Chaerephon ansorgei (Thomas, 1913):
NHMZ: 60018. - **TM:** 38275, 38841, 48545, 48600.
Chaerephon bivittatus (Heuglin, 1861):
NHMZ: 60017.
Chaerephon pumilus (Cretzschmar, 1826):
AMNH: 257461, 257471. - **NHMZ:** 59436, 84109. - **TM:** 36509, 36510, 36511, 36512, 36610, 36931, 37072, 37119, 38284, 38286, 39508, 48530, 48531, 48532, 48581.
Epomophorus crypturus Peters, 1852:
NHMZ: 84099, 84100. - **TM:** 48605, 48606, 48607.
Epomophorus wahlbergi (Sundevall, 1846):
CM: 69662, 69663, 69664. - **KM:** 31373. - **KNP:** 145. - **NMB:** 2823. - **TM:** 29833, 29834, 29840, 29841, 29842, 29867, 29868, 29869, 30540, 30542, 34243, 48561, 48562, 48563, 48585, 48604.
Eptesicus hottentotus (A. Smith, 1833):
CM: 93182. - **KNP:** 134. - **TM:** 34239, 36111, 36805, 36806, 36857, 36879, 38167.
Glauconycteris variegata (Tomes, 1861):
AMNH: 257397. - **NHMZ:** 60518. - **TM:** 34261, 36538, 36539, 37845, 48494, 48495, 48496.
Hipposideros caffer (Sundevall, 1846):
AMNH: 257175, 257176, 257177, 257186. - **KM:** 31375. - **NHMZ:** 84174, 84181, 84227. - **TM:** 30546, 34182, 36962, 36963, 36964, 36965, 36966, 36967, 36969, 38264, 39468, 48567, 48583, 48584, 48586.
Kerivoula argentata Tomes, 1861:
TM: 29839.
Macronycteris vittatus (Peters, 1852):
KNP: 167. - **TM:** 36473, 38882, 39497, 42004.
Miniopterus natalensis (A. Smith, 1833):
NHMZ: 84194. - **TM:** 29820, 36980, 36981, 37014, 37015, 37016.
Mops (Mops) condylurus (A. Smith, 1833):
KNP: 139. - **NHMZ:** 84141. - **TM:** 34348, 34349, 36868, 41998, 48511, 48512, 48513, 48514, 48541, 48543, 48544, 48601, 48602, 48603.
Mops (Mops) midas (Sundevall, 1843):
NHMZ: 33441, 59840, 59864, 59871, 59872, 59873, 59874, 59875, 59876, 59877, 59878, 59879, 59880, 59881, 59882, 59883. - **TM:** 36613, 39500.
Myotis bocagii (Peters, 1870):
TM: 34242.
Myotis bocagii bocagii (Peters, 1870):
AMNH: 257357.
Myotis tricolor (Temminck, 1832):
TM: 34241, 36784, 36867, 37846, 48507.
Neoromicia capensis (A. Smith, 1829):
AMNH: 257377. - **CM:** 69703, 69704, 69705, 98534, 98535, 98536. - **KNP:** 140. - **NHMZ:** 58903, 60476. - **TM:** 30485, 30486, 30489, 30535, 30536, 34225, 36123, 36124, 36125, 36431, 36436, 36437, 36439, 36536, 36560, 36561, 36615, 36618, 36629, 36630, 36632, 36707, 36708, 36710, 36713, 36758, 36760, 36796, 36839, 36864, 36909, 36919, 36920, 36921, 36929, 36930, 37000, 37032, 37035, 37036, 37037, 37068, 37081, 37120, 37226, 37227, 37231, 37437, 37811, 37819, 37823, 37862, 37921, 37922, 37927, 37930, 37931, 37932, 37933, 37941, 38164, 38168, 38285, 39460, 39496, 39507, 47135, 48570, 48598.
Neoromicia helios (Heller, 1912):

SNP: CHIR. KNP-UP-921. - **TM:** 48535, 48536, 48537, 48578, 48587.
Neoromicia nana (Peters, 1852):
KNP: 179. - **NHMZ:** 84138, 84192. - **TM:** 29854, 34212, 34219, 34220, 34221, 34222, 34223, 34237, 34238, 36117, 36120, 36647, 36709, 37812, 37816, 37817, 37818, 37820, 37822, 37866, 37919, 38604, 38605, 39463, 41999, 43862, 43863, 47143, 48505, 48508, 48509, 48533, 48534, 48571, 48572, 48573, 48597.
Neoromicia somalica (Thomas, 1901):
AMNH: 257395.
Neoromicia stanleyi Goodman, Kearney, Ratsimbazafy and Hassanin, 2017:
CM: 93186, 98549. - **TM:** 34185, 34186, 34240, 34263, 36778, 37923, 37924, 37929, 37943, 37944, 37945, 38132, 38599, 39506.
Neoromicia zuluensis (Roberts, 1924):
CM: 98545, 98546, 98547. - **NHMZ:** 84193. - **TM:** 30534, 34213, 36118, 36631, 36705, 36706, 36759, 36846, 37001, 37017, 37436, 37863, 38169, 38603, 47139, 47142, 48506, 48596.
Nycteris thebaica E. Geoffroy St.-Hilaire, 1818:
AMNH: 257156. - **NHMZ:** 84225. - **TM:** 34191, 34192, 34236, 36100, 36637, 36970, 37913, 47151.
Nycteris woodi K. Andersen, 1914:
TM: 29857, 29894, 29898.
Nycticeinops schlieffenii (Peters, 1859):
AMNH: 257405, 257406, 257407, 257408. - **KNP:** 143, 178. - **NHMZ:** 60475, 84095. - **TM:** 30476, 30477, 30478, 30479, 30480, 30481, 30482, 30483, 30484, 30500, 30501, 30502, 30503, 30515, 30526, 30537, 30538, 30539, 30541, 34171, 34172, 34173, 34174, 34176, 34177, 34178, 34179, 34180, 34187, 34188, 34189, 34194, 34195, 34196, 34198, 34199, 34211, 34224, 34226, 34227, 35842, 36112, 36113, 36114, 36115, 36116, 36424, 36425, 36438, 36442, 36443, 36451, 36452, 36453, 36454, 36455, 36456, 36457, 36531, 36532, 36533, 36534, 36535, 36558, 36559, 36607, 36614, 36617, 36633, 36634, 36635, 36638, 36639, 36640, 36641, 36642, 36737, 36738, 36739, 36740, 36741, 36742, 36743, 36744, 36745, 36746, 36747, 36819, 36820, 36821, 36840, 36841, 36842, 36843, 36844, 36845, 36907, 36908, 36922, 36923, 36924, 36925, 36933, 36946, 36947, 36948, 37002, 37003, 37004, 37005, 37006, 37007, 37065, 37066, 37067, 37077, 37078, 37079, 37080, 37085, 37086, 37087, 37121, 37122, 37123, 37125, 37126, 37127, 37128, 37129, 37130, 37131, 37132, 37224, 37225, 37232, 37268, 37269, 37270, 37271, 37280, 37429, 37430, 37431, 37432, 37433, 37434, 37435, 37657, 37658, 37659, 37660, 37722, 37723, 37724, 37725, 37726, 37727, 37728, 37729, 37730, 38145, 38146, 38147, 38148, 38152, 38156, 38157, 38158, 38159, 38160, 38161, 38715, 38835, 38836, 38837, 38840, 39461, 39462, 42000, 42001, 42005, 47136, 47138, 47140, 47141, 47145, 48498, 48500, 48501, 48502, 48546, 48547, 48548, 48549, 48550, 48551, 48568, 48569.
Pipistrellus hesperidus (Temminck, 1840):
KNP: 144. - **TM:** 36619, 36783.
Pipistrellus rueppellii (Fischer, 1829):
CM: 93189. - **NHMZ:** 60463, 60464. - **TM:** 36122, 36609, 36934, 37034, 37074, 37908, 38279, 48599.
Pipistrellus rusticus (Tomes, 1861):
AMNH: 257373, 257393, 257394. - **KNP:** 142, 144A. - **NHMZ:** 84078, 84137. - **TM:** 30490, 30491, 30492, 30493, 30494, 30495, 30496, 30497, 30498, 30512, 30513, 30514, 30527, 34175, 34190, 34197, 34200, 34218, 34264, 36119, 36121, 36427, 36428, 36429, 36440, 36441, 36711, 36712, 36714, 36775, 36776, 36777, 36782, 36790, 36792, 36793, 36794, 36795, 36813, 36814, 36815, 36816, 36817, 36818, 36838, 36982, 36983, 37075, 37076, 37661, 37809, 37810, 37821, 37847, 37860, 37861, 37920, 37925, 37926, 37928, 38606, 38716, 39501, 39502, 39911, 39912, 39913, 47137, 47144, 48523, 48524, 48525, 48526, 48527, 48579.
Rhinolophus Lacépède, 1799:
TM: 40523.
Rhinolophus blasii Peters, 1867:
TM: 37039.
Rhinolophus clivosus Cretzschmar, 1828:
TM: 36968.
Rhinolophus darlingi K. Andersen, 1905:
NHMZ: 58388, 84092. - **TM:** 36972, 42008, 42009.
Rhinolophus fumigatus Rüppell, 1842:
KNP: 141, 149, 86. - **TM:** 30472, 34262, 36608, 36611, 36789, 36812, 36878, 36935, 36936, 40833, 40834, 40835, 41726, 48510, 48529.
Rhinolophus lobatus Peters, 1852:
TM: 36866, 38131, 48582.
Rhinolophus rhodesiae Roberts, 1946:
KNP: 135, 166. - **TM:** 34210, 34265, 36101, 36937, 36938, 36971, 37040.

Appendix 2j: Accumulation curves

In this appendix, we illustrate the accumulation of species and specimens over the years in the various museum collections.

The first graph shows the details for all of the African bats recorded in our database, as far as their collection dates were available to us. The subsequent graphs show the details for the various museums, which are identified by their acronyms. For details on these acronyms see the appropriate appendix.

On each of the graphs, two lines are given:
The blue, uninterrupted line represents the species accumulation curve, indicating when a species was first collected for the specific museum.
The red, dotted line represents the specimens accumulation curve, indicating the years when specimens (identified to at least species level) were collected.

Appendix 3: Synonyms

Appendix 3a: Synonyms by Name

This appendix contains all of the synonyms found in the literature (excluding new name combinations and lapsi calami). For each of these synonyms the current name is included to be able to link the name to the information in the main text and the other appendices.

Original Name	**Current Name**
? anjouanensis Dorst, 1960	*Myotis anjouanensis* (Dorst, 1960)
?Necromantis fragmentum Ravel, 2016	*Necromantis fragmentum* (Ravel, 2016)
?Palaeophyllophora tunisiensis Ravel, 2016	*Palaeophyllophora tunisiensis* (Ravel, 2016)
?Vespertiliavus aenigma Ravel, 2016	*Vespertiliavus aenigma* (Ravel, 2016)
[Epomophorus (]Nanonycteris[)] Matschie, 1899	*Nanonycteris* Matschie, 1899
[Epomophorus macrocephalus] var. angolensis Gray, 1870	*Epomophorus angolensis* Gray, 1870
[Epomophorus macrocephalus] var. unicolor Gray, 1870	*Epomophorus wahlbergi* (Sundevall, 1846)
[Nyctinomus (Nyctinomus) pumilus] Var. Major Trouessart, 1897	*Chaerephon major* (Trouessart, 1897)
[Pipistrellus Kühli] latastei Laurent, 1937	*Pipistrellus kuhlii* (Kuhl, 1817)
[Rhinolophus hipposideros] escaleræ K. Andersen, 1918	*Rhinolophus hipposideros* (Bechstein, 1800)
[Triaenops] furinea Tate, 1941	*Paratriaenops pauliani* (Goodman and Ranivo, 2008)
[Vesperugo (Vesperus) serotinus] Var. Gabonensis Trouessart, 1897	*Eptesicus isabellinus* (Temminck, 1840)
[Xantharpyia (]Myonycteris[)] Matschie, 1899	*Myonycteris* Matschie, 1899
acrotis G.M. Allen, 1914	*Rhinolophus fumigatus* Rüppell, 1842
Adelonycteris H. Allen, 1892	*Eptesicus* Rafinesque, 1820
Aegyptonycteridae Simmons, Seiffert and Gunnell, 2016	*AEGYPTONYCTERIDAE* Simmons, Seiffert and Gunnell, 2016
Aegyptonycteris Simmons, Seiffert and Gunnell, 2016	*Aegyptonycteris* Simmons, Seiffert and Gunnell, 2016
Aegyptonycteris knightae Simmons, Seiffert and Gunnell, 2016	*Aegyptonycteris knightae* Simmons, Seiffert and Gunnell, 2016
Aëorestes Fitzinger, 1870	*Myotis* Kaup, 1829
Afropipistrellus Thorn, Kock and Cuisin, 2007	*Pipistrellus* Kaup, 1829
Afropterus Lavocat, 1961	*Megaderma* E. Geoffroy St.-Hilaire, 1810
Afropterus gigas Lavocat, 1961	*Megaderma gaillardi* (Trouessart, 1898)
Afropterus gigas Lavocat, 1961	*Megaderma gigas* (Lavocat, 1961)
Allomops J.A. Allen, 1917	*Mops (Mops)* Lesson, 1842
Alobus Peters, 1868	*Pipistrellus* Kaup, 1829
Amblyotus Kolenati, 1858	*Eptesicus* Rafinesque, 1820
Anamygdon Troughton, 1929	*Myotis* Kaup, 1829
ANIMALIVORA Gill, 1872	*VESPERTILIONIFORMI* Van Cakenberghe, Kearney and Seamark, 2007
Aquias Gray, 1847	*Rhinolophus* Lacépède, 1799
Aristippe Kolenati, 1863	*Eptesicus* Rafinesque, 1820
Asellia Gray, 1838	*Asellia* Gray, 1838
Asellia patrizii de Beaux, 1931	*Asellia patrizii* de Beaux, 1931
Asellia tridens diluta K. Andersen, 1918	*Asellia tridens* (E. Geoffroy St.-Hilaire, 1813)
Asellia tridens italo-somalica de Beaux, 1931	*Asellia italosomalica* de Beaux, 1931
Asellia tridens pallida Laurent, 1937	*Asellia tridens* (E. Geoffroy St.-Hilaire, 1813)
Asellia vetus Lavocat, 1961	*Hipposideros vetus* (Lavocat, 1961)
Attalepharca Menu, 1987	*Pipistrellus* Kaup, 1829
Austronomus Troughton, 1941	*Tadarida* Rafinesque, 1814
Austronomus Iredale and Troughton, 1934	*Tadarida* Rafinesque, 1814
Barbastella Gray, 1821	*Barbastella* Gray, 1821
Barbastella barbastellus guanchae Trujillo, Ibáñez and Juste, 2002	*Barbastella barbastellus* (Schreber, 1774)
Barbastellus Kaup, 1829	*Barbastella* Gray, 1821
Barbastellus communis Gray, 1838	*Barbastella barbastellus* (Schreber, 1774)
Brachipposideros Sigé, 1968	*Brachipposideros* Sigé, 1968
Brachyotus Kolenati, 1856	*Myotis* Kaup, 1829
Brachyura Peters, 1865	*EMBALLONURIDAE* Gervais, 1855
Brevipalatus Hand and Archer, 2005	*Brevipalatus* Hand and Archer, 2005
C[oleura] g[allarum] nilosa Thomas, 1915	*Coleura afra* (Peters, 1852)

Original Name	Current Name
C[oleura] gallarum Thomas, 1915	*Coleura afra* (Peters, 1852)
C[oleura] silhouettæ Thomas, 1915	*Coleura seychellensis* Peters, 1868
Capaccinius Bonaparte, 1841	*Myotis* Kaup, 1829
Cardioderma Peters, 1873	*Cardioderma* Peters, 1873
Cardioderma leakeyi Gunnell, Butler, Greenwood and Simmons, 2015	*Cardioderma leakeyi* Gunnell, Butler, Greenwood and Simmons, 2015
Casinycteris Thomas, 1910	*Casinycteris* Thomas, 1910
Casinycteris argynnis Thomas, 1910	*Casinycteris argynnis* Thomas, 1910
Casinycteris campomaanensis Hassanin, 2014	*Casinycteris campomaanensis* Hassanin, 2014
Cateorus Kolenati, 1856	*Eptesicus* Rafinesque, 1820
Cephalotes teniotis Rafinesque, 1814	*Tadarida teniotis* (Rafinesque, 1814)
Cephalotidae Gray, 1821	*PTEROPODIDAE* Gray, 1821
Cercopteropus Burnett, 1829	*Rousettus* Gray, 1821
Cerivoula Blanford, 1891	*Kerivoula* Gray, 1842
Chærephon (Lophomops) J.A. Allen, 1917	*Chaerephon* Dobson, 1874
Chærephon (Lophomops) abæ J.A. Allen, 1917	*Chaerephon major* (Trouessart, 1897)
Chærephon (Lophomops) chapini J.A. Allen, 1917	*Chaerephon chapini* J.A. Allen, 1917
Chærephon (Lophomops) cristatus J.A. Allen, 1917	*Chaerephon leucogaster* (A. Grandidier, 1869)
Chaerephon (Lophomops) shortridgei Thomas, 1926	*Chaerephon chapini* J.A. Allen, 1917
Chaerephon atsinanana Goodman, Buccas, Naidoo, Ratrimomanarivo, Taylor and Lamb, 2010	*Chaerephon atsinanana* Goodman, Buccas, Naidoo, Ratrimomanarivo, Taylor and Lamb, 2010
Chærephon emini Wroughton, 1911	*Mops (Mops) condylurus* (A. Smith, 1833)
Chærephon frater J.A. Allen, 1917	*Chaerephon leucogaster* (A. Grandidier, 1869)
Chaerephon jobimena Goodman and Cardiff, 2004	*Chaerephon jobimena* Goodman and Cardiff, 2004
Chærephon lancasteri Hayman, 1938	*Chaerephon chapini* J.A. Allen, 1917
Chaerephon leucostigma G.M. Allen, 1918	*Mops (Mops) leucostigma* (G.M. Allen, 1918)
Chærephon nigeriæ Thomas, 1913	*Chaerephon nigeriae* Thomas, 1913
Chærephon nigeriæ Thomas, 1913	*Chaerephon nigeriae nigeriae* Thomas, 1913
Chaerephon pumilus naivashæ Hollister, 1916	*Chaerephon pumilus* (Cretzschmar, 1826)
Chærephon russatus J.A. Allen, 1917	*Chaerephon russatus* J.A. Allen, 1917
Chærophon (Lophomops) nigri Hatt, 1928	*Chaerephon leucogaster* (A. Grandidier, 1869)
Chaerophon pumilus elphicki Roberts, 1926	*Chaerephon pumilus* (Cretzschmar, 1826)
Chalinolobus , 9999	*Glauconycteris* Dobson, 1875
Chalinolobus argentatus Dobson, 1875	*Glauconycteris argentata* (Dobson, 1875)
Chalinolobus congicus Noack, 1889	*Glauconycteris argentata* (Dobson, 1875)
Chambinycteris Ravel, 2016	*Chambinycteris* Ravel, 2016
Chambinycteris pusilli Ravel, 2016	*Chambinycteris pusilli* Ravel, 2016
Chamtwaria Butler, 1984	*Chamtwaria* Butler, 1984
Chamtwaria pickfordi Butler, 1984	*Chamtwaria pickfordi* Butler, 1984
Cheiromelinae Legendre, 1984	*Molossinae* Gervais, 1856
CHEIROPTERA Gray, 1821	*CHIROPTERA* Blumenbach, 1779
CHEIROPTERA Flemming, 1822	*CHIROPTERA* Blumenbach, 1779
CHIROPTERA Blumenbach, 1779	*CHIROPTERA* Blumenbach, 1779
Choerephon (Lophomops) langi Roberts, 1932	*Chaerephon pumilus* (Cretzschmar, 1826)
Chœrephon websteri Dollman, 1908	*Chaerephon leucogaster* (A. Grandidier, 1869)
Chrysonycteris Gray, 1866	*Hipposideros* Gray, 1831
Chrysopteron Jentink, 1910	*Myotis* Kaup, 1829
Cistugo Thomas, 1912	*Cistugo* Thomas, 1912
Cistugo lesueuri Roberts, 1919	*Cistugo lesueuri* Roberts, 1919

Cynonycteris torquata Dobson, 1878	*Myonycteris torquata* (Dobson, 1878)
Cynopterinae K. Andersen, 1912	*Pteropodinae* Gray, 1821
Cynopterini Koopman and J.K. Jones Jr., 1970	*Pteropodinae* Gray, 1821
Cynopterus collaris Gray, 1870	*Myonycteris torquata* (Dobson, 1878)
DERMAPTERA Aristotle, -330	*CHIROPTERA* Blumenbach, 1779
Dhofarella Sigé, Thomas, Sen, Gheerbrant, Roger and Al-Sulaimani, 1994	*Dhofarella* Sigé, Thomas, Sen, Gheerbrant, Roger, and Al-Sulaimani, 1985
Dhofarella sigei Gunnell, Simons and Seiffert, 2008	*Dhofarella sigei* Gunnell, Simons and Seiffert, 2008
Dhofarella thaleri Sigé, Thomas, Sen, Gheerbrant, Roger and Al-Sulaimani, 1994	*Dhofarella thaleri* Sigé et al., 1994
Dichromyotis Bianchi, 1917	*Myotis* Kaup, 1829
Diclidurina Gray, 1866	*EMBALLONURIDAE* Gervais, 1855
Diclidurinae Miller, 1907	*EMBALLONURIDAE* Gervais, 1855
Dinops Savi, 1825	*Tadarida* Rafinesque, 1814
Dinops Cestonii Savi, 1825	*Tadarida teniotis* (Rafinesque, 1814)
Dizzya Sigé, 1991	*Dizzya* Sigé, 1991
Dizzya exsultans Sigé, 1991	*Dizzya exsultans* Sigé, 1991
Doryrhina Peters, 1871	*Doryrhina* Peters, 1871
Drakonycteris Ravel, 2016	*Drakonycteris* Ravel, 2016
Drakonycteris glibzegdouensis Ravel, 2016	*Drakonycteris glibzegdouensis* Ravel, 2016
Dysopes Cretzschmar, 1830-1831	*Tadarida* Rafinesque, 1814
Dysopes brachypterus Peters, 1852	*Mops (Xiphonycteris) brachypterus* (Peters, 1852)
Dysopes dubius Peters, 1852	*Chaerephon pumilus* (Cretzschmar, 1826)
Dysopes geoffroyi Temminck, 1827	*Tadarida aegyptiaca aegyptiaca* (E. Geoffroy St.-Hilaire, 1818)
Dysopes hepaticus Heuglin, 1864	*Mops (Mops) condylurus* (A. Smith, 1833)
Dysopes limbatus Peters, 1852	*Chaerephon pumilus* (Cretzschmar, 1826)
Dysopes midas Sundevall, 1843	*Mops (Mops) midas* (Sundevall, 1843)
Dysopes midas Sundevall, 1843	*Mops (Mops) midas midas* (Sundevall, 1843)
Dysopes natalensis A. Smith, 1847	*Mormopterus acetabulosus natalensis* (A. Smith, 1847)
Dysopes pumilus Cretzschmar, 1826	*Chaerephon pumilus* (Cretzschmar, 1826)
Dysopes rüpelii Temminck, 1827	*Tadarida teniotis* (Rafinesque, 1814)
Dysopes Savii Schinz, 1840	*Tadarida teniotis* (Rafinesque, 1814)
Dysopes talpinus Heuglin, 1877	*Tadarida aegyptiaca aegyptiaca* (E. Geoffroy St.-Hilaire, 1818)
E[uryalus] atlanticus K. Andersen and Matschie, 1904	*Rhinolophus euryale* Blasius, 1853
E[uryalus] barbarus K. Andersen and Matschie, 1904	*Rhinolophus mehelyi* Matschie, 1901
E[uryalus] Cabreræ K. Andersen and Matschie, 1904	*Rhinolophus euryale* Blasius, 1853
E[uryalus] meridionalis K. Andersen and Matschie, 1904	*Rhinolophus mehelyi* Matschie, 1901
Eidolinae Almeida, Giannini and Simmons, 2016	*Eidolinae* Almeida, Giannini and Simmons, 2016
Eidolon Rafinesque, 1815	*Eidolon* Rafinesque, 1815
Eidolon helvum annobonensis Juste, Ibáñez and Machordom, 2000	*Eidolon helvum helvum* (Kerr, 1792)
Eleutherura Gray, 1844	*Rousettus* Gray, 1821
Eleutherura unicolor Gray, 1870	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)
Emballonura afra Peters, 1852	*Coleura afra* (Peters, 1852)
Emballonura atrata Peters, 1874	*Paremballonura atrata* (Peters, 1874)
Emballonura tiavato Goodman, Cardiff, Ranivo, Russell and Yoder, 2006	*Paremballonura tiavato* (Goodman, Cardiff, Ranivo, Russell, and Yoder, 2006)
Emballonuridae Gervais, 1855	*EMBALLONURIDAE* Gervais, 1855
Emballonurina Gray, 1866	*EMBALLONURIDAE* Gervais, 1855
Emballonuroidea Teeling, Springer, Madsen, Bates, O'Brien, and Murphy, 2005	*NYCTEROIDEA* Van der Hoeven, 1855
Eomops Thomas, 1905	*Myopterus* E. Geoffroy St.-Hilaire, 1818
Ep[omophorus (Epomophorus)] büttikoferi Matschie, 1899	*Epomops buettikoferi* (Matschie, 1899)
Ep[omophorus (Epomophorus)] doriae Matschie, 1899	*Epomophorus labiatus* (Temminck, 1837)
Ep[omophorus (Epomophorus)] neumanni Matschie, 1899	*Epomophorus wahlbergi* (Sundevall, 1846)

Original Name	Current Name
Ep[omophorus (Epomophorus)] stuhlmanni Matschie, 1899	*Epomophorus wahlbergi* (Sundevall, 1846)
Ep[omophorus (Epomophorus)] zechi Matschie, 1899	*Epomophorus gambianus gambianus* (Ogilby, 1835)
Ep[omophorus (Epomophorus)] zenkeri Matschie, 1899	*Epomophorus wahlbergi* (Sundevall, 1846)
Epomophorina Gray, 1866	*Pteropodinae* Gray, 1821
Epomophorinae K. Andersen, 1912	*Rousettinae* Andersen, 1912
Epomophorus Bennett, 1836	*Epomophorus* Bennett, 1836
Epomophorus anchietæ Seabra, 1900	*Plerotes anchietae* (Seabra, 1900)

Appendix 3b: Synonyms by Author

This appendix contains all of the synonyms covered in this report (excluding new name combinations and lapsi calami). The synonyms are sorted by author and year of description and are linked to the current name.

Some of the synonyms might be linked to several current names, indicating that they can only be partly assigned to these current names, e.g. *Vesperugo* Keyserling and Blasius, 1839 in part covers *Eptesicus* Rafinesque, 1820, *Nyctalus* Bowdich, 1825, and *Pipistrellus* Kaup, 1829.

Unknown Author

9999	*Epomophorus labiatus anurus*	*Epomophorus minor* Dobson, 1880
9999	*Laephotis cf. angolensis*	*Laephotis angolensis* Monard, 1935
9999	*Myotis anjouanensis*	*Myotis anjouanensis* (Dorst, 1960)
9999	*Neoromicia "incertae-sedis"*	*Neoromicia "incertae-sedis"*
9999	*Noctilionoidea*	*NOCTILIONOIDEA* Gray, 1821
9999	*Rousettus sp. cf. R. madagascariensis*	*Rousettus madagascariensis* G. Grandidier, 1929
9999	*Yangochiroptera*	*VESPERTILIONIFORMACEI* Van Cakenberghe, Kearney and Seamark, 2007
9999	*Yinochiroptera*	*RHINOLOPHIFORMACEI* Van Cakenberghe, Kearney and Seamark, 2007
9999	*Chalinolobus*	*Glauconycteris* Dobson, 1875
9999	*Miniopterus sp.*	*Miniopterus* Bonaparte, 1837
9999	*Neoromicia cf. capensis*	*Neoromicia capensis* (A. Smith, 1829)
9999	*Pteropus ægyptiacus*	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)
9999	*Rhinonicteridae*	*RHINONYCTERIDAE* J. E. Gray, 1866
9999	*Scotophilus cf. viridis*	*Scotophilus viridis* (Peters, 1852)

Appendix 3c: Synonyms by Publication Date

In this appendix, the synonyms are sorted according to the date they were published.
If a complete date could be found, this date is given. In most cases, however, only the year of publication is known, in which case (according to the International Code of Zoological Nomenclature) the last day of the year is considered to be the date of publication (i.e. 31 December). If a month is known too, the final date of the month is entered.

In a large number of cases the publication date is taken from the (cover of the) publication, and as such the date might not be 100 % correct, since these dates tend to be earlier than the exact date the publication was published.

For names published in "*Annals and Magazine of Natural History*" and "*Journal of Natural History*" the publication dates are taken from Evenhuis (2003). For names published in the "*Proceedings of the Zoological Society of London*", the publication dates are taken from Duncan (1937). The publication dates from Schreber's "Die Säugethiere" are taken from Sherborn (1892). For E. Geoffroy St.-Hilaire's "Description de l'Egypte", the dates are taken from Sherborn (1897). For Kerr's "Animal Kingdom" see Allen (1895).

Publication date	Original Name	Current Name
31 Dec 1774	*Vespertilio barbastellus* Schreber	*Barbastella barbastellus* (Schreber, 1774)

Appendix 3d: Synonyms by Country of Type Specimen

In this appendix the synonyms are ordered by country from which they were described and by year or publication.

Synonyms for which "Null" is mentioned as author simply indicate incomplete entries, for which this information could not be found (yet).

Unknown Country

1777	*Pteropus* Erxleben	*Pteropus* Erxleben, 1777
1779	*CHIROPTERA* Blumenbach	*CHIROPTERA* Blumenbach, 1779
1795	*Nycteris* G. Cuvier and E. Geoffroy	*Nycteris* G. Cuvier and E. Geoffroy, 1795
1797	*Vespertilio caninus* Blumenbach	*Pteropus niger* (Kerr, 1792)
1799	*Rhinolophus* Lacépède	*Rhinolophus* Lacépède, 1799
1799	*Spectrum* Lacépède	*Pteropus* Erxleben, 1777
1803	*major* E. Geoffroy Saint-Hilaire	*Rhinolophus ferrumequinum* (Schreber, 1774)
1809	*Vespertilio caninus var. b* Goldfuss	*Eidolon helvum helvum* (Kerr, 1792)
1810	*Megaderma* E. Geoffroy St.-Hillaire	*Megaderma* E. Geoffroy St.-Hilaire, 1810
1814	*Tadarida* Rafinesque	*Tadarida* Rafinesque, 1814
1814	*Pteropus torquatus* G. Fischer	*Pteropus subniger* (Kerr, 1792)
1815	*Eidolon* Rafinesque	*Eidolon* Rafinesque, 1815
1815	*Pteropus flavus* Illiger	*Eidolon helvum helvum* (Kerr, 1792)
1815	*Vespertilia* Rafinesque	*VESPERTILIONIDAE* Gray, 1821
1816	*Macrotus* Leach	*Plecotus* E. Geoffroy St.-Hilaire, 1818
1816	*Phyllorhina* Leach	*Rhinolophus* Lacépède, 1799
1818	*Myopterus* E. Geoffroy Saint-Hilaire	*Myopterus* E. Geoffroy St.-Hilaire, 1818
1818	*Nyctinomus* E. Geoffroy Saint-Hilaire	*Tadarida* Rafinesque, 1814
1818	*Plecotus* E. Geoffroy Saint-Hilaire	*Plecotus* E. Geoffroy St.-Hilaire, 1818
1818	*Pteropus aegyptiacus* E. Geoffroy Saint-Hilaire	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)
1818	*Rhinopoma* E. Geoffroy Saint-Hilaire	*Rhinopoma* E. Geoffroy St.-Hilaire, 1818
1818	*Taphozous* E. Geoffroy Saint-Hilaire	*Taphozous* E. Geoffroy St.-Hilaire, 1818
1819	*Vespertilio dasykarpos* Kuhl	*Nyctalus leisleri* (Kuhl, 1817)
1820	*Eptesicus* Rafinesque	*Eptesicus* Rafinesque, 1820
1820	*Myopteris* Desmarest	*Myopterus* E. Geoffroy St.-Hilaire, 1818
1821	*Barbastella* Gray	*Barbastella* Gray, 1821
1821	*Nyctinomes* Gray	*Tadarida* Rafinesque, 1814
1821	*Pteropidae* Gray	*PTEROPODIDAE* Gray, 1821
1821	*Vespertilionidae* Gray	*VESPERTILIONIDAE* Gray, 1821
1821	*Vespertilioninae* Gray	*Vespertilioninae* Gray, 1821
1821	*Vespertilionoidea* Gray	*VESPERTILIONOIDEA* Gray, 1821
1821	*Scotophilus* Leach	*Scotophilus* Leach, 1821
1821	*Cephalotidae* Gray	*PTEROPODIDAE* Gray, 1821
1821	*CHEIROPTERA* Gray	*CHIROPTERA* Blumenbach, 1779
1821	*FRUCTIVORAE* Gray	*PTEROPODIFORMI* Van Cakenberghe, Kearney and Seamark, 2007
1821	*INSECTIVORAE* Gray	*VESPERTILIONIFORMI* Van Cakenberghe, Kearney and Seamark, 2007
1821	*Nyctinoma* Bowdich	*Tadarida* Rafinesque, 1814
1821	*Pteropodinae* Gray	*Pteropodinae* Gray, 1821
1821	*PTEROPODOIDEA* Gray	*PTEROPODOIDEA* Gray, 1821
1821	*Rhynopoma* Bowdich	*Rhinopoma* E. Geoffroy St.-Hilaire, 1818
1822	*CHEIROPTERA* Flemming	*CHIROPTERA* Blumenbach, 1779
1822	*Nyctinomia* Fleming	*Tadarida* Rafinesque, 1814
1825	*Dinops* Savi	*Tadarida* Rafinesque, 1814
1825	*Nyctalus* Bowdich	*Nyctalus* Bowdich, 1825
1825	*Rhinolophidae* Gray	*RHINOLOPHIDAE* Gray, 1825
1825	*Rhinolophoidea* Gray	*RHINOLOPHOIDEA* J. E. Gray, 1825
1826	*Vespertilio leucomelas* Cretzschmar	*Barbastella leucomelas* (Cretzschmar, 1826)
1827	*Dysopes geoffroyi* Temminck	*Tadarida aegyptiaca aegyptiaca* (E. Geoffroy St.-Hilaire, 1818)
1827	*Rhinolophina* Lesson	*RHINOLOPHIDAE* Gray, 1825
1829	*Cercopteropus* Burnett	*Rousettus* Gray, 1821
1829	*Barbastellus* Kaup	*Barbastella* Gray, 1821
1829	*Cnephæus* Kaup	*Eptesicus* Rafinesque, 1820
1829	*Myotis* Kaup	*Myotis* Kaup, 1829
1829	*Nystactes* Kaup	*Myotis* Kaup, 1829
1829	*Pipistrellus* Kaup	*Pipistrellus* Kaup, 1829
1829	*Pterygistes* Kaup	*Nyctalus* Bowdich, 1825
1829	*Vespertilio auritus ß aegyptius* J.B. Fischer	*Plecotus christii* Gray, 1838
1830	*Loeconoë* Boie	*Myotis* Kaup, 1829

1830-1831	*Dysopes* Cretzschmar	*Tadarida* Rafinesque, 1814
1831	*Hipposideros* Gray	*Hipposideros* Gray, 1831
1831	*Pachyotus* Gray	*Scotophilus* Leach, 1821
1834	*Hipposiderus* Gray	*Hipposideros* Gray, 1831
1836	*Epomophorus* Bennett	*Epomophorus* Bennett, 1836
1836	*Rhinocrepis* Gervais	*Rhinolophus* Lacépède, 1799
1837	*Miniopterus* Bonaparte	*Miniopterus* Bonaparte, 1837
1837	*Myoptera* de Blainville	*Myopterus* E. Geoffroy St.-Hilaire, 1818
1837	*Noctula* Bonaparte	*Eptesicus* Rafinesque, 1820
1837	*Pipistrella* Bonaparte	*Pipistrellus* Kaup, 1829
1837	*Pteropus vulgaris* Temminck	*Pteropus subniger* (Kerr, 1792)
1838	*Asellia* Gray	*Asellia* Gray, 1838

1906	*H[ipposiderus]. gigas gambiensis* K. Andersen	*Macronycteris gigas* (Wagner, 1845)

Tunisia

1955	*Rhinolophus euryale tuneti* Deleuil and Labbé	*Rhinolophus mehelyi* Matschie, 1901
1977	*Myotis blythii punicus* Felten	*Myotis punicus* Felten, 1977
1991	*Dizzya exsultans* Sigé	*Dizzya exsultans* Sigé, 1991
2012	*Witwatia sigei* Ravel, Marivaux, Tabuce, Bel Haj Ali, Essid, and Vianey-Liaud	*Witwatia sigei* Ravel, Marivaux, Tabuce, Bel Haj Ali, Essid, and Vianey-Liaud, 2012
2016	*?Necromantis fragmentum* Ravel	*Necromantis fragmentum* (Ravel, 2016)
2016	*?Palaeophyllophora tunisiensis* Ravel	*Palaeophyllophora tunisiensis* (Ravel, 2016)
2016	*?Vespertiliavus aenigma* Ravel	*Vespertiliavus aenigma* (Ravel, 2016)
2016	*Hipposideros (Pseudorhinolophus) africanum* Ravel	*Hipposideros africanum* Ravel, 2016
2016	*Khoufechia gunnelli* Ravel	*Khoufechia gunnelli* Ravel, 2016
2016	*Vespertliavus kasserinensis* Ravel	*Vespertiliavus kasserinensis* (Ravel, 2016)

Uganda

1905	*Glauconycteris papilio* Thomas	*Glauconycteris variegata* (Tomes, 1861)
1905	*Rhinolophus Hildebrandti eloquens* K. Andersen	*Rhinolophus eloquens* K. Andersen, 1905
1906	*Hipposiderus caffer centralis* K. Andersen	*Hipposideros ruber* (Noack, 1893)
1906	*Rousettus lanosus* Thomas	*Stenonycteris lanosus* (Thomas, 1906)
1907	*Nyctinomus aloysii-sabaudiae* Festa	*Chaerephon aloysiisabaudiae* (Festa, 1907)
1913	*Pipistrellus fuscipes* Thomas	*Pipistrellus rueppellii fuscipes* Thomas, 1913
1965	*Rousettus angolensis ruwenzorii* Eisentraut	*Myonycteris angolensis ruwenzorii* (Eisentraut, 1965)

United Kingdom

1825	*Vespertilio Pygmæus* Leach	*Pipistrellus pygmaeus* (Leach, 1825)

Yemen

1869	*Vesperus Bottae* Peters	*Eptesicus bottae* (Peters, 1869)

Zambia

1914	*Nycteris woodi* K. Andersen	*Nycteris woodi* K. Andersen, 1914
1920	*Mimetillus thomasi* Hinton	*Mimetillus thomasi* Hinton, 1920
1938	*Chærephon lancasteri* Hayman	*Chaerephon chapini* J.A. Allen, 1917
1960	*Epomophorus gambianus parvus* Ansell	*Epomophorus crypturus* Peters, 1852
2002	*Rhinolophus sakejiensis* Cotterill	*Rhinolophus sakejiensis* Cotterill, 2002

Zimbabwe

1904	*Rhinolophus simulator* K. Andersen	*Rhinolophus simulator* K. Andersen, 1904
1905	*Rhinolophus Darlingi* K. Andersen	*Rhinolophus darlingi* K. Andersen, 1905
1914	*Rhinolophus bembanicus* Senna	*Rhinolophus simulator* K. Andersen, 1904
1920	*Kerivoula lucia* Hinton	*Kerivoula lanosa* (A. Smith, 1847)
1946	*Nycteris woodi sabiensis* Roberts	*Nycteris woodi* K. Andersen, 1914
1946	*Nyctinomus mastersoni* Roberts	*Tadarida fulminans* (Thomas, 1903)
1946	*Nyctinomus rhodesiae* Roberts	*Chaerephon ansorgei* (Thomas, 1913)
1946	*Rhinolophus swinnyi rhodesiae* Roberts	*Rhinolophus rhodesiae* Roberts, 1946
1962	*Taphozous sudani australis* Harrison	*Taphozous perforatus sudani* Thomas, 1915
1997	*Lissonycteris angolensis goliath* Bergmans	*Myonycteris angolensis goliath* (Bergmans, 1997)
2012	*Rhinolophus smithersi* Taylor, Stoffberg, Monadjem, Schoeman, Bayliss and Cotterill	*Rhinolophus smithersi* Taylor, Stoffberg, Monadjem, Schoeman, Bayliss and Cotterill, 2012

Appendix 3e: Common Names in Alphabetical Order

Common Name	Taxon Name
(Bolshoj podkovonos) (Russian)	*Rhinolophus ferrumequinum* (Schreber, 1774)
(Evropejskaya shirokoushka) (Russian)	*Barbastella barbastellus* (Schreber, 1774)
(Gewone) Dwergvleermuis (Dutch)	*Pipistrellus pipistrellus* (Schreber, 1774)
(Gigantskaya vechernicha) (Russian)	*Nyctalus lasiopterus* (Schreber, 1780)
(Grote) Langvleugelvleermuis (Dutch)	*Miniopterus schreibersii* (Kuhl, 1817)
(Mapaya vechernicha) (Russian)	*Nyctalus leisleri* (Kuhl, 1817)
(Netopyr karlik) (Russian)	*Pipistrellus pipistrellus* (Schreber, 1774)
(Obyknovennyj dlinnokryl) (Russian)	*Miniopterus schreibersii* (Kuhl, 1817)
(Yuzhnyj podkovonos) (Russian)	*Rhinolophus euryale* Blasius, 1853
Họ dơi cánh (Vietnamese)	*MINIOPTERIDAE* Dobson, 1875
Họ dơi thò đuôi (Vietnamese)	*MOLOSSIDAE* Gervais, 1856
Họ dơi quạ (Vietnamese)	*PTEROPODIDAE* Gray, 1821
Họ dơi lá (Vietnamese)	*RHINOLOPHIDAE* Gray, 1825
Họ dơi ma (Vietnamese)	*MEGADERMATIDAE* H. Allen, 1864
Họ dơi muỗi (Vietnamese)	*VESPERTILIONIDAE* Gray, 1821
Họ dơi mũi (Vietnamese)	*HIPPOSIDERIDAE* Lydekker, 1891
Họ dơi bao (Vietnamese)	*EMBALLONURIDAE* Gervais, 1855
šerowec senegalský (Czech)	*Nycteris hispida* (Schreber, 1774)
šerowec tébský (Czech)	*Nycteris thebaica* E. Geoffroy St.-Hilaire, 1818
šerowecové (Czech)	*Nycteris* G. Cuvier and E. Geoffroy, 1795
širokouší morousi (hroznohledové (Czech)	*Tadarida* Rafinesque, 1814
širokouší ušanové (Czech)	*Barbastella* Gray, 1821
žlázokřídlec Lesueurův (Czech)	*Cistugo lesueuri* Roberts, 1919
žlázokřídlec Seabrův (Czech)	*Cistugo seabrae* Thomas, 1912
žlázokřídlecové (Czech)	*Cistugo* Thomas, 1912
žlázokřídlecovití (Czech)	*CISTUGONIDAE* Lack, Roehrs, Stanley, Ruedi and Van den Bussche, 2010
žlutokřídlí lyronosi (Czech)	*Lavia* Gray, 1838
Гладконосые (Russian)	*VESPERTILIONIDAE* Gray, 1821
Βουνονυχτερίδα (Greek)	*Hypsugo savii* (Bonaparte, 1837)
Λευκονυχτερίδα (Greek)	*Pipistrellus kuhlii* (Kuhl, 1817)
Μεσορινόλοφος (Greek)	*Rhinolophus euryale* Blasius, 1853
Μικρονυκτοβάτης (Greek)	*Nyctalus leisleri* (Kuhl, 1817)
Μικρονυχτερίδα (Greek)	*Pipistrellus pygmaeus* (Leach, 1825)
Μικροριόλοφος (Greek)	*Rhinolophus hipposideros* (Bechstein, 1800)
Μουστακονυχερίδα (Greek)	*Myotis mystacinus* (Kuhl, 1817)
Νανονυχτερίδα (Greek)	*Pipistrellus pipistrellus* (Schreber, 1774)
Νυχτονόμος (Greek)	*Tadarida teniotis* (Rafinesque, 1814)
Ποδαρομνωίδα (Greek)	*Myotis capaccinii* (Bonaparte, 1837)
Πτρυγονυχτερίδα (Greek)	*Miniopterus schreibersii* (Kuhl, 1817)
Πυρρομυωτιδα (Greek)	*Myotis emarginatus* (E. Geoffroy St.-Hilaire, 1806)
Ρινόλοφος του Blasius (Greek)	*Rhinolophus blasii* Peters, 1867
Τρανορινόλοφος (Greek)	*Rhinolophus ferrumequinum* (Schreber, 1774)
Азиатская широкоушка [= Aeiatskaya shirokouchka]; (Russian)	*Barbastella leucomelas* (Cretzschmar, 1826)
Большой подковонос (Russian)	*Rhinolophus ferrumequinum* (Schreber, 1774)
Бульдоговые (Russian)	*MOLOSSIDAE* Gervais, 1856
Гигантская вечерница (Russian)	*Nyctalus lasiopterus* (Schreber, 1780)
Длиннокрыловые (Russian)	*MINIOPTERIDAE* Dobson, 1875
Европейская широкоушка (Russian)	*Barbastella barbastellus* (Schreber, 1774)
Кожановидный нетопырь (Russian)	*Hypsugo savii* (Bonaparte, 1837)
КрылановыеRussian)	*PTEROPODIDAE* Gray, 1821
Лжевампиры (Russian)	*MEGADERMATIDAE* H. Allen, 1864
Листоносы (Russian)	*HIPPOSIDERIDAE* Lydekker, 1891
Ложные подковоносы (Russian)	*HIPPOSIDERIDAE* Lydekker, 1891
Малая вечерница (Russian)	*Nyctalus leisleri* (Kuhl, 1817)
Малый подковонос (Malyj podkovonos) (Russian)	*Rhinolophus hipposideros* (Bechstein, 1800)
Малый нетопырь [=Malyj Neopyr], (Russian)	*Pipistrellus pygmaeus* (Leach, 1825)
Нетопырь Куля (Russian)	*Pipistrellus kuhlii* (Kuhl, 1817)
Нетопырь-карлик (Russian)	*Pipistrellus pipistrellus* (Schreber, 1774)
Нічниця вусата (Ukrainian)	*Myotis mystacinus* (Kuhl, 1817)
Обыкновенный длиннокрыл (Russian)	*Miniopterus schreibersii* (Kuhl, 1817)
Очковый подковонос (Russian)	*Rhinolophus mehelyi* Matschie, 1901
Подковогубы (Russian)	*HIPPOSIDERIDAE* Lydekker, 1891
Подковоносые (Russian)	*RHINOLOPHIDAE* Gray, 1825
Свободнохвостые (Russian)	*MOLOSSIDAE* Gervais, 1856
Футлярохвостые (Russian)	*EMBALLONURIDAE* Gervais, 1855
Широковух європейський (Ukrainian)	*Barbastella barbastellus* (Schreber, 1774)
Широкоухий складчатогуб (Russian)	*Tadarida teniotis* (Rafinesque, 1814)
Южный подковонос (Russian)	*Rhinolophus euryale* Blasius, 1853

