiropteren-Kontakten kein Beschwerden mehr.

We describe a 31 years-old atopic patient, in whom after occupational exposure to Chiroptera bronchial asthma developed. The performed tests (skin test and RAST with bat allergens) confirmed the presence of an IgE-dependent allergic reaction to bat allergens. While the patient, as an engaged scientist, was not able to abandon the contact with Chiroptera, a specifi immunotherapy with bat allergen extracts was undertaken. After one year of therapy the patient had no more symptoms at contact to the Chiroptera.

Spinage, C. A. (1988). First steps in the ecology of the Bamingui-Bangoran National Park, Central African Republic.

A description is given of the 11,560 km^2 Bamingui-Bangoran National Park situated in the mid-Sudanian phytogeographic domain of the Central African Republic. Attention is drawn to the interest of the ecology of this little-known zone, which lies between north-south and east-west ecotones, of the sahel-tropical forest and oriental region west Africa, respectively. Preliminary collections of plants and small mammals were made. An analysis of the flora and the large mammals observed suggests a predominantly West African affinity. The subspecific endemism shown by the large mammals appears more probably linked to Pleistocene isolation by the Chari-Logone river system, than to a mega Lake Chad as has been postulated elsewhere.

Spitzenberger, F. and K. Bauer (1979). Die Säugetierfauna Zyperns. Teil II: Chiroptera, Lagomorpha, Carnivora und Artiodactyla

Auf Zypern leben 1 Megachiropteren- und 11 Microchiropterenarten (davon erstmals bestätigt: *Myotis blythi, Eptesicus serotinus, Nyctalus noctula*), ferner *Lepus europaeus, Vulpes vulpes* und *Ovis ammon*. Die vom frühen Neolithikum bis in die späte Bronzezeit durch Knochenreste nachgewiesene *Dama mesopotamica* wird als autochthones Säugetier betrachtet. - Die von ANDERSEN 1918 vorgenommene Zuordnung zypriotischer *Rhinolopus hipposideros* zu *midas* wird bestätigt. Die *Myotis blythi*-Population Zyperns entspricht in der Größe *omari*, weicht jedoch in der Schnauzenproportion davon ab. - Eine tiergeographische Analyse der Säugetierfauna Zyperns ergibt ein Überwiegen mediterrano-turkestanischer, bzw. irano-turanischer Elemente und gleicht verblüffend der pflanzengeographischen Analyse durch ZOHARY 1973. Bei vielen Arten lassen sich Verbindungen zum angrenzenden Festland (vorwiegend SE-Anatolien) nachweisen. Die Eigenständigkeit vieler Populationen weist auf relativ lange Isolierungszeit hin. Es wird daraus auf eine natürliche Einwanderung der rezenten Säugetierfauna im (Oberen ?) Pleistozän geschlossen. - Körper- und Schädelmaße von 258 *Rousettus aegyptiacus* werden auf Alters- und Geschlechtsvariabilität untersucht. Die beiden Phasen des bimodalen Fortpflanzungszyklus sind bei der zypriotischen Population in Anpassung an das mediterrane Klima zeitlich so eng zusammengerückt, daß ein ? in der Regel nur an einem Zyklus pro Fortpflanzungsperiode teilnimmt. Superfoetation kommt vor.

The Mammal Fauna of Cyprus, Part II: Chiroptera, Lagomorpha, Carnivora and Artiodactyla

In Cyprus live 1 species of Megachiroptera and 11 species of Microchiroptera (from which confirmed for the first time: *Myotis blythi, Eptesicus serotinus, Nyctalus noctula*) as well as *Lepus europaeus, Vulpes vulpes* and *Ovis ammon*. *Dama mesopotamica*, recorded from the Neolithic to the Bronze Age, is regarded as an autochthonous member of the island fauna. - ANDERSEN's 1918 allocation of the Cyprus *Rhinolophus hipposideros* to *midas* is confirmed. The Cyprus *M. blythi* population matches *Omari* in size, but shows peculiarities in proportion of rostrum. A zoogeographical analysis of the Cyprus mammal fauna shows, that mediterrano-turkestanian and irano-turanian elements predominate and displays close parallelism to the phytogeographical analysis by ZOHARY 1973. In many species relationships to neighbouring mainland-populations (mainly S-Anatolia) can be traced. Morphological peculiarities indicate a more or less complete isolation for a rather long time. It is therefore held, that

recent mammals invaded the island through natural land bridges probably in the (Upper ?) Pleistocene. - Age- and sex-variations of skull and body-measurements of 258 *Rousettus aegyptiacus* were investigated. Probably as an adaptation to the mediterranean climate in Cyprus the succession of the two phases of the bimodal reproduction cycle of *R. aegyptiacus* is so quick, that one female usually takes part in only one cycle. Superfetatio does occur.

Stanhope, M. J., J. Czelusniak, J.-S. Si, J. Nickerson and M. Goodman (1992). A molecular perspective on mammalian evolution from the gene encoding interphotoreceptor retinoid binding protein, with convincing evidence for bat monophyly.

The evolutionary relationships of the various orders of placental mammals remain an issue of uncertainty and controversy. Molecular studies of mammalian phylogeny at the DNA level that include more than just a few orders are still relatively meager. Here we report results on mammalian phylogeny deduced from the coding sequence of the single-copy nuclear gene for the interphotoreceptor retinoid binding protein (IRBP). Analysis of 13 species representing eight eutherian orders and one marsupial yielded results that falsify the hypothesis that megachiropteran bats are "flying primates," only convergently resembling microchiropteran bats. Instead, in agreement with more traditional views, as well as those from other recent molecular studies, the results strongly support a monophyletic Chiroptera (micro- and megabats grouped together). The IRBP results also offer some rare molecular support for the Glires concept, in which rodents and lagomorphs form a superordinal grouping. Also in congruence with other recent molecular evidence, IRBP sequences do not support the view of a superorder Archonta that includes Chiroptera along with Dermoptera (flying lemur), Scandentia (tree shrew), and Primates. IRBP was not however, without its shortcomings as a molecular phylogenetic system: high levels of homoplasy, evident in the marsupial outgroup, did not allow us to properly root the tree, and several of the higher level eutherian clades were only weakly supported (e.g., a Carnivora/Chiroptera clade and an Artiodactyla/Carnivora/Chiroptera clade). We suggest that these shortcomings may be diminished as the phylogenetic density of the data set is increased.

Stanley, W. T., J. C. Kerbis Peterhans, R. M. Kityo and L. Davenport (1996). New records of bats for Uganda and Burundi.

The collection of *Myotis welwitschii* and *Pipistrellus kuhlii fuscatus* in Uganda and *Pipistrellus kuhlii fuscatus* from Burundi is reported. These species were previously unknown from these countries. External and skull measurements are presented, as well as descriptions of pelage coloration and collecting locality and comments on distribution of the taxa.

Lors de récentes recherches sur la faune en Ouganda et au Burundi, on a récolté deux espèces de chauves-souris qui n'avaient jamais été signalées dans ces deux pays. On a récolté un spécimen de *Myotis welwitschii* Gray sur le Ruwenzori en Ouganda et des spécimens de *Pipistrellus kuhlii* Kuhl sur le Ruwenzori et sur le mont Elgon, en Ouganda et au Parc National de Kibira, au Burundi. On présente des mesures corporelles et craniennes, ainsi que des descriptions de la couleur du pelage, de l'endroit exact de la récolte et des commentaires sur la distribution des taxons. Le but premier de ces études était de récolter des données de base au sujet de la distribution et l'écologie des oiseaux et des petits mammifères à différentes altitudes dans les aires protégées et les zones avoisinantes. Ces informations sont essentielles pour la conception des plans de gestion des ces régions et pour l'évaluation de l'efficacité des efforts de conservation actuels et futurs.

Start, A. N. (1969). A note on three species of bats (Chiroptera) not previously recorded from Kenya.

Les conditions de capture des spécimens de *Tadarida cistura* au Kenya laissent penser qu'ils effectuaient un important déplacement. La présence de *Tadarida nanula*, connue des forces humides de l'ouest africain (du Congo à la Sierra Leone), dans la savane a acacias du Kenya (avec seulement quelques forets galeries peu denses) implique un déplacement de l'espèce vers l'est à travers des

régions au climat peu propice. Ce déplacement a probablement été favorisé par la dernière période pluviale du Pleistocène. *Mimetillus moloneyi* n'est commune dans aucune des régions occidentales ou centrales de l'Afrique où elle était connue jusqu'à présent, un seul spécimen de cette espèce a été capturé dans l'ouest du Kenya.

Three species of bat not previously recorded from Kenya are noted. The first, *Tadarida cistura*, was taken in circumstances suggesting long distance travel. The second, *Tadarida nanula*, previously known from West African forests as far east as the Congo, provides a large eastward extension to the previously known range, across unsuitable habitat, apparently explained by past climatic factors. The last is *Mimetillus moloneyi* which is widely known from west and central Africa, though nowhere is it common.

Stebbings, R. E. (1973). Size clines in the bat *Pipistrellus pipistrellus* related to climatic factors.

Adult female *P. pipistrellus* from colonies have been caught and measured in various parts of Britain. Sample sizes averaged 91 bats for 21 sites. Forearm means ranged lrom 31.00 - 32.88 mm and many were significantly different. Clines of increasing bat size radiated from west central England indicating the existence of discreet breeding populations. Significant correlations were obtained between increasing bat size with decreasing temperatures and saturation deficit, and with increasing relative humidity. Thus *P. pipistrellus* seemed to conform to Bergmann's rule for a homeotherm.

Stephan, H., H. D. Frahm and G. Baron (1987). Brains of Vespertilionids. I. Subfamily characteristics.

Macromorphology and encephalization (EI) of brains were compared in 58 Vespertilionid species, brain composition in 36 species: 46 or 27 species of Vespertilioninae, 8 or 5 species of Miniopterinae, 2 species of Kerivoulinae, and 2 species of Nyctophylinae. Subfamily differences were found in the extent of the cover of the mesencephalon. It is nearly fully covered in *Keriuoula papillosa* (Kerivoulinae), at least half covered (by the cerebellum in Miniopterinae, and free (cornpletely or nearly so) in Nyctophilinae and Vespertilioninae. In relative brain size, the Kerivoulinae are highest (average EI = 130), followed by the Miniopterinae (111), Nyctophilinae (102) and Vespertilioninae (95). The higher encephalization of Kerivoulinae and Miniopterinae is accompanied by a marked increase of relative size in cerebellum and striarurn, and in Kerivoulinae, in hippocampus and neocortex as well.

St Leger, J. (1936). Dr. Karl Jordan's expedition to South-West Africa and Angola: Mammals.

The series of Mammals collected for the British Museum on the Expedition contains several species of particular interest. The specimens of two squirrels belonging to the genera *Anomalurus* and *Heliosciurus* represent new subspecies recently described by me from this material. Until Dr. Jordan obtained *Anomalurus* in Western Angola, the Flying Squirrel was not known to occur west of the Congo basin. The capture of *Platymops haagneri* at the Waterberg, *Nasilio brachyurus* at Mt. Moco, *Taterona schinzi* at Lobito, and *Leggada bella induta* at Bullsport has also considerably extended the known range of these mammals.

St Leger, J. (1937). Mammals collected by the Lake Rudolf Rift Valley Expedition, 1934.

Although the chief object of the Lake Rudolf Rift Valley Expedition was to make a geological survey and report on this region, a small and interesting collection of mammals was obtained and presented to the British Museum. The majority of the specimens were collected by Dr. W.S. Dyson, the acting medical officer of the Expedition, and by Mr. D.G. MacInnes, who accompanied the party as palaeontologist.

The country is for the main part sand and gravelly subdesert, with patches of rock and stony hills. Acacias and dom palms occur in the vegetation of the river valleys. The only forest is confined to a high altitude on the mountains, but from these no specimens were obtained. The Lake Rudolf Basin is cut off from Uganda by an escarpment 1500 feet in height, and the maximum rainfall east of this escarpment is 5"-10", as opposed to the (estimated) rainfall of 25"-30" of the Uganda plateau. This escarpment, together with the difference in the mount
of rainfall, appears to form an insurmountable barrier for the majority of species. Exceptions are the bats and a tree-squirrel, described below, which ranges, probably along the river valleys, as far west as the Nakwai Hills.

The fauna of the Lake Rudolf region, as was indicated by the collection obtained by the previous expedition in 1930-31, proves to be nearly related to that of Somaliland and the plains of Northern Kenya and South Abyssinia.

Strelkov, P. P. (1989a). New data on the structure of baculum in Palaearctic bats. 1. The genera *Myotis*, *Plecotus*, and *Barbastella*.

The structure of bacula of selected species and subspecies of Palaearctic bats from the genera *Myotis, Plecotus*, and *Barbastella* has been investigated for taxonomical purposes. Bacula of *M. ikonnikovi* and *B. leucomelas* are described for the first time. The former exhibits a very specific state, different from both *mystacinus* and *muricola*. Differences between *B. leucomelas* and *B. barbastellus* suggest these are the separate species.

Strelkov, P. P. (1989b). New data on the structure of baculum in Palaearctic bats. 2. Genus *Eptesicus*.

The diversity in the shape of the baculum has been investigated in the Palaearctic species of the genus *Eptesicus*. The possible ways of re-arrangements of this organ are discussed.

Strinati, P. (1951). Note sur les chauves-souris du Maroc.

La Mission scientifique suisse composée de MM. VILLY AELLEN, ASEN BALIKÇI, RAYMOND GIGON, HENRI GYGAX et PIERRE STRINATI, a exploré, pendant l'été 1950, plusieurs grottes dans la région du Moyen Atlas située au sud de la ville de Taza. Plusieurs dizaines de chauves-souris ont été récoltées et diverses observations ont été faites.

Strinati, P. (1953). Deuxième note sur les chauves-souris du Maroc.

In a previous note of the author (*Mammalia* 15, 23•31), the bat taken for a *Myotis myotis* was in reality a *Myotis oxygnathus*. The author further gives confirmation to the presence in Morocco of *Pipistrellus savii* and adds sorne complementary informations on bats observed in the region of Taza during april 1953.

Strinati, P. (1960). La faune actuelle de trois grottes d'Afrique équatoriale française.

Campagne de prospection biospéologique en Afrique Equatoriale Française. Description de deux grottes du Gabon et d'une grotte au Moyen Congo. Enumération de la Faune de ces grottes.

Biospeological prospection in French Equatorial Africa. Description of two caves in Gabon and of a cave in the Middle Congo. Enumeration of the fauna of these caves.

Stuart, C. T. (1975). Preliminary notes on the mammals of the Namib Desert Park.

The known distribution of sixty three species of mammals occurring in the Narnib Desert Park, South West Africa is given. Notes on the habitat preferences of most of the species as well as some taxonomic data are included

---

Stuart, C. T. and H. H. Braack (1978). Preliminary notes on the mammals of the Bontebok National Park.

A check-list of the mammals known to occur in the Bontebok National Park, Republic of South Africa, is presented, including general observations.

Stuart, C. T., T. D. Stuart and H. H. Braack (1987). New mammal records for the Karoo National Park, with notes on several other species.

Five species of mammal are recorded for the first time in the Karoo National Park: *Suncus varilla, Nycteris thebaica. Aethomys granti, Petromyscus collinus* and *Desmodillus auricularis*. The presence of a golden mole, Chrysochloridae,
is noted. Notes on three previously recorded species are presented.

Sudman, P. D., L. J. Barkley and M. S. Hafner (1994). Familial affinity of *Tomopeas ravus* (Chiroptera) based on protein electrophoretic and cytochrome *B* sequence data.

Analyses of protein electrophoretic and mitochondrial cytochrome *b* sequence data support association of *Tomopeas ravus* with the chiropteran family Molossidae. Although analyses of protein electrophoretic data present no clear placement of *Tomopeas* within the Molossidae, analyses of the sequence data support the recognition of *Tomopeas* as a basal and phylogenerically distant member of Molossidae. As a result of these analyses, we present a new taxonomic placement of this distinctive and taxonomically problematic bat.

Swanepoel, P., R. H. N. Smithers and I. L. Rautenbach (1980). A checklist and numbering system of the extant mammals of the southern African subregion.

A checklist of 292 terrestrial and 43 marine mammals currently known to occur in the Southern African Subregion is presented. The scientific name of each species is given together with the author's name, the date of its original description. and its English and Afrikaans vernacular names. Each species is assigned a number in order to facilitate handling of data in computer systems.

Tamsitt, J. R. and D. Valdivieso (1969). Hemoglobin electrophoresis in the systematics of bats (Microchiroptera).

Electrophoresis is a most useful procedure for systematically comparing proteins of different organisms, and data from electrophoretic studies of blood proteins have aided in the clarification of phylogenetic relationships and in grouping higher taxonomic categories (Foreman, 1960; Dessauer, 1966; Johnson, 1968). Hemoglobins, unlike some serum proteins, are not affected by diet, age,

reproductive state, temperature or other variables. There are, however, few electrophoretic data on bat hemoglobin. Manwell and Kerst (1966) and Mitchell (1966) found considerable individual variation and only minor differences between species in the hemoglobins of temperate bats of the family Vespertilionidae. Valdivieso *et al.* (1969) compared electrophoretic properties of hemoglobin from Puerto Rican bats of the families Phyllostomatidae, Vespertilionidae and Molossidae and found differences and similarities correlated with taxonomic affinity. Although hemoglobins of closely related species were indistinguishable, Valdivieso *et al. (op. cit.)* concluded that haemoglobin electrophoresis may be used to add additional evidence to estimates of relationships derived from traditional criteria.

Two distinct electrophoretic phenotypes of hemoglobin occur in bats of the family Vespertilionidae (Manwell and Kerst, *op. cit.*; Mitchell, *op. cit.*; Valdivieso *et al., op. cit.)*, but only one phenotype is known in bats of the families Phyllostomatidae and Molossidae (Valdivieso *et al., op. cit.*). Extensive sampling of additional taxa should indicate whether Neotropical phyllostomatid and molossid bats possess the considerable hemoglobin polymorphism found in temperate vespertilionid bats, whether there are geographic differences in hemoglobins of disjunct populations of the same taxa, and should help determine the worth of haemoglobin electrophoretic properties in systematic studies of microchiropteran bats. We therefore describe here results of new electrophoretic studies on bat hemoglobin which confirm and extend previous observations.

Tate, G. H. H. (1941a). Results of the Archbold Expeditions. Nr 36. Remarks on some Old World leaf-nose bats.

When reviewing recently the genus *Hipposideros*, it became necessary to study other available hipposiderine genera, to re-examine *Rhinolophus*, and to some extent to study the remaining leaf-nosed bats, the Megadermidae and Nyeteridae.

Material referable to *Asellia, Anthops, Cloeotis, Triaenops, Coelops, Rhinolophus, Megaderma, Lavia, Nycteris, Lyroderma* was examined. (*Rhinonycteris* is apparently unrepresented in American collections.) Notes made upon their comparative structures are presented herewith. The hipposiderine genera are considered first, then briefly the Nycteridae and Megadermidae. The isolated position of *Coelops* is pointed out. Only incidental remarks are offered on the Rhinolophinae, reviewed two years ago and now in course of extensive revision by C. C. Sanborn.

A list of materials belonging to these genera contained in the Archbold collections is appended.

Tate, G. H. H. (1942). Results of the Archbold Expeditions. Nr 47. Review of the vespertilionine bats, with specific attention to genera and species of the Archbold collection.

This paper is the eighth and last of a series of publications devoted to the study and determination of a large number of Microchiroptera assembled by Mr. Richard Archbold, which are deposited in The American Museum of Natural History, New York.

The bats in question form a part of a large collection of mammals assembled by Mr. Archbold during the decade 1930 - 1940, mainly by means of his own expeditions to Madagascar, New Guinea and Australia, but also through the work of collectors whom he sent from time to time to Celebes, Borneo, Java and Sumatra.

Our interest in the oriental region has centered upon the mammal fauna of the island of New Guinea. But in order properly to study the mammals of that island it has been necessary to work intensively with those of Australia on the one hand and of southeastern Asia and the East Indian islands on the other.

Reports based upon the fruits of Mr. Archbold's tireless collecting have been published with considerable regularity, the field of research extending far beyond mammalogy to ornithology and other zoological departments. Numerous papers on the botanical material assembled have also appeared.

The present work on the Vespertilioninae has been facilitated by the use of specimens generously lent by the curators at the museums at Chicago, Cambridge and Washington. In addition, numerous photographs of types, made by the kind permission of the authorities at various European and Australian museums, have aided materially in establishing the exact characteristics of species inadequately described.

One new species, *Pipistrellus anthonyi*, is described.

Preliminary papers relating to the Vespertilionidae have been published in which the subfamilies Miniopterinae, Murininae, Kerivoulinae and Nyctophilinae were successively dealt with. *Myotis*, the most primitive genus of the remaining subfamily, the Vespertilioninae, had been previously reviewed. But it was found in practice that the remaining vespertilionine genera were often too closely integrated one with another to permit satisfactory treatment one by one. Instead, a procedure is here adopted under which the subfamily is reviewed as a whole, and the interrelationships of the genera are pointed out, as far as understood. In many instances the data upon which certain species or races have been founded are so vague that it has not been possible to reach a conclusion regarding their status. I do not hesitate to assert that many of the names will go into synonymy. This action should occur, however, only after ample facts have been marshaled in proof. As much evidence is needed to prove synonymy of a species as to demonstrate the distinctness of a new one. It was with the above mentioned idea of an inclusive review of this very complex subfamily that the work following was undertaken.

Despite the modern concept of "the species," based upon populations relatively homogeneous both morphologically and functionally, whose individuals normally interbreed freely and breed rarely or never with other species even when they inhabit the same environment-despite this knowledge and theory and the understanding that one should deal with large samples statistically, in practice the museum student is still compelled to found his assumptions or "conclusions" upon quite small samples or often upon random individuals taken from different localities. To a great extent also he must rely upon other men's observations. Thus he still builds "species" upon morphological distinctions seen in single specimens (types). But he is nevertheless aware of his handicaps and awake to the shortcomings of methods which he must use.'

Taufflieb, R. (1965). Contribution à l'étude des *Trombiculidae (Acarina)* d'Angola.

L'auteur passe en revue 24 espèces de *Trombiculidae* connues actuellement d'Angola, principalement de la région du Nord-Est, parmi lesquelles figurent 4 spèces nouvelles et un nouveau genre: *Machadella*, décrits dans cette note. Au point de vue zoogéographique, la région de Dundo fait la preuve de son caractère frontalier entre la Sous-Région Occidentale et la Sous-Région Orientale. La spécificité parasitaire est faible et n'explique qu'imparfaitement la répartition des larves.

Twenty-four *Trombiculidae* species are known now from Angola, chiefly from the northeastern region. Four new species and a new genus: *Machadella*, are described. From the zoogeographical point of view, the region of Dundo is situated on the boundaries between Western and Eastern Sub-Regions. Larva host specificity is not of great importance and distribution of these chiggers seems to be due more likely to ecological requirements of adults.

Taufflieb, R. (1972). Trois nouveaux Trombiculidae (Acarina) du Sénégal.

Au cours d'une tournée de prospections arbovirologiques dans la région de Kédougou, au Sénégal Oriental, nous avons pu récolter un nombre important de Trornbiculidae parmi lesquels les trois espèces nouvelles suivantes.

Three new species of Trombiculidae are dcscribed from Sénégal. Genus *Chiroptella* is mentionned from Etliiopian Region for the first t.irne.

Taufflieb, R. and J. Mouchet (1959). Revue des Trombiculidae du Cameroun et description de huit espèces et sous-espèces nouvelles.

Les premiers trombiculides camerounais ont été récoltés par J. RAGEAU et déterminés par M. ANDRE (1952); il s'agissait de *Trombicula mastomyia giroudi* André, 1951 dont l'hôte était *Rattus norvegicus* capturé à Douala. Depuis 3 ans, l'examen de nombreux rongeurs, insectivores, virerridés, chauve-souris, oiseaux, nous a permis de reconnaître l'existence de 18 espèces et sous-espèces parmi lesquelles huit nouvelles que nous décrivons dans cette note.

Taylor, P. J., E. J. Richardson, J. Meester and L. Wingate (1994). New distribution records for six small mammal species in Natal, with notes on their taxonomy and ecology.

New distribution records are documented for six small mammal species, including three new to Natal (*Crocidura maquassiensis* Roberts, 1946, *Chlorotalpa sclateri* (Broom, 1907), *Cloeotis percivali* Thomas, 1901) and three species showing significant range extensions within Natal (*Grammomys cometes* Thomas and Wroughton, 1908, *Scotophilus borbonicus* (E. Geoffroy, 1803) and *Otomys laminatus* Thomas and Schwann, 1905). Discriminant analysis of *C.* cf. *maquassiensis* from four localities in Natal in relation to known samples of *C. maquassiensis, C. cyanea* and *C. silacea* confirm their identity with minimal overlap between species. Finally, equivocal records of *Graphiurus ocularis* (A. Smith, 1829) and *G.* cf. *murinus* (Desmarest, 1822) are discussed. The occurrence of *G. ocularis* in Natal is equivocal due to the antiquity of one skin from Natal and the ambiguous label data of another specimen. Specimens collected from Swaziland, Mkuzi Game Reserve and Waterpoort (Transvaal) are similar to *G. murinus* in size, colour and skull shape but differ significantly in having reduced M1 and markedly enlarged bullae, and may be an undescribed species.

Theodor, O. (1956). On the genus *Tripselia* and the group of *Basilia bathybothyra* (Nycteribiidae, Diptera).

Some species of Nycteribiidae have been recorded from widely different faunistic regions. Thus, *Eucampsipoda hyrtlii* has been recorded from Africa, Ceylon, Burma and Sumatra. Other species have been recorded from Europe and China or from Europe and South Africa. Re-examination of the material has proved in most cases that the species were wrongly identified and no species has been found so far to exist both in Europe and in East Asia. There remained finally two species which been recorded the Ethiopian and the Oriental region, *Tripselia blainvillii* and *Basilia bathybothyra*. Material of these two species from as many localities as possible was therefore brought together, in order to determine whether this wide distribution does in fact occur or whether, in these cases as well, there existed different forms, species or subspecies, with a narrower range of distribution.

The material for examination consisted of over 70 specimens of *Tripselia blainvillii* (either identified as *T. amiculata* or unidentified), of new species of *Tripselia* from Borneo, Sumatra and New Guinea and of about 150 specimens of '*Basilia bathybothyra*' from the Eastern Mediterranean, Africa, India and Indonesia. In addition, a number of specimens from Australia were examined, which also proved to belong to the genus *Tripselia*. Of these only the specimens of *Tripselia falcozi* were identified and will be included in the present paper. Some of the others have probably been described by Musgrave as species of *Nycteribia*, others are obviously new. There is, however, too little material available at present to deal with these forms.

I have to thank the authorities of the British Museum (Nat. Hist.), Dr R. Wenzel of the Natural History Museum, Chicago, Dr J. Bequaert of the Museum of Comparative Zoology, Cambridge, U.S.A., Dr V. Aellen of the Muséum d'Histoire Naturelle, Geneva, Dr. P. Basilewski of the Musée du Congo Belge, Tervueren, Dr. E. Séguy of the Muséum d'Histoire Naturelle, Paris, and the Director, Indian Museum, Calcutta, for placing their material at my disposal.

The material in the British Museum included the collection by Dr H. Scott and the Rothschild collection, both of which contained very rich and interesting material.

Theodor, O. (1968). A revision of the Streblidae (Diptera) of the Ethiopian Region.

Keys for the identification of subfamilies, genera, species-groups and species of the African Streblidae are given. A fist of species is given, and the host-parasite relationships are discussed. Two new subspecies of *Brachytarsina* are described. The genus *Raymondia* (including the Oriental species) is revised, new characters for the definition of the species are introduced and the genus is divided into species-groups. A number of species are re-described, and two new and two possibly new species are described. The nomenclature of the African species of *Ascodipteron* is revised, a number of descriptions are amplified, and a new species is described.

Thewissen, J. G. M. and S. A. Etnier (1995). Adhesive devices on the thumb of Vespertilionoid bats (Chiroptera).

We describe pads on the thumb of five vespertilionoid bats based on microanatomy and scanning microscopy and make inferences about their function. The pad of *Thyroptera* adheres by means of suction, and that of *Tylonycteris* uses dry adhesion. The pad of *Glischropus* has no true adhesive function and probably functions using friction. Topography of the pad of *Pipistrellus nanus* could interlock with substrate features, but the pad may have a minor function as a suction device. Glueing is most likely involved in the adhesion of *Myzopoda* to its substrate.

Thollesson, M. and U. M. Norberg (1991). Moments of inertia of bat wings and body.

The moments of inertia of the wings about the shoulder joint and about the roll axis were estimated in eight species of bats, using strip analysis. The moment of inertia of the bat's trunk about the roll axis was estimated by assuming the body and head to be ellipsoids. The slopes of the regressions of moment of inertia of one wing about the shoulder joint (J_W) versus body mass (m_{tot}), wing span (b) and wing area (S) were as expected for geometrically similar animals of different size. The exponent for J_w versus body mass in bats deviates from that found for birds, while the exponent for J_w versus wing span does not. A multiple regression was used to show that J_W may be estimated by:

$J_w = 4.49 \times 10^{-3}\ m_{tot}^{0.53} b^{2.15} S^{0.65}$.

The mean value of the moment of inertia originating from the trunk is 7 % of the bat's total moment of inertia (of wings and body combined) about the roll axis. The mass of one wing (m_w) was plotted against body mass for the eight bat species, which gives:

$m_w = 0.112 m_{tot}^{1.11}$.

The slope for our bats, 1.11, is similar to that obtained for birds, 1.10. Adaptations to reduce the moments of inertia may be more important for increasing a bat's flight agility (roll acceleration) than for decreasing the total mechanical power required to fly. The influences of wing moment of inertia and wing shape on manoeuvrability and agility are discussed.

Thomas, D. W. (1981a). The role of fruit bats in seed dispersal and regeneration in a Southern Guinea Savanna. Abstract.

This study was undertaken to quantify the importance of Megachiropteran fruit bats relative to frugivorous birds in some aspects of seed dispersal and regeneration. Bats consume 75% of the fruit crop of *Ficus capensis* while birds account for 15%, In the savanna/ gallery forest edge zone 86 - 93%

of the fecal seed rain comes from bats. This bat-generated rain amounted to 7, 000 - 24, 000 feces / hectare / year which, after a measured ant predation rate of 74% per 24 hours, left a seed bank of 64 - 219 feces / hectare / year for regeneration. A census of an experimental fire protected plot showed a regeneration comparable to that predicted. Thus, bats appear as the most important consumers and dispersers of some secondary colonizing plants.

Bat biomass, however, appears to be lower than that of frugivorous birds. Reasons why bats, despite low biomass may be more effective dispersers are discussed in an accompanying paper.

Thomas, D. W. (1984b). Fruit intake and energy budgets of frugivorous bats.

Paleotropical fruit bats (Pteropodidae) ingest up to 2.5 times their body mass in fruits nightly. On a mass-specific basis, this is about double the amount reported for neotropical fruit bats (Phyllostornidae). By manipulating the energy and protein contents of their diets, I found that the pteropodids' high fruit intakes are determined by the protein content of the fruits they exploit. Pteropodids appear to be obliged to overingest energy in order to obtain sufficient protein. Phyllostomid fruit bats may escape this protein constraint by supplementing their diets with insects,.thus increasing the overall protein content of the diet. Differing abilities to supplement their diets may result in important differences in how pteropodid and phyllostornid bats nutritionally evaluate fruits, regulate their intakes, and function as seed dispersers.

Thomas, D. W. and M. B. Fenton (1978). Notes on the dry season roosting and foraging behaviour of *Epomophorous gabianus* and *Roussettus aegyptiacus* (Chiroptera: Pteropodidae).