Common Name	Taxon Name
средиземноморский (Sredizemnomorskij netopyr) (Russian)	*Pipistrellus kuhlii* (Kuhl, 1817)
45 kHz Pipistrelle (English)	*Pipistrellus pipistrellus* (Schreber, 1774)
55 kHz pipistrelle (English)	*Pipistrellus pygmaeus* (Leach, 1825)
Aalwyndakvlermuis; Aalwynvlermuis (Afrikaans)	*Neoromicia zuluensis* (Roberts, 1924)
Aba Leaf-nosed Bat (English)	*Hipposideros abae* J.A. Allen, 1917
Aba Roundleaf Bat (English)	*Hipposideros abae* J.A. Allen, 1917
Aba-Rundblattnase (German)	*Hipposideros abae* J.A. Allen, 1917
Abendfledermäuse (German)	*Nycticeinops* Hill & Harrison, 1987
Abendsegler (German)	*Nyctalus* Bowdich, 1825
Abendstern-Pipistrelle (German)	*Pipistrellus hesperidus* (Temminck, 1840)
Abendstern-Zwergfledermaus (German)	*Pipistrellus hesperidus* (Temminck, 1840)
Abo Bat (English)	*Glauconycteris poensis* (Gray, 1842)
Abo Butterfly Bat (English)	*Glauconycteris poensis* (Gray, 1842)
Abo-Schmetterlingsfledermaus (German)	*Glauconycteris poensis* (Gray, 1842)
Abruzzi's Wrinkle-lipped Bat (English)	*Chaerephon aloysiisabaudiae* (Festa, 1907)
Abyssinian Horseshoe Bat (English)	*Rhinolophus fumigatus* Rüppell, 1842
Adam's Horseshoe Bat (English)	*Rhinolophus adami* Aellen and Brosset, 1968
Adams Hufeisennase (German)	*Rhinolophus adami* Aellen and Brosset, 1968
Aellens Langflügelfledermaus (German)	*Miniopterus aelleni* Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, 2009
Aellen's Leaf-nosed Bat (English)	*Hipposideros marisae* Aellen, 1954
Aellen's Long-fingered Bat (English)	*Miniopterus aelleni* Goodman, Maminirina, Weyeneth, Bradman, Christidis, Ruedi and Appleton, 2009
Aellen's Pipistrelle (English)	*Pipistrellus inexspectatus* Aellen, 1959
Aellen's Pipistrelle Bat (English)	*Pipistrellus inexspectatus* Aellen, 1959
Aellen's Roundleaf Bat (English)	*Hipposideros marisae* Aellen, 1954
Aerial Pipistrelle Bat (English)	*Pipistrellus aero* Heller, 1912
African Epauletted bats (English)	*Epomops* Gray, 1866
African False Vampire Bat (English)	*Cardioderma cor* (Peters, 1872)
African False Vampire Bats (English)	*Cardioderma* Peters, 1873
African Free-tailed Bats (English)	*Myopterus* E. Geoffroy St.-Hilaire, 1818
African Giant Free-tailed Bat (English)	*Tadarida ventralis* (Heuglin, 1861)
African Heart-nosed Bat (English)	*Cardioderma cor* (Peters, 1872)
African Long-eared Bats (English)	*Laephotis* Thomas, 1901
African Long-fingered Bat (English)	*Miniopterus africanus* Sanborn, 1936
African Long-tongued Bat (English)	*Megaloglossus woermanni* Pagenstecher, 1885
African Long-tongued Fruit-bats (English)	*Megaloglossus* Pagenstecher, 1885
African Nectar Fruit-bats (English)	*Megaloglossus* Pagenstecher, 1885
African pipistrelle (English)	*Pipistrellus hesperidus* (Temminck, 1840)
African Sheath-tailed Bat (English)	*Coleura afra* (Peters, 1852)
African Straw-coloured Fruit-bat (English)	*Eidolon helvum* (Kerr, 1792)
African Taphozous (English)	*Taphozous perforatus* E. Geoffroy St.-Hilaire, 1818
African Trident Bat (English)	*Triaenops afer* Peters, 1877
African Trident Bat (English)	*Cloeotis percivali* Thomas, 1901
African Trident Bats (English)	*Cloeotis* Thomas, 1901
African Trident-nosed Bats (English)	*Cloeotis* Thomas, 1901
African Woolly Bat (English)	*Kerivoula africana* Dobson, 1878
African Yellow Bat (English)	*Scotophilus dinganii* (A. Smith, 1833)
African Yellow House Bat (English)	*Scotophilus dinganii* (A. Smith, 1833)
African Yellow-winged Bat (English)	*Lavia frons* (E. Geoffroy St.-Hilaire, 1810)
afrifraa (Tanoboase (Ghana))	*MOLOSSIDAE* Gervais, 1856
Afrikanische Dreizahn-Blattnase (German)	*Triaenops afer* Peters, 1877
Afrikanische Langflügelfledermaus (German)	*Miniopterus africanus* Sanborn, 1936
Afrikanische Langohrfledermäuse (German)	*Laephotis* Thomas, 1901
Afrikanische Langzungen-Flughunde (German)	*Megaloglossus* Pagenstecher, 1885
Afrikanische Schiebeschwanz-Fledermaus (German)	*Coleura afra* (Peters, 1852)
Afrikanischer Langzungen-Flughund (German)	*Megaloglossus woermanni* Pagenstecher, 1885
Afrikanischer Palmenflughund (German)	*Eidolon helvum* (Kerr, 1792)
Ägyptische Bulldoggfledermaus (German)	*Tadarida aegyptiaca* (E. Geoffroy St.-Hilaire, 1818)
Ägyptische Grabfledermaus (German)	*Taphozous perforatus* E. Geoffroy St.-Hilaire, 1818
Ägyptische Mausschwanz-Fledermaus (German)	*Rhinopoma microphyllum* (Brünnich, 1782)
Ägyptische Schlitznasen-Fledermaus (German)	*Nycteris thebaica* E. Geoffroy St.-Hilaire, 1818
Ägyptischer Höhlenflughund (German)	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)
ahwenekron (Tanoboase (Ghana))	*Hypsignathus monstrosus* H. Allen, 1862
Aldabra- Dreizahnblattnase (German)	*Paratriaenops pauliani* (Goodman and Ranivo, 2008)
Aldabra Flying Fox (English)	*Pteropus aldabrensis* True, 1893
Aldabra Flying-fox (English)	*Pteropus aldabrensis* True, 1893
Aldabra-Flugfuchs (German)	*Pteropus aldabrensis* True, 1893
Allen's Butterfly Bat (English)	*Glauconycteris alboguttata* J.A. Allen, 1917
Allen's Spotted Bat (English)	*Glauconycteris humeralis* J.A. Allen, 1917
Allen's Striped Bat (English)	*Glauconycteris alboguttata* J.A. Allen, 1917
Aloe Bat (English)	*Neoromicia zuluensis* (Roberts, 1924)
Aloe Serotine (English)	*Neoromicia zuluensis* (Roberts, 1924)
Aloe Serotine Bat (English)	*Neoromicia zuluensis* (Roberts, 1924)

Common Name	Taxon Name
Alpendwergvleermuis (Dutch)	*Hypsugo savii* (Bonaparte, 1837)
Alpenfledermaus (German)	*Hypsugo savii* (Bonaparte, 1837)
Alpen-Pipistrelle (German)	*Hypsugo savii* (Bonaparte, 1837)
Alpenvleermuis (Dutch)	*Hypsugo savii* (Bonaparte, 1837)
Alpesi denevér (Hungarian)	*Hypsugo savii* (Bonaparte, 1837)
Altwelt-Rundblattnasen (German)	*Hipposideros* Gray, 1831
ampane (singular) (Tanoboase (Ghana))	*CHIROPTERA* Blumenbach, 1779
ampane ankasa (Tanoboase (Ghana))	*Eidolon helvum* (Kerr, 1792)
ampane kronfo [="thief or criminal bat"] (see Ohemeng *et al.*, 2017: 184) (Tanoboase (Ghana))	*Epomophorus gambianus* (Ogilby, 1835)
Anchieta's Bat (English)	*Hypsugo anchietae* (Seabra, 1900)
Anchietas Breitgesicht-Flughund (German)	*Plerotes anchietae* (Seabra, 1900)
Anchieta's Fruit Bat (English)	*Plerotes anchietae* (Seabra, 1900)
Anchietas Pipistrelle (German)	*Hypsugo anchietae* (Seabra, 1900)
Anchieta's Pipistrelle (English)	*Hypsugo anchietae* (Seabra, 1900)
Anchieta's Plerote Fruit-bat (English)	*Plerotes anchietae* (Seabra, 1900)
Anchietas Zwergfledermaus (German)	*Hypsugo anchietae* (Seabra, 1900)
Anchieta-vlermuis (Afrikaans)	*Hypsugo anchietae* (Seabra, 1900)
Andersens Hufeisennase (German)	*Rhinolophus eloquens* K. Andersen, 1905
Andersens Schlitznasen-Fledermaus (German)	*Nycteris aurita* (K. Andersen, 1912)
Andersen's Slit-faced Bat (English)	*Nycteris aurita* (K. Andersen, 1912)
Andrew Rebori's House Bat (English)	*Scotophilus andrewreborii* Brooks and Bickham, 2014
Angavo (Malagasy)	*Eidolon dupreanum* (Schegel, 1867)
Angola-Bulldoggfledermaus (German)	*Mops (Mops) condylurus* (A. Smith, 1833)
Angola-Epaulettenflughund (German)	*Epomophorus angolensis* Gray, 1870
Angola-langhaarvlermuis (Afrikaans)	*Cistugo seabrae* Thomas, 1912
Angola-Langohrfledermaus (German)	*Laephotis angolensis* Monard, 1935
Angola-losstertvlermuis (Afrikaans)	*Mops (Mops) condylurus* (A. Smith, 1833)
Angola-Mausohr (German)	*Cistugo seabrae* Thomas, 1912
Angolan Epauletted Fruit Bat (English)	*Epomophorus angolensis* Gray, 1870
Angolan Epauletted Fruit-bat (English)	*Epomophorus angolensis* Gray, 1870
Angolan Free-tailed Bat (English)	*Mops (Mops) condylurus* (A. Smith, 1833)
Angolan Fruit Bat (English)	*Myonycteris angolensis* (Bocage, 1898)
Angolan Hairy Bat (English)	*Cistugo seabrae* Thomas, 1912
Angolan Long-eared Bat (English)	*Laephotis angolensis* Monard, 1935
Angolan Long-haired Fruit-bat (English)	*Myonycteris angolensis* (Bocage, 1898)
Angolan Mops Bat (English)	*Mops (Mops) condylurus* (A. Smith, 1833)
Angolan Rousette (English)	*Myonycteris angolensis* (Bocage, 1898)
Angolan Soft-furred Fruit-bat (English)	*Myonycteris angolensis* (Bocage, 1898)
Angolan Wing-gland Bat (English)	*Cistugo seabrae* Thomas, 1912
Angolanischer Samtfell-Flughund (German)	*Myonycteris angolensis* (Bocage, 1898)
Angolase Losstervlermuis (Afrikaans)	*Mops (Mops) condylurus* (A. Smith, 1833)
Angolase Vlerkkliervlermuis (Afrikaans)	*Cistugo seabrae* Thomas, 1912
Angola-witkolvrugtevlermuis (Afrikaans)	*Epomophorus angolensis* Gray, 1870
angon (Fang)	*Doryrhina cyclops* (Temminck, 1853)
Anjouan Mouse-eared Bat (English)	*Myotis anjouanensis* (Dorst, 1960)
Anjouan Myotis (English)	*Myotis anjouanensis* (Dorst, 1960)
Anjouan-Mausohr (German)	*Myotis anjouanensis* (Dorst, 1960)
Ansells Epaulettenflughund (German)	*Epomophorus anselli* Bergmans and Van Strien, 2004
Ansorge se losstertvlermuis (Afrikaans)	*Chaerephon ansorgei* (Thomas, 1913)
Ansorge-losstertvlermuis (Afrikaans)	*Chaerephon ansorgei* (Thomas, 1913)
Ansorges Bulldoggfledermaus (German)	*Chaerephon ansorgei* (Thomas, 1913)
Ansorge's Free-tailed Bat (English)	*Chaerephon ansorgei* (Thomas, 1913)
Ansorge's Wrinkle-lipped Bat (English)	*Chaerephon ansorgei* (Thomas, 1913)
apan (singular) (Twi (Ghana))	*CHIROPTERA* Blumenbach, 1779
Apopo (Kinande (DRC))	*Epomophorus labiatus* (Temminck, 1837)
Arabian barbastelle (English)	*Barbastella leucomelas* (Cretzschmar, 1826)
Arabian Horseshoe Bat (English)	*Rhinolophus clivosus* Cretzschmar, 1828
Arabische mopsvleermuis (Dutch)	*Barbastella leucomelas* (Cretzschmar, 1826)
Ariel Pipistrelle (English)	*Hypsugo ariel* (Thomas, 1904)
Asellia (French)	*Asellia* Gray, 1838
Asellia à trois endentures (French)	*Asellia tridens* (E. Geoffroy St.-Hilaire, 1813)
Asellia d'Afrique orientale (French)	*Cloeotis percivali* Thomas, 1901
Asellia de Patrizi (French)	*Asellia patrizii* de Beaux, 1931
Asèllia di Patrìzi (Italian)	*Asellia patrizii* de Beaux, 1931
Asèllia italosòmala (Italian)	*Asellia italosomalica* de Beaux, 1931
Asèllie (Italian)	*Asellia* Gray, 1838
Asian Barbastelle (English)	*Barbastella leucomelas* (Cretzschmar, 1826)
Asiatic Barbastelle (English)	*Barbastella leucomelas* (Cretzschmar, 1826)
Äthiopischer Samtfell-Flughund (German)	*Myonycteris angolensis petraea* (Bergmans, 1997)
Aufgeblasene Langflügelfledermaus (German)	*Miniopterus inflatus* Thomas, 1903
Auo-rnèr (Somalian)	*CHIROPTERA* Blumenbach, 1779
Azoren-Abendsegler (German)	*Nyctalus azoreum* (Thomas, 1901)
Azorenvleermuis (Dutch)	*Nyctalus azoreum* (Thomas, 1901)

Common Name	Taxon Name
Azores noctule (English)	*Nyctalus azoreum* (Thomas, 1901)
Baardvleermuis (Dutch)	*Myotis mystacinus* (Kuhl, 1817)
Badger bat (English)	*Glauconycteris superba* Hayman, 1939

Woolly Bats (English)	*Kerivoula* Gray, 1842
Woolly Rousette (English)	*Stenonycteris lanosus* (Thomas, 1906)
wrápenec menší (Czech)	*Rhinolophus hipposideros* (Bechstein, 1800)
wrápenec pahrbečný (Czech)	*Rhinolophus clivosus* Cretzschmar, 1828
wrápenec podkowní (Czech)	*Rhinolophus ferrumequinum* (Schreber, 1774)
wrápenec trojzeykowý (Czech)	*Asellia tridens* (E. Geoffroy St.-Hilaire, 1813)
wrápenecové (Czech)	*Rhinolophus* Lacépède, 1799
Wrinkled-lipped Bats (English)	*MOLOSSIDAE* Gervais, 1856
Wrinkled-lipped Bats (English)	*Molossinae* Gervais, 1856
Wrinkle-lipped Bat (English)	*Tadarida teniotis* (Rafinesque, 1814)
Wrinkle-lipped Bats (English)	*Chaerephon* Dobson, 1874
Wüsten-Großohren (German)	*Otonycteris* Peters, 1859
Yellow bats (English)	*Scotophilus* Leach, 1821
Yellow House Bat (English)	*Scotophilus dinganii* (A. Smith, 1833)
Yellow Pipistrelle Bat (English)	*Neoromicia flavescens* (Seabra, 1900)
Yellow Serotine (English)	*Neoromicia flavescens* (Seabra, 1900)
Yellow-bellied House Bat (English)	*Scotophilus dinganii* (A. Smith, 1833)
Yellow-haired fruit bat (English)	*Eidolon helvum* (Kerr, 1792)
Yellow-winged Bat (English)	*Lavia frons* (E. Geoffroy St.-Hilaire, 1810)
Yellow-winged Bats (English)	*Lavia* Gray, 1838
Yellow-winged Short-palate Fruit-bat (English)	*Casinycteris argynnis* Thomas, 1910
Zaïre Gland-tailed Bat (English)	*Chaerephon gallagheri* (Harrison, 1975)
zakrslí netopýři (Czech)	*Pipistrellus* Kaup, 1829
Zenker's Fruit Bat (English)	*Scotonycteris zenkeri* Matschie, 1894
Zenkers Harlekin-Flughund (German)	*Scotonycteris zenkeri* Matschie, 1894
Zenker's Harlequin Fruit-bat (English)	*Scotonycteris zenkeri* Matschie, 1894
Zenker's Tear-drop Fruit-bat (English)	*Scotonycteris zenkeri* Matschie, 1894
Ziama Horseshoe Bat (first use Simmons, 2005: 365) (English)	*Rhinolophus ziama* Fahr, Vierhaus, Hutterer and Kock, 2002
Ziama-Hufeisennase (German)	*Rhinolophus ziama* Fahr, Vierhaus, Hutterer and Kock, 2002
Zorra Voladora (Spanish (Castillian))	*Epomophorus wahlbergi* (Sundevall, 1846)
Zorra Voladora Amarilla (Spanish (Castillian))	*Eidolon helvum* (Kerr, 1792)
Zorra Voladora de Collar (Spanish (Castillian))	*Myonycteris torquata* (Dobson, 1878)
Zorra Voladora de Zenker (Spanish (Castillian))	*Scotonycteris zenkeri* Matschie, 1894
Zorro volador de Aldabra (Spanish (Castillian))	*Pteropus aldabrensis* True, 1893
Zorro volador de la isla Rodrigues (Spanish (Castillian))	*Pteropus rodricensis* Dobson, 1878
Zorro volador de las Seychelles (Spanish (Castillian))	*Pteropus seychellensis* A. Milne-Edwards, 1877
Zorro Volador De Livingston (Spanish (Castillian))	*Pteropus livingstonii* Gray, 1866
Zorro volador de Madagascar (Spanish (Castillian))	*Pteropus rufus* E. Geoffroy St.-Hilaire, 1803
Zorro volador de Voeltzkow (Spanish (Castillian))	*Pteropus voeltzkowi* Matschie, 1909
Zorro volador negro de Mauricio (Spanish (Castillian))	*Pteropus niger* (Kerr, 1792)
Zorro volador oscuro de Mauricio (Spanish (Castillian))	*Pteropus subniger* (Kerr, 1792)
Zuideuropese bulvleermuis (Dutch)	*Tadarida teniotis* (Rafinesque, 1814)
Zulu Pipistrelle Bat (English)	*Neoromicia zuluensis* (Roberts, 1924)
Zulu Serotine Bat (English)	*Neoromicia zuluensis* (Roberts, 1924)
Zulu-Pipistrelle (German)	*Neoromicia zuluensis* (Roberts, 1924)
Zulu-Zwergfledermaus (German)	*Neoromicia zuluensis* (Roberts, 1924)
Zwarte Komorenkalong (Dutch)	*Pteropus livingstonii* Gray, 1866
zweistreifige Doggengrämler (German)	*Chaerephon bivittatus* (Heuglin, 1861)
Zwerg-Bulldoggfledermaus (German)	*Mops (Xiphonycteris) nanulus* J.A. Allen, 1917
Zwerg-Doggengrämler (German)	*Chaerephon pumilus* (Cretzschmar, 1826)
Zwergfledermaus (German)	*Pipistrellus pipistrellus* (Schreber, 1774)
Zwergfledermäuse (German)	*Pipistrellus* Kaup, 1829
Zwergflughunde (German)	*Nanonycteris* Matschie, 1899
Zwerg-Langflügelfledermaus (German)	*Miniopterus minor* Peters, 1867
Zwerg-Schlitznasenfledermaus (German)	*Nycteris nana* (K. Andersen, 1912)
Zyklopen-Rundblattnase (German)	*Doryrhina cyclops* (Temminck, 1853)

Appendix 3f: Common Names by Language

"Congolese"

Kubukubo	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)
Papo	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)

Afrikaans

Aalwyndakvlermuis; Aalwynvlermuis	*Neoromicia zuluensis* (Roberts, 1924)
Anchieta-vlermuis	*Hypsugo anchietae* (Seabra, 1900)
Angola-langhaarvlermuis	*Cistugo seabrae* Thomas, 1912
Angola-losstertvlermuis	*Mops (Mops) condylurus* (A. Smith, 1833)
Angolase Losstervlermuis	*Mops (Mops) condylurus* (A. Smith, 1833)
Angolase Vlerkkliervlermuis	*Cistugo seabrae* Thomas, 1912
Angola-witkolvrugtevlermuis	*Epomophorus angolensis* Gray, 1870
Ansorge se losstertvlermuis	*Chaerephon ansorgei* (Thomas, 1913)
Ansorge-losstertvlermuis	*Chaerephon ansorgei* (Thomas, 1913)
Bakoor-losstertvlermuis	*Otomops martiensseni* (Matschie, 1897)
Bleek losstertvlermuis	*Chaerephon chapini* J.A. Allen, 1917
Bocage se vrugtevlermuis	*Myonycteris angolensis* (Bocage, 1898)
Bocagese Losstertvlermuis	*Tadarida aegyptiaca bocagei* (Seabra, 1900)
Bocage-vrugtevlermuis	*Myonycteris angolensis* (Bocage, 1898)
Bosveldsaalneusvlermuis	*Rhinolophus simulator* K. Andersen, 1904
Bosveldvlermuis	*Rhinolophus simulator* K. Andersen, 1904
Botswana-langoorvlermuis	*Laephotis botswanae* Setzer, 1971
Commerson se bladneusvlermuis	*Macronycteris commersoni* (E. Geoffroy St.-Hilaire, 1813)
Commerson se bladneusvlermuis	*Macronycteris gigas* (Wagner, 1845)
Commerson-bladneusvlermuis	*Macronycteris commersoni* (E. Geoffroy St.-Hilaire, 1813)
Commerson-bladneusvlermuis	*Macronycteris gigas* (Wagner, 1845)
Commersonse Blaarneusvlermuis	*Macronycteris gigas* (Wagner, 1845)
Commersonse Blaarneusvlermuis	*Macronycteris commersoni* (E. Geoffroy St.-Hilaire, 1813)
Damaralandse Wolhaarvlermuis	*Kerivoula argentata* Tomes, 1861
Damara-wolhaarvlermuis	*Kerivoula argentata* Tomes, 1861
Darling se saalneusvlermuis	*Rhinolophus darlingi* K. Andersen, 1905
Darling-saalneusvlermuis	*Rhinolophus darlingi* K. Andersen, 1905
Dent se saalneusvlermuis	*Rhinolophus denti* Thomas, 1904
Dent-saalneusvlermuis	*Rhinolophus denti* Thomas, 1904
Dentse Vlermuis	*Rhinolophus denti* Thomas, 1904
Dobson se vrugtevlermuis	*Epomophorus dobsonii* Bocage, 1889
Dobson-vrugtevlermuis	*Epomophorus dobsonii* Bocage, 1889
Drietand-blaarneusvlermuis	*Cloeotis percivali* Thomas, 1901
Drietand-bladneusvlermuis	*Cloeotis percivali* Thomas, 1901
Egiptiese losstertvlermuis	*Tadarida aegyptiaca* (E. Geoffroy St.-Hilaire, 1818)
Egiptiese spleetneusvlermuis	*Nycteris thebaica* E. Geoffroy St.-Hilaire, 1818
Egiptiese vrugtevlermuis	*Rousettus aegyptiacus* (E. Geoffroy St.-Hilaire, 1810)
Egiptiese witlyfvlermuis	*Taphozous perforatus* E. Geoffroy St.-Hilaire, 1818
Gambiaanse witkolvrugtevlermuis	*Epomophorus gambianus* (Ogilby, 1835)
Geel Dakvlermuis	*Scotophilus dinganii* (A. Smith, 1833)
Geel vrugtevlermuis	*Eidolon helvum* (Kerr, 1792)
Geoffroy se saalneusvlermuis	*Rhinolophus clivosus* Cretzschmar, 1828
Geoffroy-saalneusvlermuis	*Rhinolophus clivosus* Cretzschmar, 1828
Geoffroyse vlermuis	*Rhinolophus clivosus* Cretzschmar, 1828
Gevlekte losstertvlermuis	*Chaerephon bivittatus* (Heuglin, 1861)
Gewone-spleetneusvlermuis	*Nycteris thebaica* E. Geoffroy St.-Hilaire, 1818
Groot geel dakvlermuis	*Scotophilus nigrita* (Schreber, 1774)
Groot grotvlermuis	*Miniopterus inflatus* Thomas, 1903
Groot spleetneusvlermuis	*Nycteris grandis* Peters, 1865
Grootoor-losstervlermuis	*Tadarida lobata* (Thomas, 1891)
Groter spleetneusvlermuis	*Nycteris macrotis* Dobson, 1876
Haagnerse Platkopvlermuis	*Sauromys petrophilus haagneri* (Roberts, 1917)
Harige Langoorvlermuis	*Nycteris hispida* (Schreber, 1774)
Harige spleetneusvlermuis	*Nycteris hispida* (Schreber, 1774)
Hildebrandt se saalneusvlermuis	*Rhinolophus hildebrandtii* Peters, 1878
Hildebrandt-saalneusvlermuis	*Rhinolophus hildebrandtii* Peters, 1878
Hildebrandtse Vlermuis	*Rhinolophus hildebrandtii* Peters, 1878
Kaapse Blaarneusvlermuis	*Hipposideros caffer* (Sundevall, 1846)
Kaapse dakvlermuis	*Neoromicia capensis* (A. Smith, 1829)
Kaapse Langhaarvlermuis	*Myotis tricolor* (Temminck, 1832)

Kaapse Langoorvlermuis	*Nycteris thebaica* E. Geoffroy St.-Hilaire, 1818
Kaapse saalneusvlermuis	*Rhinolophus capensis* Lichtenstein, 1823
Kaapse Vlermuis	*Rhinolophus capensis* Lichtenstein, 1823
Klein dakvlermuis	*Nycticeinops schlieffenii* (Peters, 1859)
Klein geel dakvlermuis	*Scotophilus viridis* (Peters, 1852)
Klein grotvlermuis	*Miniopterus fraterculus* Thomas and Schwann, 1906
Klein losstertvlermuis	*Chaerephon pumilus* (Cretzschmar, 1826)
Klein Vrugtevlermuis	*Epomophorus crypturus* Peters, 1852
Klein wolhaarvlermuis	*Kerivoula lanosa* (A. Smith, 1847)
Kuhl se vlermuis	*Pipistrellus kuhlii* (Kuhl, 1817)
Kuhl-vlermuis	*Pipistrellus kuhlii* (Kuhl, 1817)
Lander se saalneusvlermuis	*Rhinolophus landeri* Martin, 1838
Lander-saalneusvlermuis	*Rhinolophus landeri* Martin, 1838
Langoor-vlermuise	*NYCTERIDAE* Van der Hoeven, 1855
Langstert-dakvlermuis	*Eptesicus hottentotus* (A. Smith, 1833)
Lesueur se langhaarvlermuis	*Cistugo lesueuri* Roberts, 1919
Lesueur-langhaarvlermuis	*Cistugo lesueuri* Roberts, 1919
Lesueurse Vlerkkliervlermuis	*Cistugo lesueuri* Roberts, 1919
Madagaskarse grootlosstertvlermuis	*Tadarida fulminans* (Thomas, 1903)
Midas se losstertvlermuis	*Mops (Mops) midas* (Sundevall, 1843)
Midas-losstertvlermuis	*Mops (Mops) midas* (Sundevall, 1843)
Namib-langoorvlermuis	*Laephotis namibensis* Setzer, 1971
Natalse losstertvlermuis	*Mormopterus acetabulosus* (Hermann, 1804)
Nigeriese losstertvlermuis	*Chaerephon nigeriae* Thomas, 1913
Peters se witkolvrugtevlermuis	*Epomophorus crypturus* Peters, 1852
Peters-witkolvrugtevlermuis	*Epomophorus crypturus* Peters, 1852
Piesangvlermuis	*Neoromicia nana* (Peters, 1852)
Platkop-losstertvlermuis	*Sauromys petrophilus* (Roberts, 1917)
Rendal-dakvlermuis	*Neoromicia rendalli* (Thomas, 1889)
Rendall se dakvlermuis	*Neoromicia rendalli* (Thomas, 1889)
Reuse losstertvlermuis	*Tadarida ventralis* (Heuglin, 1861)
Roeskleurvlermuis	*Pipistrellus rusticus* (Tomes, 1861)
Rooi langhaarvlermuis	*Myotis bocagii* (Peters, 1870)
Rüppell se saalneusvlermuis	*Rhinolophus fumigatus* Rüppell, 1842
Rüppell se vlermuis	*Pipistrellus rueppellii* (Fischer, 1829)
Rüppell-saalneusvlermuis	*Rhinolophus fumigatus* Rüppell, 1842
Rüppell-vlermuis	*Pipistrellus rueppellii* (Fischer, 1829)
Schlieffen se vlermuis	*Nycticeinops schlieffenii* (Peters, 1859)
Schlieffen-vlermuis	*Nycticeinops schlieffenii* (Peters, 1859)
Schreiber-grotvlermuis	*Miniopterus schreibersii* (Kuhl, 1817)
Schreibers se grotvlermuis	*Miniopterus schreibersii* (Kuhl, 1817)
Skedestertvlermuis	*Coleura afra* (Peters, 1852)
Somali-dakvlermuis	*Neoromicia somalica* (Thomas, 1901)
Spitssaalneusvlermuis	*Rhinolophus blasii* Peters, 1867
Sundevall se bladneusvlermuis	*Hipposideros caffer* (Sundevall, 1846)
Sundevall-bladneusvlermuis	*Hipposideros caffer* (Sundevall, 1846)
Sundevallse blaarneusvlermuis	*Hipposideros caffer* (Sundevall, 1846)
Swinny se saalneusvlermuis	*Rhinolophus swinnyi* Gough, 1908
Swinny-saalneusvlermuis	*Rhinolophus swinnyi* Gough, 1908
Swinnyse Vlermuis	*Rhinolophus swinnyi* Gough, 1908
Temminck se langhaarvlermuis	*Myotis tricolor* (Temminck, 1832)
Temminck-langhaarvlermuis	*Myotis tricolor* (Temminck, 1832)
Thomas se vlermuis	*Scotoecus albofuscus* (Thomas, 1890)
Thomas-vlermuis	*Scotoecus albofuscus* (Thomas, 1890)
Transvaalse losstertvlermuis	*Tadarida ventralis* (Heuglin, 1861)
Vinson se spleetneusvlermuis	*Nycteris vinsoni* Dalquest, 1965
Vlindervlermuis	*Glauconycteris variegata* (Tomes, 1861)
Wahlberg se vrugtevlermuis	*Epomophorus wahlbergi* (Sundevall, 1846)
Wahlberg-witkolvrugtevlermuis	*Epomophorus wahlbergi* (Sundevall, 1846)
Welwitsch se langhaarvlermuis	*Myotis welwitschii* (Gray, 1866)
Welwitsch-langhaarvlermuis	*Myotis welwitschii* (Gray, 1866)
Winton se langoorvlermuis	*Laephotis wintoni* Thomas, 1901
Winton-langoorvlermuis	*Laephotis wintoni* Thomas, 1901
Witlyfvlermuis	*Taphozous mauritianus* E. Geoffroy St.-Hilaire, 1818
Wood se spleetneusvlermuis	*Nycteris woodi* K. Andersen, 1914
Woodse Langoorvlermuis	*Nycteris woodi* K. Andersen, 1914
Wood-spleetneusvlermuis	*Nycteris woodi* K. Andersen, 1914

Albanian

Lakuriq nate bisht-lire	*Tadarida teniotis* (Rafinesque, 1814)
Lakuriq nate gisht-gjate	*Myotis capaccinii* (Bonaparte, 1837)
Lakuriq nate hundpatkua I Blasius-it	*Rhinolophus blasii* Peters, 1867
Lakuriq nate hundpatkua i madh	*Rhinolophus ferrumequinum* (Schreber, 1774)
Lakuriq nate hundpatkua i Mesdheut	*Rhinolophus euryale* Blasius, 1853

Lakuriq nate hundpatkua i vogel	*Rhinolophus hipposideros* (Bechstein, 1800)
Lakuriq nate i Geoffroy-it	*Myotis emarginatus* (E. Geoffroy St.-Hilaire, 1806)
Lakuriq nate I Schreiber-it	*Miniopterus schreibersii* (Kuhl, 1817)
Lakuriq nate me mustage	*Myotis mystacinus* (Kuhl, 1817)
Noktule e Leisler-it	*Nyctalus leisleri* (Kuhl, 1817)
Pipistrel i Kuhl-it	*Pipistrellus kuhlii* (Kuhl, 1817)
Pipistrel I Savi-it	*Hypsugo savii* (Bonaparte, 1837)
Pipistrel i zakonshem	*Pipistrellus pipistrellus* (Schreber, 1774)

Arabian

Khafash abiad	*Otonycteris hemprichii* Peters, 1859

Appendix 3g: Original Descriptions

[Epomophorus (]Nanonycteris[)] Matschie, 1899

p. 58

Subgen. *Nanonycteris* Mtsch, subgen. nov,

Die Entfernung zwischen dem vorderen Augenwinkel und der Nasenspitze ist viel grösser als die Breite des Gesichtes an den Mundwinkeln. Auf dem Gaumen stehen parallele querfalten. Die Lippe ist nicht gefurcht. Der Schwanz ist noch kürzer als bei *Micropteropus*. Auf dem Plagiopatagium durchschneiden weniger als 32 Fascien dem vom Ellenbogen zur Spitze des fünften Fingers verlaufenden Strang. Die Reihe der Molaren ist nur so lang wie die Entfernung zwischen den Spitzen der oberen Caninen; der letzte obere Molar reicht nur bis zur Höhe des Vorderrandes des Foramen infraorbitale. Der knöcherne Gaumen ist wie bei *Epomops* gebildet. Der Unterarm ist kürzer als 60 mm.

Typus: *Ep. veldkampi* Jent.
Hab. Ober- und Mittel-Guinea.

[Epomophorus macrocephalus] var. angolensis Gray, 1870

p. 125

Pale brown; head with a dark streak from the nostrils to the front of the lower edge of the eye, and a second rather above and parallel with the upper lip; chest and beneath whitish; epaulette pale brown; forearm 3 $^{1}/_{4}$ inches. Female. B. M.

Hab. Angola, *Montiero* (in spirit).

[Epomophorus macrocephalus] var. unicolor Gray, 1870

p. 125

Brown above and below; epaulet white, rather small. B. M.

Allomops J.A. Allen, 1917

p. 470

Text Figs. 12-15.

Type, *Chærephon (Allomops) osborni* sp. nov.

Supraoccipital border of skull enormously developed in old males, the lambdoid crest high and broad, expanded upward and backward into an oblique overhang, equal in height to about one half the interorbital breadth of the skull, or considerably exceeding the width of the foramen magnum, the upper border nearly straight, equal in length; to about one half the width of the braincase, with an extension downward from the lateral upper corner on either side to the mastoid process; less developed but strongly indicated in females and young males; sagittal crest weakly developed in the smaller species of the group, very heavily so in tho larger forms.

General form of the skull as in *Nyctinomus*, the braincase broad and flattened, preorbital furrow or depression conspicuous, but preorbital processes absent; premaxillæ usually fully ossified on front border, but sometimes emarginate.

Dental formula: i $^{1\text{-}1}/_{2\text{-}2}$, c $^{1\text{-}1}/_{1\text{-}1}$, p $^{2\text{-}2}/_{2\text{-}2}$ (or $^{1\text{-}1}/_{2\text{-}2}$), p^2 being deciduous or wholly absent in some species), m $^{3\text{-}3}/_{3\text{-}3}$ = 30 (or 28). Upper incisors small, about one third the length of the canines, parallel, widely separated from each other and the canines;

p. 471

lower incisors very, small, bilobed, the outer smaller than the middle ones, postero-external to them in position, often one or both outer lower incisors deciduous. Upper canines very long, slender and sharp-pointed, with a broad, shallow longitudinal groove on the front face, and a narrow postero-internal cingulum; lower canines correspondingly slender, with a broad postero-internal cingulum. First upper premolar (p^2) minute, in the toothrow (usually) or external to the base of the canine, sometimes deciduous; p^4 about half the size of m^1, larger than m^3. First lower premolar (p_2) larger than p_4 in males, smaller than p_4 in females, the sexual difference in the size of p_2 well marked in all the (four) known species. Upper molars with m^3 small, about one third the size of m^2. Molar-premolar series in both jaws heavy, low and broad, with, very broad mandibular rami.

Males larger than the females, the sexual difference in size especially evident in the skulls, where it is emphasized by the much larger size of p_2 in the males than in the females relatively to the size of p_4. Ears of medium size, thick and heavy, united at the

base by a broad membrane, which extends forward as a conspicuous protuberance in front of the ears. Tail relatively short, about two fifths of the length of head and body, rather more than the apical half free. Sides of back naked, the nakes space continuous with the naked hind limbs and naked hinder portion of the body, which is bare of fur on both surfaces posterior to a line joining the hips. From the region of the hips arises a fringe of scattered blackish bristles, directed backward and reaching to or beyond the middle of the uropatagium, the number of these bristly hairs varying, even in different individuals of the same species, from a few to a fairly conspicuous fringe. Pelage of the upperparts exceptionally short, soft and velvety; on the underparts longer and more dense. Color pattern distinctive, - very dark

p. 472

above and along the sides of the body below, without white at the base of the patagium. Wing membranes blackish, thick and leathery.

The present group, whether considered as of generic or as only of subgeneric value, is a natural group, much more sharply defined from all others than is *Chærephon* from *Nyctinomus*, although these two groups have been long currently given recognition as genera. In the present connection it is given subgeneric rank. The four known species are here described as new, although one of them; may be the same as *Nyctinomus thersites* of Thomas, which apparently belongs to the *Allomops* group. They are small to medium sized species, one of them, *Allomops nanulus*, being the smallest known African molossid.

In working out this group, in connection with other African molossid material, I have been impressed with the small value of the character most commonly considered as an important index to the relation of species referred to *Nyctinomus* and *Chærephon*, namely, the emargination or non-emargination of the front border of the premaxillæ. In one instance in the study of a series of 23 specimens collected the same day at the same locality, and evidently beyond question conspecific, I took up the skulls first, with skulls of other species, to determine their generic affinities. Later on collating the skulls (marked only with their catalogue numbers) with the skins to which they belonged, I found I had referred part to *Nyctinomus* and part to *Chærephon*! Further study of the same series showed that in this case at least emargination and non-emargination of the front border of the premaxillæ was largely dependent on the age of the specimen, the vacuity behind the incisors becoming gradually closed by ossification with the increased age of the specimen.

In one of the species here referred to *Allomops*, represented by six adult specimens, two, on the basis of the condition of the premaxillæ, are typically *Nyctinomus* and the other four typically Chærephon. They were otherwise indistinguishable, either on the basis of external and cranial characters or by the age of the specimen. In another species here referred to *Allomops*, represented by seven specimens, all of the skulls had the front palatal border emarginate, but as all of the other characters, both external and cranial, were typical of the *Allomops* group, it seemed proper to give preference to the combined weight of the *Allomops* characters, despite the *Nyctinomus*-like condition of the premaxillæ.

Alobus Peters, 1868

p. 707

Vespertilio (Alobus) Temminckii Rüppell

Von dieser kleinen Art habe ich kürzlich ein Weingeistexemplar erhalten und dabei gefunden, dafs sie sich von allen andern der Gattung *Vesperugo* (mit $^{5}/_{(5)}$ Backzähnen) durch den gänzlichen Mangel eines Spornlappens, durch eine der von *V. dasycneme* ähnliche Ohrklappe, sowie im Schädelbau durch die besondere Kürze und Abplattung des Schnauzentheils auszeichnet, weishalb ich sie als eine besondere Untergattung, *Alobus*, trennen zu müssen glaube, welche ein Mittelglied zwischen *Vesperugo* und *Vespertilio* bildet.

Asellia tridens diluta K. Andersen, 1918

p. 375

Like *A. tridens tridens*, but averaging larger, and colour of fur conspicuously paler.

Forearm 52.2 mm.

Skull: length to foot of canine 18.7; cond.-can. 16.6; c-m^3 7; c-m_3 7.7.

Hab. (of type). El Golea, Algerian Sahara. Other specimens from Biskra.

Type. Female. B.M. no. 12.11.14.2. Original number 42. Collected 16th May, 1912, by Dr. E. Hartert. Presented by Lord Rothschild.

Asellia tridens pallida Laurent, 1937

p. 111

Le genre *Asellia* Gray, n'était jusqu'ici connu en Afrique du Nord que par une seule sous-espèce locale, *A. tridens diluta* Andersen, différente par sa taille plus grande et sa coloration plus pâle du type de l'espèce *A. tridens* Geoffroy; cette forme, dont

Lataste avait déjà observé les caractères distinctifs lorsqu'il en vit à Gafsa, le premier représentant barbaresque, n'avait pas, jusqu'à maintenant, été signalée au delà de Figuig (Foley) et nulle part ailleurs au Maroc.

Or, dans une collection de chauves-souris confiées au Muséum d'Histoire Naturelle par l'Institut scientifique Chérifien, figurait une *Asellia tridens* recueilli en 1930 dans la région de l'Oued Tatta (collecteur, le Chaouch Ahmed), soit dans l'Anti-Atlas à 400 kilomètres environ en ligne droite de Figuig. Mais cet individu diffère suffisamment tant par sa coloration que par quelques détails morphologiques de *A. tridens diluta* Andersen, pour qu'il ne soit pas possible de le rapporter à la sous-espèce du Sahara Algérien; j'ai donc cru pouvoir en faire une forme nouvelle, sans doute à étroite localisation géographique et je la décris ici sous le nom de: *Asellia tridens pallida* subsp. nov.

DESCRIPTION. - *Asellia tridens* de teinte extrêmement pâle, plus pâle encore et plus petite que *A. t. diluta*, et présentant de plus quelques particularités morphologiques.

Ornementation nasale très semblable à celle de *A. t. diluta*; toutefois la légère convexité sagittale que porte en sa partie médiane le fer à cheval apparaît au bord antérieur libre sous l'aspect d'une pointe plus saillante. La concavité semi-lunaire de

p. 112

la base du trident est par coutre moins marquée, les denticules du trident sont moins élevées, en particulier le denticule médian. Le premier repli périnasal s'insère nettement plus en avant (à peu pres 0.5 mm.) sur la lèvre supérieure, tandis que le repli qui le suit extérieurement s'insère au même niveau mais en arrières, au lieu de prendre attache un peu plus bas comme dans la forme algérienne. Enfin il existe extérieurement un 3^{e} repli pérional ou jugal, sous la forme d'une petite languette cutanée à bord libre frangé, d'une longueur de 1.2 à 1.5 mm. de direction oblique d'avant en arrière et de haut en bas, dont l'intérêt réside en ce que cette languette jugale, parfaitement visible chez l'individu marocain, est à peine distincte chez les sujets algériens, sans toutefois manquer complètement: ce qui explique pourquoi elle est omise par la description d'Andersen, que rapporte Cabrera (... herradura; con dos hojuelas accesorias a cada lado), "Mammiferos de Maruccos"... p. 89).

La lèvre supérieure glabre en sa partie moyenne, porte un petit bourrelet médian plus visible chez *A. t. diluta* que dans la forme nouvelle, mais présent chez l'une et l'autre.

Les oreilles de forme tout à fait semblable, sont striées longitudinalement d'une vingtaine (ou au moins d'une douzaine, bien

p. 113

visibles) de sillons transversaux parallèles, profondément marqués et très apparents chez *A. t. diluta*, au contraire à peine marqués et peu visibles chez *A. t. pallida*.

Le reste de la face ne présente aucun caractère particulièrement différent; le corps, les membres et la formule dentaire sont tout à fait comparables à ceux la forme algérienne. Les ailes, naturellement de même disposition, portent un gaufrage, superficiel à peu près identique.

L'insertion de la membrane interfémorale se fait sur le tiers supérieur de l'avant-dernière vertèbre; mais ce caractère n'a pas, comme je l'avais cru tout d'abord, de valeur différentielle, car l'examen de plus nombreux exemplaires algériens m'a montré qu'il était inconstant, de même que le rapport entre la partie libre de la queue et sa longueur totale. Dans l'exemplaire marocain, la longueur de la queue qui est libre en dehors de la membrane interfémorale, atteint, comme le type égyptien, le tiers de la longueur totale, et chez les individus algériens que j'ai examinés, cette même dimension varie de 30 à 42 p. 100,

Enfb. l'aspect extérieur de *A.t. pallida* est trop peu différent de celui du type de l'espèce pour l'examen complet du squelette entraînant la destruction de l'unique échantillon, soit indispensable. Il n'y a pas de raison pour que la forme nouvelle pût présenter un quelconque caractère osseux différentiel.

MENSURATIONS. - Voici les mesures somatiques du type de la description, avec dans la colonne en regard, celles d'un exemplaire de l'espèce: *A. t. diluta* du Sud-Algérien ([1]) ce sujet étant le plus grand que j'aie jusqu'ici mesuré ([a]).

F, M
Tête et corps: 46, 49
Queue: 25, 25
Queue (sa partie libre): 8, 9
Oreille: 16.5, 16.5
Oreille (sa plus grande largeur): 10.5, 13.5

Footnotes:
([a]) Cet exemplaire, don du D^{r} FOLEY, de l'Institut Pasteur d'Alger, capturé le 14 septembre 1936, à Hassi Fohra, Beni-Abbès, Sud-Oranais Saharien et qui a figuré sous le numéro 900 dans ma collection personnelle, fait maintenant partie de celle du Muséum d'Histoire Naturelle à Paris.

([1]) Cette dimension est certainement de toutes la plus sujette à caution: elle peut varier selon les observateurs et à divers stades de la conservation d'un même sujet; aussi je me demande quelle valeur peut-on attribuer pour la classification systématique à ce caractère, lorsqu'il ne s'agit quo d'une variation de quelques millimètres, alors que toutes les autres dimensions concordent.

p. 114

F, M
Largeur du fer à cheval ([2]): 6.7, 7.6
- de la bouche ([3]): 7.1, 7.1
Avant-bras: 51, 51
III^{e} doigt métacarpien ([4]): 38, 37

- - 1re phalange: 12.5 - 13, 15 - 17
- - 2e phalange: 15.5 - 16.0, 17

IVe doigt métacarpien: 36, 35 - 37
- - 1re phalange: 12, 11.5 - 12
- - 2e phalange: 8, 8

Ve doigt métacarpien: 28.5 - 29, 28.5 - 31
- - 1re phalange: 13.5 - 14.5, 13.5
- - 2e phalange: 9.5, 10

Tibia: 18.5 - 19, 20 - 20.5
Pied (sans les ongles): 8, 8.5
Poids à sec: 8 gr. 5, 9 gr. 55

COLORATION. - Animal beaucoup plus pâle que *A. t. diluta* et même presque complètement blanc, les parties nues étant elles-mêmes de teinte beaucoup plus claire. Le poil est partout d'un blanc par à sa hase, aussi bien sur le ventre que sur le dos, mais la pointe en est lavée d'une nuance bistre très clair sur les côtés du thorax, dans les aisselles, sur les épaules, et en quelques points symétriques du dos, des lombes et de la nuque. La face supérieure du crâne, les joues, le cou, la gorge, les cuisses et toutes les parties inférieures sont entièrement blanches; ce blanc étani beaucoup plus pur et plus soutenu que chez *A. t. diluta*, où il est plutôt terne et un peu jaunâtre. Le pelage couvre les joues, mais ne cache pas les yeux dont les paupières sont nues, et laisse nue la face autour et au-dessous de l'ornementation nasale, ainsi que le menton.

La lèvre supérieure, nue au milieu, porte de chaque côté une brosse de poils argentés plus régulièrement croissante extérieurement et plus fournie que chez les sujets algériens. Le bord interne de la face antérieure du pavillon porte de même une rangée de poils plus longs et d'un blanc beaucoup plus vif; par contre, les longs poils tactiles de la face présentent exactement même longueur et même disposition. Les organes génitaux sont nus dans les deux formes, mais celle du Maroc ne présente ni organes érectiles saillants

Footnotes:
([2]) D'un bord à l'autre de la convexité, laissant en dehors les replis périnasaux.
([3]) Mesuré sous le menton, d'une commissure à l'autre.
([4]) Lorsque deux chiffres sont donnés, l'un plus grand que l'autre, c'est que le segment de membre de l'un des deux côtés du corps n'a pas la même dimension que son homologue de l'autre côté: ce cas est très fréquent.

p. 115

ni mamelles apparentes (une paire abdominale, et une paire pectorale) ce qui me fait penser qu'il s'agit d'une femelle adulte mais jeune.

Les oreilles sont de teinte paille terne, les membranes alaires et interfémorales, sépia clair et non brun noirâtre comme chez *A. t. diluta*.

DIAGNOSE. - Cette forme se distingue de suite du type de l'espèce par sa teinte presque blanche, qui peut la distinguer aussi de la sous-espèce algérienne déjà claire. Du point de vue coloration, cette dernière forme est intermédiaire entre la Marocaine et l'Egyptienne typique. Les petits détails différentiels qui ont été énumérés au cours de la description, caractérisent bien *A. t. pallida*, mais leur observation nécessite l'examen comparatif des deux formes côte à côte. Je n'ai pu conserver comme caractère différentiel indubitable l'insertion de la membrane interfémorale sur l'une ou l'autre des dernières vertèbres caudales, ce caractère, qui m'avait paru constant, n'ayant pas résisté à l'examen d'un nombre plus important d'exemplaires. Je crois donc que la coloration du poil, blanche à la base partout, est e principal caractère différentiel entre les deux formes, avec, naturellement la teinte d'ensemble beaucoup plus claire. On peut ensuite accorder quelque valeur au développement plus ou moins net du 3e repli périnasal, à la bordure frangée ou non du 1er repli, à l'importance de la striation de l'oreille, etc...

Jusqu'à un certain point, la sous-espèce marocaine pourrait se rapprocher de la toute petite *Asellia patrizii* de Beaux, car son avant-bras est plutôt plus grand que la dimension métacarpien + 1re phalange du 3e doigt, caractère qui sert à De Beaux pour isoler cette forme naine de Dancalie, de toutes les *Asellia tridens* Arabes et Égyptiennes, où cette dimension dépasse de 1 à 3 millimètres celle de l'avant-bras; ce qui est aussi le cas dans toutes les *A. t. diluta* que j'ai jusqu'ici examinées (le dépassement va même jusqu'à 5 ou 6 millimètres). Mais *A. patrizii* si éloignée de par sa localisation géographique, se différencie suffisamment par ailleurs pour qu'on ne puisse accorder à ce caractère qu'une simple valeur de convergence.

Il me semble raisonnable de penser que c'est de *A. t. diluta* que la nouvelle forme se rapproche le plus, mais je n'ai actuellement pas la possibilité d'établir de comparaison avec les autres sous-espèces de *A. tridens* ce qui ne manquerait pas d'un vif intérêt.

p. 116

DISTRIBUTION GEOGRAPHIQUE. - Le Maroc montagneux et méridional est suffisamment inexploré et mal connu du point de vue scientifique, pour qu'on puisse espérer retrouver cette forme ailleur, que dans le Bled Tatta d'où elle provient; notons toutefois qu'*Asellia tridens diluta* parvient jusqu'à Figuig et Beni Abbès (d'où viennent tous les individus que j'ai examinés grâce à la complaisance du Dr Foley), à peu près situées sous la même longitude et que Heim de Balsac la signale en divers points du Sahara; elle est évidemment beaucoup plus répandue qu'*Asellia tridens pallida*, que je ne crois pas être autre chose qu'une intéressante forme évolutive locale.

Groupe Collectif: *Attalepharca* nov.

Origine du nom: de "attaleph", nom hébreu des chauves-souris dans la Bible (selon Maisonneuve, 1878), et "arca", l'arche. Il laisse sous-entendre un statut transitoire, une instance, le temps d'une réflexion.

Il est pour le principal formé par des espèces myotodontes, jusqu'alors classées dans le genre *Pipistrellus* compte tenu de leurs formules dentaires identiques à celle des pipistrelles. Il comprend aussi une espèce, *flavescens* (SEABRA, 1910), classée parmi les *Eptesicus* pour avoir perdu la P2/, alors que ses structures dentaires indiquent une origine différente, tant de ce dernier genre que de *Nycterikaupius*.

Du point de vue odontologique, les espèces rassemblées dans le Groupe Collectif *Attalepharca* sont proches entre elles, ce qui n'exclut pas certaines particularités dont l'éventuelle importance, spécifique ou générique, reste à définir. La même remarque peut être faite au regard de l'anatomie générale. Dans ces conditions, et avant une révision exhaustive, la proposition d'un Groupe Collectif s'impose pratiquement. Considérer d'emblée ces espèces comme étant congénériques, créer pour elles un taxon commun, serait user d'un faux-semblant qui compliquerait inutilement la taxonomie dans un proche avenir.

La possibilité de les rassembler à titre temporaire en un Groupe Collectif est conforme aux possibilités précisées au Chapitre I, art. 1 (d) du Code International de Nomenclature Zoologique. Notre proposition semble recevable, puisque la présente situation correspond exactement à celle définie par le Code (Edition de 1985, p. 279): "Ensemble d'espèces nominales qui ne peuvent pas être placées avec certitude dans les genres connus".

Pour faciliter les vérifications, la liste commentée des taxons placés dans le Groupe Collectif comportera les immatriculations des spécimens de référence. Ici aussi, la liste est restreinte aux espèces qu'il nous a été donné de soumettre à l'examen; elle n'a donc pas un caractère limitatif.

- Eléments spécifiques du Groupe Collectif *Attalepharca*:

anchietae (SEABRA, 1900). L'espèce présente certains caractères conservateurs: métaconules bien développés sur Ml/ et M2/; maintien d'un paralophe et d'un métalophe sur les mêmes dents; présence d'une très petite P2/ et d'un léger espace entre la canine et P4/.
Références: BMNH 69.1248, 10.2632, 10.2634 - Zambie.

bodenheimeri (HARRISON, 1960). Cette espèce conserve une P2/ résiduelle. On remarque une grande ressemblance de la denture avec celle de *Hypsugo*, constatation n'ayant d'ailleurs pas échappé au descripteur qui précisait: "Its dentition shows that it belongs to the *P. savii* group of which it appears to be a small and very distinct Arabian représentative". Nous la plaçons dans le Groupe Collectif à titre de précaution, mais la possibilité d'un rattachement à *Hypsugo*, après examen complémentaire, ne doit pas être exclue.
Références: BMNH 67.1255 - Ile Socotra.

crassulus (THOMAS, 1915). Cette petite espèce, à crâne relativement large, possède une denture proche de celle de *Hypsugo*. L'examen d'un matériel plus important,

p. 127

portant aussi sur les parties molles de l'animal, est nécessaire avant d'envisager son transfert.
Références: BMNH 63.1174 - Congo.

flavescens (SEABRA, 1900). La denture est très proche de celles de *Hypsugo savii* et de *Pipistrellus mordax*. Le fait que le matériel muséologique est, a priori, restreint ne facilite as les comparaisons souhaitables. Les II/ et C. sup. du seul spécimen examiné en font un néoeptésiforme de statut générique incertain, ce qui nous a amené à le placer en instance dans le Groupe Collectif.
Références: MNHN 1900.536 - Angola.

joffrei (THOMAS, 1915). Cette espèce bien particulière a été décrite comme appartenant au genre *Nyctalus*, puis rapportée ensuite par Tate (1942) au genre *Pipistrellus*. Sa nette myotodontie ne permet pas son maintien dans l'un ou l'autre des deux genres précités. Elle est remarquable par sa C. sup. porteuse d'une cuspide secondaire, sa P2/ résiduelle, ses M1/-M2/ à protofossa largement ouvertes vers l'arrière et sa M3/ très peu réduite. Le crâne est, entre autres particularités, caractérisé par une forte apophyse anté-orbitaire. Sous réserves, le statut générique adéquat pourrait être indépendant.
Références: BMNH 16.3.26.2 - Chin Hills, SW Mackenzie; BMNH 16.3.26.84 - Birmanie.

kitcheneri (THOMAS, 1915). La P2/ est petite, et le contact est établi entre la C. sup. et la P4/. Les molaires supérieures ne présentent pas de paralophe, sauf, parfois, à l'état résiduel, et pas de métalophe; l'importance du métaconule est très variable. La proximité de parenté de cette espèce doit être recherchée avec *macrotis* et *vordermanni*.
Références: BMNH 10.4.5.49, 10.4.5.50, 10.4.5.53, 10.4.5.154 - tous de Bornéo.

macrotis (TEMMINCK, 1835). Primitivement attribuée à *Pipistrellus*, c'est une espèce qui doit trouver place parmi les formes à crâne globuleux susceptibles de constituer une des futures subdivisions du Groupe Collectif. Au Muséum de Leiden, quatre individus, ayant préalablement fait l'objet d'une étude par Koopman, sont regroupés. Ils sont accompagnés de l'annotation suivante: "These four spécimens (cotypes from Sumatra and one other from Bornéo) are *P. macrotis*, not *imbricatus*". Ce sont les spécimens m, n, o et p du Catalogue de Jentink. Compte tenu de son ancienneté, ce matériel est en mauvais état et se prête très mal à une recherche odontologique. Il est difficile de distinguer, sur la seule base de la morphologie crânienne et de la denture, une différence marquée entre *macrotis* et *vordermanni* (souvent appelé *imbricatus*). Il semble toutefois que Ml/ soit un peu plus large sur le premier, et que la même dent tende à devenir subcarrée chez le second (voir ci-après *vordermanni*). Les *macrotis* conservent une P2/ bien cingulée qui ne s'oppose pas au contact entre les canine et P4/. Sur la rangée inférieure la P/4 est petite, et légèrement déplacée vers l'intérieur.
Références: RNH spécimens m, n, o, p du Catalogue de Jentink - Sumatra et Bornéo ; BMNH 23.1.2.12 - Sumatra.

mordax (PETERS, 1866). Sur le plan dentaire, *Pipistrellus mordax* apparaît proche des *Hypsugo*. La P2/, bien cingulée, est relativement forte, son importance est du même ordre que celle observée chez *Hypsugo pulveratus*. Nous avons examiné le spécimen n° 156 de la collection étudiée par Sody (1937), provenant de Tjiboeni, Java. Ses mensurations de l'avant-bras et du crâne correspondent à celles données par Peters pour le type.
Références: RNH n° 156 Coll. Sody - Java; MNHN 1876.356 - Philippines; BMNH 79.11.21.203 - Kumaon, et 16.3.25.5 - Darjeeling. Les deux derniers présentent une morphologie dentaire conforme à celle de mordax, cependant une plus petite taille et des provenances géographiques éloignées de celles du type

p. 128

rendent souhaitable une vérification de leur identité spécifique.

musciculus (THOMAS, 1913). La présence d'une petite P2/ a contribué au maintien de cette espèce dans le genre *Pipistrellus*. Il arrive cependant que cette dent manque. La structure de II/ et une nette myotodontie nous la font placer dans le Groupe Collectif. Sa morphologie dentaire reste très proche de celles des pipistrelles.
Références: MHNG 914.42, 914.43,914.45 - NE Zaïre ; CB 008 - Gabon.

nilssoni (KEYSERLING et BLASIUS, 1839). La position générique de cette espèce reste à définir. Nous l'avons placée provisoirement dans le Groupe Collectif pour attirer l'attention sur ce cas particulier. La morphologie de II/ l'éloigné autant des Eptesicus que des *Nycterikaupius*; son crâne plat la sépare des espèces à crâne globuleux (*macrotis, vordermanni*); elle est autre que les *Hypsugo* par l'absence permanente de P2/, les structures de la canine supérieure, et le développement du flexus labial de P4/. Nous ne serions pas étonnés que des investigations multiformes mènent à une indépendance générique. Dans ce cas, le nom du taxon qui deviendrait prioritaire serait *Amblyotus* KOLENATI, 1858.
Références: BMNH 25.11.3.4 - Norvège; MHNG 890.42, 975.83, 1492.65, 1492.93 - Suisse, et 986.4 - Autriche.

vordermanni (JENTINK, 1890). La grande proximité entre cette espèce et *macrotis* semble être définitivement établie. Comme le dernier, *vordermanni* devra prendre rang parmi les formes à crâne globuleux dont nous avons fait état précédemment. Un examen comparatif des deux espèces montre que la P4/ de *macrotis* présente un degré de réduction plus accusé que celle de *vordermanni*. Par ailleurs, les molaires supérieures de *vordermanni* possèdent un métalophe qui ferme la protofossa vers l'arrière, ce qui n'est pas le cas pour *macrotis*.

C[oleura] g[allarum] nilosa Thomas, 1915

p. 577

Essential characters of the Somali *C. gallarum*, but the colour, instead of being more or less uniformly pale brown, is a darker brown - sepia - on the surface, the bases of the hairs being strongly contrasted white; the long hairs of the name are white for about 3.5 mm., the terminal 2 mm. being sepia. Below, the general colour is rather greyer, but the bases of the hairs are similarly contrasted whitish, the contract showing well in the long hairs of the flanks, which are almost uniformly coloured in true *gallarum*.

Dimension (see table on p. 579).

Hab. Upper Nile. Type-series from near the mouth of the Bahr-el-Zeraf.

Type. Adult male. B.M. no. 15.3.6.76. Original number 77. Collected 3rd February, 1914, by Willoughby P. Lowe. Twelve specimens.

C[oleura] gallarum Thomas, 1915

p. 577

Size decidedly smaller than in *C. afra*, the forearm usually 47 - 48 mm. in length, the skull markedly smaller in all dimensions. General colour above pale brown - rather darker than "wood-brown," - the hairs slightly lighter towards their bases, but not conspicuously or abruptly bicolor. Under surface similar in general tone, but the bases of the hairs not lighter than the tips.

Skull as in *C. afra*, except for its smaller size and smaller teeth. Position and development of the small premolar variable.

Dimensions (see table on p. 579).

Hab. Suakin, Somaliland, and Aden. Type from Zeyla, Somaliland. Sea-level.

Type. Old female, B.M. no. 11.8.2.4. Collected 29th October, 1910, and presented by Dr. R. E. Drake-Brockman. Four skins and six skulls from the type-locality.

Other specimens from Suakin (*Anderson, Holled Smith*), Aden (*Yerbury*), Sheikh, Somaliland (*Drake-Brockman*), Lugh, Somali (*Bottego*).

C[oleura] silhouettæ Thomas, 1915

p. 578

Like *C. seychellensis*, but smaller.

General proportions as in *C. seychellensis*, the wings similarly longer than in the mainland species, the forearm about $3^3/_4$ times as long as the skull measured from the condyle to the front of the canines. Fur rather shorter than in *C. gallarum* and extending less upon the membranes; hairs of back about 3, of nape 4.5 mm. in length. Colour dark brown, rather darker than "bistre," the bases of the hairs scarcely lighter; under surface similar in general tone, but the tips of the hairs are slightly lighter than the bases.

Skull like that of *C. seychellensis*, but smaller throughout. A mesial septal ridge generally present in the basial pit.

Dimensions (see table on p. 579).

Hab. Silhouette Island, Seychelles.

Type. Adult male (skinned from spirit). B.M. no. 6.3.18.2. Collected and presented by Prof. J. Stanley Gardiner. Six specimens.

The Museum contains two authentic specimens, one of them a co-type, of Peters's *C. seychellensis*, besides a third from "Zanzibar." These differ so uniformly from the six examples obtained by Prof. Gardiner on Silhouette Island that it is evident that the Seychelles contain different forms of the genus, no doubt inhabiting different islands. While it is not definitely recorded on which island Dr. Percival Wright obtained the typical examples of *C. seychellensis*, for he mentions in connection with the species Mahé, Praslin, and Silhouette, it is presumably from the first of these islands that he got the specimens, as he says that "it was very common in the neighbourhood of the town of Port Victoria, Mahé"," and it was there that he stayed for most of his time in the Seychelles, merely making casual visits to Praslin and Silhouette.

The example from "Zanzibar" referred to *C. seychellensis* by Dobson appears to me to be rightly so named, but I should think it possible that its asserted locality is erroneous. It was presented by a captain in the Navy, whose station would have included the Seychelles, where the bat may have either been caught or come on board, to be afterwards captured at Zanzibar.

As illustrating the greater length of the wing in the Seychelles species, it will be seen from the table of dimensions that *C. silhouettæ* has a smaller skull than *C. gallarum*, but yet has an absolutely longer forearm.

p. 579

[table removed - eds.]

Casinycteris Thomas, 1910

p. 111

External characters, including even coloration, precisely as in *Scotonycteris*. The ears larger than in *S. zenkeri*. Wings reticulated, said to be orange-coloured in the fresh state.

Skull at once distinguishable from that of *Scotonycteris* by its palate being markedly shortened posteriorly and the bony floor to the long mesopterygoid fossa completely obsolete, so that the palation is practically at the level of the back of the single molar. In *Scotonycteris* there is the usual elongated palate. Palatal edge forming a reversed W (M), the median angle in continuation with a long and high vomerine ridge. Rostrum shorter in proportion than in *Scotonycteris*, bony palate more arched mesially, zygomata more abruptly expanded, postorbital processes and general cranial ridges more strongly developed. Rami of lower jaw thickened and expanded.

Dental formula as in *Scotonycteris*.

Teeth in a general way high, pointed, shorter in section antero-posteriorly, broader transversely than in *Scotonycteris*. Canines very long, curved, flattened. Cheek-teeth, both upper and lower, with the inner cusp well developed and separate, instead of being suppressed or joined to the outer, as in *Scotonycteris*; this is especially noticeable in p_3, the inner cusp being distinct, two-thirds the height of the outer, while in *Scotonycteris* the outer and inner enamel-ridges of the tooth are smoothly continuous with each other.

Type. *Casinycteris argynnis*, sp. n.

This striking bat, which adds another to the long list of new genera discovered by Mr. Bates, is remarkable for possessing a palate quite unlike that of other fruit-eating bats, and more recalling that found in some of the Microchiroptera. The astonishing resemblance of the type species to *Scotonycteris zenkeri* is also noticeable. Probably both bats bear a protective resemblance to the leaves, fresh or dry, of some local tree.

Casinycteris argynnis Thomas, 1910

p. 111

General external appearance - at least in the dried state - precisely as in *Scotonycteris zenkeri*, except that the size is

p. 112

materially larger, and the ears are also larger. Fur soft and fine, the general mass of the hairs about 8 mm. in length on the back, but with other longer hairs, attaining 13 - 14 mm., intermixed with them. Colour above about as in *S. zenkeri*, the hairs brown at base, then greyish white, with pale russet-brown tips. Head with the brown and white markings more strongly defined than in that animal, the ground-colour a little darker, the white patches prominent, present between the eyes, at the posterior angle of the eyes, at the anterior bases of the ears, and along the upper lips. In all other respects, in colour, degree of hairiness, and the marked reticulation of the wings, *C. argynnis* is so like *S. zenkeri* as not to need detailed description.

At least this is the case so far as dried specimens are concerned, but Mr. Bates states that in the fresh state the wings, ears, eyelids, and muzzle were "bright orange colour," and some traces of yellow are still present on such parts of the type as have been protected from light. Possibly the same may be the case with *Scotonycteris*, but we have no evidence on the subject.

Dimensions of the type (the body and ear measurements taken in the flesh): -

Forearm 60 mm.

Head and body 95; ear 20; index finger (c. u.) 44.5; third finger, metacarpus 41, first phalanx 28, second plalanx 36; lower leg and foot (c. u.) 40.

Skull: greatest length 28.3; basal length 25; zygomatic breadth 20; interorbital breadth 5.2; tip to tip of postorbital processes 11.7; brain-case, breadth 13.6; palatal length 10.6; post-palatal length 14.4; front of canine to back of m^1 9.2.

Hab. Bitye, Ja River, S.E. Kameruns. Alt. 2000'.

Type. Adult female. Original number 502. Collected 19th November, 1909, by Mr. G. L. Bates.

Cephalotes teniotis Rafinesque, 1814

p. 12

Cephalotes teniotis. Entièrement gris-brun, oreilles plus longues de la tête , sans oreillons conchiformes et striées intérieurement en travers, une verrue entre les deux incisives .- Obs. Cette nouvelle espèce remarquable se trouve en Sicile: le *Vespertilio cephalotes* de Pallas ou *Pteropus cephalotes* des modernes appartient aussi à ce genre et lui donne son nom , je le nommerrai *Cephalotes pallasi*.

P. 55

CORRECTION.

Page 12. - Je viens de m' apercevoir que Mr. Geoffroy St. Hilaire a établi en 1810, le G.*Cephalotes* avec le *Pteropus palasii* et une autre espèce *C. peronii*; mais nos caractères diffèrent en ce que dans mon *C. teniotis* il n' y a ancune incisive inférieure: s' il compose un G. particulier, il faudra le nommer TADARIDA TENIOTIS.

[the above (p. 55) is also the description of the genus *Tadarida*. This publication is conceived as a letter to Mr. Ch. H. Persoon M.D., Célèbre auteur des Sinopsis plantarum et fungorum in Paris, and was dated 3 June 1814.] - Victor Van Cakenberghe, December 2009.

Chærephon (Lophomops) J.A. Allen, 1917

p. 460

Text Figs. 9-11.

Type *Chærephon (Lophomops) chapini* sp. nov.

Skull and dentition as in the smaller species of *Chærephon*, but outer lower incisors often deciduous, giving an incisive formula of 1-1/1-1 instead of 1-1/2-2.

Ears united in front by a deep membrane, from the back of which arises a heavy crest of long straight hairs, occupying the whole posterior face of the membrane and rising above the tops of the ears as a broad frontal transverse crest, the hairs of which are dark brown for the basal half and lighter brown or (in one of the species, selected the type) white for the apical half. It is apparently a sexual character, but only males have thus far been examined except in the rather aberrant *C. (L.) abæ*. For

p. 461

decorative effect, especially when the crest hairs are parti-colored - rufous at base and pure white for the apical half, as in *C. (L.) chapini* - it vies with the spectacularhead ornamentation occurring in many groups of birds.

The taxonomic value of *Lophomops* may be open to question. The peculiar character of the crest is not only its great size and striking effect, but the fact of its origin being from the whole posterior face of the deep membrane connecting the ears, instead of from the front of the head behind the ears. A number of species of both *Chærephon* and *Nyctinomus* have slightly lengthened tufts of glandular hairs behind the ears arising from the front part of the crown (not from the connecting membrane of the ears), consisting usually of lengthened crinkled hairs, a little longer and coarser than the adjoining fur, and usually of a darker color. These patches of specialized hairs frequently appear to be restricted to males, but in some species are present in both sexes, as is the case with the gular sac. They are, however, inconspicuous in comparison with the crests of the *Lophomops* group. Three species of this group are here designated as the type.

Dysopes limbatus Peters (now regarded as a *Chærephon*) is described by de Winton as having a "long crest of erect hairs behind the connecting membrane of the ears in the males," but he does not say that they arise from its posterior face. Peters does not describe nor does his figure represent any such crest as is seen in *Lophomops*. He simply says: "Die Haare auf dem Kopfe hinter der Vereinigung der Ohren sind länger and steifer als am übrigen Körper." 'The type locality of *Dysopes limbatus* is Mozambique Island, and it is possible that the specimens de Winton had in hand were not the true *limbatus* of Peters, and are perhaps referable to some form of *Lophomops*, *C. limbatus* (Peters) is probably a near relative of *C. hindei* (Thomas).

Chærephon (Lophomops) abæ J.A. Allen, 1917

p. 464

Text Fig. 11.

Type, No. 48887, F ad.; skin and skull. Aba, northeastern Belgian Congo, Dec. 17, 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1823.

p. 465

Above hair-brown, with a slight grayish sheen; below a narrow median whitish band from breast to anal region, and a narrow white border at base of wing membranes from humerus to femur; rest of underparts like the back but without the grayish sheen; membranes lightish brown above and below. Male with a conspicuous cinnamon-brown, crest, lacking in the female.

Ears thin, dark brown, rising separately from the crown, the intervening space being occupied by an erectile membrane, convex above and about 5 mm. high, from the back of which arises, in the male, a thick muss of brown hairs, about 7 mm, in length and reaching 3 mm. above the crest of the convex membrane (Fig. 11); the basal three fifths of the hairs a darker shade of cinnamon-brown than the apical two fifths; in females (at least in dry skins), the membrane is directed backward, covering the crown) which is naked or covered only with a slight pubescence on the upper border and in front; crown beneath bare (as seen by softening and raising the disk or lappet). The size of the lappet varies in different specimens, being not fully developed in the younger examples.

Skull with the braincase broad and flat, rising only slightly above the rostral portion of the skull. Sagittal crest weakly developed or barely indicated; lambdoid crest moderate, preorbital processes strongly developed; premaxilæ well ossified in old skulls, but in young adults there is often a small U-shaped vacuity behind the incisors.

Collectors' measurements of type: Total length, 103 mm,; head and body, 69; tail, 34; foot, 16; ear, 17. Forearm (from skin), 43.

Collectors' measurements of type and 22 topotypes: Total length, 102 (97-107); head and body, 67.3 (62-73); tail, 33 (29-35); foot, 10.6 (10-11); ear, 18 (17-19).

Forearm, from skin (same specimens), 42 (40-44).

Skull (type), total length, 18.5; condylobasal length, 17.3; zygomatic breadth, 11.2; mastoid breadth, 10.7; interorbital breadth, 3.8; maxillar breadth; 8.1;

p. 466

breadth at base of canines, 5.4; breadth of braincase, 9; depth of braincase at pterygoids, 6,1; length of upper toothrow (c-m^3), 6.7; length of mandible, 12.3; angle to condyle, 3. 5; depth at coronoid, 8.4; length of lower toothrow, 7.6.

Skull, average of 10 specimens, total length, 18 (17.5-18.8); zygomatic breadth, 11.2 (11-11.4); breath of braincase, 9.2 (8.7-9.8).

Represented here by a series of 25 specimens, all collected the same day at Aba. Four additional specimens from Faradje, collected Feb. 25, 1911, are so similar in every respect to the Aba series that they seem preferably referable to the same species. The external measurements are slightly less, but the skulls indicate greater maturity and are as large as those of the Aba series. The coloration, however, is less dark and more buffy. They probably represent a slightly differential local race of the Aba form.

Chærephon (Lophomops) abæ resembles, in size and coloration, *C. major* (Trouessart) and *C. emini* (de Winton) in size, but not in color. As neither of these species, so far as known, is crested in the males, nor possess the conspicuous and (probably) erectile lappet in the females, and ununited ears, they require no special consideration in the present connection. The uniform brown coloration of the membranes, and usually the size, will readily separate abæ from the other known forms of the *Lophomops* group.

Chærephon (Lophomops) chapini J.A. Allen, 1917

p. 461

Text Fig. 9

Type, No. 48841, M ad. (skin and skull; topotype, No. 49209, M ad., alcoholic), Faradje, northeastern Belgian Congo, Nov. 11, 1912 (topotype, Jan. 12, 1913); Herbert Lang and James P.Chapin. American Museum Congo Expedition. Orig. No. 1971.

Head in males conspicuously crested, the crest arising from the posterior face of the deep membrane connecting the ears; breadth of the crest at base, 8.5 mm.; length of crest, 13 mm. in type, 14 in topotype; basal half reddish chestnut, apical

p. 462

half white; breadth of crest across the top when, expanded (Figs, 9, A, B, C) about 20 mm. A bread tuft of soft whitish hairs covers the front of the crown behind the crest. Body above pale cinnamon-brown, the fur being whitish basally; below grayish brown, the middle of the belly whitish; a narrow band of white at proximal edge of wing membranes, between humerus and femur, continuous with a similar band at base of uropatagiuin; wing membranes white, becoming yellowish proximally; the portion adjoining tho body, between humerus and femur, thickly punctated with minute blackish specks; interfemoral membrane dark brown above and below; limb bones dark brown above in strong contrast with the light colored membranes, below light brown like the membranes; tail blackish. No gular pouch.

Collectors' measurements of type: Total length, 84 mm.; head and body, 56; tail, 28; foot, 7; ear, 14.
Additional measurements from the dry skin: Forearm, 34; third metacarpal, 37; ear from crown, 8.5. Tragus minute, quadrate, about 1.5 square; antitragus small, about 5 broad at base and 3 high.

p. 463

Measurements of the alcoholic topotype: Total length, 80; head and body, 48; tail, 32; forearm, 37; third metacarpal, 30; third digit, 72; tibia, 11.8; foot, 7.7; ear from crown, 9.5, from notch behind antitragus, 12.8; expanse of both ears from tip to tip, 27.

Skull (measurements of topotype in parenthesis), total length, 15.5 (16); zygomatic breadth, - (9.5); interorbital breadth, 3.5 (3.5); mastoid breadth, - (9); breadth of braincase, 7.0 (7.7); maxillar breadth, 6.5 (6.8); upper toothrow (c-m^3), 5.4 (5.8); length of mandible, 10 (10.4); angle to condyle, 2.0 (2.0); depth at coronoid, 2.0 (2,0); lower toothrow, 5.9 (6.4). Upper incisors parallel, slightly separated, a wide space between them and the canines; lower incisors, bifid, 1-1 (in both type and topotype), completely filling the space between the canines. First upper premolar minute, in the toothrow, separating the canine and p^4; first lower premolar smaller and much lower crown than the second. Premaxillæ fully ossified; palatal foramina coalesced, forming a small U-shaped vacuity; presphenoid pits deep, slightly longer than wide; preorbital (lacrymal) processes strongly developed; median crest slightly indicated, lambdoid crest moderately strong. In general features the skull is as in other small species of *Chærephon*.

Chærephon (Lophomops) chapini is represented by only the type and a topotype, both old males from Faradje. It evidently has no close relationship to any known species. Its conspicuously heavy and long parti-colored crest distinguishes it at once from the other known species of the *Lophomops* group.

Chærephon (Lophomops) cristatus J.A. Allen, 1917

p. 463

Text Fig. 10, A, B.

Type, No 48844, M ad. (skin and skull), Boma, near mouth of Congo River, Belgian Congo, Jan. 26, 1915; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig, No. 2628.

Head crested, the crest arising from the posterior face of the deep membrane uniting the ears. Crest (Fig. 10, A, B) shorter than in *C. chapini*, the hairs reddish apically, the basal half darker, the transition between the two tones abrupt. Whole top of the head behind the crest naked, but covered by the crest hairs when the crest is laid back. Body above uniform russet, the basal portion of the fur but little lighter than the tips; underparts dark cinnamon-drab, the middle area with light tips to the hairs, in contrast with the sides; an indistinct median whitish band from the pectoral region, posteriorly; a narrow band of soft white fur along the inner edge of the wing membrane from the humerus to the femur and continued across the lower abdomen at base of the uropatugium. Face and gular region naked and blackish, bordered below by a naked flesh-colored band. Wing membranes as in *C. chapini* but whiter, the upper surface in strong contrast with the blackish limb bones; the dorsal side of tho membrane along the sides of the body, between humerus and femur, thickly set with blackish dots, most of which support a minute bristly hair, visible only under a strong lens, and more obvious than in the specimens of *C. chapini*. Interfemoral membrane dark slaty brown above, somewhat lighter below. No gular pouch. Upper lips corrugated.

p. 464

Collectors' measurements of type: Total length, 87 mm.; head and body, 56; tail, 31; foot, 9; ear, 13.
Additional measurements from the dry skin: Forearm, 36; third metacarpal, 35; tibial, 10; foot; 8.7; thumb, 6; ear from crown, 9.2; length of crest hairs, 9.5.

Three male topotypes (Nos. 49216, 49237, 49359) in alcohol: Total length, 84, 83, 80; head and body, 51.5, 53, 48; tail, 32, 31, 32; forearm, 36, 36.2, 36.4; third metacarpal, 30, 34; 35; third digit, 66, 65, 66.5; ear from crown, 9, 8, 8; height from notch behind antitragus, 14, 13, 13.5; extent of both ears from tip to tip, 28, 29, 29; tibia, 11, 11.5, 11; foot, 7, 6.7, 8; length of crest, 9, 8, 9; width at base, about 6,5.

Skull, type (topotype No. 49216, in parenthesis), total length, 16.3 (16); zygomatic breadth, 9.7 (9.8); mastoid breadth, 9 (9.2); interorbital breadth, 3.6 (3.8); maxillar breadth, 7 (7.2); breadth of braincase, 8 (8); depth of skull at pterygoids, 6 (6.3); upper toothrow (c-m^3), 5.5 (5.7); length of mandible, 10 (10.3); angle to condyle, 3 (3.2); depth at coronoid, 2.8 (2.8); lower toothrow, 6 (6.2).

Chærephon (Lophomops) cristatus is represented by the type and three topotypes, all collected at Boma, January 25-29 and June 15, 1915. The type lacks the middle pair and one of the outer lower incisors, which had been shed in life; one of the topotypes has only the middle pair, which occupies the whole space between the canines; the other has the middle pair and a minute outer incisor on the left side, showing that in the *Lophomops* group the lower incisors are doubtless normally 2-2. This species is slightly larger than *C. chapini* and differs from it strikingly in coloration, aside from the difference in the color and length of the crest.

Chaerephon (Lophomops) shortridgei Thomas, 1926

p. 289

M. 1389. Ukualukasi, N.W. Ovamboland. 3400'. 7 Oct., 1924. B.M. No. 25 12.4.24. Type

A remarkable tufted species, alone related to *C.(L.) chapini* Allen, but differently coloured.

General characters as in the smaller species of Charephon, but with a conspicuous bicolor tuft, as in the Bat figured by Allen. Size rather larger than in *chapini*. General colour of upper surface drab, the base of the hairs lighter and their extreme tips also whitish. Line of fur along the sides between humerus and femur brown, and that across the base of the interfemoral drabby brown, in neither case white as in *chapini*. Hairs of aural tuft about 13 mm. in length, their basal halves blackish brown, not reddish chestnut as in *chapini*, their terminal halves whitish. Wings pale brown throughout, quite without the contrasts of black and white and the punctation of the membranes described in *chapini*, which are apparently very much as in *C. hindei*. Under surface pale drabby, the ends of the hairs whitish. Ears apparently as in chapini, their connecting membrane high, with a distinct vertical ridge on the centre of its front surface.

Skull smooth and rounded, as usual in *Chaerephon*. First upper molar with an unusually prominent hypocone. Two lower inscisors only in the single specimen.

Dimensions of the type:-
Forearm 39 mm
Head and body 56 mm.; tail 34; ear 16. Third finger, metacarpal 40, first phalanx 15; second phalanx 18; lower leg and foot 19.5.
Skull: greatest length 16.6 mm.; zygomatic breadth 10; mastoid breadth 9.1; front of canine to back of m3 6.1.

Hab. And Type as above.
This most remarkable tufted Bat is a very intresting and valuable accession to our collections, as we had nothing showing its really wonderful specialization. But I am in considerable doubt as to the taxonomic value of this specialization, striking as it is, for the species described by Dr. Allen as *C. cristatus* and *abae* have it far less marked, while *C. hindei* also has the connecting membrane of the ear tufted behind, the character chiefly relied on by Dr. Allen in forming the subgenus *Lophomops*. The reduction to two of the lower incisors, usual in *Lophomops* according to its describer, does not occur in *C. hindei*, which has four, as in other members of *Chaerephon*.
For the present, however, as an indication of the position of the species I provisionally use Dr. Allen's sub-generic name, while thinking it possible that the character of the aural tuft will merely prove another specific specialization in the plastic genus *Chaerephon*.

I have named this striking species in honour of Capt. Shortridge, to whose energy and enthusiasm the great success of the South West African collecting expeditions has been almost wholly due, and who was greatly struck by its remarkable appearance.

Chærephon frater J.A. Allen, 1917

p. 456

Type, No. 49275, F ad. (alcoholic), Malela (near Boma), southwestern Belgian Congo, July 8, 1915; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 2613.

Similar to *Chærephon hindei* in general coloration but smaller, skull less massive and the dentition weaker, with p^2 much smaller.

Coloration, including the wing membranes, practically the same as in *C. hindei*, so far as can be determined from alcoholic material, except that the proximal border

p. 457

of the wing membranes, between the humerus and femur, is without the white band of fur seen in *hindei*.

Entire body dark brown except a broad, usually well-defined pure white median area from opposite the shoulders to base of tail, covering about one-third of the ventral surface of this part of the body, varying somewhat in extent in different specimens. Wing membranes white above, except proximately from elbow to knee where they are brownish, the tone deepening toward the body; below wholly white. Interfemoral membrane brown both above and below. Ears joined by a deep membrane, fringed above with short stiff hairs about 0.5 to 1 mm, in length, and similarly covered in front and on the central part of its posterior face. Tragus minute, quadrate, about 1 mm. square. Antitragus rounded above, about 2.5 mm. in height and about 3 mm. wide at base. In 18 of the 22 well-preserved alcoholic specimens the front half of the crown behind the membrane joining the ears is naked; in the other four this area is slightly covered with fine fur. The ears are thinner and broader than in *C. hindei*.

External measurements of the type: Total length, 80 mm.; head and body, 50; tail, 30; forearm, 37; third metacarpal, 35.5; thumb to base of the prominent pad, 6; tibia, 10.5; foot, 7,2; ear from crown, 8.7; from the notch behind the antitragus, 12.

Forearm, average of 22 topotypes, 30 (35-37). Forearm in type of *hindei*, 40; in five specimens from near the type locality, 37.6 (37-39.4).

Skull, type (corresponding measurements of type of *hindei* in parenthesis): total length, 15.2 (17.6); zygomatic breadth, 9.4 (11.4); upper toothrow, 5.4 (6.7).