We studied the movements and foraging behaviour of *Epomophorug gambianus* and *Rousettus aegyptiacus* during the dry season in Rhodesia. The nightly activity of both species was concentrated in the riparian forest where they fed on the fruits of *Diospyros senensis*. *Epomophorus gambianus* roosted during the day high in the thick canopy of *Trichelia emetica* or *Kigelia Africana* along the river banks and began foraging, each one in a preferred *D. senensis* shrub, before 1845 hrs. *Rousettus aegyptiacus* arrived in the study area approximately one hour later and appeared to forage in groups. The temporal separation of the feeding times of the two species of bats may provide a basis for the partitioning of a single species food resource.

Thomas, D. W. and A. G. Marshall (1984). Reproduction and growth in three species of West African fruit bats.

This study outlines the reproduction periods of the African fruit bats *Epomops buettikoferi, Epomophorus garnbianus*, and *Micropteropus pusillus* at two West African savanna sites: a wet southern Guinea savanna and a drier southern Sudanese savanna. At both sites the two annual birth periods were timed such that both lactation by only one weaning period coincided with the rainy season peaks in fruit availability. On this basis we propose that lactation rather than weaning was the important determinant of the timing of reproduction. There was no evidence of cycling of testes size in males corresponding with the seasonal mating periods. *E. buettikoferi* and *M. pusillus* females mated at six months and gave birth at the age of 12 months. Males of the two species reached puberty by 11 months and seven months, respectively. Growth rates did not differ between cohorts growing through the wet and dry season and *E. buettikoferi* and *M. pusillus* grew at rates of 276 mg/day and 116 mg/day, respectively.

Thomas, N. M. (1997). A systematic review of selected Afro-Asiatic Rhinolophidae (Mammalia: Chiroptera): an evaluation of taxonomic methodologies.

A taxonomic review of five members of the *Rhinolophus ferrnmequinum* group (Mammalia: Chiroptera: Rhinolophidae) from Africa and Asia is undertaken. The study incorporates a suite of taxonomic methods, using both morphological data and sequence data of the cytochrome *b* gene of mitochondrial DNA.

Six species of *Rhinolophus* are recognised from within the region, namely *R. ferrumequinum, R. clivosus, R. bocharicus, R. rouxii, R. sinicus* and *R. affinis*. *R. sinicus* is promoted to species rank, having previously been considered to represent a subspecies of *R. rouxii*. Intra-specific variation, both geographic and non-geographic is analysed, and revised classifications presented. Synonyms, and their original descriptions, are given for each species, and species limits and distributions are defined. Diagnostic characters are described, and tables of measurements included.

Inter- and intra-specific relationships are examined using classical taxonomic methods, numerical phenetics, cladistic analysis, molecular techniques, and the total evidence approach. Each method is discussed in detail, and the literature relevant to each technique reviewed. This rigorous methodological approach is undertaken in order to provide robust taxonomic classifications, and to allow for each of the methods employed to be evaluated in terms of their ability to solve a complex taxonomic problem.

The use of a combination of methods is found to provide a high degree of taxonomic resolution. The relationships of the five study taxa are clarified, with the hitherto unresolved relationship between *R. ferrumequinum, R. clivosus* and *R. bocharicus*, and the taxonomic status of *R. sinicus* being of particular note. In addition, taxa requiring further systematic investigation are identified for future research, such as *R. rouxii* from southern India and Sri Lanka, and *R. ferrumequinum Nippon* from Japan.

The evolutionary history of the *R. ferrumequinum, R. clivosus* and *R. bocharicus* complex is discussed in the light of the results of systematic analysis, as are the specific and subspecific relationships of *R. rouxii* and *R. affinis*. It is concluded that *R. clivosus* and *R. bocharicus* may have evolved from populations of *R. ferrumequinum* as a result of allopatric speciation occurring during periods of climatic change in the Pliocene and Pleistocene. Methodologically, it is concluded that the comparison of results from a number of techniques provides a robust base from which to formulate taxonomic conclusions. The optimal approach is considered to be a combination of molecular analysis and classical morphological investigation.

Thomas, N. M., D. L. Harrison and P. J. J. Bates (1994). A study of the baculum in the genus *Nycteris* (Mammalia, Chiroptera, Nycteridae) with consideration of its taxonomic importance.

The bacula of 11 of the 15 species commonly recognised within the genus *Nycteris* (Cuvier & E. Geoffroy, 1795) have been examined. The bacula are described and illustrated, and notes on the systematics of the genus, with particular refererice to bacular morphology, are included. *N. parisii* is considered distinct from *N. woodi* on the basis of bacular morphology. The baculum of *N. woodi* separates it from the other members of the *macrotis* group. *N. grandis* has a particularly distinctive baculum.

Thomas, O. (1880). XXII. On bats from Old Calabar.

Through the kindness of Dr. J. A. Smith, of Edinburgh, the British Museum has recently received a small collection of Bats obtained at Old Calabar by Dr. A. Robb, of the United Presbyterian Mission at that place.

The collection consists of four specimens of *Epomophorus comptus*, All., concerning which Dr. Smith has himself published a most valuable notice, one specimen each of *Nycteris grandis*, Ptrs., *Vesperugo nanus*, Ptrs., a new species of *Vesperugo*, a new species of *Kerivoula*, and an immature specimen of a species allied to, or identical with, *Vesperugo Kuhlii*, Natt., but which is not in a condition to be certainly determined.

Thomas, O. (1886). 2. On the mammals presented by Allan O. Hume, Esq., C.B., to the Natural History Museum.

Accompanying the magnificent donation of Indian birds recently made to the National Museum by Mr. A. O. Hume, there is a collection of nearly 400 mammals, "which, although appearing of small account beside the enormous ornithological series, is yet, viewed on its own merit, one of the finest collections of mammals ever received by the Museum. This is due not only to the large number of the specimens and the excellence of the skins, which are both in preparation and conservation very far above the average, but also to the careful manner in which they have been labelled, nearly all of them having their exact localities and dates recorded. Thus of the 371 specimens retained in the Museum, only 59 are undated, and only some 10 or 12 are without exact localities, while such large series of perfect skins, especially of the Squirrels and other small mammals, have probably never before been brought together.

The collection consists of a few specimens respectively from Simla. Delhi, the Nilghiris, and the Andaman and Nicobar Islands, but the great mass of it came from four separate localities, viz. Sambhar, in Rajpootana, Manipur, Tenasserim, and the Malay peninsula, and I have thought it better not to give one list of the whole, thereby confusing the localities and destroying any use the list might have for faunistic purposes, but to give four separate lists, each of which forms a distinct contribution to the fauna of a well-defined locality.

The total number of species represented in the collection is 106, of which 19 are from Sambhar, 19 from Manipur, 25 from Tenasserim, and 28 from the Malay peninsula, the remainder being from the other localities above mentioned.

Before commencing ihe detailed lists, I must express my obligations to Mr. W. T. Blanford for the assistance he has given me in working out this collection, an assistance the more valuable as he is himself preparing a work on the mammals of India, and has therefore the whole subject at his fingers' ends. For help also in making out details of localities, dates, &c. I must thank my colleague Mr. R. Bowdler Sharpe, who himself fetched the collection from Simla, and to whose careful packing the excellent condition in which the specimens now are is partly due.

Thomas, O. (1888). 1. On a collection of mammals obtained by Emin Pasha in Equatorial Africa, and presented by him to the Natural History Museum.

The Mammals recently received by the Natural History Museum from Dr. Emin Pasha number 115, belonging to 39 species - a collection which is of the utmost value as a contribution to our knowledge of the Central-African fauna, and one which reflects the highest credit on the energy and scientific spirit of the man by whom it was formed. When the cares and anxieties of a person in the position of responsible governor of a large and turbulent. African province are considered, it seems wonderful that Emin should have been able to make any collections at all, and still more should have made such a collection as the present, nearly every specimen of which has been carefully labelled in his own handwriting, with the date, sex, and exact locality - particulars which add enormously to its scientific value.

The great mass of the collection was not obtained at Dr. Emin's headquarters, on the Upper Nile, but in a district called Monbuttu (lat. 2° 30' N., long. 27° 50' E.), just within the Congo basin, and separated by the Congo-Nile watershed from the Wadelai region. There, practically, all the interesting forms were collected; and, considering their number, and especially their strongly marked geographical character, the general affinities of the mammal-fauna of this district may now he looked upon as settled; their affinities are discussed at the end of the present paper.

Of the more recent papers on the Central-African mammal-fauna the three following are the most important: -

1. Pagenstecher, Dr., "Die von Dr. G. A. Fischer, auf der im Auftrage der geographischen Gesellschaft in Hamburg unternommenen Reise in das Massai-Land gesammelten Saugethiere ".

2. Noack, H., "Beiträge zur Kenntniss der Säugethier-Fauna von Ost-und Central-Afrika"

3. Leche, W., "Ueber einige von Emin Pascha gesammelte afrikanische Säugethiere"

The first of these contains notes on 31 species of mammals, but the region explored by Dr. Fischer has so different a fauna from Monbuttu, that only some three or four species, and those very widely spread, are common to both collections.

Dr. Noack's paper also, based on the mammals collected by Dr. Böhm in the Marungu country, on the south-west coast of Lake Tanganyika, refers to a fauna very different to that of Monbuttu, although several species, and those some of the-most interesting (e. g. *Sciurus boehmi* and *Mus kaiseri*), are found in both districts.

Finally, Dr. Leche's paper is founded, like the present one, upon specimens collected by Emin Pasha. Fifteen species are enumerated, but these come chiefly from the Upper Nile district, only three of them occurring also in the Monbuttu collection. The localities given are so widely scattered that the paper, although important for the histories of the individual species, gives but little definite faunistic information.

There is also a list of 71 species observed in Niam-niam-land, given at the end of Dr. Schweinfurth's "Im Herzen von Afrika," but the list is a merely nominal one, except that the different native names of the animals are all carefully recorded. Two of Dr. Emin's West-African animals, the Chimpanzee and *Galago demidoffi*, occur in the list.

The 39 species in the present collection consist of 3 Primates, 8 Carnivora, 1 Insectivore, 3 Bats, 1 Ungulate, 1 Edentate, and no less than 22 Rodents, Dr. Emin having wisely paid most attention to the latter group, in which our knowledge of the smaller forms is still so exceedingly incomplete.

Thomas, O. (1890a). 3. On a collection of mammals obtained by Dr. Emin Pasha in Central and Eastern Africa.

The Mammals now described were collected partly on Dr. Emin's return march from his Equatorial Province, and partly by himself or by friends of his during his stay at Bagamoyo. The former, like the magnificent collection sent over in 1887, were presented by him direct to the Natural History Museum, and the latter were given to the Zoological Society, whose Council have in their turn passed them on to the Museum for comparison and preservation.

Afther the collections described in the previous papers were dispatched in 1887; Dr. Emin continued to investigate the fauna of the region of the grea lakesn, and it speaks volumes for his energy and enthusiasm that after all the collections then made had most unfortunately been lost, he should, nevertheless, have perseveringly continued to collect all the way down during the painful march from Equatoria to Bagamoyo, and should, under such difficulties, have been able to obtain so many valuable specimens as are here de'scribed. Later, while at Bagamoyo, he exercised his influence among his friends, and the specimens recorded as from Monda, in the Nguru Mountains, and from Mandera, a place equidistant from Saadani and Bagamoyo, about 25 miles from the coast, were obtained for him in this way. Those from the latter locality were collected by Lieut. Langheld, to whose friendly exertions we owe some of the most interesting specimens obtained.

Every skin collected during the march has been most carefully labelled by Emin himself, many of the particulars so recorded being of the utmost value, and increasing very considerably the interest of the specimens.

Thomas, O. (1890b). Description of a new *Scotophilus* from the Gambia, with remarks on some of the allied species.

In a further consignment of,bats sent to the Natural History Museum from Bathurst; on the River Gambia, by my friend Dr Percy Rendall, I find two examples, one adult :and the other immature, of the following interesting new species, of *Scotophilus*:

Thomas, O. (1894a). 1. On the mammals of Nyasaland: third contribution.

The present paper contains an account of the third and fourth collections of Mammals made and presented to the National Museum by Mr. H. H. Johnston, C.B., Consul-General for British Central Africa, with the help of his able assistant, Mr. Alexander Whyte, F.Z.S. Papers on the two previous collections have already been published.

The series now described bears out the prophecy I ventured to make in 1892, that as Mr. Whyte's knowledge of the locality increased he would be able to obtain the rarer and more local species, and that among these there would certainly be some novelties. For although there are not a very large number of species altogether represented in the present collection, yet several are new to the locality, one is a rediscovered species described thirty years ago, and two are new to science.

The Mammal-fauna is therefore evidently far from worked out, and Messrs. Johnston and Whyte should be encouraged, to continue their explorations until, after the receipt of five or sis more similar collections, we may perhaps be in a position to say that our knowledge of the Mammals of the district approaches completion.

Thomas, O. (1894b). 4. On some specimens of mammals from Oman, S.E. Arabia.

Dr. A. S. G. Jayakar, whose magnificent collections and donations of Muscat fishes are known to all ichthyologists through the papers upon them by Mr. Boulenger, has, during the past few years, collected and presented to the National Museum a certain number of mammals, and he has now sent home a further consignment, of such value as to demand a proper account.

So far as I am aware, no list of mammals from this very interesting region has ever been published, and Mr. Blanford's description of *Erinaceus niger*, the same author's passing reference to a Muscat specimen of *Vulpes leucopus*, Sir V. Brooke's description of *Gazella muscatensis*, and Sir O. St. John's notes on *Oryx beatrix* appear to be the only references to this locality that occur in mammalian literature. Dr. Jayakar having obtained examples of all these four species, his collection includes specimens of all the mammals known to occur in this part of Arabia.

The geographical relationships shown by the mammals of Muscat are, as might be expected, about equally with Africa and India, three of the species being distinctly African in affinities, three Indian, and the remainder either peculiar ,or widely-spread and of no special significance.

Of the 17 species included in the list, two are new, one of them, *Hemitragus jayakari*, the new Goat, forming a most striking and interesting discovery, on which Dr. Jayakar is much to be congratulated. The new Hare, *Lepus omanensis*, is also markedly distinct from any of its allies.

Thomas, O. (1897a). 1. On the mammals of Nyasaland: fourth Notice.

The present paper contains an account of all the mammals which have been received by the British Museum from Nyasaland since the beginning of 1894, and forms a continuation of my three previous papers on the subject. As before, it is to the generosity and scientific spirit of Sir Harry Johnston that we owe most of the specimens referred to, but in addition some other members of the British

Administration have been good enough to contribute specimens on their own account, and thus to further the cause of scientific research.

Among these contributors may be specially mentioned the names of Mr. Alfred Sharpe, Dr. Percy Rendall, and Mr. H. C. McDonald, each of whom has been lucky enough to send home specimens sufficiently distinct to be described as new.

In the following pages, where the name of tbe collector is put in brackets the specimens have been obtained as part of his official duties in the administration, and are to be considered as presented by Sir Harry Johnston; while direct donations to the Museum are shown by the words "Presented by" before the name of the collector. As usual, the majority of Sir Harry Johnston's specimens have been obtained by that indefatigable naturalist, Mr. Alexander Whyte.

In order to make the list of Nyasa mammals as complete as possible, I have here inserted the name of every species obtained during the whole of Sir H. Johnston's explorations of Nyasaland, with references to the places in the previous three papers where the species are noticed or described, and, in addition, those mentioned by Mr. Sclater in his various papers. As a result the present paper contains a complete list of all the mammals as yet received by the Museum from Nyasaland, numbering 82 in all.

Thomas, O. (1897b). 6. On the genera of Rodents: An attempt to bring up to date the current arrangement of the order.

Just over twenty years ago, in 1876, Mr. E. R. Alston contributed to this Society his invaluable paper "On the Classification of the Order Glires," a paper which in its broad outlines has formed the basis for almost every Museum Catalogue, compiler's list, and general text-book that has been written since it appeared. Based as it was on the earlier works of Waterhouse, Gervais, Brandt, and Lilljeborg, Alston's arrangement has in this way received almost universal sanction, and the present writer is far from wishing to alter the essential characteristics of the scheme.

But, owing partly to Alston's not having seen examples of many of the genera included, and partly to the great increase in the number of known forms that has taken place since he wrote, his paper has gradually become somewhat obsolete in its detailed arrangement of the subfamilies and genera, however correct his positions for the suborders and families may still be considered to be.

Now, every Museum-curator when arranging his specimens, and every writer either of a text-book or of a faunistic work, is constantly being confronted by the difficulty as to where to place in the system this or that genus of Rodents, for which he has perhaps himself neither time, inclination, or opportunity to search out a proper and appropriate position. It is for the object of helping such persons that the present paper has been prepared, so bold a venture being due to the fact that the increase in the British Museum collections has fully kept pace with the general increase of knowledge, and that there are very few genera known from any part of the world of which specimens are not in that collection. With such unrivalled material available, the opportunities for mistaken work have been reduced to a minimum; and in the following list it may be said that the specimens have been allowed to sort themselves, and where my alterations are found to be strikingly different from those of Alston it will generally be found that the forms referred to were not available for examination in his time.

One recent author only has diverged much from Alston's system, namely Dr. Winge of Copenhagen, who, in connection with his work on the Rodents of Lagoa Santa in Brazil, has written a revised general arrangement of the Rodents. His classification, however, is a rather one-sided one, being based almost entirely on the structure of the masseter muscles and the bones related to them, and, however thoughtful and clever it may be in many ways, is so widely divergent from all previous classifications that without much stronger reasons than he adduces I should not be prepared to follow it. No doubt many of his alterations are admirable, such, for example, as the reference of *Sminthus* to the *Dipodidæ*; but when we find *Pedetes* placed with *Anomalurus*, and *Platacanthomys* combined with *Myoxus* in a group set over against *Graphiurus*, we see that a good deal of confirmation will be needed before the classification the world is accustomed to is abandoned in favour of that proposed by Dr. Winge. Prof. Zittel and Dr. Tullberg have also contributed to the revision of the classification of the Rodents. The

former gets rid of the difficulties by putting all the awkward families into a separate group, the Protrogomorpha. The latter largely follows Winge, but does not as yet enter into details.

Dr. Trouessart's most useful list of Rodents is entirely based on Alston's arrangement, and is so admittedly a compilation that no special criticism of it is here necessary.

No attempt has been made to follow Alston's example of giving diagnoses of the groups and genera, partly for the simple reason that the labour and time demanded woud have rendered the preparation of the paper at all quite impossible, and partly because such diagnoses can never be really full and accurate unless prepared in connection with the working out of the species of each genus. Moreover, of all the groups he recognizes, Alston's paper contains diagnoses, and it would be superfluous to repeat them here. Where I differ from his conclusions full reasons are giyen in the footnotes.

Comparing the numbers of recent families and genera recognized in the two papers, we have 18 families in Alston against 21 now, the difference being due to the *Lophiomyidæ* being suppressed, and the *Bathyergidæ, Heteromyidæ, Erethizontidæ*, and *Pedetidæ* added. Of genera Alston recognized 100, as against 159 now considered valid; of the additional 59 just about half are formed by the breaking up of old genera and half are altogether new discoveries.

Nomenclatural questions have of necessity cropped up here and there, and the recent work of American authors in this respect has been fully utilized. It is with the greatest regret that I have had to use a good many names unfamiliar to English naturalists, but the evidence in every case is so clear as to leave no room for doubt, and none are mere matters of opinion. Recognizing that the ultimate use of these names is inevitable, I think the sooner a knowledge of them is disseminated the sooner will the intermediate stage of confusion be passed through and done with. Where comparatively unfamiliar names are used, the better-known terms are placed in brackets after them, as also are any special synonyms which it seems of importance to mention.

It should bo again repeated that the special object of the list is the proper allocation of the genera in their respective subfamilies, and I have purposely been as conservative as possible with regard to the groups of higher rank, following Alston wherever there has not been very special reason for departing from his arrangement.

In regard, however, to *Anomalurus* and *Aplodontia*, both placed by him in the Sciuromorpha, I have had to give in my adhesion to the views expressed by more recent authors, that these two aberrant genera cannot rightly be placed with the Squirrels. But where they should go is by no means clear - Winge, Zittel, and Tullberg all differing in the matter; nor can I say that I agree with any one of them. As it seems a pity to abolish the convenient and time-honoured groups Sciuromorpha, Myomorpha, arid Hystricomorpha, just for the sake of these genera, I have thought it best to put each of them under a special group-name, leaving it for further research to show their true relationships. Fortunately, their serial position in the list, like that of *Pedetes*, may be left almost exactly as in Alston's paper.

Thomas, O. (1898a). 2. On the mammals obtained by Mr. A. Whyte in Nyasaland, and presented to the British Museum by Sir H.H. Johnston, K.C.B.; being a fifth contribution to the mammal fauna of Nyasaland.

In June and July 1896 Mr. Alexander Whyte, the well-known collector, made an expedition into Northern Nyasaland for the purpose of investigating the fauna of that part of the territories administered by Sir Harry Johnston. The expedition proved remarkably successful, for besides the large number of specimens of other groups obtained, Mr. Whyte brought back the fine collection of mammals of which the present paper gives an account.

The chief localities where Mr. Whyte collected were the Nyika Plateau (about 10° 30' S., and 33° 30' E.), the Masuku Plateau, slightly further northwards, and Fort Hill (about 9° 40' S., 33° 20' E.), these localities all lying just to the west of the north of Lake Nyasa, and at altitudes of from four to seven thousand feet. A few odd specimens were also obtained at Karonga Ruarwe on the lake shores.

I have also included in the list some few additional specimens from Zomba and the south end of the lake, and among others very interesting results of a trip made by Mr. Whyte to Mount Malosa, just north of Mount Zomba, in November, where he obtained examples of several species not previously recorded Nyasaland.

Now that Mr. Whyte has retired from his labours in tropics, it is only fitting that in this, the last paper that will appear on his Mammals, special reference should be made to the great value of the services he has rendered to zoology in general, and to knowledge of mammals in particular, and to the way in which, during the past six years, he has utilized the opportunities given him the generosity and public spirit of Sir Harry Johnston.

As in previous papers, a few specimens are included which Museum owes to other members of the Nyasa Administration, notably to Mr. Alfred Sharpe, and now that Mr. Sharpe succeeded to Sir Harry Johnston's post, we may hope that by his help our knowledge of the riches of the Nyasa Protectorate will still continue to increase.

The northern region visited by Mr. Whyte proves to have very close affinity with that explored by the German travellers Böhm, Reichard, and Kaiser south and south-west of Tanganyika, the mammals collected by whom were worked out by Dr. Noack. Thus Mr. Whyte has obtained examples of several characteristic species described from their collections, notably *Rhynchocyon reichardi* and *Gerbillus böhmi*, both of which are forms quite new to the fauna of Nyasaland.

The following is a list of the new species contained present collection, those marked with an asterisk having described in a previous preliminary communication to the Society.

Thomas, O. (1898b). VIII. On the mammals obtained by Mr. John Whitehead during his recent Expedition to the Philippines.

Mr JOHN WHITEHEAD, whose exploration of Mount Kina Balu has already, rendered him famous as a collector, has during the last three years been engaged in the exploration of the islands of the Philippine group, partly at his own expense, and partly at that of the "subscribers to the Whitehead Fund," to whose generosity the National Museum owes the donation of the whole of the specimens that the subscribers had a claim to under Mr. Whitehead's agreement with them.

As the exploration has been so remarkably successful, it is only fitting that an acknowledgment of their generosity should be appended to this account of the Mammals obtained during the expedition. Their names are as follows: - Messrs. Matthew, James, and Andrew Arthur, the Duke of Bedford, Major Cooper Cooper, the late Mr. Alexander Dennistoun, Mr. John Dennistoun, the late Lady Huntingtower, the late Mr. Henry Seebohm, Mr. J. G. Sandeman, and Mr. J. T. Thomasson.

The Philippine Islands, however rich in birds, have always previously been looked upon as a group very poor in Mammals, especially in comparison with the rich faunas of the other islands of the East Indian- Archipelago. This poverty was particularly evident in regard to really peculiar indigenous Mammals; for, with the exception of *Phlœomys cumingi*, scarcely a Mammal was known from the group other than members of widely-distributed genera, of which the Philippine species were either identical with or closely allied "to Palawan, Bornean, or Celebean forms.

Little, therefore, could have been expected from the expedition further than the discovery of a few fresh species of genera known to inhabit the group, and this, so far as regards the islands other than Luzon, is just what has occurred. But in the great northern island of the group Mr. Whitehead has made a most-wonderful and unexpected discovery, that of a new and peculiar Mammal-fauna inhabiting the Luzon highlands, and, so far as is yet known, mostly isolated on a small plateau on the top of Monte Data, in the centre of Northern Luzon, at an altitude of from 7000 to 8000 feet.

The plateau itself, as will be seen by Mr. Whitehead's notes below, is of extremely small size, but in spite of this fact he obtained there specimens of the following remarkable series of animals.

Thomas, O. (1900). 2. On the mammals obtained in South-western Arabia by Messrs. Percival and Dodson.

On the initiative of Mr. Ogilvie Grant, and by the active assistance of General Creagh, Governor of Aden, an expedition was arranged during the past autumn to South-western Arabia for the purpose of obtaining zoological specimens for the British Museum. The expedition consisted of Mr. A. B. Percival and Mr. W. Dodson, the latter having especial charge of the mammal-collecting.

Mr. Dodson had already had some experience as a collector of .small mammals during a trip to Roumania in the spring, and he had shown such keenness and aptitude for the work that he would evidently have become an exceptionally able collector, but most unfortunately he contracted fever at El Khaur, and having been brought back to Aden by Mr. Percival, died there on the 20th of October.

The present collection, in the formation of which Mr. Dodson took, to the last, the most vivid interest, is naturally very similar in character to that obtained by Col. Yerbury in the same region in the spring of 1895, of which an account was given by its collector and myself in the Society's ' Proceedings' for that year. Further examples of the interesting Gerbilles discovered by Col. Yerbury were obtained and valuable series of various other forms.

The following species are additional to those recorded in the previous list: - *Papio arabicus, Canis pallipes, Vulpes leucopus, Mellivora ratel, Gerbillus gerbillus, Procavia syriaca jayakari*.

The animal that proves to be of greatest interest is the Baboon, of which one specimen, unfortunately a female, but fully adult, and in good condition, was obtained. This specimen is so different from the African *Papio hamadryas* as to require specific distinction.

Tho collection was made mainly in two districts - the one at and around Lahej, Col. Yerbury's chief collecting-ground, and the other in the neighbourhood of El Khaur, a place about forty miles north-east of Aden, and some twenty-live miles west of Shukra. But, as might be expected, no definable difference is to be found in the animals of the two localities.

The notes on habits &c. placed in inverted commas have been contributed by Mr. Percival.

Thomas, O. (1901b). XXXIII. A new Scotophiline bat from British East Africa, with the description of a new genus of the group.

Among some small mammals sent to the British Museum by Mr. S. L. Hinde occurs the skin, with skull, of a Scotophiline bat which does not appear to have been described, and which I propose to name in honour of its collector, who has contributed large numbers of specimens at various times to the National Museum.

It is allied only to *Scotophilus albofuscus*, Thos., and *S. hirundo*, de Wint., and with them forms a special group, which, on a reconsideration of the question, and fortified by the published opinion of Mr. de Winton, I propose to regard
as a genus.

Thomas, O. (1901c). List of mammals obtained by Dr. Donaldson Smith during his recent journey from Lake Rudolf to the Upper Nile.

On his return from his recent adventurous journey to the Upper Nile from Somaliland via Lake Rudolf, Dr. Donaldson Smith has been so good as to entrust to rne for description the specimens of mammals that he obtained, and has further been generous enough to present a number of them, including all the types, to the British Museum.

Owing to the great difficulties of transport large series of specimens were not brought home, nor were many small mammals obtained, but, from the knowledge gained on his previous expeditions, Dr. Smith was enabled to select those that were most likely to be interesting, and this knowledge has been rewarded by the considerable proportion of novelty that the examination of his specimens reveals.

The specimens were mostly prepared by Mr. W. Carlile Fraser, who accompanied Dr. Smith as collector and taxidermist.

Thomas, O. (1901f). XXXVIII. On a collection of small mammals from the Upper Nile obtained by Mr. R.M. Hawker.

Mr. R. MACDONALD HAWKER, to whom the National Museum already owes many valuable mammals collected by him during his various expeditions into northern and northeastern Africa, has now presented to the Museum the specimens obtained during his last winter's trip to the Soudan. They were mostly obtained on the White Nile between Fashoda and Khartoum, and are highly valuable both as supplementing the Museum collection, still very incomplete, from the Soudan, and as illustrating the many species described by Heuglin from specimens no longer in existence. The definite identification of these species of Heuglin's is a matter of
the utmost value.

The number of species in Mr. Hawker's collection is not very large, but among them there are a new hare and a new gerbille; and I have also taken the opportunity to describe a new member of the latter group obtained by Lord Delamere in East Africa.

Thomas, O. (1902). 1. On the mammals collected during the Whitaker Expedition to Tripoli.

Mr. J. I. S. Whitaker, F.Z.S., who has already done so much for the exploration of the Vertebrate Fauna of Northern Africa, and to whom our National Museum is indebted for importand collections of Mammals from Sicily, Tunis, and Morocco, has long wished to send a collecting expedition into the little-known country of Tripoli. Last year, by the kind intervention of the Foreign Office, permission was obtained from the Sultan for Mr. Edward Dodson and a companion, Mr. Drake, to travel through that country, collecting specimens, and it is the Mammalian results of this expedition of which the present paper gives an account.

The expedition was carried out entirely at Mr. Whitaker's expense, and, as in the case of the previous Moroccan expedition, he has generously presented the great majority of the Mammals collected to the National Museum, to which they form a most valuable addition.

As so often happens in such cases, the material available for comparison with the Tripoli collection is most imperfect, and badly needs supplementing by specimens collected in modern fashion. Indeed, of Barbary Mammals the only modern specimens are those of Mr. Eaton from Biskra, and Mr. Dodson's own previous collections from Morocco. Zoologists, therefore, who spend their winters in the south would do a great service to Science and the Museum if they would collect any mammals, however common, at the places they go to

Mr. Dodson left the town of Tripoli on April 2nd, 1901, and travelled southwards by way of Sokna to Murzuk, then returned to Sokna, and from there travelled north-eastwards to the Syrt district, where he worked eastwards along the coast to Ben-Ghazi.

His localities are thus divisible into four groups, as follows: -
I. Inland country north of Sokna. March 1901 and middle of June to middle of July. Specimens collected at Tarhuna, Wadi Sofedjin, W.' Nefed; W. Bey; Bonjem; Erdeul; Ain Hammam; W. Titti; W. Agarib; W. Wagis ; Oumsinerma; Limhursuk; Gebel Binsertia.

This is a desert region, without marked elevations; interspersed with small oases.

II. Soda Mountain district just south of Sokna (28° 55' N., 16° 15' E.). Beginning of May and second week of June. *Localities*. Tamari-Ferdjan; W. Sultan; Getefa; Linzerat.

The Soda Mountains rise to about 3000 ft. above the general level of the plain, not high enough therefore to have any noticeable climatic or faunal peculiarity. There is a map of this distinct in Rohlf's 'Kufra' (1881).

III. Level and descending country southwards to Murzuk (sea-level or below). *Localities*. Shup; Oum el Abid; Zighen; Sebha; Ghodua; Murzuk.

IV. Coast district eastwards from Syrt towards Ben Ghazi. End of July and beginning of August. W. Aggar; Elcusher; Bon Cheifa; Sidi Sweya; Sidi Faradje.

From a geographical standpoint, therefore, the region traversed is of a very good representative character. But, zoologically, there must be many more species which, on account of the hurried nature of the march, and the difficulties in collecting in so wild and semi-hostile a country, must have been missed by Mr. Dodson's party. Indeed, under the circumstances it is surprising how admirable a collection has been made.