Seven skulls (removed from alcoholic specimens), 1 male and 6 females, measure as follows: Total length, 15.9 (15.4-16.4); condylobasal length (4 skulls), 14.3 (13.8-14.8); zygomatic breadth, 9.5 (9.0-9.9); mastoid breadth, 8.9 (8.7-9.2); breadth of braincase, 8.3 (7.9-8.4); interorbital breadth, 3.4 (3.3-3.6); breadth at base of canines, 4.2 (3.6-4.5); maxillar breadth, 6.8 (6.4-7.8); upper toothrow (c-m^3), 5.4 (5.2-5.6); length of mandible, 10.1 (9.5-10.6); angle to condyle, 2.5 (2.3-2.9); depth at coronoid, 2.6 (2.2-2,9); lower toothrow (c-m_3), 5.9 (5.6-6.1).

Represented by 22 specimens in alcohol, all from Malela, the type locality.

Six skulls of *C. hindei*, two from the type locality (Fort Hall, B. E. Africa) and three from a nearby point (collection of United States National Museum) measure as follows (the corresponding measurements of six skulls of *C. frater* are given in brackets): Total length, 17.5 (17.3-18) [15.9 (15.4-16.4)]; zygomatic breadth, 10.6 (10.5-10.8) [9.5 (9.2-9.9)]; length of mandible, 11.4 (11.2-12) [10.1 (9.5-10.6)]. A single skull from Mombasa (collection of Museum of Comparative Zoology), exactly agrees in measurements with the average of the five from the Fort Hall region.

In general form the skull is a miniature of that of *C. hindei* but disproportionally weaker, especiallly in respect to the mandible and dentition. In four of the seven skulls examined, the premaxillæ are fully ossified, as in typical *Chærephon*; in the others there is a U-shaped vacuity behind the incisors : and the incisors are not united by an osseous border. In this species; as in *C. abæ* and some other species of *Chærephon* of which I have been able to examine a series of skulls, a similar condition exists, the younger specimens often having the premaxillæ imperfectly ossified at the incisive border. In one skull p^2 is in the toothrow on the left side, but on the right

p. 458

side is on the outer edge of the toothrow, as it is on both sides in all of the other five skulls. Usually p^2 separates the canine from p^4, but in two instances p^2 is crowded so far out that the canine and p^4 are in contact. The first lower premolar is about one-third smaller than p_4.

The nearest known form to *C. frater* is *C. hindei* (type locality, Fort Hall, Kenya district, British East Africa), from which frater differs in smaller size, especially in the smaller size of the skull and much weaker dentition. It also differs in color, particularly in having a larger area of white on the middle of the belly and in the absence of white on the proximal border of the wing membranes. As shown above, in a series of six skulls of each form, the extreme measurements do not overlap, the smallest *hindei* skull being considerably larger than the largest *frater* skull. The males of *hindei* have a low broad tuft of dark hair behind the membrane joining the ears, arising from the front part of the crown (not from the back of the frontal membrane, as in *Lophomops*), but in frater this part of the crown is usually bare in both sexes, and hence of course without the frontal tuft found in the males of *hindei*.

C. frater is about the size of *C. limbatus* (Peters) from Mozambique, with which it shares the character of white wing membranes, but *limbatus* evidently (judging from descriptions) belongs to a different section of the genus (*Lophomops*), the males being said to have a "long crest of erect hairs behind the connecting membrane of the ears" (de Winton). The absence of white on the lower parts and the character of p^2 would also exclude *limbatus* from further consideration in this connection.

Chærephon lancasteri Hayman, 1938

p. 383

Type. - B.M. no. 1937.12.8.25. Original number 724. M skin and skull, collected August 1936 at Lunzi River, Lundazi District, Loangwa Valley, N.E. Rhodesia, by D. Gordon Lancaster.

Description. - Closely similar in size to *C. (Lophomops) shortridgei* Thomas, slightly larger than *C. (L.) chapini* Allen. Crest long and bicoloured as in both these forms. Body above greyish drab, the hairs paler at the bases and slightly paled at the tips, thus producing a not very noticeable frosted effect. On the nape the hairs are notably paler throughout. The aural crest, rising from the back of the deep connecting membrane between the ears, is strongly bicoloured. The basal third is dark brown, the remainder pale buff, much as in *shortridgei*. Its length at the centre is 14.9 mm. A triangular patch on the crown, with its apex at the base of the centre of the tuft, is naked, and is entirely covered by the crest when laid flat. On the entire underside every hair is pure white from base to tip, including the narrow band along the edge of the membrane from humerus to groin. The wing-membranes are whitish, in strong contrast with the

p. 384

interfemoral membrane, which is dark greyish brown. The membrane connecting humerus and femur is heavily spotted, as in *C. limbatus* Peters and as described in *chapini*. The skull and teeth present no points of special interest. The skull in size and proportions is close to that of typical *Chærephon pumilus*. P^2 is in the toothrow, and there are four lower incisors, the inner pair slightly bifid.

Comparison. - *Chærephon lancasteri* differs from *chapini* Allen, from Faradje, N.E. Congo (the first member of the genus described with strongly developed crest), in the following respects: - *chapini* is smaller, with a forearm of 34 and 37 for type and topotype, against 39 in *lancasteri*; skull-length of 15.5 and 16, compared with 17 in the Rhodesian form; upper tooth-row 5.4 and 5.8, against 6.2. The body-colour of *chapini* is different, being described as pale cinnamon-brown above, fur whitish basally and below greyish brown, middle of belly whitish. The wing-membranes of *chapini* and *lancasteri* appear to be similar in colour.

C. (L.) cristatus Allen, from Boma, mouth of the Congo, has a short crest (9 mm.), is russet above, dark cinnamon-brown below, and has a forearm of 36.

C. (L.) abæ Allen, from Aba, N.E. Congo, has a short crest, an entirely different type of inter-aural membrane, is much larger (forearm 43), and is dark brown above and below.

C. (L.) shortridgei Thomas, from Ovamboland, S.W. Africa, is about the same size as *lancasteri*, but apart from the crest is quite distinct in colour. The dorsal surface is greyish drab rather heavily frosted by the pale hair-tips. There is a marked contrasting band of chestnut along the flanks above, between humerus and femur. Below it is pale drabby, with a pinkish tinge, only the tips of the hairs being a dirty whitish. All the membranes are of a uniform greyish hue without contrast.

C. (L.) nigri Hatt, from Bourem, Cercle de Timbouctoo, French West Africa, has a short crest (5-5 mm.), is smaller (forearm 36 mm.), has brown membranes, and is grey above and below.

C. (L.) langi Roberts, from N. Bechuanaland, in size is close to *chapini, shortridgei*, and the new form, having a forearm of 37.5 and upper tooth-row 6.1 mm. The

p. 385

colour above is dusky drab, below lighter, but only white along lower part of abdomen and along border of membrane below between humerus and femur. It has a unicoloured short crest.

Measurements of *lancasteri* (type). - Head and body 52 mm. ; tail 34.8 ; hind foot 6.3 ; ear 15 mm. height from meatus, width 12.5, connecting membrane between ears 6 mm. high; length of crest 14.9; forearm 39; third metacarpal 38.8, first phalanx 15.7, second phalanx 15.7; fourth metacarpal 37, first phalanx 12.5, second phalanx 8.5. Skull: total length 17; condylo-basal length 16.7; mastoid breadth 9.3; zygomatic breadth 9.7; breadth at m^3 7.4; upper tooth-row 6.2; greatest depth of skull 7.2.

Notes. - Allen's subgenus *Lophomops*, for *chapini, cristatus*, and *abæ*, was based on two characters: (1) the long aural crest arising from the back of the connecting membrane between the ears; (2) the reduction of the lower incisors to two. Dealing with the latter character first, it is only necessary to point out that Allen, on p. 464, in discussing *cristatus*, states that in the type and topotypes certain of the incisors had obviously been shed in life, and continues, "in the *Lophomops* group the lower incisors are doubtless normally 2-2." Allen does not mention the incisors of his third species of *Lophomops, abæ*. In *shortridgei* there are only two lower incisors, but they are obviously one inner and one outer. In other species of *Chærephon* some of the lower incisors are often found to have been shed.

The second character used (with some diffidence, it is true) by Allen for *Lophomops*, the erectile crest between the ears, has already been thoroughly dealt with in detail by Braestrup (1933). This author has shown that a crest, of greater or lesser length, may be developed at times of sexual activity by males of any species of *Chærephon*, and points out that Allen's subgenus must be given up, a course hinted at by Thomas in discussing *shortridgei*. While agreeing with Braestrup that the crest alone, being restricted to males at certain seasons, is itself not diagnostic in distinguishing forms, I think that when strongly developed crests such as are found in *chapini, shortridgei*, and *lancasteri* are associated with other differences in size and colour, these forms should be distinguished. Probably

p. 386

it will be found,, when further collecting has shed more light on the distribution of these long-crested forms, that they may be linked as races of *chapini*. Until then, in view of the present wide gaps in their known distribution, it seems best to treat them as species. I have much pleasure in associating with this Rhodesian form the name of Mr. Gordon Lancaster, in appreciation of his frequent assistance to the Museum.

p. 139

Closely allied to *Ch. plicatus*, conspicuously larger than in any of the members of the *Ch. pumilus* group.

Size about as in *Ch. plicatus*. General colour dark brown throughout, except that the band of fur on the under side of the wing-membrane bordering the body between the humerus and femur is white, strongly contrasting with the uniformly dark body. Wing-membranes dull brown above and distally below, whitish proximally below. Ears and other soft parts apparently all as in *Ch. plicatus*.

Skull about the size of that of *Ch. plicatus*, but much longer and flatter, the upper profile almost straight instead of being strongly sinuate. Teeth as in the Indian species.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 46 mm. (47 in second specimen).

Head and body 68; tail 37.5; ear 21; third finger, metacarpus 47.5, first phalanx 20, second phalanx 21; fifth finger, metacarpus 27; first phalanx 15; lower leg and hind foot (c.u.) 24.

Skull: condylo-basal length 18.6; mastoid breadth 11.5; front of canine to back of m^3 7.7.

Hab. Zaria Province, Northern Nigeria.

Type. Adult female. B.M. no. 11.3.22.1. Collected and presented by A. C. Francis, Esq. Two specimens.

This bat is no doubt most closely allied to the Abyssinian *Ch. bivittatus*, Heugl., a species we have not got, but which is said to be almost identical with the Indian *Ch. plicatus*. Heuglin's bat has, however, a pale under surface, which would distinguish it from *Ch. nigeriæ*, whether it proved to have the high brain-case of *Ch. plicatus* or the more flattened one of the present species.

Chaerephon pumilus naivashæ Hollister, 1916

p. 4.

Type, from Naivasha Station, British East Africa. United States National Museum No. 166658, male, in alcohol, with skull removed. Collected August 7, 1909, by J. Alden Loring. Orig. No. 6955.

Description. - Like *Chærephon pumilus pumilus* Cretzschmar, but larger, with longer forearm and larger skull; color averaging somewhat darker.

Measurements. - Type, compared with adult male of true *pumilus* from Saaita, Eritrea (number 143166), measurements of the latter in parentheses: Forearm, 42 (38) mm.; skull, condylobasal length, 16.0 (15.4); zygomatic breadth, 10.8 (10.4); interorbital constriction, 4.0 (3,6); mastoid breadth, 9.9 (9.2); mandible, 11.7 (11.8) ; maxillary tooth row, including canine, 6.3 (6.2); entire lower tooth row, 7.3 (7.0). Average of length of forearm in fifteen adults of *naivashæ*, 40.3; in eighteen adults of *pumilus* from Eritrea, Sudan, and Northern Uganda, 36.5.'

Chærephon russatus J.A. Allen, 1917

p. 458

Text Fig. 25, p. 550.

Type, No. 48925, M ad., skin and skull, Medje, Belgian Congo, Sept.,8, 1910. Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 993.

Above uniform russet-brown, with a large median nearly hairless spot at shoulders; below cinnamon-brown, the extreme tips of the hairs on the median area faintly lighter in some specimens but as a rule not appreciably so; a band of cinnamon-brown bordering the underside of wing membrane between humerus and femur; wing membrane (in dry skins) dark brown proximally as far us the fourth digit, the outer portion slightly paler and semitranslucenl; uropatagium dull brown, both above and below. Ears thickened on front border, blackish brown, united by a membrane at base, which projects as a rounded protuberance in front of the ears. Tragus minute, narrow, about 3.5 mm, high by about 1 mm. wide, blackish. Antitragus rather small, about 5 mm. wide at base and 3.5 in height, evenly rounded above. Tail about 34 mm, in length, the apical half free, the basal third below

p. 459

furred. Pad at the base of the thumb large. (For illustration of wing see Part II, p. 550, by Lang and Chapin.)

Collectors' measurements of type: Total length, 102 mm.; head and body, 68; tail, 31; foot, 10; ear, 21.
Additional measurements from the dry skin: Forearm, 45.7; third metacarpal, 45.4; tibia, 38; foot, 10.5; ear, length of outer border, 25.7; height from crown, 19.3.

Collectors' measurements, type land 23 adult topotypes. (4 males, 20 females): Total length, 100 (93-105); head and body, 67.8 (62-73); tail, 33.1 (29-36); foot, 11.2 (10-13); ear, 20.2 (19-22). Forearm, from the skins (same specimens), 44.6 (42-40).

Skull rather deep and narrow; median and lambdoid crests weakly developed, especially the former; preorbital ridge conspicuous; premaxillæ fully ossified, enclosing a pair of small palatal foramina. Upper incisors small, slightly separated at base with their tips nearly or actually in contact (in different specimens); lower incisors $^{2\text{-}2}/_{2\text{-}2}$ small, all bifid, the inner more deeply so than the outer with the inner lobe the larger; outer incisors partly posterior to the middle pair. Upper canines with a broad, deep longitudinal groove and small cingulum without cusps; lower canines without distinctive features. First upper premolar minute, closely crowded between the adjoining teeth and wholly separating them; second upper premolar large, more than half the size of m1; first lower premolar a little smaller than the second.

Skull (type), total length, 18.7; condylobasal length, 16.6; zygomatic breadth, 11; mastoid breadth, 10.1; interorbital breadth, 4,1; maxillar breadth, 7.9; breadth of braincase, 9,3; upper toothrow (with canine), 6.4; length of mandible, 12.2; angle to condyle, 2,5; depth at coronoid, 3; lower toothrow, 7.

Skull, type and 22 topotypes, total length, 18.5 (17.8-19.4); zygomatic breadth, 11 (10.5-11.4).

Represented by 27 specimens (24 skins with skulls, 3 alcoholic), all taken at Medje, September 8, 1910.

The series is exceedingly uniform in both coloration and measurements. The pelage of the dorsal surface is without light tips to the hairs, and the pelage of the ventral surface is nearly so, a few of the specimens, however, having the extreme tips of the hairs pale buffy over the median area. *Chærephon russatus* closely approaches *C. demonstrator* (Thomas) in size and proportions, but the latter is somewhat larger, especially in cranial measurements, the zygomatic breadth being about 2 mm. greater. The upper canine and second upper premolar are said to be in contact in *C. demonstrator*, with the minute first premolar in the outer angle between them, while *russatus* the small premolar is in the middle of the toothrow, completely separating the canine from p^4. The description of the coloration of *demonstrator* also does not agree well with that of *russatus*, nor does the indicated structure of the ears. The fleshy protuberance in front of the ears seen in *russatus* is found also in other species, which in other respects are widely different. It is said not to be present in *demonstrator*. In an alcoholic male of *russatus* there is no indication of the pair of scent glands

p. 460

at the base of the penis, mentioned as a distinctive feature of the unique type of *demonstrator*.

Chærophon (Lophomops) nigri Hatt, 1928

Type: sexe M, adulte; localité: dans la case des passagers (située sur la berge du Niger) de Bourem, subdivision de Bourem, Cercle de Tombouctou, Soudan français; date: 6 janvier 1928; dans l'alcool; collecteur: TH. MONOD (Mission saharienne Augiéràs-Draper); n° de récolte: M. S. A. D. Zoologie, n° 736 *a*; Mus. Paris.

Description: Similar to *C. (L.). cristatus* J. Allen. Pelage above and below, deep gray in oontrast to the russet back and cinnamon drab underparts of *cristatus*. There is no band of soft

p. 375

white fur along the inner edge of the wing membrane, characteristic of *cristatus*. The fur hairs of the back extend on to the base of the wing, unlike the condition in *cristatus*. The wing membranes are a ligth smoke gray, as opposed to the ivory colored membranes of *cristatus*. There is little contrast between the wing membranes and the skin covering the wing bones. The wing membranes havë a distinctly lighter posterior border, lacking in *cristatus*. The spotted area of the dorsal surface of the wings next to the body is more extensive than in *cristatus*. The body of this bat is smaller than that of *cristatus*.

Matériel examiné: trois spécimens, comme suit: 1 M adulte (type); 1 M [M. S. A. D. Z. n° 736 *b*] (de même taille que le M

p. 376

type, mais sans touffe de poils sur la couronne) et 1 F adulte [n° 736 *c*] (co-types), même localité, date, etc. que le type. Mus. Paris (F) et Amer. Mus. (M).

Les spécimens ont été comparés aux types et co-types de *C. (L.) cristatus* Allen, *C. (L.) Chapini* Allen et *C. (L.) abæ* Allen.

[table removed - eds.]

Les caractères çrâniens ônt été notés sur la F: longueur totale: 16; largeur mastoïde: 9; largeur interorbitaire: 4; largeur maxillaire: 7.5; largeur de la boîte crânienne: 8; longueur de la rangée supérieure de dents: 5; longueur de la rangée inférieure: 6.5; longueur de la mandibule: 10; mandibule, de l'angle au condyle: 4

Chaerophon pumilus elphicki Roberts, 1926

p. 245

Kershaw (*Ann. Durban Mus.* III, p. 29, 1921) has recently published an important note on the forms of *C. pumilus*, in which he places *C. limbatus* Peters as a subspecies, pointing out that the northern, typical *pumilus* has no white below as in *limbatus*, while specimens from south of the tropics again lose the white, and he therefore places them with *pumilus*. There are objections to the use of the same name for the animals occurring respectively in the northern and southern latitudes with intermediates between them, as there are sure to be differences in other respects besides those which are commonly accepted for guidance. There are a number of such cases in birds and mammals, and the present one is no exception, there being average cranial differences which require recognition. Hollister (*Bull. 99, U.S. Nat. Mus.* p. 96, 1918) has been good enough to publish dimensions of a number of specimens from E. Africa and northwards. He has apparently been guided to some extent by the length of forearm, a character dependent largely upon the distance the animals are called upon to fly from their shelters to their feeding grounds, and

p. 246

it seems evident that his Sudan and Uganda specimens should be separated, as there is a difference in the skull dimensions. Quoting his figures and adding those of specimens from Transvaal, the following results are shown:

[table removed - eds.]

Those from Zanzibar represent *pumilus*, those from Uganda and Sudan have also been allocated to the same form, but evidently require removal, those from Naivasha represent *naivashae*, those from Zanzibar *limbatus*, and those from Malelane elphicki. It is to be noted that there is an increase in size from the Equator southwards, *elphicki* representing the largest form. In colour these Transvaal specimens are very dark, glossy brown, almost black, above, and paler below on account of the paling of the tips of the hair, but still dark brown; white only appears distinctly as a narrow band between the limbs, along the flanks and inner border of the flying integument.

Type: T.M. No. 2488, adult male, Malelane Estate, E. Transvaal. Named after Capt. G. J. Elphick, to whom I am indebted for the specimens.

Chalinolobus argentatus Dobson, 1875

p. 385

The crown of the head is abruptly elevated abopv the face-line as in *Miniopterus*, but to a much less extent; muzzle short, very obtuse in front, broad and flattened above; nasal apertures wide apart in front; separated by a slightly concave space, opening sublaterally, bounded laterally by the front margins of the labial glandular prominences which are separated from the nostrils above by a sulcus on each side; as in the other species of this genus. Beneath, on each side of the chin, below the under lip, a smooth broad rounded elevation exists separated from its fellow of the opposite side by the

p. 386

small naked space on the lip in front of the lower incisors. These elevated sides of the chin are covered with short hairs and enclose a hollow space between. Ears very like those in *Miniopterus*, short and rather sloped backwards; the inner margin commences in a long lobule directed backwards; the margin of the ear is almost regularly convex all round from the commencement of the inner margin to a point in the outer margin opposite the base of the tragus, where it becomes slightly emarginated, and immediately beyond abruptly convex, forming a short erect lobe connected by a low band with a wart in front at the angle of the mouth, which is continuous with a horizontal lappet of thickened skin extending forwards along the lower lip almost as far as a point opposite the lower canine. With this lappet of the lower lip the outer margin of the ear is thus directly continuous. Tragus semilunate, the inner margin slightly concave, the outer regularly convex, at the base a rather large equilateral triangular lobule very acutely pointed.

First phalanx of longest finger short, intermediate in length between that of *Miniopterus* and that of *Vesperugo*, terminal phalanx very long, flexed forwards on the under surface of the first phalanx in repose; in this position it extends nearly to the middle of the metacarpal bone. Feet small; wings to the base of the toes; calcaneum long and straight, extending quite three fourths the distance between the ankle and the tip of the tail; no postcalcaneal lobule.

Tail as long as the head and body, wholly contained within the interfemoral membrane.

The ears and the face are nearly naked, a few short hairs only appearing on the glandular prominences between the eyes and nostrils; the fur of the body above and beneath extends upon the wing-membranes as far as a line drawn from the middle of the humerus to the middle of the femur; the interfemoral membrane above and beneath is quite naked, except where a small triangular patch of hair appears at the root of the tail.

The fur is tricoloured, the basal third of the hairs black, the middle third white, and the terminal third a beautiful dark silvery grey. This is the arrangement of the colours about the middle of the body; but the grey is more prevalent towards and on the head, while the dark shades prevail slightly over the grey towards the tail.

The integument of the ears and face pearly white; wing- and interfemoral membranes dusky white, translucent, traversed by well-defined reticulations and parallel lines.

The teeth are very peculiar. The inner upper incisors very long, remarkably slender and acute; the outer incisor on each side fills up the space between the inner incisor and the canine by its broad base; but its unicuspidate vertically directed summit is

very short, and scarcely exceeds the cingulum of the inner incisor. The canines are extremely long and slender, and are directed almost vertically downwards and slightly outwards; the lower canines are also very slender, but scarcely more than half the length of the upper ones. The upper premolar is very acute and close to the canine;

p. 387

the posterior upper molar little more than half the size of the second molar. The lower incisors are distinctly trifid, some even appearing to have a fourth lobe; they are not crowded, and form a regular semi-circle across the wide space between the canines. The lower premolars are also, like the canines, very slender and acutely pointed, the first premolar about half the size of the second.

Length (of an adult F preserved in alcohol): head and body 2".0; tail 2".0; head 0".55; ear 0".5, tragus 0".22 x 0".1; forearm 1".7; thumb 0".25; first finger 1".7; second finger-metacarp. 1".7, 1st ph. 3".6, 2nd ph. 1".3; third finger-metacarp. 1".55, 1st ph. 0".45, 2nd ph. 0".5; fourth finger-metacarp. 1".35, 1st ph. 0".4, 2nd ph. 0".3; tibia 0".72; foot and claws 0".3.

Hab. Cameroon Mountains, western equatorial Africa.

This species has a general resemblance to *Miniopterus schreibersi* in the shape of the head and ears, in the shortness of the first phalanx and great length of the terminal phalanx of the longest finger, in the long and slender tail wholly contained within the interfemoral membrane; added to which the grey colour of the fur and corresponding size would cause specimens of this species to be readily confounded, on a superficial examination, with specimens of the European grey-coloured *M. schreibersi*.

Chalinolobus congicus Noack, 1889

p. 223

Taf. II, Fig. 1; Taf. V, Fig. 66 - 68.

Genus *Chalinolobus* bei DOBSON, Cat. Chiropt., p. 252.

Acht Spiritus-Exemplare, 4 M und 4 F. Netonna, April u. Mai. Coll. HESSE.

Die vorliegende Collection bietet nicht unerhebliche Schwierigkeiten, weil die Exemplare nach Geschlecht und mehr noch nach dem Alter in der Färbung ziemlich stark abweichen, während Schädel und Gebiss beweisen, dass sie zu einer Art gehören, welche ich geglaubt habe mit *Chalinolobus* vereinigen zu müssen, obwohl die inneren I zweispitzig wie bei *Vesperus* sind. Die Bildung des Ohres dagegen und des Mundwinkels ist durchaus die von *Chalinolobus*.

Diagnose. *Chalinolobus* mit zweispitzigen inneren I, halbmondförmigem Lappen am unteren Mundwinkel und Warze über dem Mundwinkel, rundem, nach hinten umgebogenem Lappen am unteren Ohrrande, Tragus mit gerader innerer, gebogener äusserer Kaute mit spitzem Lappen am unteren Rande, weisslichgelber bis hell röthlichbrauner Flughaut, ganz von der Flughaut eingeschlossenem Schwanze und olivengelblich-silbergrauer Färbung und mehr oder weniger deutlichen weisslichen Streifen oben und unten an den Schultern.

Beschreibung. Kopf und Nase kurz, letztere breit abgerundet, die weit von einander entfernten Nasenlöcher durch eine seichte Furche getrennt. Oberlippe an den Seiten wulstig, die Lippenränder ganz vereinzelt kurz behaart. Mundwinkel mit einem grossen, halbmondförmig herunterhängenden Lappen, der nach unten mehr oder weniger scharf begrenzt ist. Auch vor dem Lappen ist die Unterlippe wulstig. Oberlippe im Mundwinkel warzig verdickt. Eine runde Warze steht über dem Mundwinkel nach dem Ohr hin. Auge sehr klein, näher dem Ohr als der Nasenspitze. Ohr gross, aber kürzer als der Kopf, breit abgerundet, innen nackt, aussen mit nackter Spitze. Der innere Hand unten zu einem runden Lappen umgebogen, der äussere verdickte Rand mit kleinem, rundem Lappen bis an den Mundwinkel vorgezogen. Tragus innen ausgehöhlt, an der Basis schmal, der aussere Rand springt über der schmalen Basis mit kleinem dreieckigem Lappen vor, mittlerer und oberer Theil des Tragus ziemlich gleich breit, die innere Kante gerade, die äussere rundlich gebogen. Zunge kurz und dick, am Rande mit einzelnen kleineren Wärzchen, sonst mit feinen Papillen. Von den 7 Gaumenfalten ist die erste und die

p. 224

letzte ungebrochen, bei den übrigen wie gewöhnlich die Innenseite der Bogen Bach hinten gezogen. Die Flughäute sind sehr zart und stark zugespitzt, zwischen Unterarm und fünftem Finger von starken, bräunlichen Adern durchzogen, sonst fein geädert, der Lappen der Schwanzflughaut unbedeutend, der Schwanz mit 7 Wirbeln ganz von der Flughaut eingeschlossen. Die Schwanzflughaut oben bis zum dritten Wirbel dünn behaart, der Humerus oben auf $^1/_3$ Länge, etwas stärker die Unterseite der Flughaut vom Ellbogengelenk bis zum Anfang des Unterschenkels. Der Daumen frei, an der Basis ohne stärkere Schwiele.

Färbung der Gesichtsseiten und des Ohrs weisslich, vor der Stirn olivenfarben, vom Auge zum Ohr ein dunkler Streifen, der nur bei einem M stärker hervortritt. Extremitäten unten weisslich, oben gelbbraun. Nägel tief schwarz. Färbung der Flughaut zwischen den Fingern weisslich, doch bei einigen M mehr rothbraun, an den Seiten und zwischen den Schenkeln hell röthlich-grau, Haar lang und fein, etwas flockig, Haarbasis etwas heller als das Haar. Färbung der Oberseite olivengrau mit silbergrauen Haarspitzen, nach hinten zu mehr olivengelb, Kehle etwas heller, sonst die Unterseite etwas dunkler als die Oberseite. Die Unterseite der Flughaut hell gelbbraun behaart. Zwei weiseliche Streifen von der Schulter bis zu den Schenkeln treten nur bei einem M deutlich hervor. Die gelbliche Färbung des Hinterrückens ist bei einem Exemplar ebenfalls streitig, übrigens der Farbenton bei den alten F heller als bei den M, nur ein M sehr hell.

Bei *Chalinolobus arqentatus* ist die Haarbasis schwarz, die Haarmitte weiss, die Spitze silbergrau, *Chal. variegatus* ist viel kleiner, bei *Chal. poensis* die Flughaut immer braun. Das Subgenus *Glauconycteris* ist grösser. Die breite Vorhaut ist

zweilappig, an der Spitze kurz borstig behaart, das kleine Scrotum dicht hinter dem 4 mm langen Penis, dicht dahinter der After. Auch die Scheide dicht vor dem After, die Clitoris sehr klein, unten gefurcht und an der Spitze durchbohrt. Die beiden Mammae nur bei einem F kahl mit angesogenen Zitzen.

Maasse. M, F adult.
Körper: 52 - 56, 50
Ohr: 9.5 - 10, 9.5
Mittlere Breite: 7, 7
Tragus: 4 - 4.5, 4.5

Humerus: 26 - 28, 25
Unterarm: 41 - 43, 40

p. 225

Daumen: 4.5, 4
II: 53 - 58, 54
III: 78 - 84, 81
IV: 57 - 61, 59
V: 50 - 52, 50
Femur: 17 - 18, 18
Unterschenkel: 17 - 18, 18
Fuss: 6 - 7, 7
Sporn: 12 - 14, 13

Schädel (Taf. V, Fig. 66) kurz und breit, der obere Theil des abgerundeten Occiput nach vorn gegen den Scheitel umgebogen, Stirnbeine etwas blasig aufgetrieben, Nasenbasis stark eingesenkt, der kurze und breite Oberkiefer nach oben gebogen, die Nase seicht gefurcht, die Seiten der Nasen beine mit rundlicher Leiste, die Bullae audit, mittelgross, aussen flach, innen kräftig entwickelt, der schlanke Jochbogen in der Mitte eckig in die Höhe gezogen.

Am Unterkiefer die Symphyse breit und kräftig, schräg nach vorn gerichtet und unten mit kleinem Zacken, der horizontale Ast gerade, der aufsteigende Ast niedrig und breit, nach hinten gerichtet, der niedrige Proc. coron. nach vorn und stark nach aussen gebogen, die obere Kante des aufsteigenden Astes flach eingebogen.

Maasse von M adult.: Scheitellänge 12, Basilarlänge 11.5, Schädelkapsel 8.5, Hinterhaupt über dem For. occipit. 5, For. occipit. 3 breit, 2.5 hoch, Scheitelbreite hinten 7.25, die Stirn hinter der Nase 5 lang und breit, Bullae aud. 3, Höhe der Schädelkapsel 6, Kieferlänge von I bis M III 5, Gaumenlänge 5, Breite 3.25. Die Schädel der F sind um ein Geringes kleiner. Unterkiefer bis zum Condylus 9, Höhe der Symphyse fast 2, des horizontalen Astes 1, des aufsteigenden Astes unter dem Proc. coron, 3.

Gebiss (Taf. V, Fig. 67 - 68) von *Chalinolobus*:

$I\ ^{2+2}/_{6}\ C\ ^{1+1}/_{1+1}\ P\ ^{1+1}/_{1+1}\ M\ ^{3+3}/_{3+3}$.

Oben I innen durch eine 1.25 breite Lücke getrennt, stark nach vorn und mit der Spitze etwas nach einwärts gerichtet, massig gebogen, stark zugespitzt mit kleinem hinteren Nebenzacken, der bei allen Exemplaren vorhanden ist. I aussen sehr klein, eng zwischen I innen und C, stumpf zugespitzt, wie I innen gerichtet. C schlank gebogen, etwas weniger nach vorn gerichtet als I innen, hinten flach cannelirt , Basalwulst wie bei I, P und M schwach, innen zackig vorspringend. P kaum $^{1}/_{2}$ C, nach innen gerichtet, an der Basis ziemlich breit, aussen cannelirt, mit schlanker

p. 226

Spitze, wenig gebogen. M I und II identisch, die Aussenzacken niedrig, der vordere stärker, erheblich nach vom gerichtet. Der hintere innere W-Zacken stärker und höher als der vordere, der innere Nebenzacken hoch, mit scharfem Rande und starkem vorderen, nach innen gerichteten Zacken. M III schmal, der vordere Aussenzacken stark, nach vorn gerichtet, die niedrigen hinteren Zacken ebenfalls nach vorn gebogen.

Unten I klein, undeutlich dreilappig, in der Richtung der Kiefer-Symphyse schräg nach vorn gerichtet. C schlank, stark nach aussen und etwas nach hinten gerichtet, vorn innen mit Nebenzacken. P I sehr klein und niedrig, kaum $^{1}/_{4}$ C, breit dreieckig zugespitzt, Aussenseite etwas nach innen gerichtet. P II schlank, = $^{1}/_{2}$ C. Die Aussenzacken von M breit dreieckig, der vordere um $^{1}/_{3}$ höher als der hintere, Die Hauptzacken der M sind etwas niedriger als C und nehmen nach hinten etwas an Grösse ab. Der innere Nebenzacken von M I ist stark nach vorn, der hintere von M In stark nach hinten gerichtet

---

Chamtwaria Butler, 1984

p. 187

CHAMTWARIA, nov. genus

Diagnosis: Resembling *Kerivoula* in having three upper premolars, the middle one (P3/) smaller than the anterior one (P2/) but less reduced than in *Myotis*; differing from *Kerivoula* in the longer, narrower face, nasals extending above canines, infraorbital foramen close to tooth row, the sharp infraorbital crest, and the less elevated paracone of P4/.

Type and only species: *Chamtwaria pickfordi* nov. spec.

Chamtwaria pickfordi Butler, 1984

p. 187

Chamtwaria pickfordi nov. spec.

Diagnosis: With the characters of the genus. P2/-M3/ 10.3 mm.

Holotype: KNM.CA 2237, the anterior part of a skull, from Chamtwara. This is the only known specimen.

The species is named after Dr. Martin Pickford.

Description (fig. 25 A, A'):
The skull is broken off posteriorly at the back of the olfactory chamber, and most of the alveolar portion of the maxilla is missing on the right side. On the left side the orbit and the root of the zygoma are preserved, and the three premolars are complete, but the canine and molars are represented only by their broken bases or roots.

Chamtwaria is large for a vespertilionid; in size of molars and width of palate it is comparable with *Scotophilus nigrita* and *S. heathi*, but the postcanine tooth-row is longer.

The face anterior to P4/ is narrower and less depressed than in *Myotis* and *Kerivoula*. Its width, behind the canines, is about equal to the total length of C - P4/, as in *Natalus*. The dorsal surface of the face is flattened, lacking the median concavity of *Kerivoula* and *Myotis* and thus resembling *Natalus*. The profile rises rapidly above the orbits. There are no sutures, except a trace of the internasal suture. Grooves show the position of the ascending processes of the premaxillae, which reached back to above the posterior end of the canines. The nasals are long, extending beyond the canines and reducing the size of the external narial opening. The large anterior emargination of the skull of other Vespertilionidae is absent, but there is more resemblance to *Natalus*. The zygomatic arch arises above M2-3/. Its dorsal edge continues as a sharp crest below and anterior to the orbit, passing in front of the lachrymal foramen, as in *Myotis*; in *Kerivoula* this crest is weak and the lachrymal foramen opens on the face. The lachrymal
foramen is above the anterior end of M1/ as in *Kerivoula* and *Myotis*; in *Nalalus* it is above M2/. The infraorbital foramen is low on the face above the anterior end of P4/; in *Kerivoula* and *Myotis* it is higher, nearly level with the lachrymal foramen; in *Natalus* it is low but over P3/. The palate is proportionately longer and narrower than in *Kerivoula* and *Myotis*, and also more arched; it resembles *Natalus* in proportions. Its anterior border is not well preserved, but the emargination did not reach beyond mid-canine level. Posteriorly, the lateral part of the palate ends immediately behind M3/; the median part extended back under the nasopharynx, but its posterior edge is not preserved.

p. 188

To judge by its broken base, the canine seems to have been comparatively small. The first two premolars (P2,3/) are proportionately larger than in *Kerivoula*, so that the total length of the premolar series is 79 % of the length of the molar series, compared with 55 -65 % in *Kerivoula*. In *Myotis* both P2/ and P3/ are reduced, especially P3/ which in some species is minute and displaced lingually. P2/ is larger than P3/ in *Chamtwaria*, as in *Kerivoula* and *Myotis*, but in *Natalus* it is much smaller. Alveoli on the right side of the specimen show that P2/ has two roots. The crown is broadly oval in outline, and less compressed anteroposteriorly than in *Kerivoula*. There is a single cusp, blunted by wear, and buccal and lingual cingula. P3/ is proportionately narrower than P2/, and not compressed as in *Kerivoula*; it is separated from P4/ by a short space. In *Natalus* P3/ is triangular. P4/ of *Chamtwaria* approaches an equilateral triangle in outline; it is much shorter and less wide than M1/. The paracone is not elevated as in *Kerivoula*, but only about as high as on P2/. As far as can be seen from their broken bases, M1/ and M2/ resemble those teeth in *Kerivoula* and *Myotis*. On M1/ the metastylar apex projects farther laterally than the parastyle, and on M2/ parastylar and metastylar apices are

p. 189

equally prominent. The lingual region is more extended on M1/ than on M2/. The roots of M3/ indicate a short, transverse tooth. In *Natalus* M1/ and M2/ are more quadrate and M3/ is less reduced in length.

Relationships:

The fossil genus that is most like *Chamtwaria* is *Stehlinia*, from the U. Eocene-Oligocene of Europe (Revilliod 1922, Sigé 1975). This agrees in having a long face, with nasals extending above the canines, though the face is flatter and there is a median dorsal concavity; the lower edge of the orbit is sharp; the infraorbital foramen is low, near the teeth. Except the dorsal concavity, these characters are also shared with *Natalus*. The premolars of *Stehlinia* resemble *Natalus* and differ from *Chamtwaria*: P2/
is small and one-rooted; P3/ is a larger, triangular tooth which frequently develops a third root; P4/ is wider in comparison with M1/, and its paracone is elevated. Sigé (1975) considers *Stehlinia* to represent a primitive vespertilionoid stock of which *Natalus* and
Kerivoula are the least modified living descendants. *Kerivoula* and *Chamtwaria* have advanced beyond *Stehlinia* in the simplification of P3/ and enlargement of P2/. *Myotis* also has P3/ smaller than P2/, but both teeth have diminished in size as the face has shortened, leading to the disappearance of P3/ in other vespertilionids. Thus *Kerivoula* and *Chamtwaria* show in their premolars an early stage in the development of a derived vespertilionid character. *Chamtwaria* is more primitive than *Kerivoula* in skull characters in which it resembles *Stehlillia* and *Natalus*.

How to express these relationships taxonomically is mainly a matter of taste. Sigé (1975) removed *Kerivoula* from the Vespertilionidae and included it with *Stehlinia* in a family Kerivoulidae, but he retained the Natalidae as a separate family. Van Valen
(1979) combined Kerivoulidae and Natalidae with Thyropteridae, Furipteridae and Myzopodidae into a single paraphyletic family Natalidae, noting that they lack derived characters of Vespertilionidae, mostly characters of the humerus. Both these arrangements
have the disadvantage of obscuring the relationship of *Kerivoula* to *Myotis*. I would therefore retain *Kerivoula* in the Vespertilionidae, subfamily Kerivoulinae, but would exclude *Stehlinia*. *Chamtwaria*, unlike *Stehlillia* but like *Kerivoula,* has advanced in the vespertilionid direction in premolar organisation, and it may also be included in the Vespertilionidae. It is provisionally placed in the Kerivoulinae, though a case might be made for making it the type of new subfamily.

Choerephon (Lophomops) langi Roberts, 1932

p. 17
Choerephon (Lophomops) langi sp. nov.

In size coming near to *C. (L.) shortridgei* Thomas of Ovamboland, but differing in colour and its shorter and uni-colour crest. Colour above dusky drab, including the whole frontal crest; below lighter coloured, becoming pure white on the lower part of abdomen and along the border of the membrane in a fairly broad band to the base of the humeri.

Type: T.M. No. 6554, adult ♂, Tsotsoroga Pan, Northern Bechuanaland, 29th June, 1930, No. 870, Vernay-Lang Kalahari, Expedition. Length of head and body 53, tail 38, hind foot (c.u.) 8, ear 16. Crest 9, forearm 37.5, first phalanx of 3rd digit 36, 2nd 16.5, 3rd 23 mm. Skull: length from canines 17, zygomatic width 10.4, width of brain case 8.5, of palate across m^2 7.6, width across canines 4.2, length of upper tooth-row ($c\text{-}m^3$) 6.1 mm.

Chrysopteron Jentink, 1910

p. 74

Chrysopteron n. g.

Dental formula: $i.\ ^{2-2}/_{3-3}$, $c.\ ^{1-1}/_{1-1}$, $pm.\ ^{3-3}/_{3-3}$, $m.\ ^{3-3}/_{3-3} = 38$.

Braincase normal; second upper premolar very small and not to be seen from without; middle and second lower incisors with four cusps.

Type of the genus is *Weberi* Jentink.

Cistugo Thomas, 1912

p. 205

Allied to *Myotis*, buth with differently proportioned teeth and with glands in the wings.

Skull essentially as in *Myotis*, but the brain-case not specially vaulted and the muzzle rather less pinched in laterally.

Dental formula as in *Myotis*.

Incisors of the same essential structure as in *Myotis*, but shorter. Canines similar. Small premolars subequal, minute, not half as large as the incisors, short, stumpy, quite without the similarity to a minute canine shown at least by the anterior one in *Myotis*, their tips barely rising to the level of the cingulum of the canine, the two closely pressed togehter and just filling the space between the canine and the large premolar. Large premolar with an unusually well-developed antero-internal cusp, as high as the large inner cusp of the molars. Lower incisors as in *Myotis*; canines proportionally short, barely rising as high as the posterior premolar; premolars all with their antero-posterior less than their transverse diameter, the two small ones closely crowded together between the canine and posterior premolar.

General external characters as in the smaller species of *Myotis*. Tragus of medium length, differing from that of most species of *Myotis* by being broader slightly above its base than at the base, its inner and outer edges both slightly convex.

Wings with peculiar thickened glands in them on the outer side of the forearms distally; three present on the left side and two on the right in the single specimen, but the situation of the third one is perceptible in the right wing, so that the normal number is probably three; the glands themselves about 3 - 3.5 mm. in length by 1 - 1.5 in breadth, more sharply outlined than the corresponding glands in *Pizonyx*; also situated closer to the forearm than in that genus, less in the centre of the wing.

Type: -

Cistugo lesueuri Roberts, 1919

p. 112

This genus was first described by Thomas (*ann. and Mag. N.H.* ser. 8, vol. x. pp; 204-206, 1907) on a single specimen taken in Angola. Apparently no more specimens have since been collected, and it is therefore pleasing to be able to record yet another specimen from so far south, and apparently resembling another species. The present one differs most markedly from *Cistugo seabrae* in size, the cranial and external characters seemingly differing but little; there appear to be no glands on the wing, however, and the colouration is somewhat different, both of which may eventually prove to be of little importance. *C. seabrae* is described as: "General colour dull drag, the bases of the hairs everywhere slaty, the tips above drab, below whitish. Membranes brown, with whitish edges, the light-coloured reticulations conspicuous." In the present species, the base of the hair is black, the upper parts as far as the crown terminally "honey-yellow" (Ridgway, 1912), the under parts as far as the chin much paler, yellowish white. The top of the head shows less of the yellowish colour and merges into the dark brown which characterises the face. Hair on the edge of the wing membrane merging from

p. 113

the yellow of the back to brown externally. Ears and nose almost naked, the former more thickly haired at the base posteriorly. The specimen being a dried skin cannot be accurately described as regards the ears; but apparently the tragus is almost straight on its inner margin, the outer margin convex. In the teeth, which are worn, the inner anterior cusp of P^4 is in line between the same cusps of P^3 and M^1.

The following comparative measurements will serve to show the difference in size:

Cistugo seabrae; Cistugo lesueuri
Head and body: 40; 47
Tail: 40; 43
Tibia and hind foot (c.u.): 18.2; 19.5
Ear: 12; 13
Skull: greatest length: 13.2; 14
Brain case: 6.6; 7
Front of canine to back of M^3: 4.6; 5.3
Forearm: 32.5; 34.5
Third metacarpal: 31.5; 33.8
First phalanx: 10.7; 11
Second phalanx: 9.7; 10.8

Type, old M, T. M. no. 2286, taken at Lormarins, Paarl District, 15th September, 1917, by J. S. Le Sueur, Esquire, by whom it was rescued from a cat.