As might be expected from the position of Tripoli between Egypt and Algeria, and the homogeneous nature of all three regions, the mammals have no marked general affinity or peculiarity. Some, such as *Acomys, Gerbillus pyramidum, G. eatoni*, and *Dopodillus vivax*, are Egyptian in affinity; and others, notably the *Ctenodactylus*, are distinctly Algerian; but these affinities are evidently only the eastward and westward extensions, hitherto unknown, of Algerian and Egyptian forms, and there seems to be no special faunal relationship with either of the two countries more than the other.

The proportionate number of new forms in the collection is remarkable, the most notable being the *Ctenodactylus* and the fine Hare which I have named in honour of Mr. Whitaker, to whose enterprise and generosity the expedition is due, and who is to be congratulated on its very successful outcome.

Thomas, O. (1903b). LXXII. On the species of the genus *Rhinopoma*.

The Egyptian Pyramids are inhabited by large numbers of bats of the genus *Rhinopoma*, the mouse-tailed bat, first recorded by Belon as long ago as 1554. By Dobson, in his Catalogue, the members of this genus, whether from Egypt or India, were all combined under one heading, *R. microphyllum*, "Geoffrey," although both Peters and Heuglin had pointed out that in Egypt two forms were present, a larger and a smaller, the former having the tail shorter than the forearm, the latter longer.

But in giving new names the two German authors, misled by their belief that Geoffrey's measurements were the original ones, affixed the names to the larger form. Now, however, that Anderson and de Winton's work has drawn attention to the fact that it was Brünnich, and not Geoffroy, who first described the species, I am able to state, on measurements kindly furnished me by Dr. Winge, that the type, still preserved in the Copenhagen Museum, is the large form with short tail (forearm 67.5 millim., tail 61). The smaller one, as to whose distinction from the larger no one who had compared the skulls could doubt for one moment, will therefore require a new name, and may be called.

Thomas, O. (1904a). XXII. New bats from British East Africa collected by Mrs. Hinde, and from the Cameroons by Mr. G.L. Bates.

The British Museum owes to the kindness of Mrs. Hinde, wife of Dr. S. L. Hinde, of Fort Hall, British East Africa, a further collection of bats, and these include three well-marked new forms, which I have described below, in conjunction with two others obtained by Mr. Gr. L. Bates in West Africa.

The new *Myotis* from Fort Hall, which I have named in honour of its captor, is an especially noticeable discovery.

Thomas, O. (1904c). XLVIII. On mammals from northern Angola collected by Dr. W.J. Ansorge.

During 1903 the well-known collector Dr. W. J. Ansorge, to whom the British Museum is already indebted for series of specimens from British East Africa, Uganda, and Nigeria, made a collecting-trip to Northern Angola, and obtained about two hundred specimens belonging to forty-six species, and of these a complete set has been acquired for the Museum.

The mammalogy of Angola has hitherto remained almost entirely in the hands of the Portuguese, as represented - most admirably - by Prof. Barboza du Bocage in Lisbon and by M. Anchieta and other collectors in the country under consideration. Thanks to the enlightened generosity of Prof. Bocage many institutions, and notably the British Museum, had received specimens representing the species discovered in Angola by the Portuguese naturalists, and on these specimens such comments on the Angolan fauna as have been made by Gray, de Winton, myself, and others have been based.

But these specimens, valuable as they have proved to be, have been all preserved in spirit, and the freshly made skins obtained by Dr. Ansorge are therefore of very great interest for comparison with similarly made specimens from other regions of Africa.

Complete as have been Prof. Bocage's researches on the subject, the present collection contains a fair number species not included in his lists, while, owing to my having been able to compare the remainder directly with typical specimens from other localities, I have found it necessary describe several of those he mentions as local species subspecies.

Dr. Ansorge has therefore to be congratulated on the considerable number of new and interesting forms which collection has enabled me to discriminate.

Thomas, O. (1904d). XXIV. On some small mammals collected by Mr. A.M. Mackilligin in the Eastern Desert of Egypt.

MR. ARTHUR M. MACKILLIGIN has recently collected some small mammals in the eastern desert of .Egypt, near the Soudan frontier, about lat. 22° and long. 35°, and these prove to be of much interest; for even with the magnificent accession to our knowledge of the mammals of Egypt represented by the late Dr. Anderson's work on the subject, this eastern desert has by no means been worked out, and Mr. Mackilligin has now discovered two new species, a bat and a gerbille, while an examination of his specimens of another bat, already obtained by Dr. Anderson, show this also to need a special name.

Besides the species described in detail below Mr. Mackilligin obtained in the same district examples of *Asellia tridens, Gerbillus gerbillus, Acomys* sp., and *Jaculus jaculus*.

Thomas, O. (1910d). XXXVI. List of mammals from Mount Kilimandjaro, obtained by Mr. Robin Kemp, and presented to the British Museum by Mr. C.D. Rudd.

By the generous assistance of Mr. C. D. Rudd, whose zoological exploration of S. Africa is known to all mammalogists, a collector - Mr. Robin Kemp - has been employed for the past year in obtaining small mammals in British East Africa for the benefit of the National Museum. A considerable number of new species have been obtained, and these have been described on arrival in successive numbers of the 'Annals.'

Mr. Kemp has recently sent a collection from Mount Kilimanjaro, and it is thought that a complete list of them may in this case prove of utility to other workers on African mammals.

The collection was obtained at two localities - Taveta, alt. 2500', at the foot of the mountain, on the British East African side; and Rombo, a mission station on the German side of the frontier, at an altitude

on the mountain of about 6000'. Mr. Kemp was much indebted to the missionaries at Rombo for help and hospitality.

In nearly all cases the species obtained at the two places prove to be different, those from Rombo being Kilimanjaro mountain forms, while those from Taveta belong to the hot country and desert fauna which stretches northwards through Voi arid Kitui to the:region north-east of Mount Kenya.

Thomas, O. (1911). XIII. List of small mammals obtained by Mr. G. Fenwick Owen on the Upper Gambia and in Fouta Djallon.

During the early part of 1910 Mr. G. Fenwick Owen made an expedition to Western Africa in search of large game, with the especial wish to obtain a male Derby's eland for the National Museum. In this latter purpose he was unsuccessful, but he brought home a female eland, besides specimens of the local buffalo, hartebeest, water-buck, roan antelope, ovibi, and blue-backed duiker.

Of small mammals he obtained a considerable series, and these prove to be of such interest as to deserve a special list, in addition to the descriptions already published of *Tatera gambiana, Arvicanthis linulus*, and *Uranomys oweni*.

Mr. Fenwick Owen's collecting was mostly done in French Gambia, on the upper part of the river of that name; but some of the specimens came from rather further south, in the Fouta Djallon district of French Guinea - a region about 3000 - 4000 feet in altitude. More complete collections from this latter region might prove of great interest.

Mr. Owen was accompanied by Mr. G. Russell Roberts, 'who assisted in making the collection.

The whole series has been presented to the National Museum by Mr. Owen, and forms a very valuable addition to its African collections.

Thomas, O. (1912c). A new Vespertilionine bat from Angola.

A few years ago, by the kindness of the authorities of the Lisbon Museum, the British Museum obtained an example of a peculiar Vespertilionine bat which had been received from Angola, and whose systematic position seemed by no means readily determinable.

I have now been able to make a careful study of this specimen, and have come to the conclusin that it represents a new genus, which may be called:

Thomas, O. (1913a). On some specimens of *Glauconycteris* from the Cameroons.

Among some mammals from the Cameroons sent for determination by Prof. E. Lampe, of the Wiesbaden Museum, there occur three examples of *Glauconycteris*, representing three different species, one being new and the others of sufficient interest to deserve some notice.

Specimens of this genus are somewhat rare in collections, and any addition to our knowledge of them is very welcome. The type of the new species and a selection of specimens of the other mammals represented (including *Crocidura dolichura*, Peters) have been generously ceded to the British Museum by the authorities at Wiesbaden

---

Thomas, O. (1915a). On three new bats obtained by Mr. Willoughby Lowe in the Sudan.

During Mr. Abel Chapman's recent expedition to the Sudan, Mr. Willougnby Lowe obtained a considerable collection of mammals, and among them a number of bats. These include, besides *Coleura afra, Mops demonstrator*, and others, examples of the three following new species.

Thomas, O. (1915b). Notes on bats of the genus *Coleura*.

A study of the British Museum collection of the genus *Coleura*, amounting to nearly sixty specimens from more than a dozen localities, shows that on the mainland of Africa there are two species: a north-eastern, inhabiting Suakin, Aden, Somaliland, and the Upper Nile; and a southern, which ranges from the Congo to the Zambezi. The former is separable into two colour-races.

Then in the Seychelles there are two forms, both distinguished from those on the mainland by their proportionally longer wings.

Thomas, O. (1915d). List of mammals (exclusive of Ungulata) collected on the Upper Congo by Dr. Christy for the Congo Museum, Tervueren.

In the 'Annals' for last August I published a few of the more striking novelties from the fine series of Mammalia brought home from the Congo by Dr. Cuthbert Christy, who had been employed by the Congo Museum to make a collection for them on the Ituri and Welle, and, by request of the Belgian authorities, I now give a list of all the species obtained by him, with the exception of the Ungulates.

Such a list is always valuable for zoo-geographical reasons, and Dr. Christy's fine collection so supplements those made in the same region by Emin Pasha, the Alexander-Gosling Expedition, and the members of the Ruwenzori Expedition, as to make the complete list a very long one.

In a general way, there is a great uniformity in the Mammal life from the Cameroons to Uganda, as might be expected from the uniform nature of the country, but in a few cases there is enough local difference to authorise the distinction of special subspecies for the Upper Congo forms.

In all, Dr. Christy's collection contains 74 species and subspecies, of which 10 have proved to need description as new. Five of these were described in the previous paper.

Dr. Christy's numbers run up to 1530, but the present account only deals with the latter two-thirds of the collection, the earlier series having either been already named by Mr. Dollman or else gone elsewhere for determination.

The great majority of the mammals here referred to were obtained at two localities, Medje, on a branch of the Ituri, about 27° 40' E., 2° 20' N., and Poko, some 20 or 30 miles north-west of it, but across the watershed in the Welle basin. The latter is not very far from Emin's locality, Tingasi. The other localities mentioned are mostly in the Aruwimi-Ituri basin.

By the generosity of the authorities at Tervueren, the British Museum has been allowed to retain examples of nearly all the species obtained, including all those described as new. In particular, we have to thank Dr. Schouteden for his kindness both in placing the collection in our hands for determinatin and for the liberality with which we have been allowed to select duplicates. The sum of these latter forms a very valuable donation to the British Museum.

In normal times this list would have been prepared by Mr. Dollman in continuation of the papar he published in the Tervueren Journal in 1914, but he has gone to serve his country, and it is quite impossible for publication to take place in Belgium. With the consent of the Belgian authorities the paper is therefor prepared by me and published in the 'Annals.'

Thomas, O. (1917). XXIII. A new bat of the genus *Scotæcus*.

Among a series of well-prepared skins from Nyasaland presented to the National Museum by Mr. Rodney C. Wood, there occur examples of several rare bats, notably *Myotis welwitschii* and *bocagei, Glauconycteris papilio, Eptesicus megalurus*, and a *Scotoecus* which appears to be new. The last may be called:

Thomas, O. (1919). Some new mammals from Mesopotamia.

Among some mammals obtained by members of the Mesopotamian Expeditionary Force, and submitted to me for determination by the Bombay Natural History Society there are examples of the following five new species. In pursuance of its habitual public-spirited policy the Society has presented all the types to the National Museum.

Thomas, O. (1920). A new *Taphozous* from the Sudan.

Among a number of small mammals collected in the Sudan by Major J. Stevenson Hamilton, and sent to the British Museum for determination by the Wellcome Research Laboratories, Khartoum, there occurs a specimen of the following new bat, which I have great pleasure in naming in honour of its discoverer:

Thomas, O. (1922). XXXII. The generic classification of the *Taphozous* group.

When, in 1915, I wrote my "Notes on *Taphozous* and *Saccolaimus*", and recognized the latter as a distinct genus from the former, as had Hollister previously under another name, I did not sufficiently weigh the characters which separate *Taphozous nudiventris* and its allies from the typical members of *Taphozous*.

On reconsidering the subject, I now think that these remarkable half-naked bats should be separated as a distinct genus from the ordinary hairy species, and would suggest that the whole group .might be synoptically arranged as follows:

Thomas, O. (1925). On the mammals (other than Ruminants) collected by Captain Angus Buchanan during his Second Saharan Expedition, and presented by him to the National Museum.

Following his first expedition into the Sahara, when he visited Asben (Aïr) and made the highly interesting collection of small mammals of which Mr. Hinton and I gave an account in two previous papers, Captain Angus Buchanan started again in March 1922 for the same little-known country, and this time he was able to traverse it completely from south to north, arriving at Algiers on 7th June, 1925. During this adventurous journey he collected a considerable number of mammals, mostly in Asben and the Ahaggar Mountains, and these he has been so generous as to present partly to the British Museum and partly to that of Edinburgh. As before, the skins are quite exceptionally well prepared, and, being from so interesting an area, the donation is one of very great value, for which the National Museum has every reason to be grateful to its patriotic donor.

With the many Algerian and Saharan collections that we already owe to the generosity of Lord Rothschild, combined with the possession of the Lataste collection from Algeria and the Fox collection from Nigeria, we thus have a very fine representation of the mammals of North Africa on the line connecting these two countries - a region which only a few years ago was completely unknown zoologically.

The present paper gives a full list of the specimens obtained, with the exception of a small number which have been added to the Tring Museum, where they will probably form the basis of papers by Lord Rothschild. The serial number of every specimen is recorded, in ordinary type for those now in the British Museum and in italics those that have gone to Edinburgh, the paper thus forming a record of both.

As might be expected, the collection contains several interesting novelties, such as the Asben ratel and porcupine, and there is a very pretty new dormouse which I have named in honour of Mrs. Buchanan.

In addition, he has made a most noteworthy rediscovery in the capture of an example of Loche's *Felis margarita*, described in 1858, but never obtained since. The specimen is to be preserved in the Tring Museum, and Lord Rothschild proposed to give some notes on it, so that further reference to it is here unnecessary.

On the other hand, the specimens from the mountains of the Ahaggar region are disappointingly similar to those of southern Algeria, no evidence occurring of the presence of a special local fauna.

Thomas, O. (1926). On mammals from Ovamboland and the Cunene river, obtained during Capt. Shortridge's third Percy Sladen and Kaffrarian Museum Expedition into South-West Africa.

For the third time, during the southern winter, Capt. Guy C. Shortridge, so well known for his collecting abilities in various parts of the world, and now Curator of the King William's Town Museum, has made a most successful expedition into the little-explored regions of South-West Africa. This he has been able to do owing to the continued generosity of the Percy Sladen Trustees, who provided the necessary funds, and of the Trustees of the Kaffrarian Museum, King William's Town, who found Capt. Shortridge's time, personal expenses, and other local necessities. Special credit has also to be given to Mr. G. R. Hofmeyr, C.M.G., the Government Administrator of S.W. Africa, on whose recommendation this further expedition was made, to whose action and official help Capt. Shortridge was enormously indebted in all sorts of ways, such as local help, transport, both by rail and wagon, and in many other respects.

Capt. Shortridge's first expedition of 1922 was to the region of the Middle Orange River, approximately lat. 28° 30' S., long. 21°.20'E.; the second (1923) into Damaraland, lat. 22° 25' S., long. 16° 18' E., some 200 to 500 miles north-west of the first-named region; and then this third expedition of 1924 was carried some 200 - 300 miles farther north still, through Ovamboland to the Lower Cunene River, the southern boundary of Angola.

Accounts of the Mammalia obtained dining the two first expeditions have already been published in the 'Proceedings' of the Society.

The collection now obtained proves that in this region Capt. Shortridge penetrated into a region strikingly different, from a zoological standpoint, from those he had previously explored, and one hitherto almost completely unknown. As a result, quite a large number of the small in animals have proved to be peculiar, equally different from those of Central Damaraland to the south and of Angola to the north, and having a quite special facies.

For, no doubt due to the general coloration of the environment, the peculiar mammals are nearly all of a very pale greyish colour, not the pale buffy so usual in deserts in other parts of the world, but of a much more greyish, less buffy tone. The same tendency to grey is also found in many of the Kalahari mammal and presumably results from an environment more or less common to these two contiguous and practically continuous areas.

Of previous collections in this region there are almost none to be recorded, apart from a few specimens obtained at Elephant Vley (18° S., 17° 30' E.) by the famous Swedish explorer Andersson about 1859, though those obtained by Messrs. Woosnam and Dent in the Central Southern Kalahari, and worked out by Mr. Schwann and Capt. Dollman, have commonly had a bearing on the zoological relationships of the animals mentioned.

Ungulates and other large mammals from the same region are also referred to in the work by Dr. Zukowsky quoted in the paper on the results of Capt. Shortridge's second expedition.

The very special thanks of all Mammalogists are due to the generous co-operators who have enabled Capt. Shortridge to make the three magnificent collections of which this is the third and most important. The present series consists of about 500 specimens, referable to 55 species and subspecies, and containing no less than 22 new forms.

The many field-notes and accounts of habits written by Capt. Shortridge are not now published, but have been postponed for a later occasion, when it is hoped that they may appear under the collector's own authorship.

In the papers on the mammnls of the two former expeditions I had the advantage of Mr. Hinton's co-operation, but on this the pressure of his other work, he has been unable to take a share, and I have had to bear sole responsibility for the whole.

Miss Jane St. Leger has been good enough to give me valuable and much appreciated assistance in the sorting and handling of the considerable number of skins and skulls.

Thomas, O. (1929). On mammals from the Kaoko-Veld, South-West Africa obtained during Captain Shortridge's Fifth Percy Sladen and Kaffrarian Museum Expedition.

The high region of the Kaoko-Veld, in South-West Africa, north-west Damaraland and south of the Cunene River, has long been a *terra incognita*, it is only recently, since the general region has become a constituent part of British Empire, that any exploration of it has been possible.

Now, however, Captain Guy C. Shortridge has been enabled to make one of his wonderful collecting expeditions, the fifth of the series, into this hitherto unknown area, and the present paper gives an account of the collection he made, the largest of the whole series.

With some help from the British Museum itself, this expedition has been made possible by the generosity of the Percy Sladen Trustees, the Administrator of South-West African Territory, the South African Research Fund Board, of Mr. Abel Chapman, whose sporting instincts have made him sympathetic towards such exploratory adventures. To all of these thanks are due for material advancement in our knowledge of the South African Fauna represented by this really remarkable fifth collection. And equally to the Trustees of Kaffrarian Museum for their very generous co-operation in the work by sparing Captain Shortridge from King William's Town for so long a period.

The collection itself numbers nearly 1500 specimens, and considering that was made by a single man with only native help, it is a great tribute to Captain Shortridge's enthusiasm and powers of work.

It is accompanied by very ample field-notes on the habits and distribution the various species. These notes, however, are so full and excellent that they ought not to be used merely as a supplement to a technical paper on the mammals, and I therefore do not now publish them, but hope that they will in due course be brought out in South Africa under Captain Shortridge's own supervision. Native names, distribution, and habits are all included, and we may hope these observations will form a basis for a general work on such lines.

After the successive collections from (1) the Orange River, (2) Namaqualancl, (3) Ovamboland, and (4) Eastern Damaraland that we already owe to Captain Shortridge's expeditions, it is natural that there should not be very many novelties to be described from Kaokoland, which, in a broad sense, is of the same faunistic nature, and whose mammals prove to be generally the same as those of the areas previously explored. This is a little disappointing, as we had hoped that forests and mountainous areas of the Kaoko-Veld might prove to be inhabited various special forms. But numbers of them had already been obtained Captain Shortridge in the outlying regions of the faunal area - on the Cunene in the north, in Ovamboland to the east, and at Karibib in the south-east - so that we ought not to be surprised if there were not a large number more to be discovered.

None the less several well-marked new forms have been obtained, notably the two black Mungooses, *Myonax nigratus* and *Helogale parvula nero*, the Ground-Squirrel *Geosciurus princeps*, quite unexpectedly peculiar, and the Rooi-haas *Pronolagus caucinus*.

In all, 70 species are contained in the collection, while the presence and ranges of some few others are recorded in Captain Shortridge's field-notes.

The localities at which Captain Shortridge made collections are 21 in number, and are situated broadly on a north and south line about 100 - 200 miles from the coast, and running from the Cunene River to Outjo in South Kaokoland, at about 20° South latitude. These localities are mostly at a considerable elevation, from 1000 to 4000 feet altitude.

Their names are: in the Outjo district of Damaraland - Outjo, Otjikondo, and Cauas Okawa; in S. Kaoko - Kamanjab, Otjitemba, Qoabendus, Kovares, Otjijekua, Katijhuru; in Central Kaokoland - Otjitundua, Ombombo, Kaoko-Otavi, Okorosave; in north Kaokoland - Otjipongo, Ombathu, Epembe, Otjitambi, Mount Ehomba; and in the close neighbourhood of the Cunene, which is here about 100 yards in breadth - Tshimhaka, Hondoto-Cunene Junction, and Otjimbundu.

Detailed accounts of their local characteristics are contained in Captain Shortridge's field-notes.

Thomas, O. and M. A. C. Hinton (1920). Captain Angus Buchanan's Aïr Expedition. I. On a series of small mammals from Kano.

By the kindness of the authorities of the Tring Museum we have been entrusted with the examination of a number of small mammals obtained by Captain Angus Buchanan, while stopping at Farniso, near Kano, North Nigeria (altitude 1,700 ft.), in December 1919, on his way to explore the unknown regions farther north.

These Kano Mammals have proved to be of so much interest and to include so many novelties that we have thought it worth while to give a complete list of them.

The most striking form from a zoological point of view is undoubtedly the little short-tailed Gerbil *Desmodilliscus buchanani*, which represents, a genus only discovered in 1917 and hitherto not included in the British Museum collections.

The handsome little carnivore *Pœcilictis rothschildi* is also a discovery of some interest, as it greatly extends the known range of its genus, which has only recently been distinguished from *Ictonyx*.

By the generosity of Lord Rothschild, a set of the species obtained by Captain Buchanan, including the types of new species and subspecies, has been presented to the British Museum.

The only place towards Kano from which the British Museum has hitherto received any noticeable collection of mammals is the Bauchi Plateau, some 160 miles to the south-east, where the missionary brothers G. T. and J. C. Fox collected a number which formed the basis of papers by Thomas in 1911-12. Practically all the species, however, prove .to be different, and show that the two places are in different fauna! areas, of which Kano is strikingly more of a desert character.

Thomas, O. and M. A. C. Hinton (1923a). On the mammals obtained in Darfur by the Lynes-Lowe Expedition.

Thanks to the generosity and public spirit of the two explorers, the British Museum has received as a donation the whole of the fine collection of Mammals made by Rear-Admiral Hubert Lynes and Mr. Willoughby P. Lowe during their recent expedition to Darfur.

The expedition took place during the whole of 1921 and the early part of last year, and a complete survey of the country was made, equally of the comparatively flat desert region round El Fasher, the capital of Darfur, the still more desert area northward to the bare find unproductive Jebel Maidob, the zoologically unknown dominating mountain Jebel Marra, running up to a height of 10,000', and, finally, of the lower region of Wadi Aribo, in the south-western part of Darfur, where the drainage is to wards Lake Chad.

No mammal collection had ever been made In this area, so that the present fine series (which numbers upwards of 800 specimens) adds very greatly to the material available for the study of African Mammalia, and we have reason to be most grateful to the donors for the generosity and patriotism which have resulted in this notable accession to the Museum - the largest: single collection that the latter has ever received.

On the whole, the species contained in the collection are most nearly related, as is natural, to those of Kordofan and other parts of the Egyptian Sudan, and are generally different from those of the more humid Bahr-el-Ghazal.

So far as the mammals are concerned, Darfur would seem to be just on the southern boundary of the northern desert fauna, the collection containing quite a number of forms which are either the most southern records of northern species (*Jaculus jaculus, Dipodillus campestris* group, etc.) or the most northern records of southern ones (*Steatomys*, &c.).

The great mountain Jebel Marra, isolated as it is from other, high ground, has naturally a number of interesting forms peculiar to it and different from those of the plains. Thus there is a mountain species of Striped Mouse (*Lemniscomys*) found on it, which we have named in honour of Admiral Lynes, and a Gerbil (*Dipodillus lowei*), whose nearest ally is found in Algiers.

In all, the collection proves to consist of 62 species, of which we have had occasion to describe 19 as new, either as species or subspecies.

A few mammals were obtained by Admiral Lynes on a previous visit to the country, and these have been here incorporated. Their immbers run from 1 to 24, while those of the main collection start at 400.

Thomas, O. and H. Schwann (1905b). The Rudd exploration of South Africa. III. List of mammals obtained by Mr. Grant in Zululand.

[The complete account of the new species described in this communication appears here; but as the names and preliminary diagnoses were published in the ' Abstract,' such species are distinguished by the name being underlined. - EDITOR.]

In continuation of the collecting-work carried on by Mr. C.. D. Rudd's generosity, by which our National Museum has already been so large a gainer, Mr. C. H. B. Grant spent November and December 1903, and again, after a visit to the Transvaal, June to September 1904, in Zululand, where he collected the specimens of which the present paper gives an account.

It was at Mr. Rudd's own suggestion that Mr. Grant went to Zululand, and the resulting collections have more than fulfilled any expectations that could have been formed as to the value and interest of a series obtained there, for quite a number of the species have proved to be altogether new to science, while in other cases forms only hitherto known from isolated or unlocalised specimens are now illustrated by good series of trustworthy skins.

In several instances we have been able to revise confused or little-known groups, such as *Myosorex* and the Golden Moles, with the result that a number of new forms have proved to need description.

Of these by far the most noteworthy is the handsome Hare which we have named *Pronolagus ruddi*, while other interesting species are the Golden Moles, *Amblysomus iris* and *A. chrysillus*, and the different forms of *Myosorex*.

The localities at which the specimens were obtained are as follows: -
Eshowe. Altitude 550 m.
Sibudeni and the Jususie Valley, about 20 miles to the N.W. of Eshowe. Altitudes 1100 to 1700 and 350 m. respectively.
Ngoye Hills, 15 miles E. of Eshowe, and about 8 miles inland from the coast. Altitude 200 - 300 m.
Umvolosi Station, 3 miles from the river of the same name and about 15 miles from the sea. Altitude 30 - 60 m.
Hlupluwe Stream; about 20 miles N. of Umvolosi.

Of the last localities Mr. Grant says: -
"Round the Umvolosi Station sandy grass-covered flats and undulating country stretch away to the south and east, dotted with palms and thorn-bush, the thorns in places forming patches and thickets interspersed with a few good-sized trees, the surface broken with both dry and swampy pans and vleys, and deep swampy sluits filled with dense reeds intersect the country towards the river. A low range of hills runs along the coast. To the north the country becomes more broken and hills and deeper ravines begin to appear.

"About 8 miles to the south of the station is a dense thorn-forest of considerable size, called by the natives the 'Dukuduku,' which joins and disappaers in the great swamps and reed-beds through which the Umvolosi River runs.

"Towards the Hlupeuwe and opposite the north end of the Lake the country is broken and hilly, palms are not so noticeable, but the thorns become common and more regular in appearance; often as one looks across some hillside or down a long valley they look park-like in their regularity. One would almost believe they had been planted by hand. Belts of thick bush fringe nearly all the rivers, often being very dense and wide."

After putting aside the duplicates, the Zulu collection, which, as in the previous cases, is presented to the Museum by Mr. Rudd, numbers 222 specimens belonging to no less than 49 species. It thus forms not only one of the most important accessions that the National Collection has ever received from this part of Africa, but, owing to the number of the new forms contained in it, affords a remarkable example of the need for such a scientific survey of the fauna as Mr. Rudd is carrying on in South Africa. Mr. Grant, the actual collector, is also to be congratulated on the striking results that have been obtained from his materials.

Thomas, O. and H. Schwann (1906a). 3. The Rudd exploration of South Africa. IV. List of mammals obtained by Mr. Grant at Knysna.

Owing to its possession of one of the few forest areas in Cape Colony, Knysna, at the centre of the southern coast, has always occupied an important position in the history of South African zoology. The name occurs again and again in the literature, from the date of Sir Andrew Smith onwards, and it was therefore thought advisable that a series from so interesting a locality should be obtained by Mr. Grant as part of Mr. C.D. Rudd's magnificent exploration of South African Zoology.

Mr. Grant therefore went to Knysna in December 1904, and stayed until the middle of January 1905, when he went for a month to Plettenberg Bay, in the near neighbourhood, after which he again worked at Knysna until April 23rd, when he left for the Transvaal. He was thus in the Knysna district throughout the southern summer.

The series now dealt with consists of about 150 specimens belonging to 31 species and subspecies, of which four have required descriptions as new. Of these by far the most interesting is the district Forest Golden Mole, named in honour of Mrs. Rudd *Amblysomus corriæ*, of which Mr. Grant obtained a good series. The species was described in an earlier communication, in order that its skull might be figured in company with that of the Zululand form discovered previously by Mr. Grant.

As usual, the whole series is and will be of the utmost value in more fully working out the details of S. African Mammalogy. Indeed, the lists we are giving of the Rudd collections as they come in are only

a first commencement of the use that they will be to Science. For as they accumulate different specialists are enabled to take up group after group, and such useful revisions as that of the *Arvicanthis pumilio* group by Mr. R. C. Wroughton, or of the South African *Rhinolophi* by Mr. Knud Andersen, are thereby rendered possible. To such revisions our lists are a mere preliminary, though we hope that in addition to fulfilling the necessary work of describing the new forms they may also serve a useful purpose from a geographical point of view.

Mr. Grant's notes on the collection are as follows:

The country around Knysna is decidedly mountainous, varying from sea-level to over 4000' within a few miles. The highest point of the Outeniqua Mountains is 4666'.

Many miles of the country, especially to the N.E. of Knysna, are covered with dense forest, which becomes more patchy to the east and west, and in many parts is confined to the kloofs and rivers. The principal trees are yellow wood, iron-wood, stinkwood (laurel), witel, and coomassie. In the more open places along the banks of the main road ferns are very plentiful.

The open parts are grassy downlands, covered here and there with scrub (fine bush) and sugar-bush.

The first half of my visit was spent in the forest-region and the latter half in the open veldt at Plettenberg Bay, which is about 20 miles east of Knysna.

Thomas, O. and H. Schwann (1906b). 1. The Rudd exploration of South Africa. V. List of mammals obtained by Mr. Grant in N.E. Transvaal.

After completing the work at Knysna, of which we gave an account in our last paper, Mr. Grant journeyed by way of Delagoa Bay and Pretoria to the Zoutpansberg District of the Transvaal, a region hitherto practically untouched, so far as the collections in the National Museum are concerned. Indeed, the whole drainage-area of the Limpopo had been remarkably little worked, such few collection as had been sent from within it having been from its northern part in Matabililand or the western in Bechuanaland, the Limpopo part of the Transvaal having been quite neglected.

In this interesting region Mr. Grant has worked with his usual energy and success, and his collection includes 250 specimens belonging to 51 species. This fine series, by Mr. Rudd's generosity, is as before, added to the treasures of our National Museum.

The localities at which the collection was made were two - Klein Letaba on the low veldt, and Woodbush on the high veldt; and these localities are so distinct from each other both geographically and zoologically, that we have thought it advisable to separate altogether the collections received from them and to write two distinct lists as follows: -

I. Klein Letaba.
Klein Letaba is situated in about 23° 21' S. and 30° 40' E., on a branch of the Letaba River, which runs south-eastwards to ??? the Olifants River, uniting again still further eastwards with the main stream of the Lower Limpopo. It is at an altitude of about 1000 feet to the east of and below the high range of the ???kensbers.

Its mammal fauna proves to be more like that of the high veldt than one would have expected from the difference in altitude, so that we are disappointed to find fewer of the coast and tropical forms than we had hoped, and it is evident that to get the true coast fauna a still lower level must be visited.

Even here, however, several interesting northern forms have been added to the South African list, the most notable being a representative of the Nyasan *Raphicerus sharpei*, an Antelope so strikingly different from any South African species that the tardiness of its discovery is somewhat surprising. Other interesting forms are a new *Helogale* and two new Genets.

Mr. Grant's notes on the Klein Letaba district are as follows: "The low veldt, that is the country under the Berg, is mainly undulating grass country with long stony rises and some few kopjes and mountains.

"It is thickly timbered, principally with Mopani (Shinatsi of the Tchangaan); a large, fine-growing tree called Ntuma, which bears a small green fruit; the Marula, on the berries of which *Funisciurus cepapi* feeds and from which the natives make beer; 'wait-a-bit' thorns ("Ikaya"); and wild fig and cream-of-tartar trees.

"Water is scarce in the dry season and only to be found in the main rivers that intersect the country, except for some few pools left in the rocks in some of the spruits. The soil is sandy and very fertile in good rainy seasons. The climate is not healthy, and the weather generally very warm. The thermometer frequently records 106° and seldom less than 90° in the shade.

"The natives are tribe called the Tchangaan, and are an offshoot of the Zulu nation. They have a language of their own, but all understand Zulu and speak it readily. Though very keen on hunting big game, they gave but little assistance in securing small mammals."

Thomas, O. and H. Schwann (1907). 4. The Rudd exploration of South Africa. VI. List of mammals obtained by Mr. Grant in the Eastern Transvaal.

During April and May, before going down into the hotter coast-belt, Mr. Grant made a stay at Legogot, a village in the northern part of the Barberton district, at an altitude of about 3000 feet. There he obtained the Mammals recorded in the following list.

One species, a Shrew, is new, while the most valuable of the other animals are the additional specimens of *Pronolagus ruddi*, the large ally of the Rooi-haas, the description of which was based on a specimen collected in Zululand at an earlier stage of the Rudd Exploration.

Before going to Legogot Mr. Grant made a small collection at a place called Turfloop, between Pietersburg and Woodbush, in the North-Eastern Transvaal; but as he obtained no examples of species not mentioned in our list of his Woodbush collection, we do not think any list of them.is necessary.

Thomas, O. and R. C. Wroughton (1908a). The Rudd exploration of South Africa. VIII. List of mammals obtained by Mr. Grant at Beira.

Long as the region of Beira and the Pungwe River has been known as a paradise for sportsmen, no scientific collection of mammals appears ever to have been made there, and certainly our own National Museum has never received any specimens from the district. Consequently the present collection, obtained by Mr. Grant for the Rudd Exploration, is of very great value as filling in the geographical gap between Inhambane, whence came the magnificent series enumerated in our previous paper, and the better known regions of the Zambezi and Nyasaland.

The results, from the point of view of geographical distribution, are in many cases most curious and interesting, and show the necessity for such systematic explorations as this of Mr. Rudd's before we can consider our knowledge on the subject to be at all complete. For example, in the case of *Petrodromus* one would have supposed that the same form would occur as at Inhambane further southwards, since a closely allied one is found on the coast further north in East Africa. But instead a member of quite another group - *P. tetradactylus*, an inhabitant of the higher inland region from Nyasa to S. Rhodesia - here reaches the East coast area, and isolates the Inhambane species from its northern ally.

Then, again, the *Georychus* is much more closely allied to the Bechuanaland *G. lugardi* than to *G. darlingi* of Mashonaland, intermediate in geographical position.

There are evidently therefore very many interesting problems still to be determined about the geographical distribution of the species, and about the faunal areas into which the country should be divided.

Twenty-nine species are included in the present collection, represented by 129 specimens, all, as before, added to the National Museum by the generosity of Mr. C. D. Rudd.

The collection was made in two localities, the one just outside Beira, and the other, Masembeti, on the Railway 23 miles from that place.

Mr. Grant's report on the region is as follows:

"The Beira District may briefly be described as low lying, flat country, with patches and stretches of forest alternating with open plains clotted with palmetto, bamboo brakes and ant-heaps, and with vleis and lakes in the lowest parts.

"In the wet season the whole country, except the higher forested portions, is one vast swamp and the vegetation is both thick and high.

"Natives are few and scattered, as there is little habitable veldt on which crops can be grown.

"The climate during the wet season is by no means healthy, and although the thermometer may not always record high temperature, it is generally sultry and muggy. Collecting work is difficult and the damp heat is most enervating.

"Throughout the trip the weather was warm, average temperature 86° in the shade. There was plenty of rain, especially during the latter half, which was undoubtedly bad for trapping work; this combined with the scarcity of mammals in the district, and the ravages of ants which completely destroyed numbers of trapped specimens, prevented the collection made from being larger.

"The scarcity of mammals, especially the smaller ones, is probably due to the annual flooding of the country, as numbers must be drowned out and killed during the rainy season."

Thomas, O. and R. C. Wroughton (1908c). The Rudd exploration of South Africa. X. List of mammals collected by Mr. Grant near Tette, Zambesia.

We now come to the final collection of the Rudd Exploration, for after making it Mr. Grant had a severe attack of fever, and by arrangement with Mr. Rudd he has now come home, so that this magnificent exploration, which has been going on for the last five years, thus comes to an end.

Further details of the papers written on the different collections are appended to the present account, but we may here say that the results of Mr. Rudd's splendid generosity have far surpassed, in their great and permanent value, our most sanguine -expectations - a fact for which the fullest credit must also be given to the collector, Mr. C. H. B. Grant, who has risen in the ablest manner to the great opportunity afforded him by Mr. Rudd.

The total results form the largest collection of Mammals ever received by the National Museum from any one source, the nearest approaches to it being the products of the Simons and Robert expeditions to S. America, and the Duke of Bedford's Exploration of Eastern Asia, the last-named being still in progress.

In all 1541 mammals, exclusive of duplicates, have been registered as presented to the National Museum by Mr. Rudd, while duplicates have been presented to the Royal Scottish Museum, Edinburgh, and the South African Museum, Cape Town.

A considerable and quite unexpected number of new species and subspecies have been discovered, and, what is quite as important, most of the old species, insufficiently or inexactly described on specimens now deteriorated, have been definitely identified by topotypes, and are represented by good modern material, which may be made the basis of further progress.

In this connection the Tette series, of which we give an account in the present paper, is of especial importance; for every worker on South African zoology has been hampered by the difficulty of making

out with exactitude the species obtained during Dr. Peters's famous expedition to Zambesia, and described by him in his 'Reise nach Mossambique,' of which the 'Saugethiere' was published in 1852.

In order, therefore, to get a series of the species described by Peters, Mr. Grant went to Tette, Peters's chief collecting-place, and formed the series enumerated below.

While we were working out this series, the definite determination of Peters's species has enabled us to sort out a number of the groups, with the result that many forms hitherto assigned, in our papers and elsewhere, to Peters's species, now prove to need description.

Mr. Grant's notes on the Tette district are as follows:

"It was the driest time of the year when I reached Tette, and, except in the main rivers, there was practically no water anywhere, and as, on the Zambesi near Tette, there were too many natives present for it to be possible to collect, I moved southwards and pitched my camp at the junction of the Luenya and Mazoe Rivers, which is some 20 miles due south of Tette.

"The country there is exactly similar to that along the Zambesi, being hilly, and in places somewhat mountainous; the soil is sandy and very stony, especially on the hill-sides, but there are no krantzes that would harbour dassies or red hares.

"All the vegetation, except along the rivers, was dried and dead and the trees leafless, the course of the rivers being plainly shown from a distance by the verdure of the trees on their banks.

"Everywhere the veldt is well bushed, amounting to thickets in most parts, with a fair amount of larger timber, mainly *mopani* and 'cream-of-tartar,' the latter being very plentiful and growing to an enormous size.

"Except in favourable situations, grass does not seem to grow freely, and the cereal crops of the natives are not nearly so good as in many districts to the southward, although tomatoes, onions, &c. are grown freely on the banks and in the beds of the rivers.

"The natives are mixed local tribes variously known as Nyungwis, Tongas, Baruds, &c. When not too lazy they give much of their time to the capture of small buck, cats, squirrels, rats, &c., the majority of which they utilize for food.

"The climate cannot be considered healthy, even in the dry season, and the temperature is generally high during the day and makes good collecting difficult.

"In the five weeks I spent in the Mazoe camp the average temperature was 95°, 104° being the highest recorded; no rain fell."

Thomas, O. and R. C. Wroughton (1910). Ruwenzori expedition reports. 17. Mammalia.

The collection of Mammalia formed by the members of the Ruwenzori Expedition is, perhaps, both for number and quality, the finest ever made in any one locality in Africa, the British Museum set alone consisting of 363 perfectly prepared modern skins and 62 spirit-specimens, representing 85 species and subspecies, of which no less than 34 have proved to be new. In addition, a considerable number of duplicates have been distributed.

This excellent result is due partly to the extreme richness of the Fauna, which combines elements of Congo, Cameroons, Uganda, and Great Lakes origin, and partly to the fact that no less than three members of the Expedition had had previous and successful experience in mammal-collecting - Messrs. Woosnam and Dent in Bechuanaland, and Mr. Carruthers in Palestine. All were trained and enthusiastic trappers, and, as a result, in spite of the climatic conditions under which they worked, the preparation of the skins is absolutely perfect.

So rich and varied, however, is the Fauna of Ruwenzori that no doubt much still remains to be done, especially among such forms as are not to be obtained by trapping, the list of Monkeys, Bats, and Ungulates being particularly likely to be increased in the future, while the series of Rodents is probably more complete in proportion than that of any other group.

As was to be expected, a considerable number of new species were discovered by the Expedition, many of them of a very striking and distinct character. Particularly noticeable are *Cercopithecus denti, Rousettus lanosus* (the Mountain Fruit-Bat), *Lophuromys woosnami, Otomys dartmouthi*, and *Funisciurus carruthersi*,

The following is a complete list of the new forms discovered, with references to the original notices. A. is the first set of descriptions published by Thomas (Ann. Mag. N. H. (7) xviii. pp. 136 *et seqg.*, 1906) and B. the second (*op. cit.* six. pp. 118 *et seqq.*, 1907).

Thorn, E. (1988a). Re-evaluation of *Pipistrellus capensis capensis* (A. Smith, 1829) (Chiroptera, Vespertilionidae) and neighbouring subspecies in Southern Africa.

The considerable differences typifying several subspecies of *Pipistrellus capensis*, and the overlapping distribution of these forms in South Africa, suggest that they have evolved for some time in isolation but are presently re-integrating and sporadically interbreeding as a result of recent ecological changes. Confusion has been superimposed on this unusual situation by the choice as lectotype for *P. c. capensis* of a specimen typical of the larger western subspecies, and subsequent designation of its type locality in a place marginal to that form.

Les tres importantes différences qui existent entre plusieurs sous-espèces de *Pipistrellus capensis*, et Ie fait que leur répartition se superpose en Afrique du Sud, permet de penser qu'elles ont évolué de facon isolée pendant un certain temps et qu'ensuite leurs populations se sont étendues et se sont par place métissées a la suite de récentes modifications écologiques. Une certaine confusion a été introduite dans la systématique du fait qu'on a choisi comme lectotype de *P. c. capensis* un specimen d'une plus grande sous-espèce occidentale, dans une localite type qui est marginale dans la répartition de cette forme.

Thorn, E. (1988b). The status of *Pipistrellus capensis notius* (=*Scabrifer notius* G.M. Allen, 1908) as prior synonym for *Eptesicus melckorum* Roberts, 1919).

From the study of type specimens and other material it is now concluded that *Eptesicus melckorum* Roberts is a junior synonym of *Pipistrellus capensis notius* (G. Allen), the largest and most southern subspecies of this common Vespertilionid bat.

La description par G. Allen (1908) de *Scabrifer notius* a tenu compte de "verrues" sur les avant-bras; à cause de cela l'holotype (qui est resté unique) avait été longtemps apparenté à d'autres espèces garnies de boutons sur les ailes et originaires du Soudan et d'ailleurs. En 1975, Koopman a suggéré que *notius* n'est pas autre chose qu'un representant de *P. capensis* parasité par des nematodes. L'examen par l'auteur de l'holotype de *notius* et de celui de *melckorum*, et des échantillons attribués à ce dernier, montre ici que *melckorum* de la région du Cap doit être considéré cornme synonyme de *Pipistrellus capensis notius*. Des spécimens additionnels indiquent la répartition normale de *P. c. notius*, et parmi quelques individus vagabonds l'un a pénétré à mille kilomètres au nord. II y a d'autres exemples de *P. capensis* avec des vésicules sur les ailes. D'après certains témoignages, on peut aussi reconnaître comme une espèce distincte *P. "melckorum"* (*sensu* Ansell 1960, 1967) de Zambie, Tanzanie, Mocambique, et récemment découvert au nord-est du Transvaal.

Tomes, R. F. (1861b). 1. Notes on a collection of bats made by Mr. Andersson in the Damara country, South-western Africa, with notices of some other African species.

Through the kindness of J. H. Gurney, Esq., M.P., I have been enabled to examine a very interesting, though not very extensive, collection of Bats, made by Mr. Andersson in South-western Africa during the year 1859. It contains three new species; and I propose, when describing them, to add notices of some others previously collected by Mr. Andersson at Lake Ngama, and of one or two species which, although already well known, may, from their affinity with some of those in the present collection, be advantageously introduced here. To prevent any confusion regarding the species forming the collection recently received from Mr. Andersson, they may be mentioned here, as follows: - *Kerivoula argentata*, n. s., *Nycticejus planirostris*, Peters, *Scotophilus minutus*, Temm., *S. rusticus*, n. s., and *S. variegates*, n. s.

The remaining species mentioned in this paper are - *Scotophilus capensis*, from the Cape of Good Hope, collected by M. Verreaux, *Miniopteris schreibersii* and *Molossus limbatus*, both collected by Mr. Andersson at Lake Ngama, and *Scotophilus kuhlii*, collected in Algeria by the Rev. H. B. Tristram.

Toschi, A. (1954). Elenco preliminare dei mammiferi della Libia.

A tassonomic checklist of species and subspecies of the Mammals known for the Lybian territory and its southern boundaries is given.

Besides some mammals recently collected by Mr. KENNETH GUICHARD in the last country have bepu identified and mentioned.

The checklist is completed by some kies and outlines for the identification of genera aud species and comments on the validity and systematic position of some forms.

Toschi, A. (1956). Missione del prof. G. Scortecci in Somalia nel 1955. Mammiferi.

Ringrazio il Chiar.mo Prof. Scortecci per avermi offerta la opportunità di studiare la piccola collezione di Mammiferi da Lui raccolti in Somalia ed il Sig. R. W. Hayman del British Museum (Natural History) di Londra per l'assistenza prestatami nelle determinazioni.

La raccolta comprende n. 29 esemplari appartenenti a 15 forme diverse e non manca di interesse sistematico e faunistico, poiché comprende esemplari scarsamente raccolti e studiati di un paese in cui questo gruppo di animali non può certo ritenersi ben noto.

Trewhella, W. J., P. F. Reason, K. M. Clark and S. R. T. Garrett (1998). The current status of Livingstone's flying fox (*Pteropus livingstonil*) in the Federal Islamic Republic (RFI) of the Cornores.

Pteropus livingstonii is an Old World fruit bat (Megachiroptera Pteropodidae) from the RFI Comores. Recent surveys show a population estimate of around 400 individuals, with natural forest being its preferred habitat. *P. livingstonii* is currently categorized as Critically Endangered (A1c+2cd, B1+2c, C2a) in the IUCN Red List categories for animals. In light of the survey results and the known distribution of this species, it appears that this categorization may be over-cautious. Although more data are desirable, we conclude that Endangered (A1c+2cd, B1+2c, C2a) is presently a more appropriate category for this species.

Trujillo, D. (1992). Murcielagos de las Islas Canarias.

Desde TOMES (1859) hasta HUTTERER (1979), la información conocida sobre murciélagos de las Islas Canarias, como muy bien señalan IBÁÑEZ y FERNANDEZ (1985b), era más bien escasa, reduciéndose a citas aisladas y a otras que formaban parte de publicaciones faunísticas más amplias.

En 1985, IBÁÑEZ y FERNANDEZ recopilan y amplían los datos existentes sobre quirópteros de la Comunidad Canaria y publican también ese año un trabajo sobre el estatus taxonómico de *Plecotus teneriffae*. Posteriormente, en 1988, TRUJILLO, BARONE y GONZALEZ citan *Nyctalus leisleri* para las islas, elevando a siete el número de especies conocidas para esta región.

Desde junio/julio de 1980, que fue el primer contacto que tuvimos con este orden de mamíferos, hasta el 10 de mayo de 1988, junto con RUBEN BARONE TOSCO, habíamos realizado los trabajos de campo sin ningún tipo de financiación oficial. Además, del 9 al 26 de septiembre del 87, la recogida de datos se llevó a cabo junto con el Dr. CARLOS IBÁÑEZ ULARGUI.

A partir del 10 de mayo del 88, hasta el 31 de diciembre de ese mismo año, el ICONA financió un estudio sobre los murciélagos de las Islas Canarias, com especial dedicación al conocimiento de esta fauna en sus Parques Nacionales al autor de este trabajo.

Los objetivos que se fijaron fueron:
- Conocer las especies de quirópteros que habitaban en los Parques Nacionales de las Islas Canarias.
- Ampliar los conocimientos sobre biología, ecología, distribución y estatus de las especies.
- Establecer las medidas necesarias para proteger y conservar estas especies.

Considero que, dado el escaso presupuesto con el que se contaba, el insuficiente material y el corto período de estudio, los resultados han sido positivos y los objetivos han sido alcanzados e incluso ampliados, ya que la información que se ofrece en este trabajo no se limita tan sólo a los cuatro Parques Nacionales de las Islas Canarias, sino que recoge todo nuestro trabajo llevado a cabo desde 1980.

Señalar algunas consideraciones generales que permiten entender mejor las características biológicas de los murciélagos de Canarias. El hecho de que las Canarias Occidentales tengan mayor número de espécies de quirópteros que las Orientales (al menos que Lanzarote y Fuerteventura) se debe a la mayor altitud de las primeras y, consiguientemente, a que poseen una gran diversidad de hábitats, como ya señalaron IBÁÑEZ y FERNANDEZ (1985b).

Los insecticidas utilizados en la década de los años 50 para combatir las plagas de langosta africana *Schistocerca gregária*, debieron de diezmar de manera muy notable las poblaciones de murciélagos de las Islas Canarias, sobre todo em las islas de Gran Canaria y Tenerife, a tenor de los numeroros comentarios de los lugareños de ambas islas, y a nuestra propia experiencia. Como ejemplo decir que en un viaje realizado a la isla de Gran Canaria en julio de 1987, visitamos 11 cuadrículas, de las cuales, sólo en una detectamos la presencia de quirópteros, concretamente 2 *Pipistrellus* sp.

Es interesante señalar que en Canarias se observan quirópteros durante todos los meses del año, al menos en las zonas bajas y medias de las islas; evidentemente este hecho se produce debido a la benignidad del clima del Archipiélago Canario.

Por otro lado, parece un tanto curioso, teniendo en cuenta la peculiaridad anteriormente señalada del clima de estas islas, que la fenología de la reproducción tenga lugar, en principio, y basándonos en los escasos datos de que disponemos, en los mismos meses que en la Península Ibérica. No obstante, este hecho hay que tomarlo con ciertas reservas, no descartando la posibilidad de que en islãs como Fuerteventura, de poca altitud y muy árida, pudiera ocurrir más tempranamente.

Comentario aparte merece la isla de Lanzarote. En las dos visitas realizadas a esa isla y al Parque Nacional de Timanfaya, no observé ni un sólo ejemplar de murciélago viviente. Además de las cuevas prospectadas (ver Anexo II), se registraron tres galerías de agua en el Risco de Famara, colocando redes japonesas en ellas, sin obtener resultado alguno.

También coloqué redes japonesas en el Jameo de los Almecenes (donde se han hallado restos óseos de *Pipistrellus kuhli*), y nylon s en el estanque del Barranco de Chafarís. Realicé varias visitas a la Presa de Mala y al Barranco de Tenegüime ... , en definitiva, recorrí la mayor parte de los lugares que

pudieran resultar adecuados para los murciélagos, y la búsqueda resultó infructuosa. Probablemente, la razón principal estriba en la escasez de vegetación, lo que trae consigo una densidad baja de lepidópteros nocturnos. En todos los trayectos realizados por la isla, durante la noche, no se veían apenas insectos. Por las mismas fechas en la isla de Fuerteventura, se podía observar gran densidad de lepidópteros nocturnos, y también de quirópteros.

Trujillo, D. and R. Barone (1991). La fauna de quiropteros del archipelago Canario.

La fauna de quirópteros Del Archipiélago Canário está compuesta por um total de siete espécies: *Pipistrellus kuhlii, P. maderensis, H. savii, Nyctalus leisleri, Barbastella barbastellus, Plecotus teneriffae* y *Tadarida teniotis*.

En esta artículo se amplían y actualizan los conocimientos sobre cada uma de las espécies (corologia, ecologia, biologia, estatus y conservacíon).

El Orejudo Canario (*P. teneriffae*) ES uma espécie endêmica del Archipiélago Canário, mientras que el Murciélago de Madeira (*P. maderensis*) es um endemismo macaronésico (Canarias y Madeira). También es muy probable que el murciélago de Bosque (*B. barbastellus*) represente un táxon exclusivo a nível subespecífico en nuestra Comunidad Autônoma.

In Canary Islands bat fauna is composed by seven species: *Pipistrellus kuhlii, Pipistrellus maderensis, Hypsugo savii, Nyctalus leisleri, Barbastella barbastellus, Plecotus teneriffae* y *Tadarida teniotis*.

In this paper knowledges on corology, ecology, biology and conservation of all Canary species are updated.

Plecotus teneriffae is an endemic species of this islands, being *Pipistrellus maderensis* as macaronesic endemism (Madeira and Canary Islands). *Barbastella barbastellus* could also likely represent an endemic subspecies of our Islands.

Tsita, J. N. (1993). Reproductive biology of the Egyptian free-tailed bat, *Tadarida aegyptiaca*.

The reproductive biology of *Tadarida aegyptiaca* was studied using specimens collected in the Cape Province of South Africa. The morphology of the reproductive tract of the species was generally similar to that of other molossids, however, the absence of Cowpers glands was unusual. Spermatogenesis began in February and spermatozoa were released to the cauda epididymis during August and September. Follicular development started in March and culminated with the appearance of Graafian follicles in July. Ovulation probably occurred in August and specimens were pregnant by September. Gestation length was estimated to be four to five months and a single young was born in December. The data suggest that *T. aegyptiaca* is monotocous and monoestrous.

Tuttle, M. D. and D. Stevenson (1982). Growth and survival of bats.

The literature on bat growth and survival is extensive. Nevertheless, few studies have made or permit within or among species comparisons of performance under varied combinations of biological and physiological parameters. In particular, surprisingly few studies have taken advantage of the fact that many species occupy wide ranges of environmental conditions. Growth and survival frequently have been treated as species-specific constants. Such treatment neglects many important determinants of success and likely has inhibited meaningful hypothesis testing and further investigation. Despite these limitations, existing studies demonstrate impressive variation. In fact, available literature indicates that few if any details of growth and survival are constant over time, even for individual colonies within a single species.

Detailed descriptions of growth and developmental stages in bats are already available (Orr, 1970). Krátky (1970), Fenton (1970b), Kunz (1973), and Pagels and Jones (1974) provide additional observations on the development of dentition and pelage, and Buchler (1980), and Brown and Grinnell (1980) review and report on the ontogeny of echolocation. Further specifics of growth and development and maternal care in phyllostomid bats are provided by Kleiman and Davis (1979). A number of survival studies are available and will be cited along with a discussion of their methods of analysis. Where possible, we will not restate previously available details of chiropteran growth and survival, but we will emphasize within and among species comparisons of adaptive responses to different environments. Our discussion will focus on variation and its probable causes, in an attempt to stimulate future investigations of a comparative nature.

Uchikawa, K. (1985a). Mites of the genus *Calcarmyobia* (Acarina, Myobiidae) with information on the taxonomy of their host bats of the genus *Miniopterus* (Chiroptera, Miniopteridae).

The tendency to regard the genus *Calcarmyobia* Radford as monotypic was prevalent until the beginning of the 1970s. The eight known species of the genus have been described on strict definition of each species (Uchikawa, 1982), and it is gradually proved that the mites of the genus *Calcarmyobia* are specific parasites of bats of the genus *Miniopterus*. Referring to the present knowledge of the mites, such formerly proposed specific names *Calcarmyobia miniopteris* and *C. parenzani* for species from South Africa and Europe, respectively, as well as some host records, should be revised (Uchikawa, 1984).

Mites of the genus *Calcarmyobia* have been evaluated as good indicators in the taxonomy and phylogeny of their host bats (Uchikawa & Harada, 1981). As the taxonomy of *Miniopterus* is not in a satisfactory state, an accumulation of records of the mites is believed to give a clue for solving some complicated problems in this area.

The present author had an opportunity to examine for ectoparasites the bat specimens deposited in the collections of the big museums in Europe and the United States. The present paper presents the records of the five species of the genus *Calcarmyobia* taken during the trip to add to the knowledge of the mites themselves and their host taxonomy.

Uchikawa, K. (1985b). *Calcarmyobia* from the Ethiopian region (Acarina, Myobiidae).

The author has sought to locate as many species and specimens of bats of the genus *Miniopterus* from the Ethiopian region as possible in the collections of the big museums in the United States and Europe for mites of the genus *Calcarmyobia*. All the four known species of the mites from the region were again recorded in the present study (Uchikawa, 1985*b*), and the five new species or subspecies were also found as described below.

All the specimens dealt with in the present paper will be deposited in the collections of the American Museum of Natural History, New York (AMNH), the British Museum (Natural History), London (BMNH), the Museum National d'Histoire Naturelle, Paris (MNHN), Forschungs-Institut Senkenberg, Frankfurt (SMF) or the US National Museum (USNM), where they were collected.

The scales for Figures are the same to those in Figs 1-6.

As the present paper is the fourth and last report on the mites of the family Myobiidae taken from the bats of the genus *Miniopterus* in the big museums, a summary of the mites themselves and, adopting them as indicators, problems in host systematics will be made in discussion.

Uchikawa, K. (1985c). Mites of the genus *Pteracarus* (Acarina, Myobiidae) taken from the bats of the genus *Miniopterus* (Chiroptera, Miniopteridae).

Despite the examination of a large number of specimens of various bats of the genus *Miniopterus*, any mite of the genus *Pteracarus* other than the so far known species, *P. faini* Uchikawa and *P. miniopteri* Uchikawa, was not found from them. This strongly suggests that only the two species represent the *Pteracarus* fauna of *Miniopterus*. It is proved that *P. miniopteri* is prevailing in almost whole range of *Miniopterus*, while *P. faini* is distributed in the Oriental, Australasian and estern Palearctic regions. Based on the host records of the mites, it is suggested that the specific name *schreibersi* has been adopted indiscriminately for so many forms of the bats of the genus *Miniopterus*.

Uchikawa, K. (1991). *Glauconyssus*: a new genus associated with African bats (Acari: Macronyssidae).

Glauconyssus, n. g., is elected for *Glauconyssus tarizaniensis*, n. sp., a parasitic mite of *Glauconycteris poensis* from Mt. Kilimanjaro, Tanzania.

Uchikawa, W. and D. Kock (1989). Revision of the Genera *Hipposiderobia, Triaenomyobia*, and *Binunculoides* (Acarina: Myobiidae) associated mainly with the chiropteran family Hipposideridae (Mammalia).

The 3 myobiid genera, *Hipposiderobia, Triaenomyobia*, and *Binunculoides* are redefined on the basis of recently acquired knowledge on chiropteran Myobiidae. The genus *Hipposiderobia* is divided into the nominate subgenus and new subgenus *Orientobia* represented by 6 and 9 species, respectively. Two new species and a new synonymy within the genus *Hipposiderobia* are presented. The genera *Triaenomyobia* and *Binunculoides* are still monotypic. Measurements and key characters for all species of those genera are tabulated.

Valdivieso, D., R. L. Peterson and J. R. Tamsitt (1979). Morphology of the basisphenoid pits and related structures of the bat *Otomops martiensseni* (Chiroptera: Molossidae).

The morphology and histology of the basisphenoid pits were studied in the bat *Otomops martiensseni* (Chiroptera: Molossidae). The pits are deep and well-defined bony cavities located posteriorly in the nasal pharynx. They are juxtaposed to the opening between the nasal and laryngeal pharynges and anatomically communicate with the middle ear through the auditory tube. Basisphenoid pits may function as resonating chambers for sound waves emitted by the larynx, but experimental research is needed to determine their importance in the sonar system.

Van Cakenberghe, V. (1990). Notes on the systematics of the Rhinopomatidae Dobson, 1878. Abstract.

The Afro-Asiatic family of the Rhinopomatidae of Mouse- or Rat-tailed bats only contains one genus: *Rhinopoma* Geoffroy, 1813, which can be divided into four species: *R. microphyllum* (Brunnich, 1782), *R. hardwickei* Gray, 1831, *R. muscatellum* Thomas, 1903 and *R. macinnesi* Hayman, 1937. This conclusion is based on the study of 15 skull and 14 external measurements and 5 morphological characters of approximately 1150 specimens.

The metrical data were examined using uni- and multivariate statistical techniques. The multivariate analyses substantiate that *R. macinnesi*, which up until now was considered to be a subspecies of *R. hardwickei*, is much smaller than any other representative of *R. hardwickei* and should be retained as a separate species.

The univariate analyses of external measurements show that *R. muscatellum* and *R. macinnesi* can only be separated with great difficulty. This might be an explanation for the literature citations of *R. muscatellum* in Africa. Based on the size of the narial inflations and the dimensions, all these African

specimens are considered to belong to *R. macinnesi*. The specimens from Genji represent the first material of *R. muscatellum* from India. *R. muscatellum* is divided into two subspecies: *R. m. muscatellum* and *R. m. seianum*.

Three of the currently recognized subspecies of *R. hardwickei* are retained: *R. h. hardwickei, R. h. cystops* and *R. h. arabium*. *R. hardwickei* has also been examined from the Sundae archipelago. The large geographical separation between these specimens arid their nearest neighbours, *R. h. hardwickei*, in India might lead to the recognition of another subspecies.

Four subspecies are recognized in *R. microphyllum: R. m. microphyllum, R. m. sumatrae, R. m. kinneari* and *R. m. asirensis*. Almost no metrical differences were found between the specimens from Indian and these from Sumatra. However, based on the large geographical separation, the animals from both regions are considered to belong to different subspecies: *R. m. sumatrae* in Indonesia and *R. m. kinneari* in India. Finally, the holotype of *R. m. asirensis* seems to be quite different and is retained as a separate subspecies for the Arabian peninsula.

Van Cakenberghe, V. and F. De Vree (1985). Systematics of African *Nycteris* (Mammalia: Chiroptera).

Based on a number of morphological characters, including the shape of the tragus and the upper incisors and the height of the second lower premolar, four species groups couldbe identified in African *Nycteris*. Of these, only the *N. arge* and the *N. macrotis* groups are discussed in this paper.

Using multivariate statistical techniques on 1343 specimens, we were able to retain four species in the *N. arge* group and only two in the *N. macrotis* group. The distribution and the dimensions of all six species are discussed, along with some remarks on the status of certain forms. Lists of literature citations and material examined are given as well.

Van Cakenberghe, V. and F. De Vree (1993a). The systematic status of Southeast Asian *Nycteris* (Chiroptera: Nycteridae).