Cistugo seabræ Thomas, 1912

p. 206

General appearance that of a *Pipistrellus*, say *P. kuhlii*, to which there is a considerable resemblance in size and colour. Ears of average size, their anterior margin convex at base, then nearly straight to the tip, which is narrowly

p. 206

rounded; outer edge angularly concave above, convex below. Tragus pointed, its inner and outer edges both slightly convex, a rounded lobe at its outer base. Wings from the base of the toes. No post-calcareal lobule. Tip of tail projecting. General colour dull drab, the bases of the hairs everywhere slaty, the tips above drab, below whitish. Membranes brown, with whitish edges, the light-coloured reticulations conspicuous.

Skull and teeth as described above.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 32.5 mm.

Head and body 40 mm.; tail 40; ear 12; tragus on inner edge 5; third finger, metacarpal 31.5, first phalanx 10.7, second phalanx 9.7; lower leg and foot (c. u.) 18.2.

Skull: greatest length 13.2; basi-sinual length 10.1; breadth of brain-case 6.6; front of canine to back of m^3 4.6.

Hab. Mossamedes.

Type. Adult female. B.M. no. 6.1.3.3. Presented by the Lisbon Museum.

This interesting little bat, which I have named in honour of Senhor A. F. de Seabra, C.M.Z.S., of the Lisbon Museum, is distinguishable from *Myotis* by the presence of glands in its wings, by the reduced proportions of its anterior premolars, and the large antero-internal cusp on p^4. Its general appearance is rather that of a *Pipistrellus* than a *Myotis*.

Clœotis Thomas, 1901

p. 28

Allied to *Hipposiderus, Asellia*, and *Triænops*.

Nose-leaf tridentate, its details apparently somewhat as in *Triænops*.

Ears short, rim-like, almost without tip, their outer and inner edges arising close together.

Thumbs extremely minute.

Tail scarcely projecting from membrane.

Anterior upper premolars present, but minute. Last molars nearly as large as the penultimate.

Nasal part of skull disproportionally small and feeble. Basal region broad between bullæ, without vacuities, strongly ridged laterally.

This bat does not appear to be assignable to any known genus. Its ear-structure, described in detail below, is quite unique, the shape of the ears being in this family very characteristic of the different genera. The complicated tridentate structure of the nose-leaf recalls *Triænops*, but the proportions of the skull are very different, nor is there any trace of the remarkable vertical expansion of the zygomata present in that bat. Nor do any of the species of *Asellia* show any approximation to *Clœotis*.

It is unfortunate that the two specimens were both sent as skins, so that, although one has been softened, the nose-leaf cannot yet be accurately described in detail, nor can any figure be given.

Clœotis Percivali Thomas, 1901

p. 28

Size very small, perhaps less than in any other member of the family. General build very light and delicate. Nose-

p. 29

leaf with many resemblances to that of *Triænops*, the posterior part similarly tridentate, the three points thinly hairy; below them in the middle line there is a small median projection, not so long as in *Triænops*; in front of that, again, there is something representing the anterior median plate in *Triænops*, but it is produced forwards into two small projecting points; horizontal horseshoe small, a narrow supplementary leaf apparently present. Outside and behind the tridentate leaf, between it and the eyes, there are two small projections covered with long hairs. Ears short, their outer and inner margins rising close together some way behind the eyes; the two margins are symmetrical with each other, rising vertically a short distance, then bending round abruptly and passing straight back to meet each other at the scarcely perceptible tip; the greatest height of the ear behind is only about one fifth higher than the point at which the two margins bend backwards in front. In fact the whole ear is very like a man's "stand-up" collar with the angles in front rounded off.

Wings very delicately made; thumbs quite minute, the terminal part free from the membrane only about 2 millim. long, including the claw. Wings attached to the distal end of the tibiæ. Calcars short, reaching only about halfway up the tibiæ. Tail apparently of only five joints, the last one scarcely projecting from the membrane, which is acutely pointed behind.

Fur fine, soft, and silky, about 6 millim. long on the back. Face bright buffy; crown greyish; back greyish brown, the hairs uniformly coloured. Hairs of underside slaty grey basally, yellowish white terminally.

Wing and interfemoral membranes uniformly smoky brown.

Skull with the part in front of the orbits much less broad and swollen than in other members of the family, the braincase being disproportionally large. Zygomata strongly convergent forwards. Palate ending opposite the middle of m^2. Basal region of skull broad between the bullæ, without vacuities, but with two strongly marked divergent ridges running from the base of the pterygoids to the antero-internal corners of the bullæ; sphenoidal fissures large and widely open.

Upper incisors spatulate, indistinctly bicuspid. Canines with a small posterior secondary cusp at half their height. Anterior upper premolars minute, crushed in in the outer angle between the approximated canine and posterior premolar. Last molar about four fifths the size in cross-section of

p. 30

penultimate molar. Lower incisors tricuspid, overlapping. Anterior lower premolar well developed, two thirds the height of the next.

Dimensions of the type: -

Forearm 31 millim.

Head and body (in flesh) 35; tail 28; ear 8.

Skull: greatest length 13; basal length 9.5; zygomatic breadth 7; breadth above orbits 3.3; interorbital constriction 1.8; mastoid breadth 6.5; front of canine to back of m^3 3.8.

Dimensions of a specimen softened and put in spirit: -

Forearm 32.

Head and body (c.) 34; tail 26; height of ear behind 5; third finger, metacarpus 26, first phalanx 10.5, second phalanx 14; lower leg 13.5; hind foot (s. u.) 5.5 ; calcar 8.

Hab. Takaungu, N. of Mombasa, British East Africa.

Type. Male. B.M. no. 1.5.1.11. Collected 15th February, 1901, and presented by Mr. A. B. Percival.

Mr. Percival is to be congratulated on the discovery of this interesting little bat, which is widely different from anything hitherto known.

Cloeotis percivali australis Roberts, 1917

p. 264

3 MM, 5 FF, Mooimeisjesfontein, Rustenburg (Powell).

This southern race differs from the typical one in being slightly larger, and in the lower anterior premolar not reaching to half the height of the posterior premolar. The following are maximum arid minimum measurements taken from the series as compared with the typical race :-
C. p. australis; *C. p. percivali**
Head and body: 41-33; 35
Tail: 31-22; 28
Ear: 9-8; 8
Skull-
Extreme length: 13.6-13.2; 13
Greatest width:7.6-7.2; 7
Mastoid width: 7.6-6.8; 6,5
Dental series: 4.3-4.1; 3.8
Forearm: 35-33; 31
Third finger, metacarpus: 29-27; 26
Third finger, first phalanx: 11 .8-10.6; 10.5
*Cf. *Ann. and Mag, Hat. Hist.* (7), Vol. VIII (1901), p. 28.

p. 265

Colour.- Face "warm buffy," browner towards and round the lips; top of head and back buffish-brown, lighter on the posterior margin of the wings; under surface varying from light buff to golden orange, the base of the fur darker, in proportion to the colour of the tips.

Type. - T.M. No. M 1670, F.

Coleura kummeri Monard, 1939

p. 55

Collection: N^{os} 879 M, 880 F, 881 F, 882 F, 883 F, 884 M, 885 F, 886 M, 887 M, 888 F, 889 F, 890 M, 891 F, 3 crânes 892, Madina, Boé. Tous les exemplaires proviennent de la même station, une case indigène dans les environs de Madina Boé.

Le genre *Coleura* comprend de petites Chauves-souris appartenant à la famille des Emballonuridæ. Les espèces de ce genre sont extrêmement rares dans les collections, peu nombreuses et répandues seulement dans l'Est du continent et dans les îles Seychelles. Le Catalogue de DOBSON (1878) n'en cite que deux espèces: la première, *seychellensis* de PETERS (1868), la seconde *afra*, du même auteur (1867); la première vient, comme son nom l'indique des îles Seychelles et de Zanzibar; la seconde est du continent. du Moçambique. Le Catalogue de TROUESSART et son Supplément n'ajoutent rien à ces renseignements. En 1915, OLDFIELD THOMAS décrit deux nouvelles espèces de ce genre, *gallarum* et *silhouettæ*, (avec deux sous-espèces de *gallarum*) et la distribution du genre gagne un peu vers le centre du continent: Suakim, Aden, Somaliland, réqion du Nil supérieur, du Congo au Zambèze. Les dernières citations de ce genre sont celles de ALLEN, LANG et CHAPIN (Bull. Am. Museum 37, 1917. p. 424) à Aba (Congo Belge) et de ALLEN et LOVERIDGE (1933) qui ont trouvé l'espèce dans les matériaux de l'expédition amêricaine au Tanganyika; la surface distributive est accrue de Voi, à la côte, jusque dans la région des grands lacs (Mwanza). Ainsi donc, le genre *Coleura* apparaît à la fois comme fort rare, oligomorphe, étroitement localisé dans les Seychelles et dans

p. 56

la partie Est du continent. Ce me fut donc une très grande surprise d'en trouver des exemplaires dans l'extrême Ouest africain, en Guinée portugaise, dans l'intéressante région du Boé. L'énorme hiatus qui sépare le Boé du lac Tanganyika est de l'ordre de 5000 km au moins.

Comme il fallait s'y attendre, les exemplaires de Guinée montrent avec *Coleure afra* des différences constantes dans les 13 exemplaires rapportés; ces différences sont suffisantes pour élever au rang d'espèce la forme guinéenne; elles sont du même ordre, pour le moins, que celles utilisées par THOMAS POUR LA CREATION DE SES ESPECES; EN OUTRE, CHOSE CURIEUSE, NOTRE NOUVELLE ESPECE OFFRE SOUVENT DES CARACTERES INTERMEDIAIRES ENTRE *SEYCHELLENSIS* ET *AFRA*.

NOUS NE POUVONS MIEUX FAIRE QUE DE DEDIER CETTE INTERESSANTE ESPECE A M. ALBERT KUMMER, agent de la Compagnie française, à Bissau, notre ami à qui nous avons dû un aimable foyer et une aide toujours active et bienveillante.

Description. Voisine de *afra* PETERS et en offrant les dimensions, à l'exception du tibia, toujours plus long que dans cette espèce et intermédiaire entre *afra* et *seychellensis*.

Museau allongé. conique, dépassant l'ouverture buccale de 3 mm environ; narines ouvertes là l'extrémité de deux courts tubes juxtaposés, séparés par un profond sillon longitudinal; le milieu de la lèvre supérieure montre un petit tubercule nu. Lèvre supérieure et commissure buccale garnies d'une frange de cils raides. Lèvre inférieure munie en son milieu d'un organe (glandulaire ?) nu, saillant, cordiforrne, souvent partagé par un sillon médian, comme dans *seychellensis*, mais à la différence de *afra*.

Oreille large, arrondie, atteignant, rabattue en avant, l'origine des tubes nasaux; le lobe commissural est plus redressé que dans *afra*. Tragus de trois mm environ, à bords parallèles. à sommet arrondi, muni là sa base, du côté externe, d'un petit tubercule.

Membranes aliformes brunes transparentes; le pelage, à la diffêrence de *afra* où il s'étend du milieu de l'humérus au tiers distal du fémur et jusqu'au point de sortie de la queue, ne dépasse pas le corps dans la région interfémorale et le déborde à peine sur les côtés du corps. La longueur de l'uropatagium, prise sur l'axe, est de deux fois celle de la queue. La membrane naît de la cheville ou légèrement en dessus.

p. 58

Le pelage est entièrement brun-roux, la base des poils blanchâtres, comme dans *gallarum nilosa* THOS.

Mâchoire supérieure: incisives obliques, convergentes, largement séparées, leurs pointes séparées par un intervalle égal à celui qui les sépare des canines. Celles-ci avec cingulum développé, formant en avant et en arrière des pointes accessoires, l'antérieure longue et aiguë, la postérieure plus courte. Première prémolaire toute petite, n'atteiqnant que le milieu de la pointe accessoire postérieure, formée d'une base cylindrique large d'où s'élèvent deux petits tubercules. Deuxième prémolaire presqu'aussi grande que la canine. Molaires bien conformées, la première avec parastyle et première commissure rudimentaires, la deuxième complète avec la première commissure recourbée là son origine en avant et en dedans, la troisième avec métastyle, quatrième commissure et hypocône absents ou rudimentaires. Protocônes diminuant de la première à la seconde molaires.

Mâchoire inférieure: les trois incisives trifides, juxtaposées, un peu séparées des canines. Cingulum de la canine bien dèveioppé, formant une pointe accessoire, bien visible en avant, cachée par la prémolaire en arrière. Première prémolaire bien développée, plus petite que la seconde. Molaires toutes à cinq tubercules bien développés, les protoconides les plus hauts.

Crâne: Rostre large et plat, à peine concave au milieu. Bord antêro-infêrieur de l'orbite saillant, cachant la série dentaire en vue sagittale. Processus postorbitaire long, étroit, falciforme. Impression du basisphênoïde large, profonde, bordée en arrière par une crête saillante du basioccipital. Dimensions là peu près celles de *afra* les plus grandes du genre.

Les points principaux qui permettent de différencier cette espèce sont: longueur du tibia (18 mm), présence d'un sillon à la lèvre inférieure, membranes nues dès le corps. Ces caractères placent *C. kummeri* entre *seychellensis* et *afra*. La nudité des membranes, la présence d'un sillon labial sont de *seychellensis*; la forme du museau et des narines, les dimensions sont de *afra*; enfin la longueur du tibia est intermédiaire entre ces deux espèces (15 mm dans *afra* et 25 dans *seychellensis*). La grandeur est celle de *afra* et non de *gallarum*, plus petit.

Série dentaire supérieure: 8

Mœurs. Les mœurs sont crépusculaires et nocturnes; l'espèce forme ordinairement des troupes assez nombreuses. Au repos, la première phalange du doigt II se replie sur le métacarpe et la seconde sur la première. Au troisième doigt, ce même mouvement n'est qu'ébauché par la première phalange, mais accompli nettement par la deuxième, à la manière de *Saccolaimus peli* TEM. (v. Bull. Am. Museum 37, 1917, p. 515).

Dentes primores $^{4}/_{4}$, canini $^{1\,1}/_{1\,1}$, molares $^{5\,5}/_{6\,6}$; index unguiculatus; cranium maxime ante processum zygomaticum ossis frontis coarctatum; mammae anteriores; qlans penis mollis; pollex patagio involutus; cauda brevis vel brevissima.

Die Arten sind zum Theil in Indien, zum Theil in Africa zu Hause

Cynonycteris Angolensis Bocage, 1898

p. 133

Cynonycteris Angolensis.

Syn. *Cynonicteris ægyptiaca*, Bocage (non Geoffroy). *Jorn. Ac. Sc. Lisboa.*, 2ª serie, t. I, 1889, p. 15; *Cynonycteris* sp? Bocage, *Jorn. Ac. Sc. Lisboa*, 2.ª serie, t. II, 1892, p. 174, fig. 2.

Taille à peine inférieure à celle de la *C. collaris*. Tête de forme pyramidale, large en arrière, à museau étroit et obtus; les yeux plus rapprochés de l'oreille que de la narine; les oreilles beaucoup plus longues que la distance de la narine à l'œil, ovales, arrondies au bout. Membranes de l'aile et des oreilles noirâtres.

Pelage laineux et abondant, plus court sur la poitrine et l'abdomen; les poils de chaque côté de la tête, de la gorge et de la face intérieure du cou, sensiblement plus longs.

Les membres sont couverts en dessus de poils longs et serrés, les antérieurs jusqu'à un peu plus de la moitié de l'avant-bras, les postérieurs jusqu'à l'articulation du pied; en dessous, les poils couvrent les membres antérieurs jusqu'à la moitié de l'avant-bras, et sur les membres postérieurs arrivent à peine jusqu'au premier tiers de la jambe. Les ailes présentent sur leur face supérieure, de chaque côté de l'avant-bras, une étroite bande de poils et une bande plus large de chaque côté du corps, allant de la moitié de l'humerus à l'extrémité supérieure du tibia, et se prolongeant sur le côté externe de celuici jusqu'au pied. La membrane interfémorale est presque entièrement couverte en dessous de poils aussi longs et aussi fournis que ceux du dos.

La membrane pré-brachiale est garnie en dessous de petits poils laineux clairsemés; des poils de même nature forment au dessous du membre antérieur une bordure, limitée par une ligne courbe, qui finit sur le milieu de l'avant-bras. L'interfémorale, couverte de poils dans sa portion centrale, laisse de chaque côté un espace nu.

p. 134

Sur le dos et la face supérieure des ailes les poils sont bruns, couleur de tabac; le dessous de la tête est d'une teinte un peu plus claire, mais le museau est plus rembruni. Le cou et la gorge sont d'un brun pâle tirant au grisâtre; la couleur des parties inférieures se rapproche de celle du dos mais prend un ton plus clair, grisâtre, sur le milieu de la poitrine et du ventre.

Plis du palais au nombre de sept, dont trois simples suivis de quatre divisés; les deux derniers dentelés, tous les autres lisses. Les trois plis antérieurs, simples, touchent respectivement par leurs extrémités à la première, à la seconde et à la troisième prémolaire; des quatre plis divises, les deux premiers sont en rapport avec les deux molaires et les deux derniers les suivent, gardant, entre eux et avec celui qui les précède, à peu prés la même distance. Le fond du palais est limite en avant par deux lignes dentelées concentriques assez rapprochées entre elles.*

*: L'examen du palais de trois espèces d'Angola, dans nos collections, nous autorise à considérer les différences qu'elles présentent dans la forme et la disposition de ses plis, comme,pouvant fournir des caracteres différentiels de quelque valeur pour la détermination spécifique des Chiroptères du genre *Cynonycteris*. Le palais du *C. stramínea* porte quatre plis simples et trois

divisés, dont les deux derniers sont dentelés; et en arrière de ces plis, au fond du palais, se trouvent quatre lignes courbes concentriques également dentelées; chez le *C. collaris* il y a aussi quatre plis simples et trois divisés, mais le fond du palais est limité en avant par une seule ligne dentelée disposée en angle aigu; enfin le palais du *C. angolensis* nous présente trois plis simples et quatre divisés, et plus en arrière deux lignes dentelées. (V. *Jorn. Ac. Sc. de Lisboa*, II ser., t. 2.^{do} p.p. 174 a 177, figs. 1, 2, 3.)

Nous appelons sur ce sujet, qui nous semble assez intéressant, l'attention des zoologistes que seraient à même de pouvoir examiner le palais des autres espèces du genre *Cynonycteris*.

p. 135

Habitat: *Pungo-Andongo* au nord du Quanza, *Cahata* et *Quibula* dans l'intérieur de Benguella.

La *C. angolensis* est une espèce à ajouter aux troís espèces dont on avait déjà constate l'existence en Angola: *C. straminea* dont nous possédons des exemplaires recueillis par Anchieta dans plusiears localités; *C. Collaris* très répandue dans l'Afrique équatoriale et australe et à laquelle nous croyons pouvoir rapporter des individus envoyés par notre regretté naturaliste de *Pungo Andongo* et de *Quidumbo*; enfin, *C. torquata*. Dobson, dont les exemplaires typiques, provenant d'Angola, font partie des collections du Muséum Britannique.

II est impossible de confondre la nouvelle espèce, avec la *C. straminea* et la *C. collaris*. En effet, même sans tenir compte d'autres caractères différentiels, tels que l'infériorité de la taille, la diverse conformation de certaines parties, et la différente coloration du pelage, la sculpture de son palais nous permet de la séparer, nettement, de ses deux congénères, car, comme nous l'avons déjà observé, le palais de la *C. angolensis* présente trois plis simples et quatre plis divisés, tandis que les deux autres espèces ont quatre plis simples et trois plis divisés.

Quant à la *C. torquata*, la description publiée par Dobson, et sourtout les dimentions sigalées par cet auteur, d'après un individu adulte du Muséum Britannique nous semblaient contraires à toute idée d'assimilation; mais désirant arriver par comparaison directe à un résultat plus positif, nous avons adressé à notre ami Mr. Oldfield Thomas un de nos exemplaires de *Quibula* avec prière de vouloir bien le comparer aux exemplaires typiques du Muséum Britannique. Or le savant zoologiste du Muséum Britanniqae, vient de nous informer, que la *Cynonycteris* de *Quibula* ressemble à la *C. torquata* sous le rapport des plis du palais, trois simples et quatre divisés, mais qu'elle en diffère par la supériorité de sa taille, par sa tête plus longue, par ses oreilles presque doubles en longueur, par l'absence d'un collier etc, ce qui nous permet de conclure quil s'agit réellement d'une espèce inédite.

Cynonycteris torquata Dobson, 1878

p. 76

Cynopterus collaris, Gray (non *Geoffroy*), *Catal. Monkeys and Fruit-eating Bats*, p. 123 (1870).

Slightly more than half the size of *C. collaris*. The head also is comparatively broader and shorter, and the crown of the skull more elevated above the face-line.

The male has the under surface of the neck clothed with remarkably long, densely set yellow hairs, which extend outward upon the shoulders and backwards upon the breast, terminating abruptly, forming a broad well-defined ruff, very distinct from the short fur of the body (Plate V. fig. 2).

Above, half the forearm is covered with short hairs, and the wing-membrane as far as a line drawn from the middle of the humerus to the knee; nearly the whole of the interfemoral is thickly covered, but the lower third of the tibiæ and the legs are quite naked. Beneath, a few fine hairs appear upon the antebrachial membrane and upon the wing-membrane between the humerus and the femur and behind the elbow, but no band of fur passes outwards behind the forearm to the carpus.

Above, reddish brown, head paler; beneath, pale brown except the ruff, which is bright reddish yellow.

P. 77

Upper incisors arranged in an angular series between the canines; last lower premolar placed on the commencement of the ascending ramus of the jaw, so that, although much smaller, its crown is higher than that of the antepenultimate molar.

In the following columns are given the measurements of an adult male (a dried specimen) and of a younger male (the type, preserved in alcohol) :

Length, head and body: -; 3.5
" Tail: -; 0.35
" head: -; 1.3
Distance of the eye from the nostril: -; 0.45

p. 59

Tafel XV. Fig. 1.

D. ferrugineofuscus, gastraeo medio griseo; auriculis multo latioribus quam altis, connatis; labris plicatis, crassis, in margine glabris; cauda ultra medium involuta; calcaribus brevioribus.

Longitudo tota 0,090; capitis 0,026; caudae 0,029; antibrachii 0,037; volatus 0,230.

Habitatio: Africa orientalis, Insula Mossambique, 15° Lat. Austr.

Diese Art is der vorhergehenden sehr ähnlich. Die Ohren haben fast dieselbe Gestalt wie bei *Dysopes limbatus*, doch bildet der vordere Theil der Helix einen deutlichen Lappen, und der Tragus ist am Ende abgerundet. Die Lippen sind weniger faltig und am Rande ungekerbt, glatt. Der Kopf und Körper sind gröfser und stärker, die Flughäute dagegen kürzer, ebenso der Schwanz und die Spornen. Die Behaarung des Körpers ist sehr kurz, am Vorderhalse langer, und bekleidet den angrenzenden Theil der Seitenflughäute; die Schenkelflughaut ist aber weniger stark behaart, und umfafst den Schwanz weit über die Hälfte bis zum viertletzten Gliede. Die Phalangen des dritten Fingers sind kürzer als das Mittelhandglied desselhen.

Die Farbe des Rückens und der Seiten des Halses, der Brust und des Bauches ist dunkel rostbraun, die ganze Mitte der Bauchseite dagegen vom nackten Kinn bis zum After zeigt eine graue Färbung. Sammtliche Haare sind an der Basis und Endspitze blasser, weifslich, indem entweder das Braune, wie am Rücken und an den Seiten des Bauches, oder das Weifse, wie an der Mitte der Unterseite, überwiegend ist; einige Haare der Kehle sind ganz weifs. Die Flughäute und Ohren sind von derselben Farbe, aber dunkler; die Nägel bräunlich weifs.

Der Schädel ist viel gröfser als der von *D. limbatus*. Die Zahl der Zähne ist dieselbe, $^{3\,2}/_{3\,2}{}^{1}/_{1}{}^{1\,1}/_{4}{}^{1}/_{1}{}^{2\,3}/_{2\,3}$ = 30; der letzte obere Backzahn ist aber nur halb so grofs wie der vorhergehende, so dafs seine Schmelzfalte V förmig ist, während dieselbe bei *D. limbatus* ein schief gestelltes N bildet. Ebenso ist der hinterste untere Backzahn weniger vollständig als bei *D. limbatus*. Die Form des Skelets, die Zahl der Wirbel und Rippen, so wie der Bau der Eingeweide ist Ganz wie bei der vorhergehenden Art. Den Blasenhals umfafst eine grofse Prostata ebenso wie bei den Mannehen von *D. limbatus*; die Testikel, obwohl sehr entwickelt, liegen aber nicht aufserhalb sondern innerhalb der Bauchhöhle.

Ein einziges Exemplar dieser Art, ein Männchen, fand ich in einem Kamine in Mossambique.

Mafse in Millimetern.

Länge d. 4ten Fingers (Mittelh. 35. 1.Gl. 12. 2.Gl. $8^1/_2$. 3.Gl. $1^1/_4$): $56^3/_4$
Länge d. 5ten Fingers (Mittelh. 22. 1.Gl. $3^1/_4$. 2.Gl. $3^1/_4$. 3.Gl. $1^1/_4$): $35^1/_2$
Länge des Oberschenkels: 14
Länge des Unterschenkels: 12
Länge des Fulses mit den Krallen: $8^1/_2$
Länge des Schwanzes: 29
Länge des freien Theils desselben: $11^1/_2$
Länge des Sporns: 10
Länge des Schädels: $21^1/_2$
Länge der Wirbelsäule vom Atlas bis zum ersten Schwanzwirbel: 47

Obgleich diese Art mit der vorhergehenden grofse Ähnlichkeit hat, so ist sie doch durch die Gröfse des Schädels, durch die gröfsere Länge der Schenkelfluguaut, durch die Kürze der Spornen, durch die Form einiger Theile des Ohres und endlich durch die Färbung zu sehr von ihr verschieden, um mit derselben vereinigt werden zu können.

Dysopes dubius Peters, 1852

p. 60

Tafel XV. Fig. 2.

D. priori similis, sed multo major.

Habitatio: Africa orientalis, Sena, 17° Lat. Austr.

Obgleich ich von dieser Art nur ein einziges ganz junges Exemplar zur Vergieichung benutzen kann, so geht doch daraus hervor, dafs sie sich nicht mit einer der bekannten vereinigen lasse. Die Ohren sind viel breiter als hoch, über der Stirn mit einander verwachsen, und die Lippen sind faltig, wie bei den vorhergehenden Arten. Durch die Form der Ohren unterscheidet sie sich auch sogleich von den übrigen africanischen Arten. Die Füfse sind von bedeutender Gröfse, 3 Mm. länger als die von *D. brachypterus*, woraus, ebenso wie aus den Verhältnissen des Schädels hervorgeht, dafs das ausgewachsene Thier viel gröfser ist, als *D. brachypterus* oder *D. Geoffroyi*.

p. 61

Am Schädel ist besonders zu bemerken, dafs die Nasenbeino nur aus einem einzigen Knochenstücke bestehen, dafs sich zwischen den grofsen Scheitelbeinen und der Hinterhauptsschuppe zwei quadratische Ossa interparietalia befinden, und dafs die Pars mastoidea des Schläfenbeins einen besondern Knochen bildet. Von den bleibenden Zähnen sind noch keine zum Durchbruch gekommen: jeder Zwischenkiefer trägt zwei feine conische, an der Spitze nach aufsen gekrümmte Schneidezähne, und in jedem Oberkiefer steht ein ganz ähnlich geformter Wechsel-Eckzahn. Im Unterkiefer stehen sechs feine zweilappige grade Schneidezähne und zwei Eckzähne, welche ihre hakenförmige Spitze nach aufsen wenden.

Dieses Thier wurde mir in Sena von einem Neger gebracht, welcher es im Walde gefunden hahen wollte.

Dysopes hepaticus Heuglin, 1864

p. 14

Minor; supra cinereo-fuscus; gastraeo medio albido, reliquo lateribusque laete hepatico-brunneis, hypochondriis magis cinerascentibus; mento et gula nudiusculis, carnicoloribus; auriculis, facie et unguibus fuscis; cauda nigricante; patagiis pallide fuscis, pellucidis, subtus basin versus coerulescentibus.

Labris rugosis, hispidis; auriculis latis trapezoidiformibus, operculatis, margine superiore replicatis, fronte connatis, basi anteriore lobulo accessorio rotundato et trago minore arrecto, acutiusculo instructis; patagio anali plicato, tertiam partem caudae circumdante; cauda crassiuscula, dimidii corporis longitudine.

Long. corporis ad basin caudae 2" 10"' - caud. 1" 5"' - extens. patag. 13" - antibrach, 1" 9"'. -

Obiges die Maasse eines alten F. Die MM scheinen constant kleiner, bei einigen ist die ganze Oberseite des Körpers fein weiss gescheckt, bei andern das Gesicht ganz schwärzlich.

Die Nasenlöcher stehen etwas seitlich und sind stumpf röhrenförmig aufgetrieben; die wulstige Oberlippe mit 7 - 8 Querfalten; die Behaarung des Gesichtes rauh. Das verhältnissmässig grosse Auge liegt in zwei tiefen Furchen nahe an der vordern Ohrbasis. An der hintern Basis des kurzen, breiten unregelmässig viereckigen Ohres ist ein grösserer häutiger Ansatz, der

umgeschlagen den Gehörgang schliesst; vor der Basis des Vorderrandes des Ohres ein kleiner rundlicher, beweglicher Lappen, der sich an der Oberlippenwulst hinter dem Mundwinkel anschliesst.

Im Alter $^{1}/_{1}$, in der Jugend $^{1}/_{2}$ Schneidezähne. Die obern kräftig, mit der Spitze etwas convergirend, die untern mit unbewaffnetem Auge kaum sichtbar.

p. 15

Die obern Eckzähne vorne einfach gefurcht, die untern mit stark divergirenden Spitzen und einem spitzigen, nebenzahn-artigen Absatz auf der vordern, innern Seite der Basis der Krone.

Im Gaumen 5 - 6 undeutliche Falten.

Auf dem äussersten Glied der ersten und fünften Zehe und am Daumen einige lange, rauhe, die Nägel weit überragende weissliche Borsten.

Die Flughäute fast ganz nackt.

Diese hübsch gefärbte Art lebt gesellschaftlich in dürrem, dichtem Laub auf unersteiglichen Doleb-palmen (*Borassus aethiopius*) im Lande der Req-Neger bis zum Djurfluss. Selten sieht man sie bei Tage fliegen, doch ist sie immer munter und sieht bei grellstem Sonnenlicht.

Dysopes limbatus Peters, 1852

Tafel XIV.

D. nigrofuscus, subtus pallidior, ventre medio lateribusque albis; auriculis multo tatioribus quam altis, connatis; labris crassis plicatis; cauda ultra medium libera; patagio anali piloso.

Longitudo tota 0,095; capitis 0,022; caudae 0,034; antibrachii 0,037; volatus 0,260.

Habitatio: Africa orientalis, Insula Mossambique, Sena, a 15° ad 17° Lat. Aust.

Eine der kleinsten Arten dieser Gattung. Die Ohren ragen mit ihrem vordem Ende bis in die Mitte zwischen Auge und Schnauzenspitze, sind niedrig, breit, auf der Stirn durch eine breite Hautwulst vereinigt, am innern Rande der Helix und an der Basis dicht behaart der untere Theil der Helix ist schmal, und läfst keinen besondern Lappen erkennen; der Tragus ist sehr klein, eckig, am obern Rande fast grade abgeschnitten. Die Haare auf den Kopfe hinter der Vereinigung der Ohren sind länger und steifer als am übrigen Körper. Die Schnauze is breit, stumpf, niedergedrückt, un vorn schräg von oben nach unter und hinter eingeschr..en. Die Oberlippe ist dick, .. am Rande ge... und mit kurzen steifen Haaren besetzt. Die Behaarung des Korpers ist sehr fein und weich, am Rücken und Bauch gleich lang, an der Vorderseite des Halses ein wenig länger, und geht zu beiden Seiten in einem breiten Saum auf die Flughäute über. Diese letzteren sind schmal

p. 57

zwischen dem Oberarm und Schenkel mit punctförmigen Rüscheln von Härchen besetzt. Nur das Mittelhandblied des Daumens wird von der Halsflughaut umfafst. Vor dem Gelenke zwischen dem Mittelhand und dem ersten Gliede des Daumens befindet sich eine hornartige nackte Hautscheibe. Die Glieder des dritten Fingers zusammen sind so lang oder länger als die Mittelhand desselben. Die Flughäute gehen nicht ganz bis zum Ende des Unterschenkels herab. Der Schwanz ragt mit seier grofseren Endhollte aus der Schenkelflughaut hervor, welche der Quere nach gefaltet und sowell oben wie unten zur Hänte behaart is.

Die Farbe des ausgewachsenen Männchen Fig 1., ist auf dem Rücken dunkel schwärlich röstbraun, an der Bauchseite etwas blasser, die Mitte und die Seiten des Unterleibs so wie das ... weifs. Die Ohren sind schwarzbraun; die Flughäute neben den Körperseiten braun, die ubrigen Theile derselben durchscheinend bräunlich. Die braune Theile viel heller rostfarbig. Die Rückenhaare haben eine blasse weifsliche Basis; die braunen Haare der Bauchseite zeigen aufserdem hellere Spitzen. Die Nägel sind bruin, am convexen Rande dunkler gefärbt.

Zähne im erwachsenen Zustande $^{3\ 2}/_{3\ 2}{}^{1}/_{1}{}^{1\ 1}/_{4}{}^{1}/_{1}{}^{2\ 3}/_{2\ 3}$ = 30. Die jungen Thiere zeigen vor ihren beiden oberen bleibenden Vorderzähnen die vier noch nicht ausgestofsenen Wechselzähen (Fig. 3a.). Die Wirbelsäule wird aus 41 Wirbelkörpern gebildet; darunter sind 7 Halswirbel, 13 Rückenwirbel, 6 Lendenwirbel, 5 Kreuzbeinwirbel, 10 Schwanzwirbel. Das Brustbein besteht aus drei Knochenstücken: der Kiel desselben ist sehr schwach; es verbinden sich sechs Paar Rippen mit demselben. Der zweite Finger hat eine Phalanx, der Mittelfinger drei, und eben so der vierte und funfte Finger, bei denen aber das letzte Glied kurz un umgebogen ist. Die Fibula is vollständig entwickelt. Die Schleimhaut des Gaumens zeigt sechs Querfalten. Die Papillen der vordern Hälfte der Zunge sind platt und schuppenförmig; auf der hintern Hälfte sind sie grösfer, zerstreuter, warzenförmig; nahe der Basis finden sich mehrere in ringförmigen Vertiefungen, von denen zwei durch ihre Gröfse sich auszeichnen. Zu jeder Seite am Halse liegt eine grofse 7 Millim. im Durchmesser haltende Speicheldrüse. Der Oesophagus mündet nahe unter dem Zwerchfell in einen grofsen sackförmigen Magen, welcher in einen nur anfangs etwas weiteren 130 Mm. langen Darm übergeht. Die Leber liegt mit ihrem gröfsen Theil in der rechten Seite, hat einen mittleren schwachen, einen rechten tiefen Einschnitt; in letzterem liegt die Gallenblase. Die Milz is 15 Mm. lang, am breitesten Theile 4 Mm. breit. Die Nieren sind einfach, bohnenförmig, 6 Mm. lang, 4 Mm. breit; die linke liegt viel tiefer als die rechte. Die Blase ist dünnwandig, und wird, bei dem Männchen, an

ihrem Halse oben und an den Seiten von einer halbmondförmigen 6 Mm. im Durchmesser haltenden Prostata umgeben. Die Ruthe ist ganz weich, ohne innere Skelettheile; nehen ihrer Wurzel liegen die 5 Mm. langen Hoden, und treiben die Haut so hervor, dafs die äufseren Genitalien mit den menschlichen eine aufscrordentliche Ähnlichkcit haben. Der Kehlkopf ist 5 Mm. lang. Die Luflröhre, welche keine Anschwellungen zeigt, enthält 24 knorpfelige Halbringe. Die rechte

p. 58

Lunge zeigt zwei kleine Nebenlappen; die linke ist einlappig. Das Herz ist länglich, 10 Mm lang, 5 Mm. breit.

Diesen Grämler erhielt ich auf der Insel Mossamnbique und in Sena aus dunkele Räumen der Wohnungen. Der Inhalt des Verdauungscanals verschiedener Individuen liefs Theile von Insecten erkennen.

Nyctinomus aegyptiacus Geoffr. (*Dysopes Geoffroyi* Temm.) hat am meisten Ähnlichkeit mit dieser Art, ist aber viel gröfser (Vorderarm bei dem jungen Thier 50 Mm.), und auch durch die Form und Stellung der oberen Schneidezähne, welche kürzer sind und nahe beisammen stehen, verschieden. *Dysopus pumilus* Rüpp. unterscheidet sich von ihr durch gröfsere Länge der Ohren und durch verschiedene Färbung der Bauchseite. *Dysopes midas*, Hedenborg, und *Dysopes Rüppellii* Temm. (*Dysopes Cestonii* Savi) sind durch ihre viel bedeutendere Gröfse, durch viel höhere Ohren, erstere auch durch die nackten Flughäute leicht von ihr zu unterscheiden. *Dysopes natalensis*, Smith, die einzige bisher bekannte südafricanische Form dieser Gattung, ist oben und unten braun gefärbt, hat dreieckige zugespitzte Ohren, glatte Lippen, und eine viel breitere Schwanzflughaut, so dafs sie in keiner Weise mit unserer Art zu verwechseln ist.

Beschreibung

Das Haar äußerst fine und wollig, nicht sehr lang aber dicht. Die Farbe auf ben oberen Theilen des Körpers schwarzbraun, auf den unteren heller. Die Flügel- und Zwischenschenkel-Membranen schwarzbraun. Dieselbe Färbung an den Ohren. Diese mit starken wulstigen Knorpeln versehen, haben einen kleinen $^1/_2$ Linie langen Ohrdeckel (*operculum*), welcher bei dem nach dem Gesicht sehr vorliegenden Ohre nicht gesehen werden kann, ohne dass dasselbe nach hinten zurück gebogen worden, und welchen wir hier deswegen anführen, da wir ihn bei allen aus Afrika erhaltenen Grämlern vorfinden. Er ist von dem eigentlichen Ohrläppchen (auricula) bedeckt **). Im übrigen ist dieser Grämler seinen Formen nach ein Miniaturbild von dem Dysopes Rüppelli, welchen Temminck in den *Monographies de mammalogie* pag. 224 beschrieben und planche XVIII abgebildet hat, weswegen wir in Hinsicht der Characteristik dieses Geschlechtes als auch unserer hier bezeichneten Art im allgemeinen auf die vorzügliche Bearbeitung derselben hinweisen. Die kleinen schwarzblauen Augen sind von dem Ohre fast ganz bedeckt.

Vaterland. Massauah.

Aufenthalt. Alte verödete Wohnungen.

**) Geoffroy hat diesen Ohrdeckel nicht angegeben. Temminck dagegen desselben erwähnt, aber die *auricula* als eine doppelte, eine äußere und eine innere angeführt, während diese Theile ihrem Baue und ihrer Bedeutung gemäß, wie schon Kuhl angegeben, verschieden sind.

Eleutherura unicolor Gray, 1870

p. 117

Fur soft, uniform grey brown, rather paler below; hair one-coloured; ears large; wings pale, with white hairs near margin; forearm 3 inches 8 lines; tail very short; false grinders in each jaw well developed, lower largest.

Hab. West Africa: Gaboon, *Verreaux*.

See *Pteropus mollipilosus*, Allen, Proc. Acad. N. Sci. Philad. 1861, p. 159. Head small; ears large; tail very small, free; fur olive-brown, brighter on the back of the neck. *Hab*. Western Africa (Gaboon), *Du Chaillu*. "The intermaxillary bone of the skull is not thrown forwards and downwards as in other *Pteropi*, but is on the same level as the roof of the mouth, the first upper premolar larger than the incisors, the same tooth of lower of a good size and less tubercular than in other species." - Allen. Perhaps male of preceding.

Emballonura afra Peters, 1852

p. 51

Tafel XII. Tafel XIII. Fig. 18. 19.

E. ferrugineofusca, gastraeo pallidiore, auriculis trianqularibus rotundatis, trago mediocri; rostro prominente, apice bifido; dentibus primoribus superioribus duobus; phalangibus primis digiti quarti et quinti duplo longioribus quam secundis.

Longitudo tota 0,080; caudae 0,020; antibrachii 0,050; volatus 0,310.

Habitatio: Africa orientalis, Tette.

Von der Gröfse unserer *Vespertilio discolor*. Die Ohren stehen weit von einander getrennt, sind um ein Viertel kürzer als der Kopf, von dreieckig abgerundeter Gestalt, und nur an der Basis und am Längskiel behaart. Ihr vorderer grader Rand steht mitten über dem Auge, ihr hinterer convexer, unten schwach ausgeschnittener Rand setzt sich geschwungen bis nahe hinter und unter dem Mundwinkel fort. Es lassen sich an ihnen neun, oben gedrängter stehende, Querfalten unterscheiden. Der Tragus ist frei, doppelt so lang wie breit, an seiner Basis hinten mit einer kleinen nach vorn umgeschlagenen Spitze versehen, am Rande behaart. Die Augen sind gröfser als sie gewöhnlich bei den Thieren dieser Ordnung erscheinen, und haben ihre Lage in der Mitte zwischen dem vorderen Ohrrande und dem Mundwinkel. Die Plica semilunaris in ihrem innern Winkel ist sehr entwickelt. Die Nase tritt oben doppelröhrig hervor, und bildet den am meisten vorspringenden Theil der Schnauze; sie ist zu jeder Seite schräg abgestutzt, so dafs die Nasenlöcher unter einem stumpfen Winkel

p. 52

von einander abgewandt sind. Das Maul ist bis unter die Augen gespalten. Die Oberlippe ragt mit ihrem breiten platten Rande über die Unterlippe hervor, ist mit steifen über der Mundrand gerichteten Haaren besetzt, jederseits an ihrer innern Oberfläche durch einen warzigen Vorsprung, und vor der Mitte durch eine platte Erhabnuheit ausgezeichnet, welche in eine mittlere Vertiefung der Unterlippe eingreift, deren Schleimhaut sich hier mit einer dreieckigen breiten Platte nach aufsen umschlägt. Eine hintere Erweiterurig der Backen in taschen förmige Vertiefungen ist nicht vorhanden. Die Gaumenhaut bildet sechs quere Falten; die erste derselben ist kurz und liegt mitten zwischen den Eckzahnen; die zweite ungetheilte liegt zwischen dem vordern Ende der beiden grofsen Lückenzähne; die dritte und vierte sind in der Mitte getrennt und nehmen den Raum zwischen dem ersten Paar der grofsen Backzähne ein; die fünfte ist ebenfalls in der Mitte getheilt, und bildet einen nach vorn stark convexen Bogen, so dafs ihre äufseren Enden mit der letzten graden Querfalte zwischen und an dem hintersten Theile des zweiten Paares der wahren Backzähne zusammenstofsen. Die Behaarung des Körpers ist dicht und weich, vor der Brust und dem Halse etwas länger als an den übrigen Theilen, wo man sie eher kurz nennen kann; sie geht in einem breiten Saum auf die Seitenflughäute über, an der Bauchseite etwas weiter aber lichter als an der Rückenseite; ebenso setzt sie sich auf der obern Seite der Schenkelflughaut bis zur Durchbohrungsstelle des Schwanzes fort. Die Flughäute sind lang und schmal, schliefsen von Daumen nur das Mittelhandglied ein, und gehen nicht über das untere Ende des Unterschenkels herab; die Rückenseite der Halsflughaut ist leicht von kurzem wolligen Haar bedeckt, und auf den erhabenen Linien zwischen Arm und Schenkel lassen sich Reihen kurzer Härchen wahrnehmen. Der Oberarm hat die Länge des Kopfes; der Unterarm ragt neben dem Körper gelegt weit über die Spitze der Schnauze hervor, und ist länger als die Entfernung der Schnauzenspitze vom After. Die Mittelhand des Daumens ist ebenso lang wie das erste Glied desselben; die Haut vor dem Gelenke zwischen diesen Gliedern bildet eine kleine nackte Scheibe. Der zweite Finger erreicht lange nicht das Ende der Mittelhand des dritten Fingers, und diese ragt doppelt so weit über das Mittelhandglied des vierten Fingers wie dieses über dasselbe Glied des fünften Fingers hinaus. Die erste Phalanx des vierten und fünften Fingers ist doppelt so lang wie die zweite. Die Beine sind im Verhältnifs zur obern Extremität nur kurz, indem sowohl Ober- wie Unterschenkel kaum ein Drittheil so lang wie der Vorderarm sind. Die Füfse dagegen sind ziemlich lang, länger als die Hälfte des Unterschenkels: die Zehen ragen alle fast gleich weit vor, doch ist die äufsere und innere ein wenig

kürzer als die drei mittleren gleich langen. Die Krallen der Zehen sind etwas länger als die Daumenkrallen. Der Schwanz und die Spornen sind ungefahr so lang wie der Unterschenkel. Die Schenkelflughaut ist am Endrande schwach bogenförmig ausgeschnitten, wird ungefähr in ihrer Mitte oben vom Schwanzende, welches sich wie in eine Scheide zurückziehen kann, durchbohrt, und zeichnet sich durch zahlreiche Querfalten aus, welche an der Bauchseite mit weifsen Härchen bewimpert sind.

p. 53

Die Farbe des ganzen Thieres ist braun, rauchbraun, chocoladenbraun oder, wie in den meisten Fällen, dunkelrostbraun, an der Bauchseite etwas heller. Die einzelnen Haare sind auf der Rückenseite und dem Kopfe einfarbig braun bis auf den ganz kurzen weifslichen Grundtheil, die Bauchhaare haben aufser dem hellen Grundtheile auch noch ganz kurze blasse Spitzen. Die Flügel und Ohren sind von derselben braunen Farbe, aber etwas dunkler. Die Nägel sind bräunlich weifs.