Based on multi- and univariate statistical analyses on 233 Southeast Asian *Nycteris* specimens, two species are recognized: *Nycteris javanica* and *Nycteris tragata*. The represent the single, separate *Nycteris javanica* group, which is distinct from the four African species groups: the *hispida, thebaica, macrotis* and *arge* groups.

Par les analyses statistiques multi- en univariées sur 233 spécimens provenant du sud-est de l'Asie, deux espèces de *Nycteris* sont reconnues: *Nycteris javanica* et *Nycteris tragata*. Ces deux espèces représentent un seul groupe: le groupe *Nycteris javanica*, qui se distingue des quatre groupes d'espèces africaines: les groupes *hispida, thebaica, macrotis* et *arge*.

Van Cakenberghe, V. and F. De Vree (1993b). Systematics of African *Nycteris* (Mammalia: Chiroptera) Part II. The *Nycteris hispida* group.

In this paper the systematics of the African *Nycteris hispida* species group is discussed. Using multivariate statistical techniques, three species can be distinguished in this grou: one extremely large *Nycteris grandis* Peters, 1865, and two smaller species: *Nycteris hispida* (Schreber, 1771) and *Nycteris aurita* (K. Andersen, 1912). It is shown why both latter species are generally lumped together, since they are very alike when externa measurements are compared univariably. None of the three species shows sufficient geographical differences to permit subspecific division. Besides biometrical data, the distribution of the three species is discussed and a review of all publications concerning the various forms is presented. Additionally the sexual dimorphism is the different species was examined,

indicating that one must be very careful in attributing sexual dimorphism if the specimens originate from a large geographic area.

Van Cakenberghe, V. and F. De Vree (1994). A revision of the Rhinopomatidae Dobson 1872, with the description of a new subspecies (Mammalia: Chiroptera).

The bat family Rhinopomatidae DOBSON 1872 only contains a single genus: *Rhinopoma* GEOFFROY 1813, which can be subdivided into four species: *R. microphyllum* (BRÜNNICH 1782), *R. hardwickei* GRAY 1831, *R. muscatellum* THOMAS 1903 and *R. macinnesi* HAYMAN 1937. This conclusion is based on a biometrical study of 15 skull and 14 external measurements on approximately 1150 specimens. In addition six morphological characters were evaluated. In *R. microphyllum* four subspecies are retained, whereas only two subspecies are recognised in *R. muscatellum* and non for *R. macinnesi*. In addition to the three already known subspecies of *R. hardwickei*, a new one from the Sunda archipelago is described.

Van Den Bussche, R. A., R. J. Baker, J. P. Huelsenbeck and D. M. Hillis (1998). Base compositional bias and phylogenetic analyses: a test of the "Flying DNA" hypothesis.

Phylogenetic methods can produce biased estimates of phylogeny when base composition varies along different lineages. Pettigrew (1994, Curr. Biol. 4: 277 - 280) has suggested that base composition bias is responsible for the apparent support for the monophyly of bats (Chiroptera: megabats and microbats) from several different nuclear and mitochondrial genes. Pettigrew's "flying DNA" hypothesis makes several predictions: (1) that metabolic constraints associated with flying result in elevated levels of adenine and thymine throughout the genome of both megabats and microbats, (2) that the resulting base compositional bias in bats is sufficient to mislead phylogenetic methods and account for the support for bat monophyly from several nuclear and mitochondrial genes, and (3) that phylogenetic analysis using pairwise distances corrected for compositional bias should eliminate the support for bat monophyly. We tested these predictions by analyzing DNA sequences from two nuclear and three mitochondrial genes. The predicted base compositional bias does not appear to exist in some of the genes, and in other genes the differences in AT content are very small. Analyses under a wide diversity of criteria and models of evolution, including analyses that take base composition into account (using log-determinant distances), all strongly support bat monophyly. Moreover, simulation analyses indicate that even extreme bias toward AT-base composition in bats would be insufficient to explain the observed levels of support for bat monophyly. These analyses provide no support for the "flying DNA" hypothesis, whereas the monophyly of bats appears to be well supported by the DNA sequence data.

---

van der Merwe, M. (1973a). Aspects of temperature and humidity in preferred hibernation sites of the Natal clinging bat *Miniopterus schreibersi natalensis* (A. Smith, 1834).

In the Transvaal, *Miniopterus schreibersi natalensis* forms hibernating colonies during May-July on the highveld where the ambient and cave temperatures are lower than in the lowveld. In two highveld caves, mating and hibernating colonies were resident from January to the end of July, but only one cave was occupied for hibernating during the winter. In the cave selected for hibernation humidity was lower, and fluctuated more, than in the other cave. Temperature also fluctuated more, but tended to average lower, than in the unused cave. It appears that low temperature rather than high humidity determined the choice of a hibernating cave.

---

van der Merwe, M. (1973b). Aspects of social behaviour of the natal clinging bat *Miniopterus schreibersi natalensis* (A. Smith, 1834).

Les chauves-souris appartenant à l'espèce *Miniopterus schreibersi* sont de véritables troglodytes; elles se groupent en un ou plusieurs essaims très denses au plafond ou sur les parois. Ces essaims sont

de tailles très variables allant de quelques individus à plusieurs milliers (jusqu'à 100000). A Uitkmost, Transvaal, les males arrivent dans les grottes d'hibernation au mois de Janvier, les femelles en avril. II est probable que l'accouplement ait lieu dans les grottes d'hibernation, juste avant celle-ci, au mois d'avril. Il a été trouvé des colonies de pré-mise-bas dans une grotte du Bushveld, au Transvaal, ou des milliers tant de males que de femelles (ces dernières étant généralement gravides) s'étaient groupés avant le départ des femelles vers les lieux de mise-bas. Des colonies de mise-bas ont été trouvées dans deux grottes situées également au Bushveld, où des milliers de femelles s'étaient assemblées afin de mettre bas. Les premiers jeunes sont nés vers la fin du printemps: fin octobre et début novembre.

The Natal clinging bat, *Miniopterus schreibersi natalensis*, is one of the most widespread and abundant Microchiropteran forms in Southern Africa, distributed throughout most of the Republic of South Africa, Mocambique, Rhodesia, Botswana, South West Africa, Zambia, Malawi and southern Zaire. Between May 1967 and December 1968 social organization was studied at several roosts, most intensively in two adjoining caves, in the Jack Scott Private Nature Reserve on the southern Transvaal high veld. Bats were closely observed and periodically collected at roosts by hand-picking or netting. Bats were also frequently banded and recaptures recorded. *M. s. natalensis* are typically cave dwellers, where they usually form tightly packed clusters against the roof or walls. These clusters varied greatly in size, from a few individuals to a few thousand per cluster as sometimes found at the maternity colonies, where numbers of up to 100 000 adults were estimated. Some clusters occurring at Uitkomst can be considered as permanent colonies as they have used the same cave year after year for the same activities. The first males arrived at Uitkomst from their summer quarters during January while the females and young arrived only in April. The place and period of mating is still uncertain. However, it appeared to take place at the wintering caves, such as Uitkomst, prior to hibernation, from the beginning until the end of April. Pre-maternity colonies were formed in one cave, Rookpoort Guano Cave, Rooiberg, where thousands of females and males congregated before the females dispersed to the various maternity caves to give birth. During the spring and summer (October-February) thousands of females congregated at the maternity caves, Sandspruit Cave No. 1, Rooiberg, and Peppercorn's Cave, Makapansgat. The first juveniles were born at the end of October and the beginning of November.

---

van der Merwe, M. (1979a). Foetal growth curves and seasonal breeding in the Natal clinging bat *Miniopterus schreibersi natalensis*.

Growth of the foetus of *Miniopterus schreibersi natalensis* is described. The gestation period in this subspecies is 240 days of which 120 days is the period of delayed implantation. Birth mass is taken as 2.7 g from measurements of near-term foetuses. Foetal growth follows a typical *J*-shaped curve during the last half of the gestation period. Young of *M. s. natalensis* are proportionately lighter at birth than many other mammals.

Fetale groei in *Miniopterus schreibersi natalensis* word beskryf. Ole dragtigheidsperiode in hierdie subspesies is 240 dae, waarvan 120 dae 'n periode van vertraagde implantering is. Geboortemassa is 2.7 g en is bereken uit gegewens verkry van fetusse net voor geboorte. Fetale groei volg 'n tipies *J*-vormige kurwe gedurende die laaste helfte van die dragtigheidsperiode. Die kleintjies van *M. s. natalensis* is proporsioneel ligter by geboorte as baie ander soogdiere.

---

van der Merwe, M. (1979b). Growth of ovarian follicles in the Natal clinging bat.

Growth and atresia of the ovarian follicles of *Miniopterus schreibersi natalensis* (A. Smith, 1834) were studied from females collected on the southern Transvaal Highveld. In this hibernating subspecies no storage of sperm or delayed ovulation occur and females enter hibernation in a pregnant condition. Only one Graafian follicle develops, which is characterized by a large antrum with the ovum-bearing mass of cells occupying only a relatively small portion of the antrum. Many follicles develop to a medium size before undergoing regression. Basically two types of regression occur; usually destruction of the stratum granulosum takes place before the oocyte is affected. The reverse condition

was also observed but was very uncommon. Corpora lutea atretica resulting from the luteinization of medium-sized Graafian follicles were commonly found.

Die groei en atresie van die ovariumfollikels van *Miniopterus schreibersi natalensis* (A. Smith, 1834) is bestudeer by wyfies wat versamel is op die Suid-Transvaalse Hoëveld. In hierdie hibernerende subspesie vind geen storing van sperms of vertraagde ovulering plaas nie, en wyfies is alreeds dragtig met die aanvang van hibernasie. Slegs een Graaffollikel ontwikkel en dit word gekenmerk deur 'n groot antrum en relatief klein eierdraende selmassa wat slegs 'n relatief klein gedeelte van die antrum in beslag neem. Baie follikels ontwikkel tot 'n mediumgrootte voordat hulle regressie ondergaan. Twee tipes regressie is waargeneem: Gewoonlik vind vernietiging van die stratum granulosum eers plaas voordat die oösiet beïnvloed word. Die omgekeerde proses is ook waargeneem, maar dit kom baie selde voor. Korpora lutea atretika wat ontstaan as gevolg van die luteïnisering van mediumgrootte Graaffollikels het algemeen voorgekom.

---

van der Merwe, M. (1981). Fetal development of the bat *Miniopterus schreibersi natalensis*.

Prenatal development in the fetus of *Miniopterus schreibersi natalensis* is discussed. Due to the long period of delayed implantation in this subspecies, the age of even the smallest fetuses, where the fore-limb buds just become visible will be around 150 days. The most reliable criterion for age determination proved to be body mass, and all fetal ages were estimated by using the equation $t = W^{1/3}/0.0145 + 144$.

Voorgeboortelike ontwikkeling van die fetus van *Miniopterus schreibersi natalensis* word bespreek. As gevolg van die lang periode van vertraagde implantering in hierdie subspesie is die ouderdom van selfs die kleinste fetusse, waar die voorste ledemaatknoppies net sigbaar word, alreeds ongeveer 150 dae. Die betroubaarste maatstaf vir ouderdom is liggaamsmassa, en die ouderdomme van al die fetusse is bereken met die formule $t = W^{1/3}/0.0145 + 144$.

---

van der Merwe, M. (1982b). Histological study of implantation in the Natal clinging bat (*Miniopterus schreibersii natalensis*).

In the Natal clinging bat, *Miniopterus schreibersii natalensis*, implantation is centric and superficial in the right uterine horn. The blastocyst implants during the bilaminar stage with the inner cell mass orientated antimesometrially. During the preimplantation period the blastocyst becomes completely enclosed by uterine mucosae with the trophoblast in close contact with the surrounding uterine epithelium. Just before implantation the trophoblast becomes bilaminar over the greater part of the embryonic hemisphere of the blastocyst. The uterine epithelium is very persistent and parts were still present mesometrially although penetration of the uterine endometrium had already occurred on the antimesometrial side.

---

van der Merwe, M. (1985a). Deciduous teeth and their replacement in *Miniopterus schreibersii natalensis*.

The sequence of replacement of the deciduous teeth by permanent teeth in *Miniopterus schreibersii natalensis* is described. A table showing the changes in tooth characteristics from birth until seven weeks of age is given.

Die volgorde van melktandvervanging deur permanente tande in *Miniopterus schreibersii natalensis* word beskryf. 'n Tabel wat die veranderinge in tandkenmerke vanaf geboorte tot en met die sewende week na geboorte beskryf, word gegee.

---

van der Merwe, M. (1985b). The vestigial teeth of *Miniopterus fraterculus* and *Miniopterus inflatus*.

Both *Miniopterus fraterculus* and *Miniopterus inflatus* have a vestigial tooth on the maxilla situated between the canine and following premolar.

Beide *Miniopterus fraterculus* en *Miniopterus inflatus* het 'n vestigiale tand op die maksilla wat geleë is tussen die slagtand en daaropvolgende voorkiestand.

---

van der Merwe, M. (1987b). Other bat species in maternity caves occupied by *Miniopterus schreibersii natalensis*.

During visits to known maternity caves of *Miniopterus schreibersii natalensis* in the Transvaal (where vast numbers of females arrive seasonally to give birth and suckle their young), it has become apparent that these caves are not frequently used by other species during those periods when large numbers of *M. s, natalensis* females are present.

Gedurende besoeke aan bekende broeigrotte van *Miniopterus schreibersii natalensis* in Transvaal (wat seisoenaal deur groot getalle wyfies beset word om geboorte te gee en hul kleintjies te soog) het dit duidelik geword dat hierdie grotte nie gereeld deur ander vlermuisspesles benut word ten tye van *M. s. natalensis* wyfies se teenwoordigheid nie.

van der Merwe, M. (1989a). Reproduction in the Rusty Bat, *Pipistrellus rusticus* in the Northern Transvaal Bushveld, South Africa. Abstract. Eigth International Bat Research Conference, Sydney, Australia, 9 - 15 July 1989.

Rusty bats are seasonally monoestrous and give birth to twins between mid November and mid December. Spermatozoa are present in the epididymides from March to August but absent from the testes from April until September. Spermatozoa are therefore stored in the epididymides for five months of the year (April-August). Copulations are initiated during April with females having increasingly more spermatozoa in their uterine horns from then towards the end of July. Ovulations and fertilization occur between mid August and mid September.

---

van der Merwe, M. (1989b). Longevity in Schreibers' long-fingered bat.

Longevity in a hibernating and migratory vespertilionid, *Miniopterus schreibersii natalensis*, was studied with mark-recapture techniques. Data from this study suggest that 13 years may be the maximum life expectancy of this species in the wild.

Langslewendheid in 'n hibernerende en migrerende vespervlêrmuis, *Miniopterus schreibersii natalensis*, is bestudeer deur middel van merk-hervangmetodes. Gegewens uit hierdie studie toon dat 13 jaar die maksimum lewensverwagting van hierdie spesie in die natuur kan wees.

---

van der Merwe, M. (1990). Polytocy in the Cape serotine bat *Eptesicus capensis* (A. Smith 1829) from the southern African subregion.

Polytocy is described in the Cape serotine bat, *Eptesicus capensis*, and discussed in relation to the occurrence of multiple births in other microchiropteran bat species in the southern African subregion.

Although twins appear to be characteristic of the Cape serotine bat, triplets and even the occasional quadruplets occur.

Politokie in die Kaapse dakvlermuis, *Eptesicus capensis*, word beskryf en bespreek met verwysing na die voorkoms van veelvoudige geboortes in ander mikrochiroptera vlermuisspesies in die Suider-Afrikaanse substreek. Alhoewel dit wil voorkom asof tweelinge kenmerkend is by die Kaapse dakvlermuis, blyk dit dat drielinge en selfs die periodieke vierling voorkom.

---

van der Merwe, M. (1994). Reproductive biology of the Cape serotine bat, *Eptesicus capensis* in the Transvaal, South Africa.

The reproductive biology of the Cape serotine bat, *Eptesicus capensis*, was investigated histologically. The study was based on 67 specimens collected over a six-year period. This species is seasonally monoestrous, normally giving birth to twins during November. Spermatogenesis peaks during autumn (March-May) when masses of spermatozoa are released into the epididymides, and spermatozoa are present in the epididymides from March to October. Copulations are initiated during this period from the end of March to the beginning of April, with the first ovulations occurring during August. During the pre-ovulation period leucocytes are commonly found within the uterine lumen and uterine glands of females.

Die voortplantingsbiologie van die Kaapse dakvlermuis, *Eptesicus capensis*, is histologies ondersoek. Die studie is gebaseer op 67 monsters wat oar 'n periode van ses jaar versamel is. Hierdie spesie is seisoenaal monestrus, en skenk gewoonlik geboorte aan tweelinge gedurende November. Spermatogenese bereik 'n piek gedurende die herts (Maart-Mei) wanneer massas sperme in die epididimi gestort word, en sperme is teenwoordig in die epididimi vanaf Maart tot Oktober. Kopulasie neem 'n aanvang gedurende die periode einde Maar! en begin April, terwyl die eerste ovulasies gedurende Augustus plaasvind. Gedurende die preovulasie periode is leukosiete algemeen in die uteruslumen en -kliere van wyfies gevind.

---

van der Merwe, M. (1996). Amniogenesis in Schreiber's long-fingered bat *Miniopterus schreibersii natalensis*.

Schreiber's long-fingered bat, *Miniopterus schreibersii natalensis* is seasonally monoestrous, carrying a single foetus in the right uterine horn. Implantation is superficial, the amnion being a pleuramnion. Lateral folds, originating from the ends of the caudal and cephalic folds, are the main contributors in the formation of the definitive amnion. The formation of the amnion by folding is preceded by the development of a primitive amniotic cavity within the inner cell mass which eventually disappears.

---

van der Merwe, M. (1997). Vestigial teeth in the genus *Scotoecus* (Mammalia: Chiroptera): adapted dental formulae for vespertilionids with vestigial teeth.

Some members of the genus *Scotoecus* Thomas, 1901 have an inconspicuous vestigial tooth which occurs on both sides of the upper jaw between the canine and following premolar. This tooth is regarded as permanent premolar pi in vestigial form.

---

van der Merwe, M. and I. L. Rautenbach (1986). Multiple births in Schlieffen's bat, *Nycticeius schlieffenii* (Peters, 1859) (Chiroptera: Vespertilionidae) from the southern African subregion.

Nycticeius schlieffenii is a monestrous species that breeds during the spring months in the northern parts of the Kruger National Park. During spring 1983 the average number of corpora lutea in 11

Nycticeius schlieffenii females was 3.1 (range 1 - 4), with the average number of fetuses recorded 2.8. In the present study this bat has been found to be a polyovular seasonal breeder, giving birth to as many as three young per estrous cycle.

Nycticeius schlieffenii is 'n monestrus spesie wat gedurende die lente in die noordelike gebied van die Nasionale Kruger Wildtuin teel. Gedurende die lente van 1983 was die gemiddelde aantal corpus luteums wat deur 11 *Nycticeius schlieffenii*-wyfies afgeskei is 3.1 (bestek 1 - 4), met die gemiddelde aantal fetusse waargeneem 2.8. In die huidige studie is bevind dat hierdie vlermuisspesie 'n poliovulêre seisoenale voortplanter is wat aan so veel as drie kleintjies per estrussiklus geboorte gegee het.

---

van der Merwe, M. and I. L. Rautenbach (1987). Reproduction in Schlieffen's bat, *Nycticeius schlieffenii*, in the eastern Transvaal lowveld, South Africa.

The present study is based on 153 Schlieffen's bats collected over a 2-year period from September 1983 to September 1985. Spermatogenesis extends over a 10-month period with the first signs of spermatozoa in the epididymides by the end of April. Spermatozoa were present in the epididymides from the end of April until the beginning of September. Copulation begins during June (early winter) and the females have spermatozoa in the uterine horns from then until the end of August (late winter) when ovulation occurs. These bats are seasonally monoestrous with the great majority of births occurring during November. The number of conceptuses varied; a maximum of 5 pre-implanted embryos was recorded, but the maximum number of fetuses observed was 3.

---

van der Merwe, M. and I. L. Rautenbach (1990). Reproduction in the rusty bat, *Pipistrellus rusticus*, in the northern Transvaal bushveld, South Africa.

Rusty bats are seasonally monoestrous and give birth to twins during November. Spermatozoa are present in the epididymides from March to August but absent from the testes from April until September. Males thus store spermatozoa in the epididymis for 5 months of the year (April-August). Mating is initiated during April with uterine horns exhibiting a 3-fold increase in sperm volume between April and July samples. It is concluded that ovulation and fertilization occur during the second half of August. Up to 5 conceptuses per female were recorded, but a maximum of only 2 implantations was observed.

---

van der Merwe, M., I. L. Rautenbach and W. J. van der Col (1986). Reproduction in females of the little free-tailed bat, *Tadarida (Chaerephon) pumila*, in the eastern Transvaal, South Africa.

Little free-tailed bats (2 - 9/month) were collected over 15 months in the eastern Transvaal lowveld (latitude 24°59'S). There was an extended but distinct breeding season of 8 months per year. Females appeared to be polyoestrous and able to bear 3 pregnancies per breeding season. There was a progressive decrease in the magnitude of the three birth peaks during the breeding season, with a concomitant slight loss in birth synchronization. Gestation period was ~ 60 days and one young per female was the rule, with implantation occurring only in the right uterine horn of the bicornuate uterus. It is suggested that offspring are weaned before the age of 21 days, and that females become sexually mature in the following breeding season at the age of 5 - 12 months.

---

van der Merwe, M. and R. J. van Aarde (1989a). Plasma progesterone concentrations in the female Natal Clinging Bat (*Miniopterus schreibersii natalensis*). Abstract. Eigth International Bat Research Conference, Sydney, Australia, 9 - 15 July 1989.

Plasma progesterone concentrations measured by radioimmunoassay in the Natal clinging bat remained below 2.01 ng/ml during lactational anoestrus but increased significantly during the period of delayed implantation. Values peaked at implantation but were followed by a significant decrease

thereafter. Concentrations remained low (< 7.0 ng/ml) during the initial period of foetal development (153 - 201days *post coitum*) and attained peak values (85.6 - 181.3 ng/ml) 216 - 222 days after fertilization. The sharp postlrnplantatlon increase in progesterone levels coincided with a significant increase in placental weight.

---

van der Merwe, M. and R. J. van Aarde (1989b). Plasma progesterone concentrations in the female Natal Clinging Bat (*Miniopterus schreibersii natalensis*).

Plasma progesterone concentrations measured by radioimmunoassay in the Natal clinging bat remained below 2.01 ng/ml during lactational anoestrus but increased significantly during the period of delayed implantation. Values peaked at implantation but were followed by a significant decrease thereafter. Concentrations remained low (< 6.0 ng/ml) during the initial period of fetal development (153 - 180 days *post coitum*) and attained peak values (85.6 - 181.3 ng/ml) 216 - 222 days after fertilization. The marked post-implantation increase in progesterone concentrations coincided with a significant increase in placental weight.

van der Merwe, N. J. and I. L. Rautenbach (1988). The placenta and foetal membranes of the lesser yellow house bat, *Scotophilus borbonicus* (E. Geoffroy, 1803) (Chiroptera: Vespertilionidae).

A discoidal hemodichorial placenta is present in *Scotophilus borbonicus*. Evidence is presented which suggests that histotrophic nutrition, in addition to hemotrophic nutrition, occurs. The foetal trophospongium phagocytoses cell debris and glandular secretions derived from the maternal endometrium (decidua basalis). This cell debris forms a detritus zone between the decidua basalis and trophospongium. The existing concept of the basal lamina (intrasyncytial membrane) of the hemodichorial placenta is described in a modified form.

'n Diskoidale hemodikoriale plasenta is teenwoordig in *Scotophilus borbonicus*. Bevindinge word voorgele wat aandui dat histotrofe voeding, bykomstig tot hemotrofe voeding, plaasvind. Die fetale trophospongium fagositeer seldebris en klierafskeidings afkomstig van die endometrium (decidua basalis). Die seldebris vorm 'n detritussone tussen die trophospongium en die decidua basalis. Die bestaande konsep van die basale lamina (intrasinsitiale membraan) van die hemodikoriale plasenta word in 'n gewysigde vorm beskryf.

---

van der Merwe, N. J. and I. L. Rautenbach (1989). The male reproductive pattern and histology of the testes of the lesser yellow house bat, *Scotophilus borbonicus* (E Geoffroy, 1803) (Chiroptera: Vespertilionidae).

Monthly samples of the testes of the vespertilionid bat, *Scotophilus borbonicus* were collected, sectioned and examined by light microscopy. Spermatogenesis was prolonged and extended over 8 months, coinciding with spring, summer and autumn. During any particular month only certain spermatogenic cells are present in the seminiferous tubules. The mediastinum is, unlike that of most other mammals, situated towards the caudal border of the testis. This species is eminently suited for the study of the process of spermatocytogenesis.

---

van der Merwe, N. J., I. L. Rautenbach and B. L. Penzhorn (1988). A new pattern of early embryonic development in the seasonally breeding non-hibernating lesser yellow house bat, *Scotophilus borbonicus* (E. Geoffroy, 1803) (Chiroptera: Vespertilionidae).

Monthly collections of *Scotophilus borbonicus* females and examination of serially sectioned female genital tracts showed that it is a monoestrous species. Insemination, ovulation and fertilization take

place in autumn. Early embryonic growth is retarded, but not arrested. The conceptus remains in the morula stage for 6 to 8 weeks, followed by a blastocyst stage of c. two months. With the onset of warmer weather, a higher rate of embryogenesis is observed.

Van der Westhuyzen, J., R. C. Cantrill, F. Fernandes-Costa and J. Metz (1983). Effect of a vitamin B-12-deficient diet on lipid and fatty acid composition of spinal cord myelin in the fruit bat.

The effects of vitamin B-12 deficiency on lipids and fatty acids of spinal cord myelin were studied in control and vitamin B-12-deficient fruit bats. Very low plasma and brain vitamin B-12 concentrations were present in animals fed the vitamin B-12-free, all fruit diet. Myelin was isolated from the spinal cord of control and vitamin B-12-deficient animals (n = 3 pools) by means of a flotation method in a discontinuous sucrose gradient. The molar concentration of cholineglycerophosphatide was significantly lower in the deficient bats than in the controls. The molar cholesterol:phospholipid ratio in the deficient bats was also significantly lower. The odd-chain fatty acid 15:1 was not detected in cholineglycerophosphatide from the controls, but comprised 1.4 % of the total fatty acids in the deficient group. The odd-chain fatty acids 15:0, 17:1 and 19:0 were present in slightly higher amounts in cholineglycerophosphatide of deficient bats. Lipid and fatty acid differences were related to the vitamin B-12-requiring methionine synthetase and methylmalonyl CoA mutase reactions.

Van Neer, W. (1990). Les faunes de vertébrés quaternaires en Afrique centrale.

Les ensembles fauniques de vertébrés quaternaires de l'Afrique Centrale sont actuellement au nombre d'une vingtaine et représentent, à une exception près, des restes archéozoologiques. Ce matériel paléontologique, dont le principal agent taphonomique* est l'homme, est jusqu'à présent très dispersé dans le temps et l'espace, mais il permet néanmoins une évaluation paléoécologique et paléoéconomique. Trois sites, Ntadi Yomba, Matupi et Ishango témoignent par leurs faunes de la période aride fin Pléistocène. Sur plusieurs sites datant des deux derniers millénaires (Ngovo, Dimba, Akameru, Cyinkomane, couches supérieures de Shum Laka) les vertébrés préservés démontrent un milieu plus boisé que l'actuel, ce qui indique qu'une déforestation probablement surtout anthropique s'est effectuée entre temps. En ce qui concerne l'introduction des animaux domestiques en Afrique centrale, il semble que celle-ci s'est effectuée dans le premier millénaire de notre ère. Le nombre restreint de sites avec préservation faunique de cette période empêche pourtant de dater ces événements plus précisément

---

Van Orshoven, J. and P. J. H. Van Bree (1968). Quelques données sur six espèces de Megachiroptères de la République de Guinée.

A collection of Megachiroptera captured in mistnets at Kankasili (10° 11' N,12° 29' W), Republic of Guinea, Africa, during 1966-1967, is described. The following species were represented: *Rousettus aegyptiacus* (10 specimens), *Lissonycteris angolensis* (2 specimens), *Epomophorus gambianus* (1 specimen), *Epomops buettikoferi* (13 specimens), *Micropteropus pusillus* (104 specimens) and *Nanonycteris veldkampi* (4 specimens). Measurements, as well as descriptions of the colours and of the palatal ridges of the bats are given.

Varty, N. and J. E. Hill (1988). Notes on a collection of bats from the riverine forests of the Jubba Valley, southern Somalia, including two species new to Somalia.

Fifty-eight bats of eight species were collected from the riverine forests of the Middle Jubba Valley, Somalia during August and September 1986. *Epomophorus wahlbergi* was the most commonly-caught species. Two species *Pipistrellus eisentrauti* and *Scotoecus albigula* had not been previously recorded for Somalia and two other species, *Nycteris parisii* and *Hipposideros commersoni*, are rare within Somalia. Seven of the eight species showed evidence of breeding during this period (dry season).

The forests are rapidly being destroyed and there is an urgent need to conserve the remainning stretches of riverine forest to protect the rare species.

Vattier, G. and J. P. Adam (1966). Capture de Cératopogonidae (Diptera) dans des grottes de la république gabonaise.

Au cours d'une brève mission au Gabon, en janvier 1966, l'un de nous (J.P.A.) a eu l'occasion de prospecter deux grottes situées aux environs de Belinga sur le cours supérieur de l'Ivindo, et une troisième à quelques kms au Nord du village de Batouala.

Dans deux d'entre elles il a été possible de capturer une importante série de Cératopogonidés appartenant à trois espèces distinctes dont deux inédites.

Nous donnons ici, un bref aperçu du biotope et des conditions de capture. La description des nouvelles espèces.

Vattier-Bernard, G. (1970). Contribution à l'étude systématique et biologique des Phlébotomes cavernicoles en Afrique intertropicale. 1re partie.

Ce travail comprend:

- une étude systématique et morphologique des Phlébotomes cavernicoles vivant au Congo-Brazzaville. Adultes et stades préimaginaux de *Spelaephlehotomus gigas* et de *Phlehotomus mirabilis* sont décrits;

- une mise au point de la répartition géographique des huit espèces de Phlébotomes cavernicoles africains.

Diverses techniques (capture, élevage...) sont décrites.

This work includes:

- a systematical and morphological study of the cavernicolous sandflies from the Congo. The adults and the immature stages of *Spelaephlebotomus gigas* and *Phlebotomus mirabilis* are described;

- the geographical distribution of the cavernicolous African sandflies (eight species).

Different methods (capture, rearing...) are given

Vaughan, N. and J. E. Hill (1996). Bat (Chiroptera) diversity and abundance in banana plantations and rain forest, and three records for St. Vincent, Lesser Antilles.

Mist netting in banana plantations and rain forest showed that rain forest had higher numerical bat species richness, but fewer bats, than banana plantations. The conservation of the few remaining tracts of rain forest on St. Vincent may be important for the survival of several species of bat and for the maintenance of bat diversity. Three bat species previously unrecorded from St. Vincent were caught there, namely; *Pteronotus parnellii, Micronycteris megalotis* and *Tadarida brasiliensis antillularum*.

Les captures au filet ont montré que si la richesse spécifique du peuplement de chiroptères de la forêt pluvieuse est plus élevée que celle des plantations de bananes, la situation inverse prévaut en ce qui conceme l'abondance des individus. La conservation des dernières portions de forêt pluvieuse de St. Vincent est probablement très importante pour le maintien de plusieurs espèces de chiroptères et de

la diversité des communautés présentes. Trois nouvelles espèces de microchiroptères ont été récemrnent découvertes à St. Vincent: *Pteronotus parnellii, Micronycteris megalotis* et *Tadarida brasiliensis antillularum*.