Der Schädel (Tafel XIII. Fig. 18. 19) zeigt ganz die der Gattung *Emballonura* eigenthümliche Form und die Entwickclung der Processus zygomatici des Stirnbeins, wie wir sie auch bei den *Taphozous* wiederfinden. Zähne: $^{3\,2}/_{3\,2}{}^{1}/_{1}{}^{1\,1}/_{6}{}^{1}/_{1}{}^{2\,3}/_{2\,3}$ = 32. Bei mehr als hundert Exemplaren fand ich stets nur zwei obere Schneidezähne, und nach dem Bau der Zwischenkiefer zu urtheilen, ist auch nur für einen einzigen Zahn in jedem derselben Platz. Diese beiden Zähne stehen weit auseinander, mit den inneren lang ausgezogenen Spitzen convergirend. Die unteren sechs Vorderzähne stehen in der Richtung des Kieferrandes und sind dreilappig. Die oberen Eckzähne sind gekrümmt, sowohl vorn wie hinten mit einem deutlichen Absatz versehen. Gleich hinter ihnen liegt ein kleiner, rundlicher, einwurzeliger Lückenzahn, der nicht über den hinteren Absatz des Eckzahns herabragt, und an seiner Krone, genau betrachtet, dreispitzig ist. Hierauf folgt durch eine Lücke getrennt ein grofser zweiwurzeliger Lückenzahn, welcher in seiner Form der ersten Hälfte des daran stofsenden ersten wahren Backzahns entspricht. Dieser letztere ist nicht ganz so grofs wie der folgende vierte, welcher allein eine vollstandig W förmige Schmelzfalte besitzt, und daher aufsen drei, innen zwei Spitzen, und oben an seiner Basis noch zwei durch die Entwickelung des Cingulums gebildete Höcker zeigt. Der fünfte und letzte obere Backzahn ist nur halb so grofs wie der vierte. Die unteren Eckzähne sind von der Gestalt der oberen, aber beträchtlich kleiner. Der erste Lückenzahn des Unterkiefers ist einwurzelig, doppelt so grofs wie der entsprechende obere, mit niedriger, unregelmäfsig dreikantiger Spitze. Der zweite Lückenzahn ist zweiwurzelig, etwas länger und breiter, um das Doppelte höher, und von der Gestalt des Eckzahns. Die drei folgenden wahren Backzähne sind viel schmäler als die entsprechenden oberen, sämmtlich fünfspitzig mit nach innen offenstehender W förmiger Schmelzfalte.

Die Wirbelsäule wird von 39 Wirbelkörpern zusammengesetzt; hiervon sind 7 Halswirbel, 14 Rückenwirbel, 5 Lendenwirbel, 7 Kreuzbeinwirbel und 6 Schwanzwirbel. Mit dem Brustbein, welches nur am Manubrium gekielt erscheint, verbinden sich 8 Paar Rippen, die übrigen 6 Paare sind falsche. Der Unterschenkel zeigt eine vollständig entwickelte Fibula.

Die Zunge ist mit feinen schuppenartigen Papillen bedeckt, weiche nach der Mitte hin am Rande gestachelt erscheinen; an der Basis stehen gröfsere knopfförmige Papillen und zwei von einer ringförmingen Vertiefung umgebene Warzen. Der Oesophagus geht sogleich unter dem Zwerchfell in einen einfachen kleinen rundlichen Magen über, weicher durch eine schwache Pförtner-Einschnürung vom Darm abgesetzt ist. Dieser letztere ist anfangs ein wenig erweitert, und hat eine Länge von 150 Mm. Die Leber liegt mit ihrem gröfsten Theile

p. 54

in der linken Seite, und hat zwei Einschnitte; unter dem rechten liegt eine ziemlich grofse Gallenblase. Am Fundus des Magens liegt die Milz, ein schmaler, platter Körper von 10 Mm Länge. Die Nieren sind ungelappt, bohnenförmig, 6 Mm. lang und 4 Mm, breit. Die Harn bläse ist dick und musculös. Der Uterus geht in zwei lange Hörner aus. An den Seiten der Brust liegt ein einziges Paar von Zitzen; am Bauche ist keine Spur von zitzenähnlichen Vorsprüngen vorhanden. Die Ruthe des Männchens ist ganz weich, ohne Knorpel oder Knochen zu beiden Seiten vor den Schambeinen liegen die platten, rundlichen Hoden aufserhalb den Bauchhöhle. Der Schildknorpel des Kehlkopfs bildet einen schmalen Halbring, den man leicht mit dem Zungenbein verwechseln könnte, von dessen hinteren Enden ein kurzer obere Fortsatz zur Verbindung mit dem grofsen Horn des Zungenbeins, ein sehr langer unterer zu Verbindung mit dem Ringknorpel abgeht. Der Ringknorpel ist dagegen sehr lang, an seinen hintern Fläche mit einer sehr hohen Leiste versehen, mit welcher sich oben die Giefsbeckenknorpel verbinden. Die Luftröhre besteht bis zur Theilungsstelle aus 17 knorpligen Halbringen; ihr häutiger Theil bildet im ersten Drittel eine grofse spindelförmige Erweiterung. Die Lungen bestehen jederseits aus einem einzigen Lappen. Das Herz ist breit und abgerundet, 7 Mm. lang, 5 Mm. breit.

Ich fand diese erste africanische Art der Gattung *Emballonura* in dunkeln Kellerräumen in Tette. Sie lebt in grofsen Gesellschaften beisammen, in denen die Zahl der Männchen überwiegend zu sein scheint, indem ich unter hundert Exemplaren nur zwanzig Weibchen fund. Im Darm fand sich eine breiartige Masse mit Schalenrudimenten von Insecten vermischt.

Emballonura monticola, Temminck, mit welcher diese Art in der Färbung und Gestalt die meiste Verwandtschaft hat, unterscheidet sich von ihr durch geringere Gröfse, so wie, nach der Temminckschen Abbildung zu urtheilen, durch gröfsere Länge des fünften Mittelhandgliedes, und durch die ziemlich gleiche Länge der Phalangen des vierten und fünften Fingers.

Eomops Thomas, 1905

p. 572

In 1900 Dr. Scharff described a bat from Benin under the name of *Mormopterus Whitleyi* and was good enough to transfer the typical specimen to the British Museum.

Later on Dr. W. J. Ansorge obtained on the Lower Niger two examples of the same bat, and in examining these I find that a mistake has inadvertently been made in the dental formula given, and that, instead of being a *Mormopterus*, this

p. 573

bat belongs to quite a different group, hitherto unknown in the Old World.

For it proves to have the characteristic incisors of *Molossus*, the upper pair being large, nearly filling up the space between the canines, and touching each other in the middle line. The lower ones are only two in number, not four as originally stated, and while appearing from the front to be of the normal shape - i.e., narrow, broadening upward, each with a deep central notch dividing it into two cusps, of which the inner is the higher - they are curiously deep antero-posteriorly, deeper than broad, their hinder part running back between the canines.

The premaxillary region of the palate is very completely ossified, in great contrast to all the members of the *Nyctinomus* group, the only remnant of the premaxillary notch being two minute foramina on each side of the middle line, between and opposite the centre of the canines.

The skull is smooth and rounded, not broadened and flattened across the muzzle as it is in *Myopterus*, nor specially crested as in *Molossus*. The base of the skull has a narrow median ridge between two well-defined sphenoid pits.

Under these circumstances it is clear that this bat cannot be referred to *Nyctinomus* or *Mormopterus*, but is more nearly allied to *Molossus, Myopterus*, and their allies. The peculiar shape of its lower incisors, however, and the detailed structure of its skull prevent its being referred to any one of the existing American genera, and I would therefore propose to erect for its reception a special genus, which might bear the name of *Eomops*.

It is also to be noted that, owing to the bad condition of his specimens, Dr. Scharff described the underside of *Eomops Whitleyi* as "of a light reddish-yellow colour"; but Dr. Ansorge's fresh examples show that this is pure white, as are also the wing-membranes above and below, the digits, and the underside of the interfemoral; the upper surface of the forearms, tibiæ, and interfemoral are pale whitish brown.

Ep[omophorus (Epomophorus)] büttikoferi Matschie, 1899

p. 45

1888. *Epomophorus gambianus* Jeutink, Not. Leyd. Mus. X. p.50. - 1888. Jentink, Cat, Syst. p. 137c.

Hab. Schieffelinsville, Junk River, Liberia.

Bei dem mir zu Gebote stehenden Material von *Epomophorus* variirt die Länge des Unterarms bei Exemplaren, deren letzter oberer Molar vollständig ausgebildet ist, nicht allzusehr. Die Männchen sind allerdings gewöhnlich grösser als die Weibchen, aber bei beiden Geschlechtern bleibt die Variation innerhalb von je 3 - 6 mm. Die alten Männchen von Angola erreichen eine Unterarm-Länge von 93 mm , die kleinsten ausgewachsenen Weibchen von dort haben einen Unterarm von 82 mm Länge. Die Angola-*Epomophorus* sind aber die grössten, welche ich aus der Gattung kenne. Der von Herrn Jentink erwähnte *Epomophorus* von Junk River in Liberia hat eine Unterarm-Länge von 101 mm, also 8 mm mehr als der grösste sonst bekannte *Epomophorus*.

Die Arten von *Epomophorus* s. str, bewohnen beschränkte Gebiete; es ist mir nicht gelungen nachzuweisen, dass zwei Formen dieser Gruppe neben einander in derselben Gegend leben. Wo man derartige Fälle in der Litteratur findet, da darf man stets an der Richtigkeit der Fundortsangabe oder der Bestimmung zweifeln.

Bei Bolama in Portugiesisch-Guinea lebt *Ep. macrocephalus*, an der Goldküste eine sehr ähnliche Form, die ich jetzt als *Ep. zechi* abtrenne. Von Liberia ist nur die von Jentink als *gambianus* bezeichnete Form bekannt. *Ep. gambianus* stammt aber aus den Sammlungen, welche Rendall vom Gambia heimbrachte und wird wahrscheinlich nördlich vom Gambia im Senegal-Gebiet erlangt worden sein. Es ist also von vorn herein sehr wahrscheinlich, dass in Sierra-Leone und Liberia eine neue Art von *Epomophorus* vorkommt. Jentink giebt die Unterarm-Länge für das eine der beiden im Leydener Museum befindlichen Stücke auf 101 mm an. Diagnose von *Epomophorus büttikoferi* Mtsch. Epomophorus, gambiano aff. sed multo major, radii longitudine 93 mm superante.

p. 46

Als Typus ist das von Stampfli gesammte M des Leydener Museums von Schieffelinsville am Junk River aufzufassen. Ich habe mir erlaubt, diese Art Herrn Direktor Dr. Büttikofer in Rotterdam zu widmen, durch welchen wir die Fauna von Liberia so gut kennen gelernt haben.

Das Original-Exemplar, ein sehr altes M mit schön entwickelten Schultertaschen hat nach Jentink folgende Maasse:
Unterarm: 101 mm
3. Finger, Metacarpale: 75.5
" " 1. Phalanx: 48
" " 2. " : 64.5
5. " Metacarpale: 73
" " 1. Phalanx: 35
" " 2. " : 35
Unterschenkel: 43
Auge bis zur Nasenspitze 30

Ep[omophorus (Epomophorus)] doriae Matschie, 1899

p. 54

- 1879. (?) *Ep. labiatus* Dobson, P.Z.S. p.716 - 717. - 1880. (?) Dobson, Rep. Brit. Ass. p. 2 - 3. - 1887. *Ep. labiatus* von Keren, Bogos, Monticelli, An. Mus. Civ. St. Nat. Genova, 2. ser, (V) p. 524.

Epomophorus doriae Mtsch, spec. nov, aff. *Ep. minor*, molaribus angustis, 1.5 mm latis, differt radii longitudine apud F 69.5 mm.

Ich verknüpfe mit diesem Flederhund den Namen des Herrn Marquis Doria, welchem unsere Sammlung so ausserordentlich grosse Förderung zu danken hat.

E. doriae unterscheidet sich von *Ep. labiatus* durch seine schmalen Backenzähne, welche nur 1.5 mm breit sind und durch die kurze Molarenreihe (9.2 mm); er unterscheidet sich von *minor* durch den längeren Unterarm (69.5 mm bei F) und durch die längere Schnauze (15.9 mm vom vordersten Punkte des Augenraudes neben dem Foramen infraorbitale bis zum Gnathion - gegen 14.1 bei einem *E. minor*-Weibchen).

Wie sich *Ep. doriae* zu *Ep. schoensis* verhält, vermag ich vorläufig nicht zu sagen. Von dem Kitimba-Flederhunde, mit welchem er in der Länge der Zahnreihe und der Gestalt der Molaren übereinstimmt, unterscheidet er sich durch die grössere Länge des Unterarmes und dadurch, dass bei *doriae* der erste untere Molar viel länger ist als der letzte Praemolar, während bei dem Kirimba-Fledefhund beide Zähne ungefähr gleich lang sind.

Hab. Küste des Rothen Meeres in der Erythraea.

Ich möchte vermuthen, dass die *Ep. labiatus* aus der Robb'schen Sammlung hierher gehören, ebenso wie die Exemplare von Bogos (Beccari) im Museum von Genua.

Ep[omophorus (Epomophorus)] neumanni Matschie, 1899

p. 50

- 1876. *Ep. crypturus* Ptrs. Monatsb. Akad. Berlin p. 913. - 1878. Peters l.c. p. 195. - 1879. *Ep. labiatus* Peters l.c. p. 831.

Epomophorus neumanni Mtsch. spec, nov. alis concoloribus neque ad corpis latera albido tinctis, fasciis in plagiopatagio 23 31; radii longitudo 73 - 78 mm (F), 77 - 80 mm (M).

Hab. Küstengebiet von Britisch Ost-Afrika (Mombasa, Takaungu, Malindi) und Moschi am Kilima-Ndjaro.

Ep. neumanni, den ich Herrn Oscar Neumann widme. unterscheidet sich von allen andern Flederhunden der Untergattung *Epomophorus* mit Ausnahme von *Ep. wahlbergi* und *stuhlmanni* dadurch, dass auf dem Plagiopatagium mindestens 23 Stränge den Hauptstrang durchschneiden; junge Thiere zeigen weniger Stränge, aber immerhin über 20, während junge Exemplare der übrigen Arten höchstens 16 aufweisen. Von *Ep. wahlbergi* und *stuhlmanni* unterscheidet sich *Ep. neumanni* durch die weit

geringere Grösse, von *stuhlmanni* auch durch die gleichmässig braun gefarbten, an den Körperseiten nicht weisslichen Flughäute. Die Gaumeufalten sind ungefähr so, wie sie Dobson für *gambianus* abbildet. *Ep. neumanni* sieht

p. 51

Ep. zenkeri von Kamerun sehr ähnlich, ist aber kleiner und hat zahlreichere Stränge auf der Flughaut. '

Ep[omophorus (Epomophorus)] stuhlmanni Matschie, 1899

p. 50

1878. *Ep. gambianus* von Dar es Salaam. Dobson l.c. p. 11. - 1890. (?) *Ep. minor* von Bagamoyo , Thomas , P.Z.S. p. 446. - 1891. *Ep. gambianus* Noack, Jahrb. Hamb. Wiss. Anst, IX. p. 57 - 58. - 1891. *Ep. minor* Noack, l.c. p. 58 - 59. - 1895 *Ep. gambianus* Matschie, Säugethiere Deutsch-Ost-Afrikas, p. 16 Fig. 7 (Kopf). - 1897. Matschie, Arch. Naturg. I. p. 83.

Hab. Küstengebiet von Deutsch-Ost-Afrika und Zanzibar.

Diese Abart hat ebenso wie *wahlbergi* und wie die von Mombas bekannten Flederhunde auf dem Plagiopatagium mehr als 23 Stränge, welche den Hauptstrang durchschneiden. Von *wahlbergi* und dem Mombas-Flederhund lässt sie sich leicht durch ihre gegen die Körperseiten weisslich überflogenen Flughäute unterscheiden; sie ist grösser als der Mombas-Flederhund, aber kleiner als *wahlbergi*. Ihre Diagnose könnte man in dem Satze zusammen fassen:

Epomophorus stuhlmanni Mtsch. spec. nov., alis ad corporis latera albido tinctis, fasciis in plagiopatagio 23 - 30; radii longitudo 85 - 87 mm (M), 80 - 81 mm (F).

In der Gaumenbildung steht diese Abart der Kamerun-Form sehr nahe und dem "gambianus" auf Dobson's Tafel. Noack's *Ep. minor* von Zanzibar sind junge *Ep. stuhlmanni*; ich möchte auch vermuthen, dass die *Ep. minor*, welche Oldf. Thomas von Bagamoyo aufführt, junge *ep. stuhlmanni* sind. Die grössten *Ep. minor* FF, welche ich kenne, haben einen Unterarm von 63 mm; bei den MM ist der Unterarm 64 - 68 mm lang; ganz junge *Ep. stuhlmann*i haben schon eine Unterarm-Länge von 68 - 69 mm.

Ich nenne diese Abart nach Herrn Regierungsrath Dr. Stuhlmann, dem ich den grösseren Theil der mir zur Verfügung stehenden Exemplare verdanke.

Hab. Accra, Goldküste (Jentink), Gross-Popo, Misahöhe in Togoland (B. M.), Lagos (B. M. und Stuttgarter Museum).

Epomophorus, *macrocephalo* affinis, differt alis laete brunneis, radii longitudine 85 - 87 mm (F), 88 - 90 mm (M); dorsi colore laete brunneo griseo.

Der *Epomophorus* von der Goldküste, von Togo und von Lagos ist bisher immer als *Ep. macrocephalus* aufgefasst worden, trotzdem *Ep. macrocephalus* M nur einen Unterarm von 86 mm hat und trotzdem seine Flughaut schwärzlichbraun angegeben wird. Der *Epomophorus* on Mittel-Guinea hat einen Unterarm von 85 - 87 (F) resp. 88 - 90. (M) mm und seine Flughaut ist hellbraun. Der Hauptstrang des Plagiopatagiums wird von 18 - 22 Strängen durchschnitten. Die Entfernung der Aussenkanten der letzten oberen Molaren von einander ist beim M wie bei *macrocephalus* M etwas länger als die Länge der oberen Molaren-Reihe (cf. die Abbildungen bei Barboza und Tomes) mit der Abbildung auf Taf. 10. Die Zahnreihe ist länger als die Hälfte der Entfernung der ersten von der 7. Gaumenfalte. Das Bild auf Taf. II. Fig. 2 des Dobson'schen Catalogs entspricht dem Bilde, welches der Gaumen eines F bietet. - Ich widme diese Art dem durch seine zoologischen Forschungen im Togolande verdienten Herrn Graf Zech.

Hab. Vom Kamerun-Fluss nach Süden bis zum Cuanza, nach Osten his Niam-Niam, also Süd-Kamerun, Gabun, Loango, Congo und Loanda; im besonderen bekannt vom Kamerun-Delta (Reichenow), vom Gabun (Büttner, Dobson), von Porto da Lenha (Noack), von Tschintschoscho (Falkenstein), von Netonna
(Noack), von Malandje (von Mechow), von Pungo-Andongo, Ambacca, Quissango und vom Rio Cuillo (Barboza du Bocage), von Loanda (Peters), von Semmie in Niam-Niam (Jentink), von Franceville am oberen Ogowe (dc Pousargues).

Dass diese *Epomophorus* von Nieder-Guinea nicht zu *Ep. gambianus* gehören, mit welchen sie in der Gestalt der Gaumenfalten grosse Aehnlichkeit haben, lisst sich aus folgenden Betrachtungen schliessen:

Bei *Ep. gambianus* Ogilb. variirt nach Tomes (P.Z.S. 1860 p. 531) die Länge des Unterarmes zwischen 76.2 und 85 mm, bei den Exemplaren von Nieder-Guinea zwischen 79 und 85 mm; es haben also die FF aus Nieder-Guinea einen ungefähr so langen Unterarm wie die MM von *gambianus* Ogilb. Nach der Ogilby'schen Original-Beschreibung von *gambianus* soll die Körperlänge $6^3/_4$ Zoll = 171.4 mm, die Kopflänge von der Nase zur Ohrwurzel $1^3/_4$ Zoll = 44.45 mm und die Spannweite der Flügel 1 Fuss 8 Zoll = 508 mm betragen. Die Abbildung des Schädels (P.Z.S. 1861 Taf. I. Fig. 2) beweist, dass wir es mit einem alten Exemplar zu thun haben, dessen Molaren schon stark abgekaut sind. Die entsprechenden Maasse für ein altes M von Tschintschoscho und ein altes F von Malandje betragen: 138 mm; 44 mm; ca. 555 mm resp. 127 mm, 43 mm, ca. 525 mm. Wir erkennen hieraus, dass *Ep. gambianus* von den *Epomophorus* aus Nieder-Guinea verschieden sein muss.

Von *Ep. gambianus* würde sich die hier zu betrachtende Art, welche ich nach meinem Freunde G. Zenker, dem ausgezeichneten Sammler in Kamerun, benenne, durch folgende Diagnose unterscheiden:

Epomophorus comptus H. Allen, 1862

p. 158

Hair soft ; thick above, thinner below. Color on the back a delicate reddish fawn, becoming darker on the loins and base of arms. Under surface with a large ovoid patch of dirty white, bounded laterally by longitudinal fawn colored stripes. Face covered with short brown hairs. Small yellow tufts at base of ears. Chin whitish. Epaulettes faintly marked. Lips moderate.

Dental formula, m $^3/_5$, c $^1/_1$, i $^2/_4$, c $^1/_1$, m $^3/_5$ = 26.

The fur of this bat differs from that of any other of the genus to which it belongs in not being unicolored. That upon the back of the neck and shoulders possesses three well-defined hues - the base is of a dark brown, the middle of a paler hue, while the tip forms a delicate reddish brown. This, however, can only be seen where the hair is thickest. Lower down upon the back and on the belly the entire length of each individual hair is of one color. Everywhere the hair covering is soft and yielding. All that space beginning between the eyes and terminating at the middle of the back is of thick, fine, beautiful hair. The sides are much thinner and darker; they form a continuous line with that of the ulna, where it extends down upon the wing membrane some little distance. The continuation of the dorsal fur forms on the ventral surface of the interfemoral membrane a sparsely furnished patch, which goes to make the lower portion of the lateral fawn-colored bands. These latter are narrow inferiorly, wider superiorly, where they terminate gradually in the lighter hue of the cervical region. From the external side a prolongation is sent up along the line of the humerus and ulna to within an inch of the carpal joint; both

p. 159

above and below this line the membrane has upon it several points of short lanuginous hairs of a whitish color.

The customary clumps of hair at the base of the ears are present. The anterior spot is larger than the posterior.

The characteristic shoulder tufts are by no means conspicuous; they are composed of thin long hairs of a light color. The centres are quite naked and placed more upon the neck than is usual.

The skull is smaller than that of *E. gambianus* Ogil. The post-orbital processes are small but well defined; temporal fossæ not approximate. The intermaxillaries slight, terminating in a point, not abruptly, as in *E. gambianus*, and supports but two incisors. The latter occupy the centre of the inter-canine space, and are slightly separated from one another.*

The other teeth differ in no particular from those of *E. gambianus* except in their mode of articulation, in which the inferior incisors close in front to the superior, as already seen in Hypsignathus, the superior teeth, however, are not entirely hidden.

This species holds a position between *E. gambianus* Ogil. and *E. shoensis* Rüp. It differs from the former in the relative length of the nose, in the tricolored hair of back, and in the greater extent of the epigastric patch; from the latter in being much larger, and in the absence of the dark colored abdomen.

Dimensions.

Length of head and body: 6.0
" from snout to base of ears: 1.6
" " eye to snout: 0.8
" " anterior part of eye to ear: 0.8
Height of ears: 0.9
Breadth of ears: 0.6
Length from nose to wing membrane: 2.8

" longest finger: 6.0
" fourth ": 4.8
" thumb and claws: 1.2
" basal joint: 0.3
" second joint: 0.8
" tibia: 1.6
" foot and claws: 0.8
Expanse of wing membrane: 18.0

Hab. Western Africa ; discovered by M. Duchaillu.

Epomophorus crypturus Peters, 1852

p. 26

Tafel V. Tafel XIII. Fig. 1 - 6.

E. colore corporis dilute umbrino, subtus pallidiori in cinereum migrante; patagiis umbrinis; ad basin auriculae utrinque macula alba.

Lonqitudo totalis 0,16, capitis 0,055, antibrachii 0,077; latitudo alar. expans. 0,5.

Habitatio: Africa orientalis, Tette, 17° Lat. Aust.

Der Kopf ist sehr grofs im Verhältnifs zum übrigen Körper, doppelt so lang wie breit, vor den Augen plötzlich verschmälert, so dafs die vorderen Augenwinkel nur halb so weit von einander entfernt stehen wie die hinteren. Der Abstand des Auges von der Schnauzenspitze ist viel gröfser als die Entfernung desselben vom Ohr. Die Pupille ist rund. Die Ohren sind elliptisch, an der Spitze abgerundet, ihr Rand ist ringsum saumartig verdickt, hinten schwach ausgeschnitten; an ihrer äufsern Fläche erheben sich neun bis zehn Querfalten, und der übrige Theil ist von netzförmig erhabenen Linien durchzogen; die innere Fläche ist sparsam behaart, die äufsere in ihrer obern Hälfte nackt, an der Basis aber, so wie an dem vordem und hintern Rande bis über die Hälfte hinauf ist die Behaarung lang und reich. Die Nase, welche über das Maul hinausragt, ist durch eine tiefe dreieckige Furche gespalten; die Nasenlöcher stehen seitlich und sind spiralförmig geschlitzt; die feingekörnte breite Nasenkuppe setzt sich, durch eine enge Längsspalte in der Mitte getrennt, bis zum Rande der Oberlippe fort; das vordere Ende der Unterlippe ist glatt und unbehaart. Die Entfernung der Nasen-

p. 27

löcher vom Rande der Oberlippe beträgt nur zwei Drittel von der Breite der zwischen ihnen Befindlichen Scheidewand. Die Maulöffnung reicht nicht ganz bis unter die Augen, und krümmt sich vorn in die Höhe. Der Körper, durch einen schmalen Hals vom Kopf abgesetzt, ist so kurz, dafs die Entfernung von dem obern Rande des Brustbeins bis zu dem After kaum die Länge des Kopfes erreicht; die Seitenflügel befestigen sich so an der Körperseite, dass sie in der Beckengegend nur halb so weit, 16 Millim., von einander entfernt stehen wie unter dem Oberarm. Das Schwanzrudiment liegt, in den langen Haaren versteckt, vor der Schenkelflughaut, an seiner Basis durch eine kleine Falle mit derselben verbunden. Tafel V. Fig. 3. Der Oberarm ist viel kürzer als der Kopf und etwas mehr als halb so lang wie der Vorderarm. Das erste Glied des Daumens, welches fast eben so lang ist, wie die drei Glieder des zweiten Fingers zusammen, wird beinahe zur Hälfte von der Flughaut eingehüllt. Der zweite Finger ragt mit seinem Nagel bis an das Ende vom Mittelhandknochen des dritten Fingers. Die erste Phalanx des dritten Fingers ist so lang wie das Mittelhandglied des zweiten Fingers; die zweite Phalanx desselben so lang wie sein eigenes Mittelhandglied. Die beiden Phalangen des vierten Fingers zusammen sind ein wenig länger, die des fünften Fingers ein wenig kürzer als ihre gleich langen Mittelhandglieder. Die Zehen sind an ihrer Basis bis zur Mitte ihres ersten Gliedes durch Häute mit einander verbunden. Die fünfte Zehe ist ein wenig kürzer als die drei mittleren gleich langen; die erste Zehe ragt mit ihrem ersten Gliede über das zweite Drittheil des zweiten Gliedes der folgenden hinaus. Die erste Zehe besteht aus zwei, die übrigen vier aus drei Gliedern; wol nur durch Unachtsamkeit sind in der Abbildung von *Epomophorus Whitei* (*Transact. Zool. Soc.* II. pl. 7) alle Zehen mit drei Gliedern gezeichnet. Die Körperflughaut setzt sich über den Fufsrücken bis zur Mitte des ersten Gliedes der zweiten Zehe fort. Die Schenkelflughaut ist schmal wie bei den schwanzlosen Pteropen, bogenförmig ausgeschnitten, an ihren Ecken durch einen schwachen Sporn sestützt, und endigt an der Basis des Mittelfufses. Die Krallen sind scharf und spitz, unten gefurcht; die Daumenkralle ist um ebenso viel gröfser als die Zehenkrallen, wie die letzteren die Kralle des zweiten Fingers überragen. Die Behaarung ist dicht und wollig, an der Rückenseite des Körpers länger als an der Bauchseite desselben, am Vorderhalse kragenartig verlängert, über der Schulter bei Männchen und Weibchen einen Wirbel bildend; sie geht an den Oberextremitäten über das zweite Fünftel des Vorderarms hinaus, an der Rückseite der Unterextremität bis nahe zur Fufswurzel,

an der vordem Seite derselben bis zur Mitte des Unterschenkels herab; sie dehnt sich an der Bauchseite weiter über die Flughaut aus, ist hier aber viel dünner als an der Rückseite derselben; die Schenkelflughaut wird bis auf ihre äufseren Winkel ganz durch die langen Haare verdeckt; die Rückseite der Flughaut ist aufserdem noch bis nahe zum fünften Finger hin mit zahlreichen Reihen kurzer Haarbüschel besetzt, welche nach der Fufsecke hin gedrängter und länger erscheinen. Die Zehen sind mit kurzen, steifen zerstreuten Haaren versehen. Aus den kurzen Gesichtshaaren springen zur Seite der Schnauze und über dem Auge schwache Schnurrhaare hervor.

p. 28

Die Farbe der Rückseite ist blafs umbrabraun, wie Milchkaffee, die Schultern, der Hals und die Bauchseite heller, die Mitte des Bauches ins Graue streifend; um die Augen herum und an den Seiten des Gesichts ist die Farbe gesättigtel; vor und hinter dem Ohr befindet sich ein grofser gelblichweifser Fleck. Die Iris ist bei jungen Thieren graubraun, bei den alten rothbraun. Die Nasenkuppe, Ohren und Flughäute sind ebenfalls umbrabraun aber etwas dunkler gefärbt. Die einzelnen Haare sind einfarbig, am Grunde etwas dunkler. Die Nägel sind von schwarzbrauner Farbe.

Der Schädel ist sehr niedrig, ohne Längsleiste; die Oberkiefer und Gaumenbeine sind sehr verlängert, so dafs der sehr kurze Processus postorbitalis weit hinter der Mitte des Schädels zu liegen kommt; die Breite des Schädels hinter dem Processus postorbitalis ist viel gröfser als vor demselben; der Jochbogen verläuft horizontal; der Infraorbitalcanal ist ein wirklicher Canal wie bei *Macroglossus*. Der Unterkiefer ist sehr niedrig, so dafs die gröfste Höhe fast drei Mal in der Länge desselben enthalten ist. An sieben Exemplaren verschiedene Alters besteht das Gebifs beständig aus $^{4}/_{4}$ Vorderzähnen, $^{1\,1}/_{1\,1}$ Eckzähnrnen, $^{3\,3}/_{5\,5}$ Backzähnen. Die oberen Vorderzähne sind conisch und nach hinten gekrümmt, die unteren dreilappig. Die oberen und unteren Eckzähne sind von gleicherhakenförmig gekrümmter Gestalt, and ihrer hintern Seite abgeflacht, die unteren um ein Drittel kleiner als die oberen. Die drei oberen Backzähnrn sind zweiwurzelig; die Krone des ersten ist eckzahnförmig, dreikantig, mit einer äufsern convexen, einer vordern innern graden, und einer hintern innern concaven Fläche versehen; der zweite besteht aus einer einfachen Schmelzlamelle, welche eine biscuitförmige Grube umschliefst, und aufsen einen starken, innen einen schwachen Zacken bildet; der dritte ist eben so lang wie der vorhergehende, aber viel niedriger, nur aufsen mit einem schwachen Zacken versehen. Im Unterkiefer folgt zunächst auf den Eckzahn ein kleiner einwurzeliger Lückenzahn mit kurzer conischer Spitze; darauf kommen drei zweiwurzelige Zähne, welche in ihrer Form den drei oberen Backzähnen entsprechen, aber etwas kleiner sind, und zuletzt ein kleiner zweiwurzeliger Höckerzahn, welcher nur halb so lang ist wie der vorhergehende. Die Wirbelsäule besteht aus 35 Wirbelkörpern, von denen 7 flache Halswirbel, 14 rippenttragende Rückenwirbel une 4 Lendenwirbel sind, die folgenden 7 bis zur Vereinigung der Sitzbeine als Kreuzbeinwirbel und die letzten 3 als Schwanzwirbel beträchtet werden können. Das Brustbein besteht aus 5 Stücken und trägt 7 Rippenpaare. Das Schlüsselbein ist bogenförmig gekrümmt. Das Oberarmbein ist so lang wie der Schädel, an seinem untern Ende undurchhohrt, und am Condylus externus durch ein Gelenkstück vergröfsert, welches den Streckmuskeln der Hand zum Ansatz dient. Die Ulna ist sehr dünn und mit dem Radius verwachsen; das Olecranon getrennt. Die Handwurzel besteht aus 7 Knochen, drei in der ersten, vier in der zweiten Reihe. Die Fibula ist unvollständig: die Zahl der Fufswurzelknochen ist 7; drei in der ersten, vier in zweiten Reihe; dann folgen fünf Mittelfufsknochen und endlich Phalangen, von denen man zwei an der ersten Zehe, drei an den vier übrigen zählt. Die Schleimhaut des Gaumens bildet 7 wulstige Querfalten, von denen die beiden

p. 29

letzten getheilt sind; ganz hinten befinden sich noch zwei flache Quervorsprünge mit gezähnelten Rändern. Die Lippen sind sehr breit wie bei den *Macroglossus* und an ihrer innern Seite durch gezackte Vorsprünge der Schleimhaut ausgezeichnet, welche besonders stark um Mundwinkel entwickelt sind. Die Zunge ist von hornigen rückwärts gerichteten Papillen bedeckt, die an der abgerundeten Zungenspitze fein, lanzettförmig, auf der Mitte ihres ersten Drittheils sehr grofs und dreispitzig, auf den übrigen Theilen platt und dachziegelförmig gestellt sind; an ihrer Basis stehen drei grofse warzenförmige flache Papillen. Der Oesophagus mündet in den 43 Millim. langen Magen, nur 7 Millim. vom Pförtner entfernt; der einfache Darm hat eine Länge von 960 Millim. Die Leber zerfällt durch zwei mehr oder weniger tiefgehende Einschnitte in drei Lappen; die längliche Gallenblase liegt unter dem rechten, oder zwischen diesem und dem mittlern Lappen. Die Milz ist 22 Millim. lang, 2 Millim. breit, und liegt hinter dem convexen Rande des Magens. Das Pancreas besteht in einer dünnen durchscheinenden Drüsenmasse, welche sich nur erkennen läfst, wenn man das Mesenterium gegen das Licht hält. Die Nieren sind zwei länglich abgerundete, 12 Millim. lange und 8 Millim. breite Körper, an deren oberen vorderen Enden die Nebennieren, kleine scheibenförmige Körper von 2 Millim, Durchmesser liegen. Die trächtigen Weibchen enthalten in jedem Horn des Uterus einen einzigen Fötus, der durch eine einfache Placenta ernährt wird. Die Brustwarzen sitzen am Rande des Brustmuskels auf, vor und unter der Achselgrube. Die Ruthe der Männchen besitzt weder knorpelige noch knöcherne Skelettheile; die Haut der Eichel ist in Längsfallen zusammengelegt. Das Zungenbein besteht aus einem sattelförmigen, unten breiteren Mittelstücke, mit dem jederseits unten das säbelförmige grofse Horn verbunden ist; oben setzen sich die kleinen Hörner an, welche aus zwei Gliedern bestehen, von denen das erste sehr klein, das zweite dagegen sehr grofs, auffallend breit und von lanzettförmiger Gestalt mit einem langen feinen Fortsatz versehen ist. Der Kehldeckel ist so lang wie breit, von rhomboidaler Gestalt, mit abgerundeten Ecken. Der Schildknorpel ist unten viel breiter ab oben, woselbst der Rand sich in eine mittlere Spitze verlängert. Die Luftröhre enthält bis zu ihrer Theilungsstelle 21 - 22 Halbringe. Die linke Lunge ist einlappig und vierzipflig, die rechte durch zwei bis drei tiefe Einschnitte in drei bis vier Lappen abgetheilt. Das Herz hat eine eiförmige Gestalt, eine Länge von 13, und an der Basis eine Breite von 10 Millimetern; die Spitze der linken Herzkammer ragt weit über die linke hervor; die Vorkammern stehen durch eine weite Oeffnung mit einander in Verbindung; das rechte Herzohr ist breiter und abgerundeter als das linke; der kurze Stamm der aufsteigenden Aorta theilt sich in zwei Trunci anonymi, von denen der linke etwas früher als der rechte in seine beiden Äste, die Carotis und Subclavia, zerfällt.

Diese Thiere leben, wie es scheint, ausschliefslich von Vegetabilien, da ich in ihrem Magen nie etwas andres als Ueherbleibsel und Kerne von Früchten vorfand.

Der einzige Ort, wo ich diese Art angetroffen habe, ist Tette, gegen 120 Meilen von der Küste und im 171° Südl, Br. gelegen. Die Eingebornen haben für diesen Flederhund zwei verschiedene Namen, *djæmea* und *demuanjundo*.

Diese Art steht dem *E. macrocephalus*, Ogilby (*Proceedinqs of the zool. society of London*. 1835. III. pag. 101) aufserordentlich nahe; letztere unterscheidet sich aber von ?? nach Ogilbys Beschreibung durch die sehr kurzen Flügel (1 Fufs 3 Zoll Engl.) und die schwärz-

p. 31

liche Farbe derselben, *E. gambianus*, Ogilby, besitzt nach Gray (*Magazine of zoology and botany*. 1838. II. pag 504) keine weifsen Haarbüschel an der Basis der Ohren, dagegen dergleichen über der Schulter. *E. Whitei*, Bennett (*Pteropus epomophorus*, Bennett; *Pteropus labiatus*, Temminck) ist durch die weifsen Büschel über den Schultern ausgezeichnet. *Pteropus schoënsis*, Rüppell, ist viel kleiner. *Pteropus Wahlbergii*, Sundevall, scheint nach der gegebenen Diagnose einen längeren Schwanz zu haben und vielleicht auch anderes Gebifs. Alle diese Arten sind jedoch sehr verwandt, und die Zahl derselben wird sich durch Untersuchung grofser Reihenfolgen wahrscheinlich noch vermindern. Das zoologische Museum hat ganz kürzlich ein ausgestopftes Exemplar von Herrn Temminck, aus Guinea durch Herrn Pel erhalten, welches keine weitere Unterscheidung von meiner Art aus Mossambique zuläfst, als dafs die Augen in der Mitte zwischen Ohr und Nasenende liegen

---

Epomophorus Dobsonii Bocage, 1889

p. 1

Ressemble Beaucoup à l'*E. gambianus* par son aspect, par sa taille et par ses proportions: mais il a une tête plus courte, des oreilles plus étroites vers l'extrémité, à bord extérieur légèrement concave dans leur tiers supérieur, et des couleurs différentes: d'un brun-roux uniforme sur la tête et en dessus, sans aucun mélange de teintes jaunâtres, plus pâles en dessous et tirant au grisâtre sur le partie inférieure du ventre; les membranes alaires sont de la couleur du dos.

Il porte, comme l'*E. gambianus*, une petite touffe de poils blanchâtres à l'épaule et quelques poils de la même couleur de chaque côté de la base de l'oreille.

Les dimensions du mâle adulte, représentant unique de l'espèce en notre possession, sont à peu-près celles d'un mâle de la même taille de l'*E. gambianus* à 'l'exception de la tête, qui est un peu plus longue chez celui-ci. Nous remarquons cependant une particularité que nous ne pouvons passer sous silence, en attendant qu'elle soit confirmée par l'observation d'autres exemplaires: chez tous nos individus de l'*E. gambianus* la première phalange du 4^e doigt a à peu-près la moitié de la longueur du métacarpe correspondant, tandis que chez la nouvelle espèce elle est beaucoup plus longue (V. tableau).

Les plis du palais, dont s'est servi si avantageusement M. Dobson pour bien caractériser les différentes espèces d'*Epomophorus*, nous fournissent des caractères différentiels d'une importance décisive, qui ne permettent pas de confondre cette espèce avec aucune do ses congénères. Sous ce rapport elle s'écarte absolutment de toutes les espèces connues.

Il est difficie, ... , de faire bien saisir par une ... les description la disposition et ... Formes toutes spécilistes ... de ces plis; mais la figure qui accompagne le texte ... à nous faire mieux comprendre.

p. 2

Le palais de notre individu présente 5 plis distincts, derrière lesquels se trouvent encore quelques lignes onduleuses, plus ou moins saillantes, finement denticulées. Il y a d'abord un premier pli du palais pli derrière les canines, qui ressemble au premier pli du palais chez l'*E. gambianus*, mais il forme un angle plus saillant en arrière et porte au milieu une incision bien marquée. Après celui-ci, nous remarquons dans l'intervalle de la 1^{e} à la 2^{e} prémolaire un gros pli transversal droit, dont les extrémités se divisent en doux branches qui vont terminer respectivement sur chacune des deux dents pré-citées. Le troisième pli correspond, à la molaire et ressemble assez bien au cinquième pli de l'*E. gambianus*. Plus en arrière et après un intervalle plus grand, se trouvent deux plis, l'un derrière l'autre et plus rapprochés entre eux, qui n'ont pas d'équivalents, quant à la forme, chez les autres espèces du genre; ils sont aplatis, disposés horisontalement et à bords antérieurs libres; l'antérieur (4^{e} pli) a une petite incision au centre et chacune de ses moitiés représente un triangle dont le vertes porte en dessus une petite papille; le 5^{e} pli, placé à petite distance du 4^{e} et concentrique avec lui, a à peu-près la même forme, mais ses dimensions sont plus restreintes.

Les lignes finement dentelées qui complètent le dessin du palais se trouvent bien indiquées dans la figure 1.

Notre individu, un beau mâle adulte, nous a été envoyé récemment de *Quindumbo*, dans l'intérieur de Benguella, par notre zélé naturaliste M. d'Anchieta.

Le tableau ci-après montre les principales dimensions de notre exemplaire en regard de celles d'un individu du même sexe de l'*E. gambianus*, récueilli par M. d'Anchieta dans la même localité.

E. Dobsonii, M ad.; *E. gambianus*, M ad.

p. 54

(Pl. LXXV.)

If the species in the present monograph took rank according as they are more or less typical in form, the present one should appear as second, the *E. labiatus* probably as third, followed by *E. gambianus*, and the list should be completed by the smallest and least typical species - *E. schoënsis*. But the first and most typical species is succeeded by the one which was described at very nearly the same time, as being much better known than those which were to follow.

The present one is much the largest species, attaining an expanse of more than 2 feet, and has the same singular tufts of hair on the shoulders as are recorded of the first Species in the list - *E. macrocephalus*, but much more developed than in that species, and of a pale yellow colour. The only known specimen was forwarded to the French National Collection by Dr. Franquet of the French Imperial Navy, and from it I have, by the kind permission of M. Geoffrey St. Hilaire, taken the description which follows, and have had a carefully executed drawing made by M. Oudart, from which the illustrations accompanying the present paper have heen copied. Its country is the same as that of the Gorilla.

The head is not nearly so long and narrow relatively as that of *E. macrocephalus*, but more nearly resembles that of *E. gambianus*. The ears, as in the other species of the genus, are of medium size, oval, and a little narrowed towards the tips; they are furnished with small tufts of fine white hair at the base of their inner and outer margins, like those of all the other species here described. The lips, as far as can be ascertained from the inspection of a mounted specimen, are large, although perhaps not quite equal to those of some of the other species. The interfemoral membrane is rather more ample than is usual in the genus.

The fur extends considerably on to the membranes, above and below, as in *E. macrocephalus*, and it is similarly unicolour, and possesses the same soft cottony texture. That of all the upper parts is of a cinnamon-brown colour, brighter and deeper than in the other species; the under parts similar, but the patch of whitish on the abdomen, which is faint as in the others, here takes the form of a clearly-defined oval space of pure white, as much as $2^{1}/_{2}$ inches long.

The shoulder tufts are very much developed, and differ somewhat from those of *E. macrocephalus*. They occupy a space on the shoulder of as much as $1^{1}/_{2}$ inch in length, in a descending direction; the lower half of this space consists of fur, which is of the same length and texture as that of the surrounding parts, but is of a buffy-yellow colour; whilst the upper part, constituting the real shoulder tuft, is composed of long yellow hairs, which spring outwards, and then curve downwards, partially hiding the short yellow hair already mentioned. All this yellow fur, both long and short, has a clear and well-defined outline. All the membranes are of a darkish cinnamon-brown.

The cranium is much less elongated thain in either of the preceding species, and in its general proportions bear some resemblance to that

p. 55

of *Pachysome stramineum*, especially in the expansion of the zygomatic arches; but the teeth are of precisely similar number and relative proportion with each other, as in *E. macrocephalus*, although they generally are stouter than in that species. The lower jaw exhibits most unequivocally the peculiarities mentioned in detailing the generic characters. The dimensions of the cranium will be given with those of some of the other species, so as to afford a more direct means of comparison.

Epomophorus guineensis Bocage, 1898

p. 136

Epomophorus guineensis, n. sp.

E. gambianus? Bocage, *Jorn. Ac. Sc. Lisb*, 2.e serie, t. I, pp. 2 et 3, fig. 2, (le palais).

Un mâle adulte de *Bolama* (Barahona).

Cet individu nous parait distinct de l'*E. Gambianus*, par sa tête sensiblement plus allongée à museau plus étroit et surtout par le nombre et la disposition des plis du palais. Pour s'en assurer il suffit de comparer la figure ci contre à la figure de Dobson qui represente bien exactement les plis du palais de l'*E. gambianus*.

Epomophorus reii Aellen, 1950

p. 559

MATERIEL. - Le matériel faisant l'objet de cette note préliminaire a été récolté par la Mission scientifique suisse au Cameroun, en 1947. Il appartient au musée d'histoire naturelle de La Chaux-de-Fonds.

N° 1437, type: F adulte; Rei Bouba (région de Garoua, Cameroun), 13 septembre 1947.

1430, F jeune; même lieu, même date.
1438, M jeune (sur la femelle N° 1437).

DESCRIPTION. - *Epomophorus reii* est voisin de *E. gambianus* Ogilby et *E. angolensis* Gray. Les mesures externes correspondent aux mesures données pour *gambianus* par ANDERSEN et *angolensis* par MONARD, à part celles de quelques segments alaires.

Le crâne est moins allongé que dans *gambianus*: la largeur zygomatique mesure plus de la moitié de la longueur totale du crâne. La longueur du palais est 2 1/5 fois la largeur mesurée des bords externes des molaires supérieures (M1-M1); cette dernière mesure est plus grande que la longueur du palais postdentaire. Les diverses mesures sont comprises, pour la plupart, dans les limites que donne ANDERSEN pour *E. crypturus* Peters. Les plis du palais sont disposés nettement autrement que chez les autres espèces du genre: le 4e pli palatal est plus près du 3e que du 5e, mais la distance du 4e au 5e n'est pas le double de celle du 3e au 4e. Le 4e pli n'est pas entièrement devant une ligne allant des bords antérieurs de M1-M1: il est exactement entre les prémolaires postérieures (Pm4-Pm4) et M1-M1; son bord le plus avancé atteint le tiers de la longueur de Pm4. Le 5e pli est très en arrière de la rangée dentaire. Le 6e est derrière le milieu du palais post-dentaire.

p. 560

Le pelage n'a pas une coloration différente, dans ses traits essentiels, de celle des autres *Epomophorus*:

Faces supérieures: brun-roux, assez foncé vers l'arrière. Front plus clair. Touffes de poils blancs à la base des oreilles.

Côtés: joues et flancs comme le dessus, côté du cou nettement plus clair.

Faces inférieures: brun-jaunâtre clair. Poitrine comme les côtés du cou. Ventre blanc pur, tranchant nettement avec la couleur des flancs. Parties postgénitales de la couleur du dos.

Les poils de la gorge sont plus longs que le reste du pelage.

Les autres caractères sont ceux des espèces voisines.

COMPARAISON AVEC LES ESPECES VOISINES. *Epomophorus reii* diffère des autres espèces du genre par les caractères suivants (femelles):

de *crypturus* Peters.

Les mesures externes sont plus grandes, les mesures du crâne concordent à peu près. La distance du 3^{e} au 4^{e} pli palatal est plus petite que celle du 4^{e} au 5^{e}, alors que chez *crypturus* et *gambianus* elle est plus grande. Le 4^{e} pli est situé entre les dents Pm4-Pm4 et M1-M1 au lieu d'être à côté de M1-M1. La longueur du palars est 2 1/5 fois celle mesurée des bords externes de M1-M1 (2 fois chez *crypturus*). Le rapport C-M1 / M1-M1 est de 1.40 pour *reii* et 1.20 à 1.32

p. 561

pour *crypturus*. *Epomophorus crypturus* habite le Zambèze et la vallée du Limpopo.

De *gambianus* Ogilby.

Les mesures externes sont semblables. Les mesures du crâne sont plus fortes chez *gambianus*. Pour l'arrangement des plis du palais, voir les différences signalées avec *crypturus*. La largeur zygomatique mesure plus de la moitié de la longueur totale du crâne, alors que dans *gambianus* cette largeur est plus petite. Chez *gambianus*, la longueur du palais est 2 1/3 à 2 1/4 fois celle mesurée des bords externes des molaires M1; cette dernière mesure est plus petite que la longueur'du palais postdentaire, alors qu'elle est plus grande chez *reii*. Le rapport rostr / C-M1 est de 1.05 chez *reii* et de 1.14-1.17 chez *gambianus*. L'indice digital (rapport du 3^{e} doigt au 5^{e}) est de 1.36 chez *reii* et de 1.31 à 1.32 chez *gambianus*. L'aire de répartition de *Epomophorus gambianus* comprend la zone s'étendant du Sénégal au sud de l'Abyssinie par la Sierra Leone, la Côte de l'Or, le Togo et la Nigeria.

De *angolensis* Gray.

Les mesures externes correspondent en gros. Les mesures du crâne ne sont pas comparables, car les auteurs ne donnent pas de séries complètes de mensurations de crânes de femelles: les quelques chiffres indiqués par ANDERSEN et MONARD conviennent à *reii*. Le 4^{e} pli est à côté des prémolaires Pm4, chez *angolensis*, au lieu d'être entre Pm4 et M2. Le 5^{e} pli touche à une ligne joignant les dents M1, alors qu'il est très en arrière de la rangée dentaire chez *reii*. Le 6^{e} pli est au milieu du palais postdentaire et non en arrière du milieu comme dans *reii* ou *gambianus*. *Epomophorus angolensis* habite l'Angola et le Damara.

De *pousarguesi* Trouessart.

Les mesures externes et les mesures du crâne sont plus fortes chez *pousarguesi*, connu seulement par le type: une femelle. L'arrangement des plis palataux ne serait pas différent de celui des plis de *angolensis*. Comme chez *gambianus*, la largeur zygomatique est plus petite que la moitié de la longueur du crâne (elle est plus grande

p. 562

[table removed - eds.]

chez reii). Le rapport C-M1 / M1-M1 est de 1.34 (1.40 chez reii) et le rapport rortre / C-M1 1.11 (1.05 chez *reii*). L'indice digital est de 1,30. *Epomophorus pousarguesi* a été trouvé une seule fois dans le cours supérieur du Chari.

p. 563

Par l'arrangement de ses plis palataux, par ses rapports de diverses mesures crâniennes, notre espèce se montre intermédiaire entre *gambianus* (et *crypturus*) et *angolensis*.

La nouvelle espèce est dédiée à la ville de Rei, sur la rivière du même nom (affluent de la Bénoué); dans la région de Garoua (Cameroun).

Les moeurs ne sont malheureusement pas connues, les chauves-souris nous ayant été apportées par des indigènes.

Epomophorus veldkampii Jentink, 1888

p. 51

One specimen, Buluma, Fisherman Lake (Büttikofer and Sala).

It is of the size of *Epomophorus pusillus* and is very difficult to distinguish externally from this species, but the palate-ridges are so different from the peculiar V-shaped groove in *Ep. pusillus*, that it can never be confounded with this species. First palate-ridge undivided, straight, between the canines; second and third, undivided, semicircular, between, the first and second

premolars; the following ridges, five in number, are divided in their centre, they form semicircular lines, the portion near the central groove is thickened; the remaining ridges are represented by toothed lines.

Ears with a thickened dark-colored margin ; wing-membrane from the middle of the back of the first phalanx of the second toe; tail shorter than in *Ep. pusillus*.

Measurements of the type, an adult female, in alcohol (in mm):
Eye from tip of nostrils: 9.5
ear: 15
forearm: 50
thumb: 22
third finger, metacarpal: 38
" " , 1st phalanx: 22.5
" " , 2nd " : 33
fifth finger, metacarpal: 36
" " , 1st phalanx: 16

p. 52

fifth finger, 2nd phalanx: 16
tibia: 21.5

The color of the far is somewhat lighter tinged than in *Ep. pusillus*; distribution of fur like in that species.

I call this new species, *veldkampii*, as Biittikofer wishes to connect the name of one of his Liberian friends with this new acquisition. Mr. Veldkamp, at present Consul for the Netherlands; in Liberia, has helped our travellers as much as he could, has promoted their investigations in every way and finally assisted to Sala's funeral.

Epomops Gray, 1870

p. 126

Like *Epomophorus*, but head ovate. Skull ovate, broad. Face moderate, not nearly so long as the brain-case. Zygomatic arches convex. Cutting-teeth separate, far apart in the intercanine space. Grinders $^{4}/_{5}$, close together.

Epomophorus, sp., Tomes.

Eptesicus Rafinesque, 1820

p. 2

N.G EPTESICUS. Four acute fore-teeth to the upper jaw, in two equal pairs, separated by a great interval and a large flat wart, each pair has two unequal teeth, the outside tooth is much larger and unequally bifid, the outside one much larger, inside tooth small and entire. Six fore-teeth to the lower jaw, equal

p. 3

very small, close and truncate. Canine teeth very sharp, curved and long. Grinders unequally trifid. Snout plain, nose without appendages. Ears separated, auriculated. Tail mucronate. - This genus appears to differ from all those of Geoffroy and Cuvier, among the extensive tribe of Bats. The name means house-flyer.

Eptesicus ater J.A. Allen, 1917

p. 443

Type, No. 48988, M ad., skin and skull, Faradje, March 1, 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No, 1466.

p. 444

Similar in general appearance to *E. tenuipinnis* but smaller, with black ears and foot, and wholly black above.

Pelage of upperparts brownish black to base of hairs, which are without light tips; below the hair of foreneck and upper chest brownish black tipped with whitish, rest of lower parts clear white, the hairs dusky at base; wing membranes white above and below; interfemoral membrane brownish white above, paler below; ears, feet, tail and limb bones dark brown, in strong contrast with the light-colored membranes. Size and general structure, including ears and tragus, as in *E. tenuipinnis*.

Collectors' measurements of type: Total length, 68 mm.; head and body, 39; tail, 29; foot, 6; ear, 12. Forearm (from skin), 27.5; in an adult male topotype, 27.9; in two subadult specimens from Niangara, M 27, F 25.

Skull, type, total length, 12,2; condylobasal length, 11.6; zygomatic breadth, 7.5; breadth of braincase, 6.6; interorbital breadth, 3.4; maxillar breadth, 5.2; breadth at basis of canines, 4; length of upper toothrow (c-m^3), 4; length of mandible, 8.4; angle to condyle, 1.5; depth at coronoid, 2.5.

Represented by 4 specimens: Faradje, 2 (type skin and skull and alcoholic topotype); Niangara, 2 (subadult. skins with skulls).

E. ater is nearly related to *E. tenuipinnis*, from which it differs in the much darker coloration of the pelage, the ears and feet blackish instead of pale yellow, and in slightly smaller size.

Eptesicus capensis angolensis J.Eric Hill, 1937

p. 1

TYPE. - No. 85535, Amer. Mus. Nat. Hist.; M adult, skin and skull; from Chitau, Angola. Secured by the Vernay Angola Expedition, Mr. H. Lang, collector, orig. no. 620, August 5, 1925.

The American Museum has a series of 18 from the type locality; there are two skulls, also topotypical, in the Carnegie Museum, Pittsburgh. Records of *E. capensis* in Angola, possibly referring to this race are Caconda and Huilla; Vila da Ponte. The more southern records may possibly concern *E. c. nkatiensis* Roberts.

GENERAL CHARACTERS. - A race of *Eptesicus capensis* with blackish wings and yellowish-brown body, the hairs above and below without dark bases.

COLORATION. - Upperparts darker than tawny olive, the bases of the hairs paler. Underparts slightly grayer than cinnamon-buff. Wing membranes and ears blackish, uropatagium slightly paler.

SKULL. - Braincase considerably higher than rostrum; the latter broad and short. Occipital height more than 65 per cent of mastoid breadth in adults.

DENTITION. - Medial upper incisor (I^2) deeply bifid; I^3 with small posterior cusp, only about one-third shorter than I^2. I_{1-3} placed in line with the margin of lower jaw. Other teeth about as in *E. minutus*.

p. 2

MEASUREMENTS.-Head and body, 56; tail, 34; hind foot, 10; ear, 12.5; forearm, 37.0; digit III, 34.1 X 12.9 X 12.0 X 6.8. Skull: greatest length, 14.2; basilar length, 11.6; palatilar length, 5.9; zygomatic breadth, 10.4 (approximate); interorbital breadth, 4.2; mastoid breadth, 8.5; outside breadth across M^2 - M^2, 6.9; height occiput, 5.8; maxillary alveoli, 5.4; crowns P^4- M^3, 4.3; width M^1, 1.5.

Eptesicus capensis nkatiensis Roberts, 1932

p. 16

A small form of about the same size as *E. c. gracilior* Thomas and Schwann, but altogether lighter coloured above (near clay colour or rather lighter) and below whiter, the hairs on the legs and tail pure white to the base, only the extreme base of the hair about the abdomen dark, but the white decreasing and the dark base of the hair increasing forwards to the chest and throat, the chin and cheeks like the back.

Type: T.M. No. 6549, adult F, Nkate, Northern Bechuanalard, 18th August, 1930, No. 999, Vernay-Lang Kalahari Expedition. Length of head and body 44, tail 36, hind foot (c.u.) 8, ear 14. Skull: canines to occiput 13.3, zygomatic width 8.7, width of brain case 7, width of palate across outside of m*super 2* 5.7, length of upper tooth row (c-m^3) 4.8, of mandible to condyle 10 mm.

Eptesicus faradjius J.A. Allen, 1917

p. 444

Type, No. 49045, F ad., skin and skull, Faradje, northeastern Belgian Congo, Feb. 21; 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1914.

Upperparts tawny olive, the hairs dusky at extreme base; underparts similar but much paler, the tips of the hairs light tawny on throat, breast and middle of belly, more fulvous on side and pubic region; ears pale brown; limb bones and interfemoral membrane light brown above, paler below; wing membranes pale yellow on both surfaces.

Collectors' measurements of type: Total length, 93; head and body, 59; tail, 39; foot, 8; ear, 11. Forearm (from skin), 33.

Collectors' measurements of ten topotypes (5 males, 5 females): Total length, M 88 (83-95), F 92.6 (90-96); head and body, M 51 (46-56), F 54.2 (52-56); tail, M 37 (35-38), F 39 (35-43); foot, M 8.4 (8-9), F 8.4 (8-9); ear, M 11.4 (11-12), F 11.4 (11-12). Forearm (same specimens), M 33.5 (32.5-35.6), F 34.9 (32.5-36.2).

Skull (type), total length, 13.8; condylobasal length, 13; zygomatic breadth, 8.8; breadth of braincase, 7; mastoid breadth, 8.2; interorbital breadth, 4; maxillar breadth, 6.1; breadth at base of canines, 4.0; upper toothrow (c-m^3), 4,0; length of mandible, 10.2; angle to condyles, 1.8; depth at coronoid, 3.2; lower toothrow, 5.3.

Skull, 9 topotypes (4 males, 5 females): Total length, M 13.5 (13.2-13.0), F 13.7 (13.4-13.7).

Represented by 24 specimens: 14 (topotypes) from Faradje, collected February 18-21, March 1-30, and August 2, 1911, and 10 from Niangara, collected November 16-December 26, 1910.

p. 445

The two series are indistinguishable in every respect. Each series, however, shows a considerable range of variation in color, some of it due to age but mainly purely individual, the fawn color of the upper parts varying greatly in tone in different specimens, independently of sex and age.

There is apparently a slight sexual difference in size, the females having the forearm averaging about 2 mm. longer than the males, and there is a corresponding but slighter average difference in the length of the skull.

Eptesicus faradjius appears to be related to *E. flavescens* (Seabra), but it is smaller than the latter and should be readily distinguishable from it by the deep fawn color of the upperparts (varying in different specimens from light yellowish to olivaceous and even to slightly rufescent in different specimens), combined with a forearm length of about 34 mm. as against 37 in *flavescens*. It is very different in coloration from *E. phasma*, with a large series of which it has been compared, and with which it closely agrees in size.

Eptesicus garambæ J.A. Allen, 1917

p. 445

Type (and only specimen), No. 49340, M ad. in alcohol, Garamba, March 14, 1912; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1888.

Upperparts very dark brown, the hairs without appreciably lighter tips; underparts similar but slightly paler, the tips of the hairs faintly grayish; membranes naked, blackish with a very narrow whitish edging; inner surface lighter and, slightly grayish; lower surface of limb bones whitish, in strong contrast with the dark membranes; wing membranes from base of outer toe; last caudal vertebra free for half its length; proximal vertebræ slightly hairy.

p. 446

Total length, 77.6 mm.; head and body, 44.6; tail, 33; forearm, 33; third metacarpal, 31.3; tibia, 12,6; foot, 9.1; ear from crown, 7.7; from notch, 12; length of tragus, 5.8.

Skull, total length, 13.7; condylobasal length, 13.1; zygomatic breadth, (?); mastoid breadth, 7.6; interorbital breadth, 4.7; breadth of braincase, 6.7; maxillar breadth, 5.4; breadth at canines, 4; upper toothrow (c-m^3), 4.5; length of mamdible, 9.4; angle to condyle, 1.7; depth at coronoid, 3.4; lower toothrow, 4.8.

Eptesicus garambæ, in size and external characters, resembles *E. ugandæ* Hollister, from Ledgus, Uganda, but exceeds it considerably in size, and differs from it in the form of the tragus and other characters, the last caudal vertebæ extending half its length beyond the membrane instead of wholly enclosed within it as in *ugandæ*. The skull proves, on comparison with topotype skulls of *ugandæ*, to not only exceed it greatly in size, but is much broader and flatter, and the rostral portion much broader, the skull as whole much more massive and depressed.

Eptesicus hottentotus bensoni Roberts, 1946

p. 305

Differs from *E. h. hottentotus* (A. Smith, *S. Afr. Quart. J.* ser. 2, no. 1, pt. 2, p. 581; 1833: Uitenhage and Albany districts), which I have pointed out in *Samab* (III, no. 8, p. 238, Dec. 1944) is an earlier name than *E. megalurus* (Temminck, *Monogr. de Mamm.* II, p. 206, 1835-41: 'Interior of South Africa'), in its slightly darker colour and in its smaller skull. Probably Shortridge's '*Scotophilus angusticeps*' (*Ann. S. Afr. Mus.* XXXII, 282; 1938: Hex River Estate, Citrusdal, Cape Province) is also a synonym of *E. h. hottentotus*, as it was placed in the wrong genus, as I found to be the case upon examination of the type; and also a specimen from the Cape Peninsula, in the South African Museum, does not differ materially from it and both practically conform to the descriptions of the colour by Andrew Smith and Temminck. In 1941 I collected a series of specimens on Eronga Mountain, Omaruru District, South-west Africa, which agree very well with the type of Shortridge's *E. megalurus pallidior* (*Ann. S. Afr. Mus.* XXXVI, 37; 1942: Goodhouse on the Orange River), and, although this form has somewhat longer wings than the typical southern one (wing-span in five measured from Eronga Mountain 340 - 365, as against about 12 in. = 304 according to Andrew Smith and 308 - 322 according to Temminck for *hottentotus*), the length of forearm, tibia and foot (c.u.) and skull proportions are much the same in all of them, whereas they are less in this new Nyasaland form. In colour *E. h. bensoni* is near' tawny olive' for the terminal fourth, and blackish for the basal three-fourths of the hairs of all the upper parts, and below paler, the hairs being slightly tipped with whitish from chest to abdomen, with the pubic region and hairs along the margin of the wing membrane at the abdomen distinctly white. Both above and below a shade darker than the specimen from the Cape Peninsula. In the skull, which

is unfortunately lacking the occipital part, the width of the muzzle is less, and the length of tooth rows and mandible shorter, as will be seen upon comparison of the figures given hereunder. The measurements taken by the collector of the specimen in the flesh do not indicate much difference between it and those of the typical form and *pallidior*, except the hind foot is shorter, which is confirmed by the measurements of the tibia and foot (c.u.) taken from the dried skins. The forearm length is within the range of *hottentotus* and *pallidior*, but the digits conform more to those of the former.

Measurements of the type, with those of records and other measurements in brackets for comparison: Head and body 65 (of *hottentota* A. Smith 65, of *minuta* A. Smith 65, of *megalurus* Temminck, 'Pied du Roi' 2 in. 3 lines = 63 mm., of *angusticeps* Shortridge 77, 74, of *pallidior* Shortridge 74, of fourteen from Eronga Mountain 65 - 78); tail 57 (of *hottentota* A. Smith 50.6, of *minuta* A. Smith 50.6, of *megalurus* Temminck 56, of *angusticeps* Shortridge 58, 57, of *pallidior* Shortridge 48, of fourteen from Eronga Mountain 46 - 56); hind foot (c.u.) 8 (of *angusticeps* Shortridge 12, 11.5, of *pallidior* Shortridge 11, of fourteen from Eronga Mountain 9 - 11); ear 17 (of *megalurus*, according to Dobson, 15.5, no doubt shrunken in spirits, of *angusticeps* Shortridge 18, 17.5, of *pallidior* Shortridge 19, of fourteen

p. 306

from Eronga Mountain 15.5 - 20). Forearm 49.5 (of *minuta* A. Smith 1 in. 8 lines = 42 mm., obviously wrong when it had an expanse of wings of 12 in. (304 mm.), the same as he gave for *Scotophilus dinganii*, a bat of much the same size; of *megalurus* Temminck 1 in. 10 lines (' Pied du Roi') = 50 mm.; of *angusticeps* Shortridge 53 - I made it 51.5; of *pallidior* Shortridge 53.5; of fourteen from Eronga Mountain 48 - 52.5; the specimen from the Cape Peninsula 48). 3rd digit metacarpal 45 (type of *megalurus*, according to Dobson, 43, of the Cape Peninsula specimen 44.5, of the type of *angusticeps* 49, of the type of *pallidior* 52, of fourteen from Eronga Mountain 48 - 53); 4th digit metacarpal 44 (of the type of *megalurus* according to Dobson 39, of the type of *angusticeps* 47.5, of the type of *pallidior* 50.5, of fourteen from Eronga Mountain 46 - 53). Tibia and foot (c.u.) 27 (of *megalurus* according to Dobson 31.3, of *angusticeps* type 31, of *pallidior* type 29, of fourteen from Eronga Mountain 28 - 32). Skulls were not recorded by Andrew Smith, Temminck and Dobson; but I have measured the type skulls of *angusticeps* and *pallidior*, the specimen from Cape Peninsula and the fourteen from Eronga Mountain, and get the following figures: greatest length, *angusticeps* 21.3, Cape Peninsula 21.3, *pallidior* 20.7, Eronga Mountain 20 - 21.6; length from canines to condyles, *angusticeps* 19.2, Cape Peninsula 19, *pallidior* 18+ (incomplete), 14 Eronga Mountain 18.2 - 20.7; dorsal median length from frontals, *angusticeps* 18, Cape Peninsula 11.8, *pallidior* 17.7, 14 Eronga Mountain 17.5 - 18.5; zygomatic width, *angusticeps* 13.5, Cape Peninsula 13.7, pallidior 13.5, 14 Eronga Mountain 13.2 - 14.2; mastoid width, *angusticeps* 10.5, Cape Peninsula 9.5 (?), *pallidior* 10.5, 14 Eronga Mountain 10.2 - 11; width across molars, *bensoni* 8, *angusticeps* 9, Cape Peninsula 8.7, *pallidior* 8.3, 14 Eronga Mountain 8.1 - 8.8; width across upper canines, *angusticeps* 6.5, Cape Peninsula 6.9, *pallidior* 6.5, 14 Eronga Mountain 6.2 - 6.8, *bensoni* 5.8; upper c-m^3 series, *angusticeps* 7.5, Cape Peninsula 7.5, *pallidior* 7.5, 14 Eronga Mountain 7.2 - 7.7, *bensoni* 6.8; mandible length, *angusticeps* 15.5, Cape Peninsula 15, *pallidior* 14.6, 14 Eronga Mountain 14 - 15.6, *bensoni* 13.6; c-m_3 series, *angusticeps* 8.5, Cape Peninsula 8.5, *pallidior* 8.5, 14 Eronga Mountain 8.1 - 8.7, *bensoni* 7.3.

Type: T.M. No. 9167, 6, Ncheu, Nyasaland, collected and donated by Mr C. W. Benson.

Eptesicus hottentotus portavernus Schlitter and Aggundey, 1986

p. 173

Holotype: Adult male, skin and skull, Carnegie Museum of Natural History, No. 89000, from Hell's Gate Canyon (= Njorowa Gorge), 20 km S, 14 km W Naivasha, Naivasha Dist., Rift Valley Prov., Kenya (0° 54 S, 36° 19 E); obtained 30 September 1985 by Duane A. Schlitter, original no. 6906.

Paratype: Adult female, body in alcohol with skull removed, United States National Museum of Natural History no. 375919, from Njorowa Gorge, near Lake Naivasha, Rift Valley, 6400 feet, Kenya (0° 55 S, 36° 19 E); obtained 20 September 1965 by A.D. Forbes-Watson, original number, 20 ix/l.

Measurements: Selected external measurements of the holotype and paratype respectively are: Total length, 125, 112; length of tail, 54, 48: length of hind foot, 12, 10; length of ear from notch, 19, 16; length of forearm 49., 52.3; and weight, -, 15. Cranial measurements are listed in table 2.

Diagnosis: External and cranial size large, palate short, and braincase deep for species.

[tables removed - eds.]

Description: Skull large for species; braincase relatively deep; rostrum short, flattened, lacking pronounced cocavity in dorsal aspect; pterygoid region relatively narrow; inner upper incisor shallowly bifid in unworn paratype; outer upper incisor small and single cusped. Externally large for species; ear relatively small and with anterior margin nearly straight leading to rounded tip; tragus with notch at posterior base and posterior margin rounded to rounded tip; calcar keeled. Color of dorsal pelage of holotype medium fawn basally with light brown tips on hairs; ventral pelage dark brown basally with light tan tips. Color of dorsal surface of wing and interfemoral membranes medium brown with color lightening on uropatagium; ventral surface of wing membranes dark brown, lightening to fawn on propatagium. Ears same color as wing membranes.

Comparisons: *Eptesicus hottentotus portavernus* can be distinguished from the goegraphically adjacent subspecies *E. hottentotus bensoni* by the combination of large size of forearm and skull and short palate and deep braincase in the new subspecied. The

p. 173

new subspecies is paler in color than *E. h. bensoni*. From the nominate subspecies, the new subspecies can be separated by a deep braincase and short palate relative to overall similar size of the cranium, *E. h. portavernus* can be distinguished from *E. serotinus* from North Africa and Eurasia by the long and broad palate of the latter species. *E. platyops* differs from the new subspecies by being small in length of forearm and skull.

Remarks: In *E. serotinus* and *E. hottentotus* individual variation was found in the degree of the bifid condition of the inner upper incisors. This variation would render this character less certain as a distinguishing character for species of large serotines than was used by Hayman and Hill (1971: 42) to key *E. hottentotus* from *E. platyops* and *E. serotinus* in Africa.

Etymology. - This new subspecies is named after the English name of Hell's Gate which is commonly used for Njorowa Gorge.

Eptesicus megalurus pallidior Shortridge, 1942

p. 37

Specimens from Goodhouse.

A relatively large buff-coloured bat with cranial characters as in *Eptesicus*; agreeing with the type of *Eptesicus megalurus* in skull and skin dimensions, but not altogether in colour.

p. 38

General colour above and on sides of neck pale rufous-buff; under parts drabby buff-white: all hairs above and below ashy-slate at base. Ears dusky brown: membranes horn-brown, rather translucent.

These Goodhouse specimens agree with Temminck's description of *megalurus* in that the hair is long, smooth, silky, and bicoloured throughout; but in typical *megalurus* the hair in front of the neck and abdomen is described as "cedar-brown" as far as the tip; on the flanks "dove-coloured," and on the pubic region quite white from base to tip.

Type: an adult female (Coll. No. 1157): H. & b. 74, Tl. 48, Hf. (s.u.) 11, Ear 19 mm.

A weak flyer, coming out at late dusk, about half an hour after *Cistugo* and *Platymops*. Apparently not plentiful around Goodhouse, about half a dozen observed in all.

The specimens collected were shot whilst "planing" very slowly in wide circles around a cattle kraal, to which they were attracted by swarms of flies.

These bats have a wide and broad wing span and, owing to similarity in size, were at first mistaken in flight for *Scotophilus*.

Eptesicus melckorum Roberts, 1919

p 113

With the general characteres of *E. capensis* (A. Smith), but differing there from in its much longer tail and larger size; the tail measures 40-45 mm. as against only 30-34 mm. in *E. capensis*, the forearm 35.5-37 as against 32-36, and the skull 14.5-15 as against 14. In colouration the upper parts are externally "avellaneous" (Ridgway) with the base of the hair brown, and the under parts paler, tending to white, with the base of the hair darker brown.

Type, adult female, T. M. no. 2283, taken at Kersfontein, Berg River, Cape Province, 21st November, 1917. Also four more adults and a very young specimen captured at the same time in a loft.

Dimensions: Head and body 53, tail 40, hind foot (c.u.) 7, ear 15 mm. Forearm 37; pollex (c.u.) 5.5; 3rd digit, metacarpal 36, 1st phalanx 13.2, 2nd 12.8, 3rd 9.9; 4th digit, metacarpal 35, 1st phalanx 12.2; 5th digit, metacarpal 35.8, 1st phalanx 10.5. Tibia 14. Tragus (dry) on the outer margin 6.3, breadth 2.

Eptesicus phasma G.M. Allen, 1911

p. 327

Type. - Skin and skull, male, no. 8279, M.C.Z., collected August 6, 1909, on the Meru River, British East Africa, by Glover M. Allen.

General characters. - A small pallid species (forearm 34), with white membranes; possibly related to *E. tenuipinnis*.

Description. - Color of fur above from nose to root of tail pale dust color, between buff and cream-buff of Ridgway's Nomenclature (1886), slightly darker about the muzzle. Below, the hairs of the chin are buff to the bases paling on the throat to cream-buff and on the belly to pure white. The extreme bases of the hairs of the back, chest, and belly are dark slaty but those of the flanks ventrally are pure white throughout.

Wing membranes from the base of the first metacarpal, extremely thin and delicate; both interfemoral membrane and the wings are whitish throughout, the latter, however, becoming slightly clouded at their tips. Ears, forearms, feet, and tibia pale brownish. The hair of the body extends on to the dorsal side of the interfemoral membrane and on the base of the tail slightly beyond a line joining the knees. Calcar long and slender with a well-marked low and elongate lobe; the calcar does not terminate in a lobule. Tail vertebrae entirely included within the membrane.

Ears small, triangular, their apical margins nearly straight, narrowly rounded at the tips; a prominent basal lobe at nearly right angles to the long axis of the ear at its inner margin; externally the basal notch is well developed and marks off a low rounded basal lobe. Tragus short, of nearly equal breadth throughout, bluntly tapering at its apex; its inner margin straight, its outer margin with a slight notch about opposite the inner base, thus producing two minute lobes at this point. Muzzle with rather conspicuous glandular swellings.

Measurements. - The following measurements of the type were taken in the flesh: - total length, 94 mm.; tail, 40.5; hind foot, 6; ear, 11.5; tragus, 5; forearm, 34; tibia, 12.5; calcar, 14. Skull: greatest length, 13.5; basal length, 10.5; palatal length, 5.4; interorbital constriction, 3.8; zygomatic width, 9; mastoid width, 7.8; upper cheek teeth, front of canine to back of m^3, 4.8; lower cheek teeth, 5.2; mandible, 10.

Skull. - The skull is rather broad, with the anterior edges of the orbits conspicuously ridged so as to produce a rather squarish rostrum, tipper incisors directed sharply inward; the inner is simple, about twice the length of the outer; outer incisor with a conspicuous cingu-

p. 328

lum cusp externally. The two teeth are placed in a line nearly at right angles to the long axis of the skull. Canine with an anterointernal cingulum cusp. Crowns of the lower incisors trifid, slightly overlapping; first lower premolar about three fourths the length of the second.

Remarks. - This white-winged bat does not seem referable to any of the described species. It is possibly related to *E. tenuipinnis* of West Africa, but is larger, paler, the tail is entirely included in the membrane, and the tragus has two minute pointed lobules. It is equally distinct from *E. rendalli* (Thomas) from Gambia, which also has white membranes. The latter has large hind-foot pads, the calcar ends in a projecting point, and there is a penis bone present, which *E. phasma* does not have. The upper incisors are also different, being provided with two cusps in *rendalli*.

This bat was first noticed on the Guaso Nyiro at its junction with the stream from Meru, in the arid country to the northwest of Mt. Kenia. Here it was seen but once, when at dusk a single individual, conspicuous for its white coloration, was observed flying about over the river in company with numbers of small dark bats, probably *E. minutus somalicus*. A few miles farther up the Meru River (above the ivory-nut palm region) it was much commoner. At our camp by the side of this small stream numbers were observed and several were shot in the early evening as they flew past following the course of the rivulet, which here flows through a sun-baked plain with few trees except along the water course. Its flight is very steady, direct and rather slow, so that it was easily shot. In the gathering dusk, however, the white wing membranes were almost invisible against the sky, thus producing a curious ghostly effect, as only the body and forearms could be clearly seen.

Eptesicus rectitragus Wettstein, 1916

p. 191

Am ähnlichsten *E. pumilus* (Gray), aber kleiner, mit anders geformtem Tragus. Tragusform und Größe ähnlich der von *E. bicolor* (Bocage). Die kleinste bis jetzt bekannte Art dieses Genus. Kopf und Rücken dunkelbraun, "raw umber", seidig glänzend. Das einzelne Haar tief schwarzbraun mit "wood brown" gefärbter Spitze. Unterseite tief schwarzbraun, alle Haare mit lichten Spitzen. Jene auf Kinn und Kuhle mit licht bräunlichen auf der Brust mit grauweißen und am Bauche mit reinweißen Spitzen. Postcalcanallobe klein, gestreckt; Interfemoralmembran unterseits weißlichbraun, beginnt am Fußgelenk. Ohr reicht angelegt bis zur Schnauzenspitze. Tragus lang, schmal und fast gerade, oben viel weniger stumpf wie bei anderen Arten abgterundet. Seine größte Breite lieft in der Höhe der Basis des Innenrandes und beträgt 1.4 mm. Innenrand gerade, Außenrand an der Stelle der größten Breite schwach konvex. Lg. v. Kopf und Körper 35.5, Schwanzlg. 28.5, Unterarm 27, Ohrhöhe 10, Tragus 4 x 1.5 mm.

Typus: 1 M junior, Dilling, Südkordofan, 20.III.1914.

Eptesicus somalicus malagasyensis Peterson, Eger and Mitchell, 1995

p. 100

Holotype: ROM 42713, peau et crâne de femelle adulte de Maninday, 220 km au N.-E. de Tuléar [sous-préfecture de Sakaraha, sur la route nationale 7], 22°47'S, 44°43'E (13.V.1967).

Diagnose. - Petite forme proche de *E. somalicus* d'Afrique Orientale, à fourrure dorsale longue (environ 7 mm), assez dense, fortement bicolore: brun sombre à la base et Brun Bruxelles sur environ les trois cm apicaux, l'ensemble ayant une couleur uniforme et un aspect doux. Pelage ventral fortement bicolore, les 2/3 basilaires sombres et le tiers apical d'une valeur comprise entre l'Argile et l'Olive ou le Brun Cuir. Oreilles translucides et brun moyen. Queue relativement courte. Calcar à forte carène.

Crâne à rostre relativement long et aplani dorsalement à la jonction avec

p. 101

une boîte crânienne basse, faiblement arquée et un peu aplatie, comme chez *E. s. somalicus* (fig. 49). Mesures, *cf.* tableau 17.

Comparé à *E. s. somalicus* d'Afrique Orientale (Soudan, Ouganda et Nord du Kénya) l'holotype a un pelage un peu plus foncé sur le dos. Le pelage ventral est plus foncé (plus chamois, moins grisâtre) et n'est pas pâle ou blanchâtre dans la région pelvienne. Toutes les mesures se situent à l'intérieur de la gamme de mesures de *E. s. somalicus* sauf les largeurs zygomatique et crâniale qui sont un peu plus fortes.

Comparé à *E. matroka*, la tête et le pied sont plus courts, le pelage dorsal est plus pâle et plus nettement bicolore, le pelage ventral plus pâle, la portion apicale pâle est plus étendue. Oreilles plus pâles et plus translucides. Crâne à rostre plus étroit, région supra-orbitale moins renflée; boîte crânienne relativement plus longue, plus aplatie, moins arquée en profil dorsal et moins sphérique (*cf.* fig. 51 et tableau 18).

Comparé à *E. capensis* du Zimbabwe, la fourrure est plus longue et plus foncée, avec le ventre seulement un peu plus clair que le dos, au lieu d'être brun grisâtre pâle en dessus et d'avoir la partie terminale des poils ventraux blanc à chamois pâle. Crâne plus court; boîte crânienne plus profonde, plus arrondie, et légèrement arquée derrière le rostre, sans cimier postérieur, au lieu d'être entièrement plate dorsalement et se terminant par un cimier postérieur.

Comparé à *E. zuluensis*, la fourrure est plus courte, plus serrée et plus lisse et non longue et lâche; bourre brun foncé et non noirâtre. Partie terminale des poils du dos Brun Bruxelles et non Olive-Brun; celle des poils ventraux Olive-Brun et non blanchâtre, gris clair ou chamois ocre très pâle. Calcar à carène plus marquée. Crâne plus grand, à boîte crânienne plus large, moins bulbeuse et moins relevée; rostre plus long.

Distribution. - Connue seulement par l'holotype, cette sous-espèce est, peut-être, localisée à la partie sub-aride du Sud-Ouest malgache. C'est la seule espèce d'*Eptesicus* connue de la région sub-aride.

Variabilité systématique. - La parenté avec *E. somalicus* demandera à être précisée sur un matériel plus abondant. Comme le tableau 18 le montre,

p. 102

les sexes sont très dimorphes chez *E. matroka*, comme ils le sont chez *E. s. somalicus*, les femelles étant, en moyenne, beaucoup plus grandes, pour la plupart des caractères.

Biologie. - L'holotype a été pris au filet au-dessus d'un ruisseau bordé de Pahniers, dans une savane ouverte. Cette sous-espèce semble, comme *E. s. somalicus*, occuper un milieu plus ouvert et plus sec que ne le font la plupart

[table removed - eds.]

p. 104

des autres petits *Eptesicus* qui paraissent. comme *E. matroka* à Madagascar, rechercher plutôt des stations boisées et plus humides.

L'holotype femelle était bien gras et ne montrait pas trace d'activité reproductrice (ni gravide, ni en lactation).

Remarques. - Comme nous l'avons dit plus haut, la validité de *Vesperus humbloti* A. Milne Edwards, 1881, ne peut être établie. Aucun holotype ne semble plus exister et la description originale n'établit de comparaison qu'avec *V. minutus*, autre nom qui ne répond à aucune description satisfaisante. *V. humbloti* est dit plus grand que *V. minutus*, avec les vertèbres caudales inférieures enfermées dans la membrane interfémorale. Une telle description peut s'appliquer à de nombreuses espèces mais ne correspond pas à un taxon particulier.

Eptesicus ugandæ Hollister, 1916

p. 3

Type from Ledgus, Uganda. United States National Museum No. 166520, adult female in alcohol (skull removed). Collected February 15, 1910, by J. Alden Loring. Orig. No. 9022.

Description. - A small brown species related to *Eptesicus capensis somalicus* (Thomas), but with larger, flatter skull. Ears broad, somewhat evenly triangular, with rounded tip; when laid forward reaching to tip of muzzle. Tragus comparatively long, broadest at center, the tip bluntly rounded and not turned forward; inner side nearly straight for two-thirds its length; outer side evenly convex from tip to opposite anterior notch, where there is a small sharp lobe, beneath which is a sharply concave margin and a larger triangular basal lobe, immediately above the outer notch. Wing from base of toes; tail vertebræ entirely within the interfemoral membrane, but a small fleshy tip extending very slightly beyond; postcalcaneal lobe comparatively small, sharply emarginate anteriorly and evenly sloping posteriorly. Hair extending only slightly on to wings but thinly covering the interfemoral membrane to line of ankles and, along tail, to slightly beyond. Color (from alcoholic specimens) apparently much as in *somalicus* but somewhat darker throughout; wings dark grayish brown, faintly-lined along posterior edges with buffy; interfemoral membrane slightly lighter than wings. Skull decidedly larger than in *somalicus* (as represented by specimens from the Northern Guaso Nyiro) with relatively and actually broader rostrum and braincase, and relatively much lower sinciput. Upper inner incisors broad and heavy, distinctly bifurcate at tip (except in a much worn specimen); outer upper incisors small, barely reaching beyond

cingulum of inner incisors. Lower incisors all trifid, considerably crowded in the row. Cheek teeth essentially as in *somalicus* but slightly more robust.

Measurements. - Type: Forearm, 29.6 mm.; outer height ear, 12.3; greatest breadth ear, 8.1; tragus from outer notch, 5.4; third finger metacarpal, 26.8; first phalanx, 10.3; fourth finger metacarpal, 27.7; first phalanx, 9.2; fifth finger metacarpal, 28.1; first phalanx, 7.3; tibia and foot, including claws, 16. Skull: Greatest length, 12.8; condylobasal length, 11.8; breadth of braincase, 6.8; depth of braincase, 4.6; mastoid breadth, 7.3; postorbital constriction, 3.5; mandible, 8.8. Teeth: Upper maxillary row, 4.3; breadth across upper canines, 3.9; entire lower row, 5.8.

Remarks. - In addition to other characters, this species may readily be separated from the other small forms of *Eptesicus* known in East

p. 4

Africa by its dark-colored wing membranes [distinguishing from *tenuipinnis, rendalli*, and *phasma*], short outer upper incisors [distinguishing from *grandidieri*], large, flattened skull, and distinctly bifurcate inner upper incisors [distinguishing from *somalicus*]. In addition to the type there are two topotypes and three other specimens from Gondokoro in the collection.