Vaughan, N., G. Jones and S. Harris (1996). Effects of sewage effluent on the activity of bats (Chiroptera: Vespertilionidae) foraging along rivers.

In order to investigate how a decline in river water quality might affect the foraging behaviour of bats in riparian habitats, bat activity and feeding rates were measured at sites upstream and downstream from 19 sewage outputs. Paired sampling was used to control for variation in bat activity due to environmental parameters. Bat activity (bat passes) and attempted prey captures (terminal buzzes) recorded from broad band bat detectors were counted at each site, and bat species groups could be distinguished. Overall bat activity and foraging activity were reduced downstream from sewage outputs, by 11 % (total reduction in passes) and 28 % (total reduction in buzzes). Both phonic types of *Pipistrellus pipistrellus* were less active at downstream sites than at upstream sites (total reduction in activity was 55 % for the 45 kHz phonic type and 51 % for the 55 kHz phonic type). The 45 kHz phonic type of *P. pipistrellus* concentrated its foraging effort at upstream sites (total reduction in counts of buzzes was 87 %), while *Myotis* spp. Foraged at higher rates downstream from outputs than upstream (total increase in foraging rate was 112 %). For the conservation of *P. pipistrellus*, the maintenance of high standards of water quality may be important. *Myotis daubentonii* may be able to benefit from eutrophication.

Vaughan, N., G. Jones and S. Harris (1997a). Habitat use by bats (Chiroptera) assessed by means of a broad-band acoustic method.

1. Bats foraging activity was quantified by using a broad-band acoustic method on transects in 10 land use types in south-west England. From multivariate analyses of parameters of bat echolocation calls, 83 % of bat passes could be identified to species level with quantified degrees of certainty. The remaining 17 % could be identified to species group.

2. Total bat activity was positively correlated with air temperature, and once adjusted for temperature, was significantly higher over rivers and lakes than over other land use types.

3. Bats that use frequency-modulated echolocation calls (mainly *Myotis* spp., but some *Plecotus auritus* were recorded in nine of 10 land use types, but never in villages. Rivers and lakes supported high levels of activity of these species. Bats classified as 45 kHz and 55 kHz phonic types of *Pipistrellus pipistrellus* had different habitat requirements; 45 kHz *P. pipistrellus* fed in many habitats, while 55 kHz *P. pipistrellus* fed mainly over rivers and lakes. Bats classified as *Nyctalus noctula, Nyctalus leisleri* and *Eptesicus serotinus* were most active in open habitats and over rivers and lakes.

4. Total bat activity was equally high in woodland interiors and along woodland edges, but bats were relatively more active in sheltered sections of transects than in exposed sections.

5. Plans for land management should take into account the habitat needs of bats. For most species in Britain, rivers and lakes are of primary importance. Management plans should aim to maintain physical diversity and features used by insects in freshwater habitats, woodlands and pasture.

Vaughan, N., G. Jones and S. Harris (1997b). Identification of British bat species by multivariate analysis of echolocation call parameters.

1. A method for the identification of bat species from time-expanded broad-band recordings of their echolocation calls is presented. The method may be used for the assessment of habitat use by bats.

2. Recording were made of echolocation calls produced by 536 bats of known species identity, belonging to 15 species found in Great Britain. One call was analysed per individual, and sonograms and descriptive statistics of six time and frequency variables of calls are presented. British bats can be placed in three groups according to the structure of their calls: high duty cycle FM/CF/FM bats (*Rhinolophus* spp.), low duty cycle FM bats (*Myotis* spp, and *Plecotus* spp.) and intermediate duty cycle FM/CF bats (*Pipistrellus* and *Nyctalus* spp. And *Eptesicus serotinus*).

3. FM/CF/FM bats could be identified from the peak frequency of their calls. Two separate quadratic multivariate discriminant analyses were carried out on the time and frequency parameters of calls produced by FM bats and FM/CF bats. For FM bats 67 %, and for FM/CF bats 89 %, of unknown calls were classified to species.

Vaughan, T. A. (1966). Morphology and flight characteristics of Molossid bats.

Selected aspects of the morphology of bats of the family Molossidae are described and the functional significance of these features are discussed. The structure and proportions of the ears and the wings are considered to reflect primarily ther rapid enduring flight typical of molossids. Comparisons of characteristics of the wings of three rnolossids and of four bats of the family Vespertilionidae were made, and several aerodynamic relationships were applied to a consideration of the styles and speeds of flight of these bats. Molossid bats in genera seem adapted to fast flight in open areas, whereas the vespertilionids studied are apparently suited to slower flight fairly low to the ground, near vegetation and other obstacles.

Vaughan, T. A. and R. P. Vaughan (1986). Seasonality and the behavior of the African yellow-winged bat.

The African yellow-winged bat (*Lavia frons*) was observed in Kenya, East Africa, through one wet and one dry season (December 1982 to July 1983). This opportunistic, sit-and-wait predator typically forages from the crowns of *Acacia tortilis* and captures insects through a broad range of elevations by brief, precise interceptions. *Lavia* is monogamous. Members of a pair roost together in a territory defended by the male, forage either separately or together, and share the territory for some 3 months with the single young. *Acacia tortilis* responds to erratic dry-season rains by flowering and growing new leaves; attending brief bursts of insect abundance may be of crucial importance to *Lavia* during dry-season energy bottlenecks. Many of the most distinctive aspects of the life history of *Lavia* - monogamy, territoriality, the division of labor, opportunistic foraging, a long mother-young association, and a close association between *Lavia* and *A. tortilis* - probably are adaptations to recurring periods of energy stress.

Vaughan, T. A. and R. P. Vaughan (1987). Parental behavior in the African yellow-winged bat (*Lavia frons*).

The parental behavior of five monogamous pairs of African yellow-winged bats (*Lavia frons*) was observed in Kenya. Each females bore a single young, which clung to its mother continuously until about one week before it first flew and foraged. Newly Volant young foraged with their parents and soon developed foraging performance that closely resembled that of their parents. Young were weaned about 20 days after becoming Volant. Until at least 50 days after its first flight, each young shared its parent's territory, synchronized its grooming and foraging periods with those of its parents, and periodically huddles against its mother when roosting. Recurring but unpredictable periods of low insect density have seemingly selected for an extended period of parent-young association, during which the young become skilled opportunistic foragers.

Vaughan, T. C., E. L. Cockrum and P. J. Vaughan (1977). Four Vespertilionid bats new to the fauna of Tunisia.

Quatre espèces de chauves-souris dont la répartition connue est européenne ont été trouvées dans le nord de la Tunisie: *Myotis emarginatus, M. capaccinii, Pipistrellus pipistrellus* et *P. savii*.

Four bats: *Myotis emarginatus, M. capaccinii, Pipistrellus pipistrellus*, and *P. savii*, essentially European in distribution, and previously unknown from Tunisia are reported from the northern part of that country.

Veiga-Ferreira, M. C. (1948). Notas acêrca dos Megaquiropteros da Guiné Portuguesa.

A colecção de Quirópteros obtida pela Missão Zoológica da Guiné, chefiada pelo Prof. F. Frade, em 1945 e 1946, nas várias Iocalidades do seu itinerário, eleva-se a 276 exemplares, dos quais 37, correspondentes a três espécies, pertencem à subordem *Megachiroptera* e constituem o material, conservado em álcool, em que se baseia o presente estudo. Embora na sua maioria tenham sido capturados a tiro, o estado de conservação dos referidos exemplares é muito satisfatório, mesmo para as observações craniológicas.

Uma das espécies, *Rousettus angolensis*, é, segundo cremos, registada pela primeira. vez como elemento da fauna da Guiné Portuguesa. Muito deslocada da área geográfica que lhe foi atribuída, o encontrá-la na Guiné Portuguesa parece indicar que futuras explorações revelarão a sua existência nas outras regiões entre esta colónia e Angola.

Eidolon helvum e *Epomophorus gambianus* estão, desde há muito, registados como existentes na nossa Guiné, mercê das antigas colheitas do português Francisco Newton, que forneceram o material ao Prof. Bocage, e das mais recentes do Dr. Monard.

Um fado importante se nos afigura oportuno pôr em relevo, que é o de não haver entre os exemplares coligidos pela Missão, nem pelo Dr. Monard, nenhum que se identifique com *Epomophorus guineensis* Bocage, binome geralmente incluído na sinonímia de *Epomophorus gambianus*, o que leva a admitir que se trata de aberração ou de forma muito rara, apenas uma vez encontrada.

Os Megaquirópteros são conhecidos vulgarmente, na Guiné Portuguesa, pela designação imprópria de "Vampiros", embora ali se saiba perfeitamente que estes animais são frugívoros, pelos estragos por eles produzidos. Dos seus hábitos e prejuízos que causam dá-nos ideia o Prof. Frade no relatório da Missão, de onde extraímos os seguintes passos, a pág. 286~287: "J á em Farim, durante a noite, maçam-nos os ouvidos com o seu monótono cantar, lembrando o bater do martelo na bigorna, os "Vampiros", grandes morcegos que invadem os mangueiros na época da maturação dos seus saborosos frutos. O foco da lâmpada eléctrica descobrelhes os elhitos brillhantes e incomoda-os a tal ponto que mudam de lugar, provocando querelas entre eles. No dia seguinte, lá continuam suspensos, cabeça pendente, dormindo. O chão, junto às árvores, está juncado de frutos roídos, pois estragam mais do que comem". Mais adiante, a pág. 300: "Cai a tarde. Do continente aflui à iiha de Bolama, atravessando o mar de alto, legião inumerável de morcegos de enorme envergadura, em esquadrilhas desordenadas, sem disciplina das formações ordeiras de patos. Vão tomar de assalto os mangueiras da antiga capital".

Veiga-Ferreira, M. C. (1949). Notas acêrca dos Microquiropteros da Guiné Portuguesa.

O presente trabalho regista 11 espécies de Microquirópteros da Guiné Portuguesa, provenientes das explorações (1945 - 1946) da Missão Zoológica da Guiné, chefiada pelo Prof. F. Frade. Essas espécies, representadas por mais de 200 exemplares, distribuem-se por 5 famílias (*Nycteridae, Hipposideridae, Molossidae, Vespertilionidae*, e *Embalonuridae*) e 6 géneros (*Nycteris, Hipposideros, Chaerephron, Scotophilus, Eptesicus* e *Tazophous*). Duas espécies são pela primeira vez registadas como elementos da fauna da Guiné Portuguesa: *Hi'pposideros abae* Allen e *H. cyclops* Temm.; outras

registadas pela segunda vez, como *H. gigas viegasi* Monard, *H. braima* Monard e *Mops osborni occidentalis* Monard.

Vermeil, C. (1960). Contribution à l'étude des Nycteribiidae et des Streblidae (Diptera, Pupipara) de Tunisie.

Nous avons trouvé, dans la collection de MM. Deleuil et Labbe, cinq espèces sur les sept déjà signalées de Nycteribiidæ et de Streblidæ, parasites de Chiroptères en Tunisie, c'est-à-dire: *Penicillidia conspicua, Nycteribia vexata vexata, Nycteribia latreillii, Nycteribia schmidlii, Nycteribosca kollari*. *Nycteribia biarticulata* paraît bien être une nouvelle espèce pour ce pays. Nous avons indiqué les variations, principalement chætotaxiques, observées sur ce matériel. Confirmant Theodor et Moscona, il ne nous semble pas qu'il faille retenir la sous-espèce *africana* de *N. latreillii* proposée par Karaman.

Verschuren, J. (1965b). Contribution à l'étude des cheiroptères du Parc National du Serengeti (Tanzanie).

Au cours d'une mission en 1962-1963, pour la F.A.O./O.N.U., au Parc National du Serengeti, nous avons récolté un certain nombre de Cheiroptères. Cette réserve naturelle est située en Tanzanie, un peu au Sud de l'Equateur, à des altitudes variant entre 1.200 et 2.100 mètres. Deux biotopes principaux sont représentés: la savane et la steppe, d'une part et de vastes étendues de bush, d'autre part. Les captures de Cheiroptères ont été effectuées principalement dans les affleurements granitiques, très nombreux dans la réserve naturelle et dans des arbres creux des étroites galeries forestières. Toutes les localités indiquées ci-après sont situées dans le Parc National.

Verschuren, J. (1967). Exploration du Parc National Albert. Mission F. Bourlière et J. Verschuren (1957 - 1961). Fasc. 2. Introduction a l'écologie et la biologie des cheiroptères.

Une prospection mammalogioue détaillée, axée principalement sur l'Écologie, a été entreprise, au Parc. National Albert, République du Congo, de juillet1957 à décembre 1961. Elle a été complétée par des courtes visites dans la réserve. Naturelte en 1962 et 1963; une prospection préliminaire, avec le Profr H. HEDIGER, avait eu lieu en 1948.

Plusieurs centaines de Cheiroptères ont été récoltés dans différents milieux du Parc National; une quantité assez importante de données écologiques ont été obtenues sur ces Mammifères. L'ensemble de cette documentation fait l'objet de la présente publication. On notera que les travaux sur les Cheiroptères n'ont pas été effectués en profondeur comme au Parc National de la Gararnba, au cours de la Mission H. DE SAEGER, où une monographie assez complète des Cheiroptères avait été préparée (VERSCHUREN, 1957). Par ailleurs, nous avons estimé superflu de reprendre ici une série de problèmes examinés dans ce travail.

En ce qui concerne les Cheiroptères, il est évident que des lacunes restent à combler au Parc National Albert. Deux auteurs seulement, avant nous, s'étaient occupés de ce groupe de Mamrnifères: FRECHKOP (1938 et 1943) et CURRY-LINDAHL (1961).

Verschuren, J. (1977). Les cheiroptères du Mont Nimba (Liberia).

273 Cheiroptères, répartis en 18 espèces, ont été récoltés dans la région du Mont Nimba Liberia, Afrique occidentale, vers la limite nord de la forêt, à des altitudes de 500 à 1 350 m. La majorité (90 %) des captures étaient représentées par des *Pteropidae*, par suite de l'usage intensif de filets de nylon. *Myonycteris torquata leptodon* est, de loin, l'espèce la plus abondante. Une liste de récoltes et d'observations écologiques est suivie d'une tentative de synthèse de certains problèmes généraux:

répartition des espèces, biotopes, reproduction, associations, migrations, facteurs anthropiques. 5 espèces nouvelles sont signalées pour le Liberia.

273 Bats (order: Chiroptera), includlng 18 difîerent species, have been collected in the Mount Nimba area (Liberia, West Africa), near the northern lirnit of the forest (altitudes between 500 and 1 350 m). The rnajortty of the animals (90 %) are represented by *Pteropidae*, due to the intensive use of nylon nets. *Myonycteris torquata leptodon* seems the most common bat. Lists of recolts and ecological observations are followed by more general indications concerning some problems: distributions of species, biotopes, reproduction, associations, rnigrations, anthropical factors. 5 species are new for Liberia

---

Verschuren, J. (1980). Notes sur les cheiroptères du Burundi.

La faune mammalogique du Burundi est nettement moins bien connue que celle du Zaire et du Rwanda, pays limitrophes, études de façon intensive. Un seul auteur, P.L. NIORT (1970), s'est occupé de façon spécifique des Cheiroptères de ce pays. Des élements intéressants peuvent être trouvés égamement chez des auteurs ayant effectué une étude globale des pays anciennement belges (Zaïre, Rwanda et Burundi): H. SCHOUTEDEN (1946) et R.W. HAYMAN, W. MISONNE et W. VERHEYEN (1966). Le Rwanda a fait l'objet de travaux approfondis par M. ANCIAUX DE FAVEAUX. Cet auteur s'est récemment livré à de remarquables travaux d'envergure sur la répartition biogéographique et les cycles annuels de reproduction des Cheiroptères d'Afrique centrale, en ajoutant une bibliographie approfondie, incluant pratiquement tout ce qui a été publié antérieurement sur le sujet (1972, 1976, 1977, 1978). L'auteur de la présente note a examiné aussi la faune des Cheiroptères du Zaïre - Garamba et Virunga -, du Rwanda, de Tanzanie, de même que du Liberia et du Sénégal (VERSCHUREN, 1955, 1965, 1966, 1976 et sous presse).

Pendant la période juin-août 1976, nous avons effectué des recherches sur les Cheiroptères du Burundi, à l'occasion d'une mission pour l'Adrninistration générale de la Coopération pour le Développement (Belgique), ayant pour objet essentiel le pré-lancement de Parcs Nationaux au Burundi. Ces recherches ne constituaient pas le but de base des travaux. Les récoltes, en utilisant principalement des filets, ont été réalisées près de Bujumbura, capitale du pays (alt. 600 m) et dans la vallée de la Ruvubu et ses environs (alt. 1400 - 1650 m), à l'Est du Burundi. Les collections sont conservées à l'Institut royal des Sciences naturelles de Belgique. Nous ne détaillerons pas les caractéristiques générales géographiques et biologiques du Burundi, celles-ci étant largement examinées dans plusieurs travaux récents.

Verschuren, J. (1982). XXII. Note sur les cheiroptères du Sénégal, principalement dans les pars nationaux du Niokolo-Koba et du Delta du Saloum.

Relativement peu d'auteurs se sont occupés spécifiquement des Cheiroptères du Sénégal, quoique la situation soit remarquablement en train de se modifier avec les travaux de ADAM & HUBERT (1972, 1976).

DORST (1959) signale dans la région de Richard Toll: *Scotophilus gigas, Pipistrellus ruppelli senegalensis, Tadarida limbata, Tadarida condylura, Tadarida Midas*.

AELLEN (1956) relève au Parc national du Niokolo-Koba: *Epomophorus gambianus, Micropteropus pusillus, Nycteris hispida hispida, Nycteris thebaica gambiensis, Rhinolophus alcyone, Hipposideros commersoni gambiensis, Hipposideros caffer guineensis, Hipposideros caffer tephrus, Eptesicus guineensis, Eptesicus minutus, Eptesicus rendalli, Scotophilus leucogaster leucogaster, Scotophilus nigrita nigrita, Tadarida condylura wonderi* et *Tadarida limbata websteri*.

Dans la région du Ferla, POULET (1972) indique *Rousettus aegyptiacus, Taphozous perforatus, Aselia tridens, Nycteris thebaica* et *Tadarida major*.

En basse Casamance, DUPUY (1973) signale *Eidolon helvum, Epomophorus gambianus* et *Nycteris gambiensis*.

Dans la région de Bandia, près de Dakar, ADAM & HUBERT (1972) indiquent six espèces nouvelles pour le pays: *Epomophorus anurus, Lissonycteris angolensis smithi, Rhinopoma microphyllum, Eptesicus tenuipinnis, Glauconycteris poensis,Glauconycteris variegata*, de même que *Pipistrellus rueppelli senegalensis, Hipposideros caffer guineensis* et *Hipposideros tephrus*. Les mêmes auteurs (1976) indiquent la répartition géographique de 5 *Nycteridae* au Sénégal, y compris *Nycteris grandis*.

Enfin, dans une récente publication, BOHME & HUTTERER (1978) signalent 11 espèces dans les diverses régions du Sénégal, principalement à l'ouest: *Epomophorus gambianus, Micropteropus pusillus, Nycteris macrotis, Nycteris gambiensis, Lavia frons, Rhinolophus guineensis, Hipposideros cyclops, Asellia tridens, Tadarida (Mops) condylura* et *Tadarida (Chaerephon) pumila*.

Plusieurs études ont été effectuées en Guinée; pour l'Afrique occidentale, le travail de ROSEVEAR (1965) reste l'outil de base. Pour l'Afrique centrale, l'étude ANCIAUX DE FAVEAUX (1975) est capitale.

En mai-juin 1975 et avril-mai 1 nous avons séjourné dans les Parcs nationaux du Niokolo-Koba et du delta du Saloum, les travaux étant axés sur des problèmes d'écologie et de conservation. Des récoltes et observations ont été effectuées en points de ces réserves naturelle, de même qu'à Dakar; ces observations pourront être utilisées lors de la mise au point d'une "faune" des Cheiroptères des Parcs. Quelques observations ont été effectuées aussi à Bamako, Mali, en mai 1977. Rappelons que le Parc national du Niokolo-Koba est situé en zone soudanienne dans l'est du et celui du delta du Saloum à la limite des zones soudaniennes et sahéliennes dans l'ouest du pays, mais sous climat subcanarien. Les récoltes sont conservées à l'Institut royal des Sciences naturelles de Belgique, Bruxelles.

Verschuren, J. (1986a). Notes d'écologie, principalement des mammifères, du Mont Nimba (Liberia).

Peu de régions de l'Afrique tropico-équatoriale ont été étudiées de façon aussi intensive par les naturalistes que le Mont Nimba. Jusqu'il y a deux décennies, ces travaux concernaient essentiellement le Nimba Guinéen, et dans une moindre mesure, Ivoirien. Les recherches étaient orientées principalement vers la Botanique, les Vertébrés inférieurs et les Invertébrés. Les études de LAMOTTE et de SCHNELL, de même que celles de plusieurs auteurs non cités ici, resteront longtemps des modèles du genre.

Cependant, depuis une quinzaine d'années, à l'initiative du "Nimba Research Committee", grâce à l'enthousiaste dynamisme de K. CURRY-LINDAHL, le Nimba Liberien a fait, lui aussi, l'objet d'études approfondies. Les publications sortent à un rythme accéléré. Pour le flore, il convient de citer les monumentaux travaux de J.G. ADAM. Une étude de base complète des Oiseaux est actuellement préparée par K. CURRY-LINDAHL. Concernant les Mammifères, on disposait d'excellentes informations sur la Guinée et la Côte d'Ivoire contigües. La liste globale de KUHN reste l'ouvrage de base pour les Mammifères de l'ensemble du Liberia. Notre collègue au Nimba Research Laboratory, le Dr. M. COE, a publié une remarquable étude exhaustive des Mammifères, orientée surtout au point de vue écologique.

L'auteur de cette note a séjourné au Nimba Liberien de novembre 1965 à mars 1966. Il a revu cette région en 1978-1979, dans le cadre d'une mission globale de promotion de la conservation au Liberia. Tout récemment, plusieurs auteurs, en particulier, ROBINSON, se sont occupés avec dynamisme des Mammifères du Liberia, mais pas spécifiquement du Nimba, à l'exception de l'équipe de HILL, qui s'est consacrée aux Cheiroptères. Les informations de K. CURRY-LINDAHL (comm. pers.) restent une mine de données précieuses.

Nos publications antérieures concernaient essentiellement les Insectivores (VERSCHUREN et MEESTER, 1977), les Rongeurs (MISONNE et VERSCHUREN, 1976) et lès Cheiroptères (VERSCHUREN, 1976. Il restait à examiner les autres groupes de Mammifères et à publier une synthèse des éléments de climatologie et d'écologie générale. Des remarques relatives à la Conservation trouvent également leur place ici. Par ailleurs, beaucoup d'éléments relatifs aux Mammifères "in globo" du Liberia sont

examinés dans une étude actuellement sous presse. Elle fait suite au rapport général de mission (1983), axé sur la Conservation. Les limites d'études de la zone reprise ici concernent essentiellement la partie Liberienne du Nimba (avec quelques pointes d'exploration en Guinée) et une région d'environ une dizaine de kms de large, sur le piedmont.

La base de travail était située au Nimba Research Laboratory, à Grassfield, dont les coordonnées sont les suivantes: Lat. N. 7°30', Long. W. 8°32'. Les explorations ont été effectuées à pied ou en véhicule tous terrains. Les moyens nécessaires logistiques et autres ont été mis à notre disposition par le Nimba Research Committee et la Société minière, LAMCO. Des régions forestières du Liberia, situées loin du Nimba, et qui ont été prospectées intensivement en 1978-1979, avaient déjà été visitées par l'auteur en 1965-1966 (Nord-Ouest et Centre-Est du pays).

Les données chronologiques de l'exploration 1965-1966 sont les suivantes:
11-16 novembre 1965: Monrovia.
16 novembre 1965 à fin mars 1966: exploration de la région du Mont Nimba, y compris, du 15 au 21 février 1966, avec K. CURRY-LINDAHL.
6 au 10 décembre 1965: exploration de la région de Mputu-Chien.
4 au 7 janvier: exploration des hauts sommets Guinéens.
26 au 27 février: exploration de la région de Zorzor-Voinjama.
15 au 17 mars: exploration de la région de Chien-Mputu.

Les recherches ont été poursurvies, après notre départ, par plusieurs naturalistes. Actuellement (1983), le laboratoire situé au pied de la montagne reste toujours fonctionnel, sous la supervision du technicien E. YALLAH. Celui-ci, accompagné de plusieurs collaborateurs, nous a accompagné durant tous nos déplacements.

Le laboratoire de Grassfield est situé dans une clairière herbeuse, d'origine édapho-anthropique, sur dalle latéritique. Il domine une petite galerie forestière intacte, sous-affluent de la rivière Yah (Bassin du St. John's river). Ce laboratoire avait constitué une des bases initiales de l'exploitation minière du mont Nimba.

Les collections de Mammifères, y compris quelques Primates et Pholidota, de même que la documentation iconographique, sont actuellement localisées à l'Institut royal des Sciences Naturelles de Belgique. Les peaux des grands Mammifères ont été conservées au Liberia. Les Batraciens récoltés ont été étudiés par M. LAMOTTE, à Paris.

Verschuren, J. (1988). Notes d'écologie, principalement des mammifères, du parc national de la Pendjari, Bénin.

Le Parc National de la Pendjari, entouré de plusieurs zones cynégétiques, s'étend sur 275.000 hectares dans le Nord du Bénin. Plus aux Nord encore, se trouve le Parc du W, d'environ 500.000 hectares. Ces unités protégées se continuent dans les pays voisins (Niger, Burkina Faso). L'auteur a séjourné pendant près de six mois au Bénin. en 1985, comme responsable du lancement d'un grand projet de conservation au Bénin, avec l'appui financier de la C.E.E. Il s'agissait d'une importante action pionnière de la C.E.E., suivie, depuis lors, par plusieurs autres interventions en Afrique. Sur base de ses observations et également de documents non publiés de divers spécialistes (GREEN et SAYER),l'auteur décrit le Parc de la Pendjari et examine les divers problèmes qui se posent, concernant le climat, l'eau et le feu, les milieux végétaux, la faune, en particulier celle des grands mammifères, les recensements, certaines actions anthropiques. Les grands mammifères ont été longtemps très braconnés mais les noyaux subsistant suffisent pour permettre une recolonisation de la plupart des habitats où domine la savane soudanienne, avec une très longue saison sèche et des pluies abondantes mais très localisées dans le temps. Le problème des eaux résiduelles en saison sèche est capital. Le Parc de la Pendjari constitue un des ultimes refuges pour l'éléphant de savane de l'Ouest de l'Afrique; il constitue également une des meilleures zones d'Afrique pour l'Antilope rouanne, *Hippotragus equinus*.

The Pendjari National Park, situated in N. Benin, is 275,000 hectares large and is surrounded by several cynegetic zones. The W-Park, still further north, has a surface of 500,000 hectares. Both protected areas are extending into the neighbouring countries (Niger, Burkina Fasso).

In 1985 the author spent six months in Benin, starting a large conservation project with the financial support of the E.E.C. It was an important pioneer action of the E.E.C., which was later followed by several other interventions in Africa.

On the basis of observations and of unpublished documents by different specialists (GREEN and SAYER), the author describes the Pendjari Park and considers sorne problems with relation to climate, water, fire, plant environments, fauna (especially large mammals), surveys and influence of man. Large marnmals have been severely affected by poachers, but viable groups still exist, allowing recolonisation of most of the habitats with soudanese savanna, characterized by a long dry season and by periodical heavy rainfall. The problem of residual water during the dry season remains a major one. The Pendjari Park is one of the last refuges for elephants of the W. African savanna, and one of the oost places in Africa for the roan antelope *Hippotragus equinus*.

Vielliard, J. (1974). Les chiroptères du Tchad.

Une petite collection de chauves-souris a été faite dans le bassin du Tchad entre novembre 1969 et janvier 1971 et a été déterminée avec l'aide de M. V. AELLEN. Les espèces suivantes sont signalées pour la première fois de la République du Tchad: *Micropteropus pusillus, Eptesicus rendalli, Eptesicus somalicus, Chalinolobus variegatus, Scotoecus hirundo, Tadarida nigeriae* et *Tadarida midas*. Une liste complète des Chiroptères du Tchad a été dressée en tenant compte des informations de la littérature et des collections du Muséum de Paris. Un total de 21 espèces seulement est reconnu. Les données disponibles sur chaque espèce sont discutées et des problèmes de systématique sont évoqués en particulier pour *Epomophorus anurus, Nycteris hispida. Eptesicus* spp., *Scotophilus* spp. et *Tadarida pumila*.

Eine kleine Fledermaus-Ausbeute aus Tschad würde in Zusarnmenarbeit mit V. AELLEN bearbeitet; folgende Arten werden erstmals aus der Republik Tschad gemeldet: *Micropteropus pusillus, Eptesicus rendalli, E. somalicus, Chalinolobus variegatus, Scotoecus hirundo, Tadarida nigeriae* und *T. midas*. Unter Berücksichtigung der Literatur und der Sammlung des Museums Paris wird rine vollständige Liste der Fledermäuse von Tschad zusamrnengestellt; die insgesamt nur 21 Arten urnfasst. Die erhältlichen Daten über jede Art werden diskutiert, auf systematische Probleme wird besonders bei *Epomophorus anurus, Nycteris hispida, Eptesicus* spp., *Scotophilus* spp. und *Tadarida pumila* hingcwiesen.

In collaboration with V. AELLEN, the author identified a small rnaterial of bats, collected in Tchad between novernber 1969 and january 1971. The following species are recorded for the first time from this area: *Micropteropus pusillus, Eptesicus rendalli, E. somalicus, Chalinolobus variegatus, Scotoecus hilrundo, Tadarida nigeriae*, and *T. midas*. A complete list of bats, known from the Republic of Tchad is given, comprising only 21 species. The available informations of each species are discusscd, systematic problems are pointed out particularly for *Epomophorus anurus, Nycteris hispida, Eptesicus* spp., *Scotophilus* spp., and *Tadarida pumila*.

Vivier, L. and M. Van der Merwe (1996). Reproductive pattern in the male Angolan free-tailed bat, *Tadarida (Mops) condylura* (Microchiroptera: Molossidae) in the Eastern Transvaal, South Africa.

The reproductive pattern in male Angolan free-tailed bats *Tadarida (Mops) condylura* was studied at two localities in the Eastern Transvaal during the period 1989 - 1991. Males displayed a nine-month breeding season extending from June to February. Following testicular recrudescences in early June, spermatogenic activity displayed two periods of peak activit in August/early September and

November/early December. Although testes became involuted in March, baseline spermatogenic activity was maintained and testes never regressed to preputertal conditions. Leydig cell morphology closely followed spermatogenic activity, with the diameter of Leydig cell nuclei displaying a concomitant seasonal pattern.

Vogel, P. (1977). Neue Nachweise der *Rhinopoma hardwickei* (Chiroptera) aus Westafrika.

Neue Funde der Fledermaus *Rhinopoma hardwickei* aus dem Niger aktualisieren das Problem der subspezisehen Zuordnung des bereits bekannten Nigermaterials. Ferner wird die Art erstmals für die Republik Mali nachgewiesen.

From Mali, the first record of the bat *Rhinopoma hardwickei* is communicated. From Niger, new data of the same bat actualise the problern of subspecific rank of older material from this country.

Volleth, M. and K.-G. Heller (1994). Phylogenetic relationships of vespertilionid genera (Mammalia: Chiroptera) as revealed by karyological analysis.

Banded karyotypes of 50 species belonging to 23 genera were analyzed. The diploid chromosome numbers ranged from 26 to 50. For karyotypic comparison we used a 44 chromosomes karyotype, consisting of 4 metacentric and 17 acrocentric autosomes, as "basic karyotype". Almost all of its 25 autosomal arms could be identified in each individual karyotype. In 8 chromosomes, i. e. 1/2, 7, 11, 12, 13, 15, 23 and X, small inversions were detected. As a result, each of the chromosomes mentioned occurs in two states which differ slightly in their banding patterns. These were used as character states in the cladistic analysis together with other chromosomal rearrangements.

The implications drawn from the cladogram obtained are: The Miniopterinae clearly belong to the Vespertilionidae but are the first to branch off from the common stem. The tribe Myotini should be raised to the rank of a subfamily. Within the largest subfamily Vespertilioninae, one autapomorphic chromosomal character was found for each of the tribes Vespertilionini and Pipistrellini. In addition, both tribes are distinguished from the other Vespertilioninae tribes by two svnapomorphic features. These results allow for the first time an unequivocal classification of the systematically difficult "pipistrelloid" species. The species of the genus *Pipistrellus* (sensu HILL and HARRISON 1987) are spread over the Pipistrellini and Vespertilionini. We therefore suggest the splitting of this heterogenous genus into at least four genera. Only the members of the previous subgenus *Pipistrellus* constitute the genus *Pipistrellus* and belong to the Pipistrellini. The previous subgenera *Hypsugo, Vespadelus* and *Falsistrellus*, given generic rank in some recent studies, belong to the tribe Vespertilionini and are not closely related to *Pipistrellus*. For the genera *Eptesicus* and *Hesperoptenus*, which belong neither to the Vespertilionini nor to the Pipistrellini, the tribe Eptesicini was established. The phylogenetic relations of this tribe and the status of the presumably polyphyletic tribe "Nycticeiini" could not be solved.

Wallin, L. (1969). The Japanese bat fauna. A comparative study of chorology, species diversity and ecological differentiation.

The aim and arrangement of the study are presented in section I, the introductory section. A summary description is given of the areas investigated during the author's field studies in Japan.

In section II, the taxonomical section, a description, with data on distribution and bionomy, is given of each of the 29 forms (25 species) occurring in Japan.

Hypsugo Kolenati is re-established as a subgenus for *Pipistrellus savii*. The genus *Vespertilio* is divided into a *murinus* group and a *superans* group. Two new forms are described: *Vespertilio orientalis* and *Vespertilio rnurinus ussuriensis* (the latter is extra-limital to Japan). *Vespertilio namiyei*

is considered to be a synonym of *V. superans*. The taxonomy and nomenclature of other forms are discussed (of especially *Rhinolophus ferrumequinum nippon, R. cornutus pumilus, Myotis formosus, M. capaccinii macrodactylus, Eptesicus nilssoni japonensis*, and *Tadarida teniotis*).

In section III, the general section, comparative analyses of species diversity (subsection 0) and ecological differentiation (subsection D) are given. Background information for this main item will be found in the subsections on regional climate (subsection A) and chorology (subsection B).

A comparison is made of the climate of Japan and that of the western part of the Palaearctic region. The range in temperature between the northern and southern parts of Japan corresponds to that in western Europe between Scandinavia and the Mediterranean. There is thus a southerly depression and concentration of the isotherms over Japan, compared with the western part of the Eurasian continent. The amplitude of the annual variation of temperature is similar in Japan and Scandinavia.

The steep gradient in the temperature conditions in Japan is reflected in the occurrence of both tropical (Megachiroptera) and boreal (*Plecotus auritus, Eptesicus nilssoni*) elements.

The precipitation is ampler in Japan than in western Europe. Large areas of dry-ground vegetation are lacking in Japan. Bat groups (for example, Rhinolophidae) frequently occurring in such habitats are poorly represented in Japan, as compared with Europe as a whole.

Other consequences of the relatively moist climate in Japan are presumably the exposed roosting habtts of several Japanese bat species (for example, *Vespertilio orientalis, Murina aurata* and *M. leucogaster*).

Four groups of faunal elements are recognized: endemic forms (9), northerly Palaearctic forms (8), southerly Palaearctic forms (10), and Oriental forms (2).

The relation between the Japanese bat fauna and that of the western Palaearctic region is analyzed in a survey of the chorology of the Palaearctic bat species. A numerical method is applied, giving a quantitative expression for the faunistic congruence of regions (index of faunistic congruence).

The "relative endemism" gives a numerical expression of a hypothesis about the dispersal centre (India and Indo-China) for the bat forms on the Eurasian continent.

Within each of three phytogeographical zones (subtropical, temperate and boreal) the following habitat zones are recognized: original forests, secondary forests, the cultivated landscape, transitions between open fields and forests, urban habitats, lentic habitats and lotic habitats. Short descriptions of the different habitat zones are given, together with a list of the bat forms occurring in them.

A general feature of species diversity is illustrated by the regression for the logarithm of the number of species and the logarithm of the area of the compared regions. An increasing species diversity towards the south is superimposed on this regression.

Japan is found to be comparable with central and southern European countries with respect to species diversity when the area-dependent species diversity is taken into account.

A regression for the number of endemic species and the total number of species within different regions on the Eurasian continent is demonstrated.

The distributions of the bat species in different hunting habitats in Japan and Europe are compared.

A comparison of the differentiations within the bat faunas of Japan, Europe, Scandinavia and Garamba (Africa) is made with the aid of a classification of types of roosts and behaviour at the roost.

The strongly anthropophile tendency of bats in northern Europe is not found in Japan. Only one species (*Pipistrellus abramus*) is predominantly house-dwelling there. The increasing synanthropism towards the north in Europe seems to have no counterpart in Japan. The differences in the climates, the milieu structure in the cultivated landscapes, and the architectures of the two regions are suggested as some of the reasons for this difference in habitat selection by the bats

Warner, J. W., J. L. Patton, A. L. Gardner and R. J. Baker (1974). Karyotypic analyses of 21 species of molossid bats.

Examination of 135 specimens representing 21 species from seven genera of the family Molossidae revealed diploid numbers ranging from 34 to 48. Seventeen species from six genera have diploid numbers of 48. Geographic variation and polymorphism were found only in *Eumops glaucinus*. Chromosomal variation within the family is presumed to be primarily due to changes in diploid number resulting from Robertsonian translocations.

Wassif, K. and G. Madkour (1963). Studies on the osteology of the rat-tailed bats of the genus *Rhinopoma* found in Egypt.

The genus *Rhinopoma* is represented in Egypt by the species *hardwickei* and *microphyllum*. Of the two species *hardwickei* is the more common and has, therefore, been used to show the type of organisation found in an insectivorous bat. The Skeletal differences between the two species have also been studied.

Careful review of the literature reveals that the amount of work dealing with the osteology of insectivorous bats and of *Rhnlopoma* in particular is very fragmentary. Thus, Anderson (1902) very briefly described the skull of *Rhinopoma microphyllum*. Thomas (1903) referred to cranial differences bewteen the two species. Miller (1907) wrote on the cranial and dental characters of the genus *Rhinopoma*. Wassif (1946 & 1948) described the tympanic region of *Rhinopoma microphyllum* and Garg (1955) described the orbito-temporal region in the skulls of *Rhinopoma h. hardwickei*, and *Rhinopoma kinneri* from Ajmer.

Wassif, K. and G. Madkour (1970). The structure of the hyoid bone, larynx and upper part of trachea in some Egyptian bats.

The structure of the hyobranchral skeleton of vertebrates has received considerable atlention frorn anatomists since the early work of Meckel (1829), Rathke (1832), Richer (1832), Saint-Hilaire (1832) and Owen (1866). Blainville (1841) described and figured the hyod apparatus of a large number of mammals including ..res species of *Pteropus*. Max Weber (1927) described … the hyoid region of *Rhinolophus hipposideros*. Soragues (1943) studied the hyoid apparatus and the muscles connected to it in placental mammals with special reference to bats. He described twenty three species of the Megachiroptera and twenty two species of the Microchiroptera. The species of Microchiroptera described by Sprague (1943) included *Rhinopoma micrcohyllum, Taphozous nudiventris, Nycteris aethiopica, Rhinolophus euryotis*. Romankowowa (1963) made a cornparative studv of the skeleton of the hyoid apparatus in Polish species of bats including *Rhinolophus hipposideros, Myotis myotis, Myotis mystacinus, Myotis dasycneme, Myotis daubentoni, Eptesicus serotinus, Nyctalus noctula, Pipistrellus pipistrellus* and *Plecotus auritus*.

Wassif, K. and G. Madkour (1971). The wing skeleton in Egyptian bats (Microchiroptera).

Brief descriptions of the fore-limb bones of bats appeared in the works of Dobson (1878) and Miller (1907). Greene (1931) studied the development of the carpal bones of *Tadarida* and Romankowowa (1961) described the sesamoid bones of the limbs of bats belonging to the genera *Rhinolophus, Plecotus, Barbastella* and *Myotis*. Wassif and Madkour (1970) described the wing phalanges of Egyptian bats belonging to the genera *Rhinopoma, Taphozous, Nycteris, Rhinolophus, Asel ia, Pipistreltus, Otonycteris, Plecotus* and *Tadarida*. Vaughan (1970) spoke of the characteristics of the skeleton in bats and Walton and Walton (1970) wrote on the post-cranial osteology of bats. Felten *et*

al (1973) carefully described the distal part of the humerus in European bats and used it in the identification of the different genera and species.

Bat skeletons may be found in caves and ancient tombs and it is hoped that this illustrated account of the wing skeleton in Egyptian bats can be used as an aid in the identification of such fragments.

Wassif, K. and G. Madkour (1972). The structure of the os penis in Egyptian bats (Microchiroptera).

The os penis has been studies in 13 species of bats belonging to seven families of the suborder Microchiroptera. The bone was found to be variously developed in the different species. It is very small in both species of *Taphozous* (Emballonuridae) and of *Tadarida* (Molossidae). The os penis in the four species is a minute spicule in which there is no differentiation between a basal plate and a style. In *Rhinopoma* the two species studied show a moderately developed baculum in which the basal plate is sharply demarked from the style. In all cases the differences between different species of the same genus are, in general, size differences. Larger species possess larger bacula.

The Vespertilionidae show a variety of structure. The least developed baculum is that of *Plecotus austriacus* and the largest is that of *Otonycteris hemprichi*. *Pipistrellus (Scotozous) rüppelli*, which is of the size of *P. kuhli*, has a baculum more than twice as large as that of *kuhli*. They are both built on the same general plan.

In *Rhinolophus clivosus* (Rhinolophidae) the os penis is very large and tongue-shaped. In *Asellia tridens* (Hipposideridae) it is anchor- shaped, while in *Nycteris thebaica* (Nycteridae), it is racket-shaped, with a long style.

Wassif, K., G. Madkour and S. Soliman (1984). Fauna and Flora of Egypt. 1. On a collection of bats from Egypt.

The present collection includes some 1097 specimens of bats of which 693 specimens are in the form of skins and skulls (S+S') and 404 specimens are preserved in 70 % alcohol (Alc.), besides skeletons of dissected bats. The specimens were collected from the following localities:
Cairo-Giza area
Western Desert
Oases of Siwa, Kharga, Dakhla, Bahariya and Farafra
Wadi Natroun and Faiyum
El Arish in North Sinai
Feiran and St. Katherine in South Sinai
Luxor and Aswan in Upper Egypt.

The specimens were identified to the species level, because of the lack of collections from other localities to compare with the present specimens. The collection includes the following species:

Fam. Pteropodidae
1. *Rousettus aegyptiacus* E. Geoffroy, 1810
Fam. Rhinopomatidae
2. *Rhinopoma microphyllum* Brunnich, 1782
3. *Rhinopoma hardwickei* Gray. 1831
Fam. Emballonuridae
4. *Taphozous perforatus* E. Geoffroy, 1818
5. *Taphozous nudiventris* Cretzschmar, 1831
Fam. Nycteridae
6. *Nycteris thebaica* E. Geoffroy, 1818
Fam. Rhinolophidae T. Bell. 1836
7. *Rhinolophus clivosus* Cretzschmar. 1828
8. *Rhinolophus hipposideros* Heuglin. 1861

Fam. Hipposideridae G. S. 1-1ille r, 1907
9. *Asellia tridens* E. Geoffroy, 1813
Fam. Vespertilionidae
10. *Pipistrellus kuhli* Kuhl, 1819
11. *Pipistrellus rüppelli* Fischer, 1821
12. *Eptesicus innesi* Lataste, 1887
13. *Otonycteris hemprichi* Peters, 1859
14. *Plecotus austriacus* Gray, 1838
Fam. Molossidae
15. *Tadarida aegyptiaca* E. Geoffroy, 1818
16. *Tadarida teniotis* Temminck, 1826

The single specimen of *Eptesicus innesi* collected from Abu Rawash in August 1948 is the third known specimen of this rare bat. According to Flower (I932) Dr. Walter Innes, formerly curator of the Zoological Museum at the School of Medicine in Cairo, about the year 1885 obtained two specimens, a male and a female, in a house in Cairo. These were described by Lataste (1885) as *Vesperugo innesi*. One of the specimens is now, preserved in spirits, in the British Museum, the other is said to be in the Genoa Museum.

According to Sanborn and Hoogstraal, the bats they collected from Egypt belong to the following species and subspecies:

Rousettus aegyptiacus aegyptiacus,
Rhinopoma hardwickei cystops,
Rhinopoma microphyllum,
Taphozous perforatus perforatus,
Taphozous (Liponycteris) nudiventris,
Nycteris thebaica thebaica,
Rhinolophus clivosus clivosus,
Rhlnolophus clivosus brachygnathus,
Rhinolophus mehelyi,
Rhinolophus hipposideros minimus,
Asellia tridens tridens,
Plecetus auritus christiei,
Otonycteris hemprichi hemprichi,
Pipistrellus kuhli kuhli,
Tadarida teniotis rüppelli,
Tadarida aegyptiaca aegyptiaca

Gaisler, Madkour and Pelican (1972) reported on 236 specimens of bats which they collected from Egypt during April-May 1969. *Pipistrellus deserti* collected from Luxor in April 1969 is a new addition to the bat fauna of Egypt. Since it was not previously reported from that country. The authors distinguished two subspecies of *harwickei* namely, *Rhinopoma hardwickei sennaariense*, and *Rhinopoma hardwickei cystops*. *Plecotus auritus* of previous authors was referred to as *Plecotus austriacus christiei*. The subspecies of *Pipistrellus kuhii* was found to be *marginatus*. From the Zoogeographical point of view they found that most ol the bat species found in Egypt (76.2 %) are Palaearctic forms. The remaining (23.8 %) are Ethiopian species.

Watson, J. P. (1998). New distributional records for three microchiropteran bats (Vespertilionidae, Rhinolophidae) from the Free State Province, South Africa.

Distributional data on three microchiropteran species (*Myotis lesueuri* (Roberts, 1919), *Eptesicus hottentotus* (A. Smith, 1833) and *Rhinolophus denti* Thomas, 1904), recorded in the Free State Province for first time, are presented. In all three cases these comprise range extensions for the species.

Wickler, W. and U. Seibt (1976). Field studies on the African fruit bat *Epomophorus wahlbergi* (Sundevall), with special reference to male calling.

Social interactions, site attachment and group cohesion were studied in a free-living colony of *Epomophorus* fruit bats. Daily activities in an undisturbed colony were recorded. Special attention was paid to the peculiar calling behaviour of courting ?? during the night. Structure and repetition rate of their sounds were analyzed in the laboratory. A special mode of acoustic interaction was found and related to the observed spacing out of calling ?? By following feeding animals in the field and by analysis of their faeces we found that besides fruits they eat special leaves which afford steroidal sapogenins

---

Widmaier, E. P. and T. H. Kunz (1993). Basal, diurnal, and stress-induced levels of glucose and glucocorticoids in captive bats.

Plasma levels of glucocorticoids and glucose were measured in three species of fruit bats (Chiroptera) sampled from captive populations. Three species of Old World bats (*Pteropus vampyrus, P. Hypomelanus*, and *Rousettus aegyptiacus*) had plasma levels of glucose that were within the normal mammalian range (80-100 mg/dl), with no difference between males and females. All animals had detectable levels of one or both of the major glucocorticoids (cortisol and corticosterone) found in mammals. Steroid levels were highest in *P. hypomelanus* (cortisol: 1,269 ± 207 ng/ml; corticosterone; 590 ± 154 ng/ml) and lowest in *R. aegyptiacus* (corticosterone: 36 ± 4 ng/ml; cortisol not determined). Diurnal changes in these steroids and the effects of handling and restraint stress were further investigated in *P. hypomelanus*. Experimental animals were captured in their roost quarters, bled once by venupuncture within 3 min, placed singly into a small holding chamber for 50 - 60 min, and bled again. This procedure was performed at four different times over the course of 24 h with different groups of animals. Glucose was at a minimum just before and a maximum just after the period of food presentation. Cortisol levels remained relatively constant throughout the day-roosting period and significantly declined to their lowest level in the period following food presentation. As expected, the effects of handling and isolation caused a significant increase in both plasma cortisol and glucose levels. When individual *P. hypomelanus* were subjected to 3 h restraint stress in small plastic wire-mesh restraining devices, cortisol levels rose approximately 800 % by 2h, with the first significant increase at 20 min. Thus, effects of sampling time (time of day) on plasma levels of cortisol and glucose should be considered when designing field and laboratory studies in which hormones and other blood borne parameters are being measured. Handling and bleeding times that exceeded 3 min were associated with elevated plasma levels of cortisol and glucose above resting (unstressed) levels, suggesting that field and laboratory protocols should be designed to reduce or eliminate this problem. Finally, the exceptionally high levels of plasma corticoids in *P. hypomelanus*, and to a lesser extent in *P. vampyrus*, place these bats among the highest known circulating adrenal steroid levels of all mammals.

Wilson, V. J. (1975). Mammals of the Wankie National Park, Rhodesia.

The object of this Survey was to produce a check list of the mammals occurring in the Wankie National Park, Rhodesia, to show their distribution within the Park, to present information on the habitat in which they were found to occur, their habits, the time of the year at which the young are born, predation, food and feeding habirs and such other information as might contribute to their better understanding.

As far as is practical the data presented are based on material handled during the Survey and now in the collection of the National Museums & Monuments of Rhodesia, including fringing records made during the Botswana Mammal Survey (Smithers, 1971) along the western border of the Park or gleaned from a number of smaller collections made by staff members of the Museums from about 1950 onwards.

The first systematic collecting of small mammals in the Park was undertaken by Mr. P. Wright during 1967 and 1968. The writer has incorporated the data accompanying Wright's collection, amounting to 130 specimens, in the present work.

In addition a number of specimens have been collected within recent years by the Research Staff of the Department of National Parks and Wildlife Management which are now in the National Museum collection.

While the larger mammals occurring are well known, some having been studied in detail by members of the Department of National Parks, very little is known about the wide range of smaller species which constitute by far the larger proportion of the mammals which occur. Special emphasis was, therefore, placed on the collection of these smaller species, the information presented on the larger being based, in the main, on visual observations obtained during the course of the survey; from unpublished records in the files of the Department of National Parks; or from members of the Department stationed in the Park. Where culling operations had to be undertaken by the Departrnent , the opportunity was taken to recover material and data, otherwise no larger species were collected during the survey.

The field work continued over a two-year period from August 1969 to June 1971. During this time, in addition to the daily routine, 141 nights were spent in observation and collecting of small nocturnal species which cannot normally be contacted during daylight hours.

Throughout the text reference to "record" or "recorded" indicates that material is available to support the statement. Where visual records are used, owing to the doubts which so often arise with this type of record, they are clearly designated.

The Wankie National Park is the premier wildlife conservation area in Rhodesia. It is important, therefore, that we have a knowledge of the presence of species other than those which the visitor may see, for it is the whole spectrum of wildlife that is being conserved not just the species that are large and conspicuous.

It is hoped that this paper will draw attention to the wide range of smaller, yet none the less interesting, mammalian species which occur.

The survey was undertaken by the National Museums and Monuments of Rhodesia at the request of the Department of National Parks and Wildlife Management and I should like to acknowledge the co-operation and assistance I have had from the Department, in particular its research branch and the many field officers, who have assisted me to whom due acknowledgement is made in the appropriate section of this report.

Wingate, L. R. (1978). The life history and population dynamics of six species of bats inhibiting a deserted mine tunnel in Natal, South Africa.

The life history and of six of Microchiroptera (*Nycteris thebaica, Rhinolophus clivosus, R. simulator, Hipposideros caffer, Myotis tricolour* and *Miniopterus schreibersi* roosting in Doornhoek mine tunnel, 16 km east of Pietermaritzburg, was investigated for two years. Doornhoek is a maternity colony for *R. clivosus* and *M. tricolour*; a winter roost for *M. thebaica* and *R. simulator* females; while *R. simulator* males are present throughout the year. Up to 30 *H. caffer* are present sporadically, while a few *M. schreibersi* males are sometimes seen during mid-summer. The tunnel was also used as a transitory roost by *M. schreibersi* during late spring migratory movements.

Wolton, R. J., P. A. Arak, H. C. J. Godfray and R. P. Wilson (1982). Ecological and behavioural studies of the Megachiroptera at Mount Nimba, Liberia, with notes on Microchiroptera.

Au cours d'une étude des Mégachiroptères de la partie libérienne du Mont Nimba faite entre juillet et septembre 1978, on a capturé 1007 individus annartenant à neuf espéces, presque exclusivement à l'aide de filets japonais. On a échantillonné dans une grande variété d'habitats et d'altitudes différentes.

Des informations sur les Mégachiroptères sont maintenant à notre disposition pendant presque toute l'année au Mont Nimba; beaucoup de celles-ci sont présentées et analysées ici. Les donnees sur la reproduction et l'habitat ont été regroupées et discutées pour chaque espèce. Une attention particulière a été accordée aux mouvements des chauves-souris; *Nanonycteris veldkampi* migre au Nimba. Beaucoup de chauves-souris ont été marquées et relâchées, mais pour de nornbreuses stations le taux des recaptures est resté très bas. Les méthodes par lesquelles les ressources peuvent être réparties entre les espèces sont discutées.

Six espèces ont été gardées au laboratoire pour perrnettre des observations sur: (a) le comportement de préhension de la nourriture, (b) la consomrnation nocturne de nourriture et (c) les types d'activité. Pour plusieurs espèces la concordance entre les activités au laboratoire et dans la nature est bonne. Un intérêt particulier a été accordé au comportement du rare *Scotonycteris ophiodon*.

En supplément, 280 Microchiroptères appartenant à 10 espèces ont été capturés, 6 d'entre elles sont nouvelles pour le Liberia. De courtes notes sont données sur chacune.

Les notes taxonomiques pour les espèces qui présentent un intérêt particulier sont dues à Hill (1982).

A study of the Megachiroptera of Liberian Mount Nimba was made between July and September 1978. 1,007 fruit bats of nine were captured, almost exclusively with mist nets. A wide range of habitats and altitudes was sampled. Inforrnation on Megachiroptera is now available for nearly the whole year at Mount Nimba: much of this information is presented and analysed here. Breeding and habitat information has been assembled for each species. Attention has been given to bat movements; *Nanonycteris veldkampi* is a migrant to Nimba. Many bats were marked and released, but for a variety of reasons the recapture rate was very low. Methods by which resources may be partitioned amongst species are discussed.

Six species were kept in the laboratory to allow observations on (a) food handling and settling behaviour, (b) nightly food consurnption and through-put times, and © temporal patterns of activity to be made. Agreement between laboratory and field investigations of activity patterns is good for several species. Particular attention was paid to the behaviour of the rare *Scotonycteris ophiodon*.

In addition, 280 Microchiroptera of 16 species were caught. 6 of these are new to Liberia. Short notes have made for each.

Taxonomic notes for species of particular interest are provided by Hill (1982).

Woodman, N. (1993). The correct gender of mammalian generic names ending on *-otis*.

Mammalian generic names ending in *-otis* include *Cloetis, Cryptotis, Dolichotis, Laephotis, Macrotis, Myotis, Pharotis*, and *Phyllotis*. In the literature many of these names currently are associated with a combination of feminine, masculine, and neuter adjectival species names, in violation of the Code of Zoological Nomenclature. These generic names are feminine in gender, and the species names with which they are combined must be corrected appropriately.

Wroughton, R. C. (1906). On some mammals collected by Mr. Robin Kemp in S. Nigeria.

The Natural History Museum has recently received a small collection of mammals made by Mr. Robin Kemp in S. Nigeria. As the geographical region is an interesting one and the collection contains several forms sufficiently distinct to merit separate names, a short account of it may be acceptable.

Yalden, D. W. and M. J. Largen (1992). The endemic mammals of Ethiopia.

Species which are endemic to just one country add a particular interest to its fauna, and represent a special conservation requirement and concern.

Often, endemicity is associated with particular faunal regions or habitat types which, in continental areas at least, rarely coincide with our rather arbitrary political divisions, so that the countries which we recognize are rarely characterized by endemic species. Of the 247 mammals listed for Nigeria (Happold, 1987), probably none are endemic; even the most localized species occur also in Cameroon, and the majority are distributed throughout West Africa because their habitats are extensive east-west belts of vegetation [*Crocidura longipes* is at present only known from Nigeria]. Similarly, the Somali-arid zone, which is rich in endemics, covers much of Somalia, but extends into eastern Ethiopia and northern Kenya, while the Ruwenzori mountain area also contains numerous endemics (e.g. Hutterer, Van der Straeten & Verheyen, 1987), but includes parts of Zaire, Burundi, Uganda and Rwanda.

Ethiopia is one country where a major habitat block, having a high degree of endemicity in both fauna and flora, is contained within political boundaries. This account reviews the status and distribution of the 30 mammals which are currently believed to be endemic to Ethiopia

---

Yalden, D. W., M. J. Largen, D. Kock and J. C. Hillman (1996). Catalogue of the mammals of Ethiopia and Eritrea. 7. Revised checklist, zoogeography and conservation.

This review of the Ethiopian and Eritrean mammal fauna recognises provisional totals of 277 terrestrial and 11 marine species. The terrestrial fauna is dominated by savanna forms (47.2 % of the total), most of which are widespread but with significant numbers being derived from either the East African savannas or the sub-Saharan savanna belt. Deserticolous species (16.2 %) include many which are clearly associated with the Somali-arid zone. The 29 endemics are almost exclusively confined to the central plateaux at altitudes in excess of 1800 m and most are denizens of grassland or moorland habitats; few are forest species. Sylvicolous mammals are equally poorly represented amongst non-endemic forms (6.5 %) and it is concluded that Ethiopian forests have an impoverished fauna compared with those of Uganda and Zaire.

Conservation of wildlife, perennially starved of resources, has suffered greatly from neglect, poaching and destruction of property during the political crises of recent years. This situation is not irredeemable, given the return of peace and some measure of prosperity. If the region's actual and proposed national parks were to be fully established and effectively administrated, the have the potential to provide sanctuary for 210 (76 %) of the terrestrial mammals, including all but five of the endemic species (one shrew and four rodents). Amongst largers mammals which are unprotected, the apparently precarious situation of the Dibatag (*Ammodorcas clarkei*) gives particular cause for concern.

Yom-Tov, Y., M. Cohen and Z. Wollberg (1990). On the possible function of the anterior cornu in the Microchiroptera.

We measured the size of the ossified anterior cornu (the hyoid arch) of 10 species of microchiropteran bats belonging to 5 familes. We found that it is long and articulated in nasal emitters (Rhinolophidae, Hipposideridae and Nycteridae) and short and unarticulated in mouth emitters (Vespertilionidae and Molossidae). There is, apparently, also a positive relationship between the relative size of the "free" hyoid (the part not attached to the bulla) and the frequency of the bats' calls during searching (CF calls). We suggest that the function of the attachment of the hyoid bones to the bulla is to trigger the acoustic reflex. In addition, its function in nasal emitters is to raise the pharynx towards the nasopharynx during sound production.

La tail le de la corne antérieure ossifiée (l'arc hyoide) de 10 espèces de Microchiroptères appartenant à 5 familles a été mesurée. Ces mesures montrent qu'elle est longue et articulée chez les chauves-souris dont les émissions sont nasales (Rhinolophidae, Hipposideridae, Nycteridae), courte et non articulée chez celles dont les émissions sont buccales (Vespertilionidae, Molossidae). Il semble aussi

exister une relation positive entre la taille relative de la partie libre de l'hyoïde (la partie non attachee a la bulle) et la frequence des cris ernis par les chauves-souris au cours de leur chasse.

La fixation des os hyoïdes à la bulle pourrait avoir pour fonction de provoquer le réflexe acoustique. En plus, chez les chauves-souris qui ont une émission nasale, son role est d'elever le pharynx vers le nasopharynx au cours de la production de sons.

Yoon, M. H. and T. A. Uchida (1983a). Identification of recent bats belonging to the Vespertilionidae by the humeral characters.

With the finding of many humeri of fossil bats on the Akiyoshi-dai Plateau in recent years, the investigation was carried out to determine whether bats can be classified to the species level by the humeral characters alone. Using the humeri of 23 recent species and 4 subspecies belonging to 9 genera of the Vespertilionidae including 3 subfamilies, keys based on humeral characters to various taxa from subfamily to species enabled us to identify to the species level. Furthermore, not only the functional significance of the humeral morphology but also the adaptation of bats for flight within each taxon were discussed the higher the bat was in the degree of adaptation for flight, the lower th e DW/˙W ratio (the ratio of the distal epiphysis width to the proximal one) was. Consequently, it became clear that the ratio is one of the most important criteria exhibiting directly the degree of adaptation. Taking also the wing-type ratio (the third finger to the fifth one); into consideration the adaptabiliyv for flight in bats can be estimated more exactly.

Yoon, M. H. and T. A. Uchida (1983b). Identification of recent bats belonging to the Rhinolophidae by the humeral characters.

Humeral characters of eleven recent species and one subspecies belonging to three genera of the Rhinolophidae including two subfamilies were described. A key provides for their identification as well as the identification of the fossil bats found on the Akiyoshi-dai Plateau. Further, we discussed differences in the adaptability for flight of the bats not only within each taxon of the family but also between the phylogenetically less advanced Rhinolophiae and the more advanced Vespertilionidae, taking the value of DW /PW (the ratio of the distal epiphysis width to the proximal one) and the wing-type ratio (the third finger to the fifth one) into consideration. In consequense, as a rule, the more the bat was in a phylogenetically high position, the more the adaptability for flight was high.

Yoshiyuki, M. (1995). Two rare species of the bats *Trienopus rufus* and *Mormopterus jugularis* (Mammalia, Chiroptera) from Madagascar.

Madagascan red trident bat, *Triaenops rufus* of the Hipposideridae and Peter's wrinkled-lipped bat, *Mormopterus jugularis* of the Molossidae are the endemic species in Madagascar. The material of these species have been few until present time. The present paper describes the external, cranial and dental characters of these imperfectly known species.

Young, R. A. (1975). Aging criteria, pelage colour polymorphism and moulting in *Rhinolophus megaphyllus* (Chiroptera) from south-eastern Queensland, Australia.

Plusieurs colonies de *Rhinolophus megaphyllus* ont été étudiées et marquées dans le sud-est du Queensland de 1970 à 1974. Les classes d'âge ont stabilés d'après des critères de reproduction, de morphologie et d'usure des dents. Les males atteignent la maturité sexuelle au début de leur deuxième année d'âge et les femelles dans la deuxième ou troisième année. Dans le Queensland, *R. megaphyllus* est polytypique et présente un dimorphisme sexuel en rapport avec la teinte de son pelage. Plusieurs hypothèses sont envisages pour expliquer ce polytypisme de couleur et le dimorphisme sexuel chez cette espèce.

Several colonies of *Rhinolophus megaphyllus* in south-eastern Queensland were studied by means of a mark-recapture method during the years 1970 to 1974. Age classes were established using reproductive, morphological, and molar tooth wear criteria. Males become sexually mature early in their second year and females in their second or third year. In Queensland, *R. megaphyllus* is polymorphic and sexually dimorphic with respect to pelage colour. In Queensland, rufous, grey and intermediate pelage colour phases occur in many populations, but only the grey phase has been recorded in New South Wales and Victoria. The rufous and grey colour phases appear to be the result of two different genetically controlled pigmentary systems, with intermediate pelage colours attributable to moulting and aging of the new fur. Bats with grey pelage always remain grey, but the rufous morph undergoes colour changes that vary according to age and sex. An incomplete juvenile moult occurs in many individuals. Several hypotheses are suggested to explain pelage colour polymorphism and sexual dimorphism in *R. megaphyllus*.

Zeller, U. (1984). Zur Kenntniss der Stimmapparates des Epauletten-Flughunde (Epomophorini, Pteropodidae, Megachiroptera).

Courting males of *Epomopborus, Epomops* and *Hypsignathus* emitt loud calls attracting estrous females. Studied were the organs of vocalization of a male *Epomophorus labiatus* and of a female *Epomophorus anurus* as well as male and female *Epomops buettikoferi* and *Hypsignathus monstrosus* with special emphasis on the topography of the neck and of the thoracic cavity. Compared to other Megachiroptera the larynx of the three genera is enlarged, however, to a quite different degree. *Epomophorus* is close to the supposed ancestral condition. The larynx is situated in the caudal half of the neck. There is no sexual dimorphism in the size of the larynx. The males of *Hypsignathus monstrosus* possess a huge larynx reaching caudally to the diaphragm and nearly filling up the upper and middle mediastinum. The larynx of the females is much smaller reaching only behind the manubrium sterni. *Epomops* is intermediate between *Epomophorus* and *Hypsignathus*. The male's larynx is larger than that of *Epomophorus* and partially situated in the thoracic caviry. In *Hypsignathus* the larynx enters the thoracic cavity ventrally, but in *Epomops* dorsally of the heart. To reach the bifurcation the trachea is curved cranio-dorsally in *Hypsignathus*, but cranio-ventrally in *Epomops*. The different topography of the thoracic organs dernonstrates, that the enlargement of the larynx took place independently in the phylogeny of both genera. The extreme enlargement of the larynx in the male *Hypsignathus monstrosus* can be regarded as a result of intraspecific selection in correlation with the highly specialized lek mating behaviour of this species.

Zima, J. (1982). Chromosomal homology in the complements of bats of the family Vespertilionidae. II. G-band karyotypes of some *Myotis*, *Eptesicus* and *Pipistrellus* species.

G-bands observed in the chromosomes of *Myotis myotis, M. brandti, M. mystacinus, Eptesicus nilssoni, Pipistrellus savii, P. pipistrellus* and *P. kuhli* are described. The G-band patterns found in the karyotypes of the examined species of the genera. *Myotis* and *Eptesicus* are identical with those found in the congeneric North American species. The G-band pattern found in the chromosomal arms of *Pipistrellus* spp. Is identical with that in *Myotis* spp. In the karyotypes of the species of these two genera; the biarmed autosomes consist of arms showing an identical G-band pattern.

Zima, J. and I. Horácek (1985). Synopsis of karyotypes of Vespertilionid bats (Mammalia: Chiroptera).

In this paper, a brief synopsis of karyotypes of vespertilionid bats is presented according to literary data available to the authors. The variation in the karyotype on populational, specific and generic levels and karyotypic differences among genera, tribes and subfamilies are discussed. It is striking that chromosomal differentiation on the populational, specific and generic levels is almost entirely limited to tropical and subtropical forms. On the contrary, the karyotypes of forms inhabiting the Temperate Zone are very stable on the mentioned levels. The authors suppose that this phenomenon is connected with

differences in ecological and social structures of populations and with different evolutionary potential of vespertilionid bats inhabiting the tropics and the Temperate Zone.

Zima, J., M. Volleth, I. Horácek, J. Cerveny and M. Macholán (1992b). Karyotypes of two species of bats, *Otonycteris hemprichi* and *Pipistrellus tramatus* (Chiroptera, Vespertilionidae).

The karyotype of *Otonycteris hemprichi* from Central Asia is described, and the arm composition is determined by G-banding (2n = 30, NFa = 48; 1/2,3/4, 5/6, 19/7, 21/8, 12/9, 15/10, 14/11, 18/13, '16/17', 20, 22, 23, 24?, X, Y). The metacentric fusion autosomes are identical to those of European and certain American *Plecotus* and *Barbastella* species. Robertsonian polymorphism is ascertained in a small sample of specimens of *Pipistrellus tramatus* (2n = 35, 36; NFa = 48). The karyotype of *P.tramatus* from Vietnam is different from that of *P. coromandra* from India described previously.

Zimara, R. (1935). Säugetiere Westafrikas (gesammelt von Alfred Weidholz).

Die von Herrn Altred Weidholz auf drei Expeditionen in Westafrika gesammelten Säugetiere umfassen 53 Arten und Unterarten in 123 Exemplaren.

Für die Wissenschaft sind die gesammelten Dama-Gazellen von besonderem Interesse, die uns mit ihren Fundorten über ihre Verbreitung Aufschluß geben, so daß wir einerseits von einer von Heller neuaufgestellten Rasse, den bisher unbekannten Fundort, anderseits eine neue Rasse im Nigerdreieck feststellen konnten.

Auch liegen uns von einigen Arten, wie *Felis ocreata* Gmel., *Canis pallidus* Rüpp. sowie *Canis variegatus* Kretzschm., Serien vor, die uns zeigen, wie groß die Farbenvariabilität innerhalb ein und derselben Art bei gleichen Fundorten sein kann. Bei der Bearbeitung der drei Expeditionen habe ich die einschlägige Literatur sowie die bereits erschienenen Separatas, soweit sie mir bisher zugänglich waren, verwendet. Von der bei der Darnu-Cazellen-Arbeit
verwendeten habe ich am Schlusse dieser ein genaues Verzeichnis angeschlossen.

Nachfolgend behandle ich jede Expedition für sich und lasse am Schlusse der dritten Expedition eine Übersicht über die zoogeographische Verbreitung der Dama-Gazellen sowie einen aus dieser sich ergebenden Bestimmungsschlüssel folgen.

Die erste hier bearbeitete Expedition wurde im Jahre 1927 unternommen und beschränkte sich auf Französisch-Nigerien.

Die mitgebrachten Säugetiere umfassen 13 Arten und Unterarten in 42 Exemplaren. Es befindet sich für die Wissenschaft zwar keine neue Art darunter, doch wurde durch den mitgebrachten Dama-Gazellenbock der Fundort der von Neu mann beschriebenen *Gazella dama reducta* bekannt. Diese Subspezies wurde von Heller nach einem Menagerieexemplar mit unbekanntem Fundort aufgestellt. Ferner befinden sich auch die im allgemeinen Teil erwähnten Serien darunter.

Der Zustand der mitgebrachten Präparate ist bei dieser Expedition im allgemeinen zufriedenstellend. Besonders die hier in Betracht kommenden sind sehr gut erhalten.

Die in dieser Arbeit vorkommenden nachstehenden Fundorte befinden sich alle in Französisch-Nigerien, mehr oder weniger weit von Timbuku,
Archarnbault, Fort.
Bourem.
Gourma-Bahrus.
Macina.
Nia-Funke, am Niger.

Die zweite Expedition wurde im Jahre 1928 unternommen und auf das Tschadseegebiet ausgedehnt. Die gesammelten Säugetiere umfassen 23 Arten und Unterarten in 30 Exemplaren. Der Zustand der mitgebrachten Präparate ist weit besser als bei der vorjährigen Expedition.

Nachstehend folgt ein Verzeichnis von den in dieser Arbeit vorkommenden Fundorten.
Archambault (Fort), am oberen Scharifluß, südlich vom Tschadsee.
Bagirmiland am Schari, südöstlich von Tschadsee.
Bahr-Sara, Nebenfluß des Schari, südöstlich vom Tschadsee.
Bali, Nebenfluß des Ubangi.
Bossanoa, Steppengegend, nördliches Ubangiland.
Lai, am Logone, Ubangi-Schari-Territorium.
Logone, südöstlich des Tschadsees.
Impfondo, am rechten lbangiufer (gewissermaßen das Zentrum des Schlafkrankheits-Seuchenherdes).
Marrot, zirka 150 km südlich von Fort Archambault.
Melfi, Bagirmi, rechtes Schariufer.
Moissala, am Buhr-Sara.
Scharifluß.
Ubangitluß.

Die dritte Expedition wurde 1930 unternommen und erstreckte sich vom Senegal im Westen bis Timbuktu im Osten lind Hombori im Süden. Die mitgebrachten Säugetiere umfassen 20 Arten und Unterarten in 51 Exemplaren.

Sehr interessant sind die vier mitgebrachten Dama-Gazellenweibchen, die mit dem 1927 mitgebrachten Bock zusammen zu einer Revision der Arten und Unterarten Anlaß gegeben haben und zu einer neuen Abfassurig des Bestimmungsschlüssels fuhrten.

Auch bei dieser Expedition waren wie bei der 1928 unternommenen nur wenige Präparate schadhaft.

Nachstehend das Verzeichnis der in dieser Arbeit vorkommenden Fundorte.
Bonrem bei Timbuktu.
Dialokoto, Französisch-Garnbien.
Gourma-Rahrus, zwischen Kabara und Bourem.
Hombori, südlich von Timbuktu.
Kabara, Tirnbuktus Nigerhaten.
Kayes, am Senegal.
Nampala, südwestlich von Timbuktu .
Nia-Funke am Niger.
Niokolo-Koba, Nebenfluß des Gambia.
Nioro, nordöstlich von Kayes.
Tabadienke, Sumpfgebiet unweit des Niokolo-Koba.

Appendix 9: Gazetteers

In the following series of appendices, the gazetteer information of the various localities will be presented in different sequences and/or formats. The information on the coordinates was obtained from various sources, such as museum labels, museum catalogues, literature, and the internet (e.g. Falling Rain [http://www.fallingrain.com/world/], NGA GEOnet Names Server (GNS) [http://geonames.nga.mil/gns/html/], . . .). Information on divisions within a given country were obtained from maps available on:
http://www.maplibrary.org/stacks/Africa/index.php
http://www.nationsonline.org/oneworld/

Appendix 9a: Hierarchical Gazetteer

In this gazetteer, the data for the localities are presented in hierarchical order, starting with "Planet Earth", followed by the continent (Africa, Asia, Europe, . . .), the country, the state/province, the district, . . ., to the individual locality.

Appendix 9b: General Alphabetical Gazetteer

In this gazetteer the localities are presented in an alphabetical order, independent of any higher division.

"Bissao Senegambia"	Guinea-Bissau			
"British East Africa" (see Kenya)	"British East Africa"			
"Cape of Good Hope" (see also: "Kaap Goede Hoop")	South Africa			
"Congo"	"Congo"			
"Dahomey" (see Benin)	"Dahomey"			
"Egypt or Sudan"	"Egypt or Sudan"			
"Gabon"				
"Gabon"	"Gabon"			
"Haute Volta" (see Burkina Faso)	"Haute Volta"			
"Kaap Goede Hoop" (see "Cape of Good Hope")	South Africa			
"Laisam id., Isido district" (see Laisiamis)	Kenya		1° 36' 00" N 37° 48' 00" E	568 m
"Lobito Voay"	"Lobito Voay"			
"Mosambiro", but actually Usambiro	Tanzania			
"Onmeetbare" cave (see Bredasdorp)	South Africa		34° 32' 00" S 20° 02' 00" E	114 m
"piste de Lamtu"	Côte d'Ivoire			
"Planet Earth"				
"probably cate est"	Madagascar			
"Senegal or Mauritania"	"Senegal or Mauritania"			
"Tor Sinai" (see At Tur)	Egypt		28° 14' 14" N 33° 36' 50" E	17 m
(Courrier de) Humpata	Angola			
[Southern Africa]	[Southern Africa]			
‘Ayn az Zarqa’ (see also: Ain Az Zarqa, Ain Zérga)	Libya		31° 55' 27" N 12° 00' 52" E	
18 Montagnes (former) region (see Dix-Huit Monagnes (former) region)	Côte d'Ivoire			
2002 RAP Site 1	Guinea		8° 31' 52" N 8° 54' 21" W	1350 m
2002 RAP Site 2	Guinea		8° 31' 29" N 8° 56' 12" W	600 m
5th cataract of the Nile (see Fifth cataract of the Nile)	Sudan		18° 23' 00" N 33° 47' 00" E	
A'aliPC:UN|)	South Sudan			
Aandster, Farm 147 (see Farm Aandster 147)	Namibia		25° 23' 00" S 16° 04' 00" E	
Aasvogelrand-Oost, Farm 291 (see Farm Aasvogelrand-Oost 291), Vredefort	South Africa		26° 52' 00" S 27° 22' 00" E	
Aba	Congo (Democratic Republic of the)		3° 52' 00" N 30° 14' 00" E	890 m
Abadla	Algeria		31° 01' 00" N 2° 44' 00" W	588 m
Abala (see Abela)	Ethiopia		6° 42' 00" N 37° 53' 00" E	1481 m
Abanase (see Avetile)	Ghana		6° 32' 00" N 0° 14' 00" E	307 m
Abanasi (see Avetile)	Ghana		6° 32' 00" N 0° 14' 00" E	307 m
Abatupi river (see also: Amatupi river)	Congo (Democratic Republic of the)		0° 45' 00" N 29° 49' 00" E	700 m
Abaya, lake	Ethiopia		6° 15' 00" N 37° 55' 00" E	
Abaya, lake, West bank	Ethiopia		6° 13' 00" N 37° 49' 00" E	
Abaya, W coast lake	Ethiopia		6° 13' 00" N 37° 49' 00" E	
Abbasieh (see Abbassia)	Egypt		30° 04' 00" N 31° 17' 00" E	45 m
'Abbâsîya (see Abbassia)	Egypt		30° 04' 00" N 31° 17' 00" E	45 m
'Abbasiyah (see Abbassia)	Egypt		30° 04' 00" N 31° 17' 00" E	45 m
'Abbâsîyeh (see Abbassia)	Egypt		30° 04' 00" N 31° 17' 00" E	45 m
Abbassia (see also: Abbasieh, 'Abbâsîya, 'Abbasiyah, 'Abbâsîyeh, Al 'Abbasiyah, El 'Abbasiya)	Egypt		30° 04' 00" N 31° 17' 00" E	45 m
Abbotsbury, 27.5 km N, 6 km E Graaff-Reinet (see also: Graaff-Reinet, 27.5 km N, 6 km E)	South Africa		32° 00' 14" S 24° 31' 08" E	1300 m
Abbotsford	South Africa		32° 57' 45" S 27° 55' 00" E	20 m
Abe Baily Nature Reserve (see Farm Wonderfontein 103IQ), Caltonville	South Africa		26° 18' 00" S 27° 24' 00" E	
Abela (see also: Abala, Abella)	Ethiopia		6° 42' 00" N 37° 53' 00" E	1481 m
Abella (see Abela)	Ethiopia		6° 42' 00" N 37° 53' 00" E	1481 m
Abengourou	Côte d'Ivoire		6° 43' 47" N 3° 29' 47" W	204 m
Abengourou department	Côte d'Ivoire	ca.	6° 35' 00" N 3° 25' 00" W	
Abenguru (see Abenguru) (see also: Abenguru)	Côte d'Ivoire		6° 43' 47" N 3° 29' 47" W	204 m
Abeokuta	Nigeria		7° 09' 00" N 3° 21' 00" E	66 m
Abercorn (see Mbala)	Zambia		8° 50' 00" S 31° 23' 00" E	1656 m
Aberdare mountains (see also: Aberdare range, Aberdares, Osufuko Lerego)	Kenya		0° 23' 08" S 36° 38' 08" E	
Aberdare range (see Aberdare mountains)	Kenya		0° 23' 08" S 36° 38' 08" E	
Aberdares (see Aberdare mountains)	Kenya		0° 23' 08" S 36° 38' 08" E	
Aberdeen district (see Cacadu district)	South Africa			
Aberdeen Village, 14 km from Freetown (see also: Freetown, 14 km from)	Sierra Leone		8° 29' 33" N 13° 17' 04" W	0 m
Abes (see Gabès), Qabis province	Tunisia		33° 53' 00" N 10° 07' 00" E	0 m
Abetife (see Abetifi)	Ghana		6° 40' 00" N 0° 45' 00" W	552 m

Abetifi	Ghana		6° 40' 00" N 0° 45' 00" W	552 m
(see also: Abetife)				
Abia (see Mateanong)	Lesotho		29° 21' 00" S 29° 13' 00" E	
Abialosa river	Congo (Democratic Republic of the)		0° 42' 00" N 29° 41' 00" E	800 m
Abiata, lake (see Abiyata Hayk')	Ethiopia	ca.	7° 37' 00" N 38° 36' 00" E	
Abiata, lake, E coast	Ethiopia		7° 34' 00" N 38° 39' 00" E	
Abidan (see Abidjan)	Côte d'Ivoire		5° 20' 28" N 4° 01' 41" W	74 m
Abidjan	Côte d'Ivoire		5° 20' 28" N 4° 01' 41" W	74 m
(see also: Abidan)				
Abidjan department	Côte d'Ivoire			
Abidjan district	Côte d'Ivoire			
Abidjan Plateau	Côte d'Ivoire			
Abidjan region	Côte d'Ivoire			
Abidjan, 15 km NW	Côte d'Ivoire	ca.	5° 21' 00" N 4° 05' 00" W	
Abidjan, 17 km W	Côte d'Ivoire	ca.	5° 21' 00" N 4° 05' 00" W	
Abijata, lake (see Abiyata Hayk')	Ethiopia	ca.	7° 37' 00" N 38° 36' 00" E	
Abila (see Jebel Moussa)	Morocco		35° 53' 52" N 5° 24' 44" W	
Abim district	Uganda			
Abimva	Congo (Democratic Republic of the)		3° 09' 00" N 29° 46' 00" E	1100 m
Abiy No. 3, 0.5 km S, near Gambela	Ethiopia	ca.	8° 12' 00" N 35° 20' 00" E	1364 m
Abiyacula, near Lalibela	Ethiopia	ca.	12° 02' 00" N 39° 03' 00" E	
Abiyata Hayk'	Ethiopia	ca.	7° 37' 00" N 38° 36' 00" E	
(see also: Abiata, lake, Abijata, lake, Hora Abaita, Hora Abgiata , Hora Abgiate , Hora Abyata, Lago Abeita , Lake Abiata, Lake Abijata, Lake Abiyata)				
Abo, Lower Niger river	Nigeria			
Abodomasi (see Bodomasi), 58 km from Ksi	Ghana		6° 53' 37" N 1° 15' 19" W	369 m
Abokobi	Ghana		5° 44' 00" N 0° 12' 00" W	70 m
Abol (see Oboul), on Ghilo river	Ethiopia		7° 42' 00" N 34° 06' 00" E	313 m
Abonisi, Aã'Isoc	Equatorial Guinea			
Abonnema	Nigeria			
Abore	Ethiopia		4° 40' 00" N 36° 45' 00" E	
Abore, lake	Ethiopia		4° 40' 00" N 36° 45' 00" E	
(see also: Lake Abore)				
Aboulou, 8 km SW Akoabas	Cameroon		2° 18' 00" N 12° 04' 00" E	572 m
Abu Doleb (see Dulayb), Bahr-el-Abiad, Malakal district	South Sudan		9° 21' 35" N 31° 36' 03" E	276 m
Abu Ghaleb, 2 km N	Egypt	ca.	30° 16' 00" N 30° 56' 00" E	ca. 25 m
(see also: Abu Ghalib, 2 km N)				
Abu Ghalib, 2 km N (see Abu Ghaleb, 2 km N)	Egypt	ca.	30° 16' 00" N 30° 56' 00" E	ca. 25 m
Abu Kika	South Sudan	ca.	6° 55' 00" N 31° 00' 00" E	
(see also: Abukika)				
Abu Ra??al (see Bi'r Abu Ri?al)	Egypt		25° 00' 00" N 33° 28' 00" E	
Abu Rauwâsh (see Abu Rawwash), 5 mi NW Giza	Egypt		30° 02' 44" N 31° 05' 33" E	6 m
Abu Rawash (see Abu Rawwash), 5 mi NW Giza	Egypt		30° 02' 44" N 31° 05' 33" E	6 m
Abu Rawash, 2 km N	Egypt	ca.	30° 02' 00" N 31° 05' 00" E	
Abu Rawash, 5 km W	Egypt	ca.	30° 02' 00" N 31° 05' 00" E	
Abu Rawwash, 5 mi NW Giza	Egypt		30° 02' 44" N 31° 05' 33" E	6 m
(see also: Abu Rauwâsh, Abu Rawash, Abu Roash, Abu Ruwash, Aburoash, Ezbet Abu Rauwâsh, Ezbet Abu Roash, Giza, 5 mi [=8 km] NW)				
Abu Rawwash, 2 km N	Egypt	ca.	30° 02' 00" N 31° 05' 00" E	
Abu Rawwash, 5 km W	Egypt	ca.	30° 02' 00" N 31° 05' 00" E	
Abu Rihal, W of, 90 km E of Idfn Shalatein	Egypt	ca.	25° 00' 00" N 33° 28' 00" E	
Abu Roash (see Abu Rawwash), 5 mi NW Giza	Egypt		30° 02' 44" N 31° 05' 33" E	6 m
Abu Ruwash (see Abu Rawwash), 5 mi NW Giza	Egypt		30° 02' 44" N 31° 05' 33" E	6 m
Abu Sa'fa Springs (see Abu Sa'fah, Bi'r)	Egypt		23° 18' 24" N 34° 47' 51" E	
Abu Sa'fa, Bir (see Abu Sa'fah, Bi'r)	Egypt		23° 18' 24" N 34° 47' 51" E	
Abu Sa'fah, Bi'r	Egypt		23° 18' 24" N 34° 47' 51" E	
(see also: Abu Sa'fa Springs, Abu Sa'fa, Bir, Abu Saafa, Bir, Bir Abu Saafa)				
Abu Saafa, Bir (see Abu Sa'fah, Bi'r)	Egypt		23° 18' 24" N 34° 47' 51" E	
Abu Simbel (see Abu Sunbul)	Egypt		22° 22' 00" N 31° 38' 00" E	193 m
Abu Simbel (see Abu Sunbul)	Egypt		22° 22' 00" N 31° 38' 00" E	193 m
Abu Simbil (see Abu Sunbul)	Egypt		22° 22' 00" N 31° 38' 00" E	193 m
Abu Sinbil (see Abu Sunbul)	Egypt		22° 22' 00" N 31° 38' 00" E	193 m
Abu Sir	Egypt		29° 53' 00" N 31° 13' 00" E	73 m
Abu Sir	Egypt		29° 53' 00" N 31° 13' 00" E	73 m
Abu Sir cave, W bank, by rock at cave, ca 15 m above the river	Sudan	ca.	29° 53' 00" N 31° 13' 00" E	
Abu Sumbul (see Abu Sunbul)	Egypt		22° 22' 00" N 31° 38' 00" E	193 m

Abu Sunbul (see also: Abu Simbel, Abu Simbel, Abu Simbil, Abu Sinbil, Abu Sumbul)	Egypt		22° 22' 00" N 31° 38' 00" E	193 m
Abu Tiga Forest Reserve	Sudan		12° 46' 00" N 34° 09' 00" E	
Abu Zabad (see also: Abu Zawr)	Sudan		12° 21' 00" N 29° 15' 00" E	
Abu Zanimah, 18 km N, 4 km from sea (see also: Abu Zenima, 18 km N, Abu Zuneim, 18 km N, Aby Zniema, 18 km N)	Egypt		29° 02' 59" N 33° 06' 13" E	0 m
Abu Zawr (see Abu Zabad)	Sudan		12° 21' 00" N 29° 15' 00" E	
Abu Zayd (see also: Abu Zeid, Abu Zeid Wad Umm Balli, Abu Zeit)	Sudan		15° 04' 18" N 33° 23' 30" E	
Abu Zeid (see Abu Zayd)	Sudan		15° 04' 18" N 33° 23' 30" E	
Abu Zeid Wad Umm Balli (see Abu Zayd)	Sudan		15° 04' 18" N 33° 23' 30" E	
Abu Zeit (see Abu Zayd)	Sudan		15° 04' 18" N 33° 23' 30" E	
Abu Zenima, 18 km N (see Abu Zanimah, 18 km N)	Egypt		29° 02' 59" N 33° 06' 13" E	0 m
Abu Zor	Sudan		12° 22' 00" N 34° 22' 00" E	450 m
Abu Zuneim, 18 km N (see Abu Zanimah, 18 km N)	Egypt		29° 02' 59" N 33° 06' 13" E	0 m
Abuja	Nigeria		9° 05' 00" N 7° 32' 00" E	777 m
Abuja Federal Captital Territory	Nigeria			
AbujaPC:FC|) (see also: Abuja state |PC:FC|)	Nigeria			
Abukika (see Abu Kika)	South Sudan		6° 55' 00" N 31° 00' 00" E	
Abuko Nature Reserve	The Gambia		13° 23' 29" N 16° 39' 09" W	
Abulschi	Nigeria			
Abuna Iosef, monte (see Abune Yosef, mountain)	Ethiopia		12° 09' 00" N 39° 11' 00" E	
Abuna Josef (see Abune Yosef, mountain)	Ethiopia		12° 09' 00" N 39° 11' 00" E	
Abuna Yosef (see Abune Yosef, mountain)	Ethiopia		12° 09' 00" N 39° 11' 00" E	
Abuna-Josef, monte (see Abune Yosef, mountain)	Ethiopia		12° 09' 00" N 39° 11' 00" E	
Abune Yosef (see also: Abune Yosef)	Ethiopia		12° 07' 00" N 39° 10' 00" E	3842 m
Abune Yosef (see Abune Yosef)	Ethiopia		12° 07' 00" N 39° 10' 00" E	3842 m
Abune Yosef, mount (see Abune Yosef, mountain)	Ethiopia		12° 09' 00" N 39° 11' 00" E	
Abune Yosef, mountain, near Lalibela (see also: Abuna Iosef, monte, Abuna Josef, Abuna Yosef, Abuna-Josef, monte, Abune Yosef, mount, Guli Ba Amba, Monte Abuna Iosef, Monte Abuna-Josef, Mount Abuna Yosef, Mount Abune Yosef)	Ethiopia		12° 09' 00" N 39° 11' 00" E	
Abu-Rawash and the pyramids, between	Egypt	ca.	30° 02' 00" N 31° 05' 00" E	
Aburi (see also: Aburi)	Ghana		5° 51' 00" N 0° 11' 00" W	300 m
Aburi Botanic Garden	Ghana		5° 51' 00" N 0° 11' 00" W	300 m
Aburi hills, 10 mi [=16 km] N Legon (see also: Legon, 10 mi [=16 km] N)	Ghana		5° 46' 59" N 0° 10' 59" W	
Aburoash (see Abu Rawwash)	Egypt		30° 02' 44" N 31° 05' 33" E	6 m
Aby Zniema, 18 km N (see Abu Zanimah, 18 km N)	Egypt		29° 02' 59" N 33° 06' 13" E	0 m
Abyla (see Jebel Moussa)	Morocco		35° 53' 52" N 5° 24' 44" W	
Abysse de Swanepoel II, near Kambove	Congo (Democratic Republic of the)		10° 51' 00" S 26° 41' 00" E	ca. 1350 m
Abyssinia (see also: Abyssinien)	Ethiopia			
Abyssinien (see Abyssinia)	Ethiopia			
Accra (see also: Akra)	Ghana		5° 33' 00" N 0° 13' 00" W	98 m
Accra, 9 mi [=14.5 km] NE	Ghana		5° 33' 00" N 0° 15' 00" W	
Accra, 9 mi [=14.5 km] NNE (see Legon)	Ghana		5° 39' 00" N 0° 11' 00" W	30 m
Accra-Kade Road	Ghana		5° 33' 00" N 0° 15' 00" W	
Achimota, between Legon and Accra (see also: Achimota College, Achimota Village, Archimota)	Ghana		5° 37' 00" N 0° 14' 00" W	82 m
Achimota College (see Achimota)	Ghana		5° 37' 00" N 0° 14' 00" W	82 m
Achimota Forest Reserve	Ghana		5° 40' 01" N 0° 12' 00" W	
Achimota Village (see Achimota)	Ghana		5° 37' 00" N 0° 14' 00" W	82 m
Acholi mountains (see also: Jebel Choli)	South Sudan		4° 04' 55" N 32° 35' 54" E	
Achwerase, Aburi, near, concrete culvert in a forest	Ghana		5° 39' 00" N 0° 11' 00" W	
Acoaesakira, 3 km on Nsork to Akum road (see also: Acoesakira, Akosakira, Nsork to Akum road, km 3)	Equatorial Guinea		1° 06' 32" N 11° 15' 27" E	511 m
Acoc and Micomeseng, between	Equatorial Guinea	ca.	2° 05' 00" N 10° 54' 00" E	
Acocseng and Aconibe, between (see Nzas cave)	Equatorial Guinea	ca.	1° 18' 35" N 10° 58' 17" E	
Acoesakira (see Acoaesakira), 3 km on Nsork to Akom road	Equatorial Guinea		1° 06' 32" N 11° 15' 27" E	511 m
Acornhoek, 11 km N Newinngton (see also: Newinngton, 11 km N)	South Africa		24° 35' 00" S 31° 05' 00" E	594 m

ACWA (see Adventist College of West Africa (ACWA)), 1.6 km SE Ilishan-Remo	Nigeria		6° 53' 42" N 3° 42' 51" E	76 m
Ad Dalanj (see Dilling)	Sudan		12° 03' 00" N 29° 39' 00" E	687 m
Ad Daqahliyaj governorate (see also: Al Daqahliyah governorate |PC:DQ|)	Egypt			
Ad Duwayrat (see Douirat)	Tunisia		32° 52' 00" N 10° 17' 00" E	460 m
Ada Estates, Muzarabani	Zimbabwe		16° 22' 30" S 31° 07' 30" E	
Adaba (see Adwa)	Ethiopia		14° 10' 00" N 38° 54' 00" E	1882 m
Adamaoua plateau	Cameroon			
Adamaoua region	Cameroon			
Adamawa state	Nigeria			
Adams College, 22 mi [=35 km] NE Durban (see also: Adams M.S., Adams Mission, Adams Mission Station, Durban, 22 mi [=35 km] NE)	South Africa		30° 02' 00" S 30° 49' 00" E	156 m
Adams M.S. (see Adams College), 22 mi [=35 km] NE Durban	South Africa		30° 02' 00" S 30° 49' 00" E	156 m
Adams Mission (see Adams College), 22 mi [=35 km] NE Durban	South Africa		30° 02' 00" S 30° 49' 00" E	156 m
Adams Mission Station (see Adams College), 22 mi [=35 km] NE Durban	South Africa		30° 02' 00" S 30° 49' 00" E	156 m
Adamso	Ghana		6° 04' 00" N 1° 47' 00" W	139 m
Adanka village, near, 4.5 km N Apesokubi (see also: Apesokubi, 4.5 km N, Apesokubi, 4.5 km N)	Ghana		7° 38' 00" N 0° 23' 00" E	
Adawaso (see Adawso)	Ghana		5° 57' 00" N 0° 13' 00" W	148 m
Adawaso, 1 mi [=1.6 km] E	Ghana	ca.	5° 57' 00" N 0° 13' 00" W	
Adawaso, 1.9 mi [=3 km] NW	Ghana	ca.	5° 57' 00" N 0° 13' 00" W	
Adawaso, 4.7 mi [=7.5 km] E	Ghana	ca.	5° 57' 00" N 0° 13' 00" W