Eptesicus zuluensis Roberts, 1924

p. 60

Eptesicus zuluensis spec. nov. (text-fig. I).
In external appearance very similar to *Eptesicus capensis* taken in the same place, but with a rather longer tail, and the skull smaller and deeper in the cranium even when compared with *E. capensis gracilior* Thomas and Schwann (from Eshowe, Zululand). In its deep cranium it somewhat resembles *Glischropus nanus* (Peters), but differs therefrom in the absence of the small upper premolar and in dimensions of both body and skull. In the size of the skull it is about the same as in *Pipistrellus kuhli fuscatus* Thomas, but differs from this also in the number of teeth, narrower muzzle and deeper cranium. It is altogether an interesting animal, whose affinity to our known species is not at all clear, the longer tail seeming to point to its affinity to the longer tailed

-Fig 1 [removed]-
-Fig 2 [removed]-
species *E. smithi* Wagner (Schreber, *Sauget. Suppl.* v, p. 747, footnote) and *E. melckorum* Roberts (*Ann. Transvaal Mus.* vi, p. 113), but for the skull being quite differently shaped. The following table of dimensions will serve for comparison of the type specimen with the dimensions given for the type of *gracilior*, of another specimen of the same form from Mokeetsi (N .E. Transvaal), and a series of *E. capensis* from a wide range of localities, including the type locality of zuluensis:
Type of *zulensis*; Type of *gracilor*; Mokeetsi specimen; Series of *capensis*
Head and body: 45; 47; 44; 49-55
Tail: 37; 28; 30; 30-34
Forearm: 30.5; 29; 30.3; 32-35
Canines to occiput: 12.8; 13.2; 13.2; 13.7-14.5
Basilar skull length: 9.5; 10.1; 10; 10.4-10.8
Mastoid width: 7.5; 7.6; 7.8; 7.6-8
Width across M2: 5.1; -; 5.6; 5.6-6.2
Palate length: 4.6; -; 5.5; 5.3-5.5
Upper tooth row (canine to M3): 4.4; -; 4.7; 4.7-5.
Lower tooth row: 4.9; 5.1; 5; 5-5.5
Posterior height at bullae: 6.1; -; 5.3; 5.3-5.8
The slightly raised cranium is the most marked character of the species, all members of the *Eptesicus capensis* group having the cranium on a level with the muzzle.
Type: Adult female, T.M. No. 3024, taken in the White Umfolosi Game Reserve, on June 29th, 1922. It was shot in the evening while flitting past

p. 61
my camp. A specimen of the typical *E. capensis* (text-fig. 2) was taken in an aloe at the same place, and has rather shorter hair, whereas another specimen of *capensis* taken on higher ground at Ntambanana has the hair and same external appearance, even to the shape of the ears, as the type of *zuluensis*.

Glauconycteris alboguttatus J.A. Allen, 1917

p. 449

Text Fig. 7, B

Type, No. 49317 (and only specimen) adult female in alcohol, Medje, March 14, 1914; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 2351.

Upperparts seal brown; underparts slightly paler. A patch of lengthened pure white hairs on each shoulder at base of humerus, about 8 mm. long by 5 mm. in width, separated for about 10 mm. by dark fur from a second patch of white hairs of similar extent but the area longer and narrower. They are symmetrical on both shoulders and conspicuous when the fur is floated out in clear

alcohol. Muzzle, chin and sides of face nearly naked and whitish. Propatagium and outer border of wing whitish; forearm and phalangeal bones light brown above and nearly white below. Ears blackish externally, whitish internally. Membranes and feet blackish brown, interfomoral lighter below than above.

p. 450

Total length, 94; head and body, 52; tail, 42; forearm, 41,5; third metacarpal, 38.6; thumb, 5.6; tibia, 18.3; foot, 8; calcar, 11; ear from crown, 7; from notch, 13; tragus, 5 mm. high by 2.5 in greatest width, broad lunate, with a small angular lobe at posterior base.

Skull, total length, 13.2; condylobasal length, 13; zygomatic breadth, 10; breadth of braincase, 7.4; interorbital breadth, 4.8; maxillar breadth, 6.5; breadth at base of canines, 4.8; upper toothrow (c-m^3), 4,5; length of mandible, 9.5; angle to condyle, 2; depth at coronoid, 2.9; toothrow (c-m_3), 5.2.

Similar to *Glauconycteris humeralis* but larger (the forearm 4 mm. longer and the skull fully one half larger in volume), and with two clear white spots on the shoulder (one behind the other) instead of one, and a very much broader tragus. In size it is similar to *G. congicus* (Noack) but differs from it widely in coloration.

Glauconycteris beatrix Thomas, 1901

p. 256

A small blackish species of the group with brown unicolor wings.

Size rather less than in *G. poensis*. General colour above and below uniform blackish brown without lighter markings; wings and interfemoral membranes uniformly brown throughout. Muzzle broad and tumid; lobes at corner of mouth well developed. Inner margins of ears extremely convex forwards, forming, from the rounded basal lobe to the tip, approximately the half of a circle; tip scarcely perceptible; outer margin straight above, then convex, with a well-marked angular antitragal lobe.

Tragus short, fairly broad, its inner margin straight, its tip rounded, its outer margin evenly convex, with a well-marked basal lobule.

Wings to the base of the toes. No postcalcareal lobule. Tail included in membrane to its extreme tip.

Skull, as compared with that of *G. poensis*, smaller, more delicately built, and with a narrower muzzle.

Inner uppder incisors with the secondary cusp longer and more widely separated from the main one than in *G. poensis*; outer incisor fairly large, pressed against the canines behind, and reaching vertically about half the height of the secondary cusp of i^1; in transverse section it appears to be about half the area of the same tooth. In *G. poensis* it is shorter, smaller in area, and is separated on each side from the canine. Lower incisors bifid, slightly overlapping. Anterior lower premolar with a long well-defined main cusp half the height of the posterior premolar.

Dimensions of the type (measured in spirit): -

Head and body 45; tail 43; ear 10; tragus on inner edge 3; middle finger, metacarpal 38, first phalanx 13.5, second phalanx 23; lower leg 19.5; hind foot (c. u.) 7.5; calcar 13.

Skull: occiput to gnathion 11.1; interorbital breadth 4.2; breadth across brain-case 7; front of canine to back of m^3 4.2.

Hab. Benito River, French Congo, fifteen miles from mouth.

Type. Female. B.M. no. 98.5.4.19. Collected January, 1898, by Mr. G. L. Bates.

The only near ally of this species appears to be *G. poensis*, and from that it is readily distinguishable by its smaller size,

p. 257

darker colour, and the dental and cranial characters above described. *G. congicus*, Noack, is probably synonymous with *G. poensis*, the describer having been misled by Dobson's erroneous statement that the inner upper incisors of the latter species were unicuspid.

Glauconycteris egeria Thomas, 1913

p. 144

M. No. 22. Bibundi. B.M. no. 12.12.13.3. Type.

Brown-winged; the ears very large.

Size about as in *G. poensis*, though the skull is longer. General colour uniform dusky brown, not lighter below. Membranes also all dark brown, the reticulations not specially prominent. Ears much larger than in the allied species, subquadrangular, the

anterior basal lobule long, projecting backwards; anterior margin with its basal 6 mm. straight, then strongly projecting forward, almost to an angle; the

p. 145

upper half again straight; tip broadly rounded off; outer edge straight above, convex below; the outer basal lobe well developed, rounded. Tragus fairly large, its inner edge concave, outer convex; a well-developed angular external basal lobule. Lobes at angles of mouth rather small. Wings from the base of the toes. Calcar of medium length, a rudimentary postcalcareal lobule present.

Skull large in proportion to the size of the animal, its brain-case of the usual swollen shape, though not to so exaggerated an extent as in some species.

Inner upper incisors long, their distinct secondary cusp near their tips. Outer incisors minute, their tips reaching barely halfway to the secondary cusp of the inner pair. Lower incisors not markedly overlapping.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 38 mm.

Head and body 43; tail 41; ear, from notch 13.3, from anterior projecting angle 11; greatest breadth 13.5; tragus, length on inner edge 4; third finger, metacarpus 36, first phalanx 14.5; lower leg and foot (c. u.) 24; calcar 15.5.

Skull: greatest length 13; basi-sinual length 10; zygomatic breadth 9.2; interorbital breadth 3.8; breadth of brain-case 7.5; palato-sinual length 5.3; front of canine to back of m^3 4.5; front of p^4 to back of m^2 2.2; breadth between outer corners of m^2 5.5.

Hab. and Type as above.

This well-marked species is readily distinguishable from the other two brown-winged *Glauconycteris*, *G. poensis* and *beatrix*, by its much larger and less evenly rounded ears and by the length of its skull, which is 13 mm. in length as against 12 mm. in *poensis* and 11 mm. in *beatrix*.

Peters's *Vesperus kraussi*, from Yoruba, Lagos, appears to agree with *G. poensis* in all essential respects. Its locality is almost identical, as the type of *G. poensis* came from the Lower Niger, and not from Fernando Po.

Glauconycteris Floweri de Winton, 1901

p. 45

AMONG the mammals collected in the Soudan by Mr. H. F. Witherby in the spring of this year and acquired by the late Dr. John Anderson is a small bat which appears to be new to science. The specimen, preserved as a skin, was obtained at Wad Mariun about 12 rniles from Khartoum on the White Nile on May 12th, and will be taken as the type of the species. A second specimen, which has just been put into my hands by the kindness of Mr. O. Thomas of the British Museum, is preserved in alcohol; it was collected by Capt. S.S. Flower, Director of the Zoological Gardens at Cairo, on March 14th, at Abu Zeit on the White Nile some 200 miles south of Khartoum, during his recent trip with the party sent to inspect the Sud-cutting operations.

Although the front of the head is much damaged by shot, this "spirit specimen" is valuable in enabling a fuller description of the animal to be given than would have been possible if the dried skin alone had been available.

I have great pleasure in associating the name of so keen a worker in zoology, who also collected the first specimen, with this fine new species.
Dobson made a subgenus for the African bats allied to the Australian genus *Chalinolobus*, but I think it will be much more convenient to look upon these two geographically separated groups as distinct genera; the species from the two

p. 46

regions being so distinct from one another in general appearance, and have, besides the characters given by Dobson, the very important difference in the incisor teeth.

The first upper incisor in *Glauconycteris* is bifid, having an outer or rear cusp.

Glauconycteris Floweri, sp. n.

Colour above pale fawn, the bases of the fur greyish; the lower side cream-colour, yellower on the throat, paler on the belly. The fur on the forehead ends in a point barely in advance of the eyes, and the furred area is limited in extent in all directions, barely encroaching on to the upper arms, and leaving the tail and legs entirely bare. The skin of the face and ears is nearly black and naked, with the exception of a few short hairs more conspicuous round the lips. The wing-membrane is pale and transparent, with the veins and lines showing slightly darker; the posterior portion in front of the tibiæ and the distal portion of the interfemoral membrane is yellowish white. The upperside of the forearms, legs, and tail, and all the proximal portion of the wings and interfemoral membrane, are thickly studded with dark warty papillæ.

The measurements of the type taken by the collector from the animal in the flesh, an adult male, are: Head and body 47 millim., tail 34, hind foot 5.5, ear 12, forearm 35.

The specimen in spirit gives the following measurements : -
Head and body 42, tail 34, hind foot 5.8, ear 12, forearm 36.5.

In size and general colour this bat somewhat resembles *Scotophilus Schlieffeni*: the body-colour is, however, paler above and brighter on the lower parts, and the furred area is less extensive; but the paler wing-membrane, the dark face, and the extraordinary shagreening on the forearms, tail, and surrounding membranes distinguish this new species at a glance.

The skull is readily distinguished from that of *Scotophilus* by its rounded form and short facial portion; the lower jaw is likewise more rounded or blunter.

Glauconycteris gleni Peterson and Smith, 1973

p. 3

Holotype - ROM 57125, adult female, skin and skull collected 16 June 1970 by Robert Glen and V. Ngam in a tropical forest region near Lomie, Cameroun, 3°10'N, 13°37'E.

Geographic distribution - Known only from the type locality in Cameroun and from Malabigambo Forest near Sàngo Bay, Masaka District, southern Uganda, 1°05'N, 31°30'E.

Diagnosis - Wings and uropatagium white with dark brown pigment outlining the bones of the wings, hind limbs, and tail, the basal portions of the calcars and veinations of the interfemoral membrane, and to a lesser extent the proximal areas of the wings between humeri and hind limbs (Fig. 1). The ears are relatively large for the genus and have broad tragi. The pelage of the dorsum is quadricoloured with a pale clay-coloured terminal band, a narrow and dark-brown subterminal zone, a pale, buffy, sub-basal zone, and a dark slate-gray basal band. There are no distinct dorsolateral bands of pale pelage as in *G. argentata*. Ventral hairs are bicoloured, with the base gray and the whitish terminal band varying from pure white to a wash of pale yellowish buff. The length of the tibia relative to forearm length is short compared with other species of the genus (Tables 1 and 2).

The size and general shape of the skull of *G. gleni* is similar to that of *G. variegata* but differs from the latter by the combination of a more rounded braincase (equal in

p. 4 - 5

[Tables removed - Eds.]

p. 7

width to that of *G. variegata*) and a narrower mastoid width. The upper inner incisor is usually bilobate, but the development of the posterior lobe varies considerably in individual specimens. The upper premolar has a large hypocone with its lingual margin lying in line with the lingual margins of the canine and the first molar (M^1) in occlusal view (Fig. 2). The lower incisors are typically trilobate (Fig. 3), but the outer incisor (I_3) has a well-developed cingulum extending along its anterior surface below the central lobe. The occlusal surfaces of I_3 and I_2 are each characterized by the development of a posterior projection of the cingulum to form a heel-like lobe (Fig. 4).

Measurements (mm) of the holotype - *External*: Total length 100, tail vertebrae 46, hind foot 8, ear 16, tibia 16.4, forearm 41.1, third digit - metacarpal 40.2, first phalanx 15.2, second phalanx 21.3, fourth digit - metacarpal 37.8, first phalanx 10.9, second phalanx 9.7, fifth digit - metacarpal 34.9, first phalanx 7.8, second phalanx 6.9, wing span 305, weight 9.25 grams. *Skull*: Greatest length 14.2, condylobasal length 13.6, palatal length 4.1, zygomatic width 9.9, mastoid width 8.4, breadth of braincase 8.2, height of braincase 5.9, supraorbital process width 5.3, interorbital width (from front) 5.2, postorbital constriction 4.5, width across molars (M^3-M^3) 6.4, length of toothrow (C-M^3) 4.75, width across upper canines (C-C) 4.6, length of mandible (condylo-incisive) 9.9, length of lower tooth row (C-M_3) 5.2, width across lower canines (C-C) 3.0.

Specimens examined - *Glauconycteris gleni* sp. N. - The holotype from Cameroun (ROM); plus nine adult and two subadult males, five adult and one subadult females all from Malabigambo Forest near Sàngo Bay, Masaka District, southern Uganda in the collection of the Los Angeles County Museum. *G. argentata* (Dobson) - Cameroun, 8; French Congo, 2; Uganda, 6; Kenya, 49; Tanzania, 5. *G. variegata* (Tomes) - Cameroun, 2; Congo, 11; Dahomey, 2; Ghana, 2; Nigeria, 2; Zambia, 2; Sudan, 1; Uganda, 9; Malawi, 1; South Africa (Zululand), 1. *G. albogutattus* J.A. Allen - Cameroun, 1; Congo, 1. *G. beatrix* Thomas (including *G. humeralis* J.A. Allen) - French Congo, 1; Gabon, 1; Congo, 5; Uganda, 9; Kenya, 6. *G. egeria* Thomas - Cameroun, 1; Uganda, 4. *G. machadoi* Hayman - Angola, 1. *G. superba* Hayman - Congo, 1; Ghana, 1; Ivory Coast, 1.

Comparisons - *Glauconycteris gleni* appears morphologically intermediate between *G. argentata* and *G. variegata*. Externally, *G. gleni* resembles a pale-coloured *G. argentata* in the veination of the interfemoral membrane, but markings are considerably darker and the membrane much whiter. *G. gleni* lacks the dorsolateral bands of pale-coloured pelage on the back, characteristic of *G. argentata*, and the white ventral pelage contrasts sharply with the dark-greyish or brownish coloration of that species. The ear of *G. gleni* is larger, the tragus is wider, and the tibia is distinctly shorter than in *G. argentata*. *G. gleni* is significantly larger in 11 of 16 external measurements in both sexes (Tables 1 and 2). In cranial characters, *G. gleni* is significantly larger ($P < .001$) without overlap in measurements of greatest length, condylobasal length, length of tooth row (C-M^3), and length of mandible, while the postorbital constriction of *G. gleni* is significantly narrower ($P < 0.001$) in both sexes compared with *G. argentata* (Tables 1 and 2). Of the 16

p. 8

cranial characters compared, *G. gleni* and *G. argentata* males differed significantly in 12 and females in 10. In dental morphology, specimens of *G. gleni* tended to differ from those of *G. argentata* in having a larger hypocone on the upper premolar and in the development of the cingula on the anterior surface of the crown of 13, as well as on the posterior portion of both hand 13 (Figs. 2 - 4).

When compared with *G. variegata*, *G. gleni* lacks the heavily pigmented markings on the wings, and the markings on the interfemoral membrane are less complex (typically, lines are laterally oriented and anteroposterior orientation of cross-veination is limited). The coloration of the pelage is strikingly different from any known example of *G. variegata*. The dorsal pelage is distinctly quadricoloured instead of tricoloured as in *G. variegata*. Although similar in shape, the ears are longer and the tragi are broader in the new species. The tibia of *G. gleni* is distinctly shorter (17.0 or less) than that of *G. variegata* (18.3 or more; see Tables 1 and 2). Of the 16 external measurements (Tables 1 and 2), *G. gleni* males are significantly smaller in nine and females in eight when compared with *G. variegata*. Although the crania of the two species are similar in size, differences are significant in 13 of the 16 measurements in males and 10 of the 16 in females. In dental morphology, *G. gleni* also differs from *G. variegata* by the shorter first commissure and longer third commissure of M^3 and by the greater development of the hypocone of P^4 (Fig. 2), as well as by minor differences in the development of the cingula of the lower incisors (Figs. 3 and 4).

Each of the remaining known species of *Glauconycteris* can be distinguished from *G. gleni* as follows:

G. poensis (Gray) - wings pale gray instead of white, general pelage coloration darker, and greatest length of skull less than 13.0.

G. albogutattus Allen - pelage coloration much darker, wing membranes dark instead of white, tibia greater than 17.0, and greatest length of skull shorter (13.1 and 13.2).

G. beatrix Thomas - pelage and wing membranes dark, ear shorter (12.0 or less), skull shorter (greatest length, 12.0 or less), and length of mandible less than 9.0.

G. egeria Thomas - pelage and wing membranes quite dark combined with striking whitish dorsolateral stripes on the back, larger square-shaped ears, greatest length of skull less than 13.5, and length of mandible less than 9.5.

G. machadoi Hayman - darker pelage coloration, as well as wing and interfemoral membranes with sharply defined veinations; otherwise differs in the same way as *G. variegata*.

G. superba Hayman - pelage black and white above, black below, forearm length greater than 44.0, greatest length of skull more than 16.0.

Glauconycteris humeralis J.A. Allen, 1917

p. 448

Text Fig. 7, A.

Type, No. 49013, F ad, (skin and skull), Medje, Belgian Congo, Sept. 7, 1910; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 956..

Size medium. A conspicuous tuft of while hairs at the shoulder. Pelage full and soft.

p. 449

Upperparts hair-brown, the hairs darker on basal half; a conspicuous tuft of white hairs on the shoulders; underparts similar to back but paler; membranes dark brown; limb bones pale brown on both surfaces; wing membranes attached to the whole length of basal joint of outer toe; no postcalcaneal lobe. Ears small, yellowish brown; tragus short, broad, straight on inner border, convex on outer border, expanded at middle. Tail wholly included in the interfemoral membrane.

Represented by 5 specimens, the type and 3 topotypes (2 of them in alcohol) from Medje, the other from Avakubi, collected Feb. 21, 1914.

Collectors' measurements of type: Total length, 82 mm.; head and body, 42; tail, 40; foot, 8; .ear, 9.

Forearm, type (from skin), 36.8; third metacarpal, 35.8; tibia, 26.8; foot, 7; ear, 5 X 6; tragus, 3 X 1. The forearm length in 2 alcoholic topotypes is, M 35.8, F 35.3; the Avakubi specimen, 38,8.

Skull (type), total length, 11.3; zygomatic breadth, 8.2; breadth of braincase, 7.3; interorbital breadth, 3.9; maxillar breadth, 5.1; breadth at base of canines, 3.6; upper toothrow (with canine), 3.6; length of mandible, 7.9; height at coronoid, 2.5; lower toothrow, 3,9. Skull short and very broad, the braincase greatly expanded.
Inner incisor large, with the secondary column about one fourth lower than the main cusp; outer incisor inserted posterior to the inner one, minute, about one third of the height of the inner, and wedged in between inner incisor and canine. The single upper premolar is approximately the size of m^3, and quite similar to it in form.

The pure white shoulder tuft is a conspicuous feature in the type and topotypes; it is present in the Avakubi specimen, but only the tips of the hairs are white (yellowish white instead of pure white). The collectors' measurements and the forearm are somewhat larger than in the type, but the skull measurements are practically the same in all the specimens.

Glauconycteris kenyacola Peterson, 1982

p. 2521

Figs. 1 - 4

Holotype

ROM 71305 adult female skin and skull, collected 30 December 1970 on the Galole Road, 8.5 km N Garsen, Kenya (02°12' S. 40°05' E) by Judith Eger and Robert Glen.

Geographical distribution

Known only from the type locality.

Diagnosis

Similar in size to *G. argentata* but with distinctive whitish facial markings on nose and chin and at base of ears (Fig. 1); skull with narrow postorbital constriction, short rounded braincase (Fig. 2); inner upper incisor simple (without secondary cusp but with a slight posterior bladelike ridge) resembling that of *G. variegata* (Fig. 3B); third upper molar with relatively long first commissure, with narrow angles between first and second and between second and third commissures, the lingual termination of the latter not extending conspicuously beyond level of the junction of the first and second commissures (Fig. 4B),

Description

A whitish tuft of hair extends dorsally on the nose from between the nostrils (tuft length about 3 mm and width about 2 mm); a distinct thick band of white hairs (about 1.5 mm long) extends from the antitragal lobe to the base of the ears (band about 2.0 mm x 5.0 mm); tufts of finer, longer, and darker hairs occur on the posterior surface of the lower outer base of the ears as well as the

p. 2522

posterior outer surface of the base of the leading edge of the upper (inner) portion of the ear; inner surface of the ear and base of tragus with a thin covering of long pale hairs.

Dorsal pelage long (about 5 - 6 mm), soft and bicoloured, Tawny-Olive basally and Mummy Brown at tips; head Dresden Brown, paler than back Except for the lateral flanks, which are Yellow Ocher, the ventral pelage is pale Ochraceous Buff with a thin wash of Dresden Brown.

Wing membranes of dried skin Light Ochraceous-Buff with venation outlined in Dresden Brown; uropatagiurn Drab. Skin covering wing, leg, and tail bones strongly outlined with Blackish Brown dorsally but not ventrally.

See Table I for measurements of the holotype.

Comparisons

Compared with *G. argentata, G. kenyacola* differs in its distinctive facial markings; dorsal pelage darker and lacking light lateral flank markings (dorsolateral bands); skin over wing, leg, and tail bones sharply outlined with Blackish Brown dorsally; a shorter second phalanx of third digit; skull with shorter palate; slightly narrower postorbital constriction; absence of secondary cusp on unworn first (inner) upper Incisor (Fig. 3); M^3 more compressed (anteroposteriorly) with relatively longer first commissure and smaller angles between it and the second as well as between the second and third.

Compared with *G. gleni*, the holotype of the new taxon differs in the presence of distinctive facial markings; wing membranes light Ochraceous-Buff instead of white (skin covering wing, leg, and tail bones similarly strongly outlined dorsally); dorsal and ventral pelage much darker; longer tibia, tail length, fifth digit metacarpal, and second phalanx of fifth digit; shorter second phalanx of third digit; lighter weight; shorter greatest length of skull, condylobasal length, palatal length, C-M^3, C-M_3, and mandible lengths; narrower, lower C-C width; M^3 with a more acute angle between the first and second commissures (Fig. 4B).

Compared with *G. variegata, G. kenyacola* lacks the characteristic wing membrane pattern of dark outlining of the venation (above and below); differs in the presence of the distinctive facial marking; pelage darker dorsally and ventrally; wing size smaller; weight skull smaller throughout (see Table I); a more acute angle between the first and second commissures of M^3 (Fig. 4B).

Compared with a series of 14 female and 21 male specimens of *G. poensis* from western Africa, *G. kenyacola* differs in its facial markings and pelaga colouration in much the same way as from *G. argentata* except that *G. poensis* averages much darker grey than *G. argentata*. In size the new taxon has a longer tibia (20.0 vs 18.8 maximum), forearm (40.5 vs 39.7 maximum), fourth digit metacarpal (38.7 vs. 38.5 maximum), fifth digit metacarpal (37.3 vs 34.8 maximum). Cranially it has a wider zygomatic Width (ca. 9.4 vs. 9.1 maximum) and a wider braincase (8.0 vs. 7.6 maximum). The upper incisor lacks the strongly developed posterior cusp that is even more highly developed in *G. poensis* than in *G. argentata* (Fig. 3A).

Remarks

G. kenyacola is so uniquely distinct from all known taxa of *Glauconycteris* from Africa that it cannot be confused with any other species. It is most comparable with *G. argentata* and *G. poensis* in size, and needs further comparison with only *G. gleni* and *G. variegata*.

The range of normal geographical, sexual, and age variation within this new taxon will remain unknown until additional specimens become available. The name *Glauconycteris* as a genus is provisionally retained and follows Peterson and Smith (1973) and Corbet and Hill (1980).

Only a few specimens of *Glauconycteris* have been taken near the type locality of *G. kenyacola* and these consist of *G. argentata* and *G. variegata*. As there has been rather extensive collecting in other regions of Africa without its discovery, it appears possible that that new taxon may be restricted to the lower coastal plains of Kenya and adjacent regions. The holotype was netted over a seasonal waterhole.

The etymology of the name *kenyacola* is derived from the Latin *cola* (= to inhabit), thus "Kenya inhabitant."

Glauconycteris papilio Thomas, 1905

pg. 77

Allied to *G. variegatus*, Tomes, with which it has hitherto been confounded ; but the acquisition by the British Museum of the co-types of that species in the Tomes collection enables me to clear up the confusion.

Size smaller than in *variegatus* (forearm 41 instead of 45). General colour of the ends of the hairs above uniform clay-colour from head to rump, exactly matching the posterior back of *variegatus*, but in the latter the head and shoulders are whitish, the clay-colour being only present posteriorly. Individually the hairs are pale slaty basally, then silvery cream-colour, the tips being pale brownish clay-colour. Under surface uniform cream-buff from chin to anus, the corresponding part of *C. variegatus* being white. Wings and interfemoral membrane variegated as in the allied species. Inner basal lobe of ear rounded.

Skull as in *G. variegatus*, but shorter, while nearly as broad. Inner upper incisors similarly unicuspid ; outer minute.

Dimensions of the type (measured in skin): -
Forearm 41 mm.
Third finger, metacarpus 40, first phalanx 15, second phalanx 27 ; fifth finger, metacarpus 38, first phalanx 9, second phalanx 9 ; lower leg and foot (c.u.) 27.

Skull: greatest length 13.2 ; median basal length 10.2 ; breadth of brain-case 8.2 ; front of canine to back of m^3 5.

Hab. (of type). Entebbi, Uganda. Other specimens from Gambaga, Gold Coast (*Giffard*), and Tette, Zambesi *Boyd Alexander*).

Type. B.M. no. 99. 8. 4. 14. Collected 10th April, 1895, and presented by F.J. Jackson, Esq.

Mr. Tomes's collection contains six specimens of "*Scotophilus variegatus*," among which two labelled in his hand-writing can be identified as those of which he gave the dimensions in his original description*. Dobson's statement that the type of this species was in the Berlin Museum was therefore erroneous.

The beautiful "butterfly-bat" now described has been

* P. Z. S. 1861, p. 36.

pg. 78

hitherto considered by Winton* and myself as *G. variegatus*, but it may be readily distinguished by the characters above described.

* Ann. & Mag. N. H. (6) xx. P. 317 (1897, and (7) iv. P. 354 (1899).

Glauconycteris phalæna Thomas, 1915

p. 560

Near *G. variegata*, but teeth smaller and incisors more slender.

Size as in *G. variegata*. Colour, of a spirit-specimen, apparently about as in that animal, the head and belly similar whitish, but the back hardly so strongly buffy. The colour is therefore still further from that of the neighbouring *G. variegata papilio*, in which both head and belle

p. 561

are more or less strongly buffy. Wings strongly reticulated as in the allied species.

Skull essentially as in *variegata*, though the brain-case is perhaps, a little longer and narrower and the muzzle shorter but the difference is very slight.

Incisors smaller and lighter than in *variegata*; i^1 slender, unicuspid in the type, but the presence or absence of a secondary cusp in this group appears to be variable. I^2 considerably smaller than in *variegata*, not crushed between and touching i^1 and the canine in front and behind, but clearly separated from each of them. Molars distinctly smaller than in *variegata* and *papilio*, the combined length on outer edge of m^1 and m^2 in eleven specimens of those forms, including types of both, being 2.7 - 2.8 mm., while in the type of *phalæna* it is only 2.4 mm.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 44 mm.

Head and body 54; tail 44 ; ear 11.5; third finger, metacarpal 40, first phalanx 16; lower leg and hind foot (c. u.) 28.

Skull: greatest length 13.6; condylo-basal length 13.2; interorbital breadth 4.6; breadth of brain-case 8.1; palato-sinual length 5; front of canine to back of m^3 4.8.

Hab. White Nile, near Fashoda.

Type. Adult female. B.M. no. 15.3.6.67. Original number 71. Collected 27th January, 1914, by Willoughby P. Lowe.

Glauconycteris superba Hayman, 1939

p. 219

Glauconycteris superba, sp. n.

Diagnosis. - A *Glauconycteris* distinguished from all other members of the genus by its larger size, longer,

p. 220

flattened rostrum, and, above all, by its bold black and white colour-pattern, as figured. (N.B. - The figures are semi-diagrammatic representations of the pattern, and all membranes, including ear-tips, are left uncoloured.)

Type. - In Congo Museum, R.G. no. 14.765. Adult probably ? (the sexual organs were apparently cut away by the collector in opening the body), in alcohol. Collected at Pawa, about 30 miles E.N.E. of Medje, Ituri district, Belgian Congy, by Dr. Dubois of the Congo Red Cross.

Description. - General colour of head and body above and below, limbs, ears, and all membranes, black. The hairs of the body are dark brown basally, and black for the terminal half of their 5 - 6 mm. length. The body colour is relieved by several pure white patches and bands, the hairs forming which are the same length as the black hairs. These white markings are arranged as follows: - Above (fig. 1), a roughly circular patch, 4 - 5 mm. in diameter, on the top of the muzzle between the eyes; a patch on each side of the crown at the base of each ear, about 6 mm. long and a little less wide (these patches appear to encroach on the outer surface of the ear, but do not actually do so, the proximal half of the outer surface of each ear being clothed with short black hairs); two lanceolate stripes, one on each side of the median dorsal line on the fore part of the back, each about 18 mm. long, approximately 5 mm. wide anteriorly, and tapering rapidly to their termination about the middle of the back; two longer, narrower stripes, each about 29 mm. long and 2 mm. wide, one on either side of the body, each commencing a little in advance of, and exterior to, the ends of the scapular stripes last described, and each terminating just short of the root of the tail. On each shoulder, close to the junction of the antebrachial membrane with the body, another stripe begins, about 2 mm. wide, arising exterior to and on a level with the anterior end of the long flank stripe. This shoulder stripe runs forward over the shoulder, and below (fig. 2), joins a wider band, approximately 4 mm. wide, which then turns back and runs without interruption or narrowing along the side of the under-surface of the body, widening to about 6 mm. on the perineal region, where it joins the

p. 221

corresponding stripe of the opposite side of the undersurface. Most of the throat is occupied by a white band, 8 mm. wide at the centre, which narrows laterally to about 3 mm. as it passes on either side of the throat

p. 222

to the posterior outer surface of the lower part of the ear conch. On the side of the neck this band has a narrow connection joining it to the shoulder patch.

Other External Features. - In general form *G. superba* does not differ from other species of the genus. The ears are less rounded and more subquadrangular in outline than in other forms. *G. variegata papilio* being nearest to it in this respect.

Skull and Teeth. - The skull is proportionately longer and slightly less broad than in any other *Glauconycteris*. A most marked feature is the flattening of the rostrum, so that the profile shows an angle at the junction of the brain-case and the rostrum. The occiput is high, with a minute crest, and the total height of the skull from bulla to occiput is more than half the total length instead of slightly less than half, as in all other species known. The teeth are characteristics of the genus: i^1 is not bicuspid, although there is a minute accessory cusplet on the internal angle near the cingulum. i^2 is closely crowded between i^1 and the canine.

The lower incisors are closely crowded, and there is a greater proportionate difference in size between i_1 and i_3 than in other species.

Measurements. - It should be noted that, a a result of the unique type having been preserved originally apparently in formalin, the body has set in such a way that an accurate head and body measurement would probably be nearly 10 mm. More than the figure given here. Head and body 49, tail 30, hind foot 8.3, tibia 21.3, ear 13, tragus 7.5, forearm 47.5. Second digit 44.5; third digit metacarpal 45.5, first phalanx 20.7, second phalanx 24.3; fourth digit, metacarpal 44, first phalanx 13.3, second phalanx 10.8; fifth digit, metacarpal 40, first phalanx 8.2, second phalanx 8.2. Calcar approximately 11. Skull; greatest length 16.2, condylobasal length 15.5, palatal length 5.9 to posterior notch, 6.5 to tip of median process, height from bullae to occiput 8., interorbital width 5, zygomatic width 11, mastoid breadth 9.5, width of brain-case 8.5, width across canines 6, width across m^3-m^3 7.9, upper toothrow (c-m^3) 6, lower toothrow 6.6, length of mandible 12.2.

Remarks. - Although in certain other species of *Glauconycteris*, namely *argentata* Dobson, *poensis* Thomas,

p. 223

alboguttatus J. A. Allen, and *humeralis* J. A. Allen, all of which are either fawn or brownish in colour, there is a more or less well-defined buff or whitish stripe on the lateral margin of the upper surface of the body, none shows a close approach either to the black and white colour or the pattern of spots and stripes found in *superba*, a pattern suggesting in a modified form that found in the spotted skunk, *Spilogale*. The nearest approach to this pattern is found in another Vespertilionid bat, *Scotomanes ornatus*, from S.E. Asia, a bat of a rich rufous general colour having a single median dorsal stripe and other white markings roughly corresponding in position to those of *Glauconycteris superba*, but much less well defined. The Emballonurine *Saccopteryx bilineata*, from S. America, has a pair of narrow white dorsal stripes on a black ground, but no other white markings, while the North American *Euderma maculata*, another Vespertilionid, is black with three well-defined white patches on the dorsal surface, one on each shoulder and one on the rump. That such a conspicuous new species should be found in a region which has received considerable attention from museum collectors of proved ability such as Lang and Chapin of the American Museum Congo Expedition of 1909 - 1915, Dr. Christy, and others, is somewhat surprising. It seems that much more collecting needs to be done before we can claim a complete knowledge of the mammalian fauna of tropical Africa.

Glauconycteris superba sheila Hayman, 1947

p. 547

Glauconycteris superba Sheila, subsp. nov.

Type. - B.M. no. 47.10. Adult ?, skin and skull (originally in alcohol), collected December 6th, 1946 at Oda, Oda Province, Gold Coast, by Mr. G. S. Cansdale. Collector's number 807.

Diagnosis. - Similar to *Glauconycteris superba* in size, external form and in the main features of the vivid pattern of white patches and lines on a black ground. It differs, however, in the addition of two white spots on each shoulder adjacent to the base of the humerus, in having conspicuous unpigmented areas on the upper surface of the elbow, knee and ankle joints, and in the paly grey colour of the under-surface of the interfemoral membrane, contrasting with the black of all the other membraneous surfaces.

Description of the Type. - The general colour of head and body, above and below is black, the dorsal hairs being

p. 548

dark brownish at the base, as in *superba*. The white markings above, as shown in the diagrammatic figure (all membranes left uncoloured) consist of a median nose spot, a large patch on each side of the crown close to the base of each ear, two elongated patches lying one on each side of the median line on the upper shoulder, two long narrow lines, one along each flank, and on each lower shoulder, just above the root of the humerus, two spots of approximately equal size. These latter spots are the only feature of the body pattern distinguishing the new form from typical superba. Immediately in front of the two shoulder spots is the beginning of the white area which passes below to the broad U-shaped white band almost enclosing the black abdominal area. The broad white throat band terminates laterally immediately behind the base of each ear. The entire pattern of the underside of the head and body is thus exactly as in *superba*.

p. 549

Contrasting sharply with the completely black skin of the limbs and black upper surface of all membranes are the unpigmented round patches on upper surface of elbow, knee and ankle joints. These are described by Mr. Cansdale as flesh coloured in the fresh specimen, and are quite conspicuous in the dry skin.

The entire under-surface of the interfemoral membrane, in the alcoholic specimen as received, was pale grey, in sharp contrast with the black membranes elsewhere. In the dry skin this area has become brownish rather than grey, but still contrasts with the adjoining membranes, particularly since the numerous transverse veins in the under-surface form a prominent pale network in the dry state.

Skull and Teeth. - In size and proportions the skull agrees well with that of the type of *superba*. The flattening of the rostrum produces a marked angle at its junction with the brain case. In addition the length of the rostrum is markedly greater in proportion than in other species of the genus, and has brought about a considerable lengthening of the infraorbital foramen. In other species the anterior opening of the foramen is situated over p^3, in *sheila* it is over the canine root, and the foramen is thus much longer. The basisphenoid pits are somewhat deeper proportionately than in other species examined.

The teeth are normal, except that m^3 is considerably reduced, resembling that of *Scotophilus* in this respect. An examination of the same tooth in other species shows that it is best developed in the smallest forms and becomes proportionately weaker as the skull becomes larger.

Measurements. - All figures in parentheses are those for the type of *G. superba*. Head and body 63 (49); tail 49 (39); hind foot 10 (8.3); ear 13 (13); tragus 7. Forearm 47 (47.5). In comparing the two sets of figures it should be remembered that owing to the type of *superba* having been stiffened by preservation in formalin it was not possible to give fully accurate measurements, and it was suggested (1939) that it might be found later that the figures given then might not be fully reliable. The almost exact correlation in size between the skulls of the two forms suggests that this is the case.

Skull: greatest length 16.1 (16.2); condylobasal length 15.7 (15.5); palatal length to tip of median process

p. 550

7.7 (6.5); rostrum (incisive alveolus to front of orbit) 4.1; zygomatic breadth 11.9 (11); breadth of brain-case at posterior root of zygomata 9.1 (8.5); height of brain-case from auditory bulla 9.6 (8.8); interorbital breadth 4.8 (5); breadth across m^3-m^3 8.1 (7.9); upper tooth row c-m^3 6.2 (6); length of mandible 12.9 (12.2); breadth across canines 6.2 (6).

Remarks. - This striking discovery, which I am pleased to name for Mrs. Cansdale, is obviously a distinct West African representative of *G. superba* of the eastern Belgian Congo. Its distinguishing features are very well marked; but in view of a tendency towards variability in the much simpler pattern in another species of the genus noted by the present author (1946) it is thought best to give the Gold Coast form subspecific status at present. Mr. Cansdale is to be congratulated on the addition of such a remarkable bat to the Gold Coast fauna. He informs me (in litt.) that the animal was found alive on the ground and brought in by natives, to none of whom was it previously known. In the absence of any field observations on the animal itself the significance of such a pattern remains to be explained.

H[ipposiderus]. gigas gambiensis K. Andersen, 1906

p. 42

Diagnosis. - Nose-leaves larger: width of horseshoe and posterior leaf about 13 mm.

In the specimen examined there are three supplementary leaflets only, no trace of a fourth.

Type. - F ad. (in alcohol). Gambia. Presented by the Earl of Derby. Brit. Mus. no. 42.9.27.36.

H[ypsignathus] monstrosus H. Allen, 1862

p. 157

Fur fine and short, very thin upon the face, interspersed with a few long stiff hairs. A well-marked white line extends from the facial protuberance to between the eyes. Top of head and nucleal region light ash brown, dark in the centre, lighter upon the sides, and narrowing to a whitish band which encompasses the inferior part of the anterior surface of the neck. The hair between this band and the chin is very thin and scattering, and of a pale brown. Dorsum delicate plumbeous tipped with grey, thicker above than below. The fur runs to a purer brown upon the posterior part of interfemoral membranes and thighs. The fore extremities to near the carpal joint are clothed with a thin coating of fur, while the interbrachial surface and that contained between the fourth finger and the sides of the body are studded in different directions with interrupted lines of minute hairs. The pectoral region and sides of belly of the prevailing hue - plumbeous grey - with a tendency of that in the centre of the abdomen to become whitish. Pubic region brownish. At the point of junction of the interbrachial membrane with the body a row of white hair is seen. The membranes beneath have upon them the same thin lightish hairs as above, but more extensive.

The dimensions of the skull are as follows:

Length from occiput to extremity of nose: 2.9 in.
" of cranium: 1.0
" " nose: 1.6
Height of nose: 0.9
Breadth of nasal bones: $0.3^1/_2$
" palate between canines: 0.6
" " " molars: 0.9
Distance between zygomas: 1.6

p. 158

Length of lower jaw: 2.3 in.
Breadth of symphysis: 0.6
Distance between condyles: 1.3
Height of coronoids: 0.9
Distance between first premolar and canine: 0.2
Dimensions of the body:
From snout to interfemoral membrane: 12.0

" " ears: 3.4
" " eyes: 2.0
" anterior part of eyes to ears: 1.4
Length of mouth: 1.4
Breadth of snout: 1.4
Height of snout: 0.8
" face: 1.1
Breadth of chin: 0.9
Length ": $0.4^{1}/_{2}$
Breadth between eyes: 1.3
" " ears: 1.6
Distance from snout to wing membrane: 5.7
Length of ulna: 4.6
" thumb: 2.0
" first joint: 0.9
" second joint: 1.3
" index finger: 3.9
" third ": 9.6
" fourth ": 7.1
" fifth ": 6.6
" inferior extremity: 3.6
" tibia: 2.1
" foot and claws: 1.3
Expanse of wing membranes: 27.0

Hab. Western Africa. Discovered by M. Duchaillu

Hipposideros abæ J.A. Allen, 1917

p. 432

Type, No. 49123, M ad. (skin and skull), Aba, Uele district, Belgian Congo, Dec. 13, 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig, No. 1715.

Upperparts (type, an average specimen of the dark phase) heavily washed with bistre from the shoulders posteriorly; lighter anteriorly through the shorter dark tips of the hairs, which nearly disappear on sides of head, neck and shoulders, which are thus much lighter than the back; underparts buffy gray, much lighter on throat; ears light brown, rather small, tip obtusely rounded; feet and ventral surface of limbs light brown; membranes dark brown.

Type, total length (collectors' measurements), 104 mm.; head and body, 66; tail, 38; foot, 12; ear (from outer base), 20. Forearm (from skin), 58.5; tarsus, 23.2; foot, 11; ear (from inner base), 16. Skull (type), total length, 23; zygomatic breadth, 13; width of braincase, 11; maxillar breadth (across m^3), 8.8; breadth at base of canines, 6.1; upper toothrow (c-m^3), 8.2; length of mandible, 14; lower toothrow, 9.4.

Posterior border of nose-loaf rounded; three secondary cutaneous leaflets, the outer one slightly developed; a frontal sac in the males, absent or much less devel-

p. 433

oped in females. P^2 uniformly present on both sides in each of the 35 skulls, inserted on the outer border of tho toothrow, closely crowded in between the canine and p^3.

Represented by 35 specimens (16 males, 19 females, all adult, skins with perfect skulls), all taken at Aba, December 13, 1911.

The collectors' measurements from the fresh specimens (16 males, 19 females), are as follows:

Total length (MM; FF): 101.2 (97 - 107); 101.4 (95 - 105); Head and body: 65.5 (60 - 70); 65.4 (60 - 70); Tail: 34.2 (32 - 39); 36 (32 - 40); Foot: 12 (11 - 13); 12.2 (11 - 13); Ear: 21.4 (20 - 22); 21.5 (20 - 22)

The forearm and skull measurements (total length and zygomatic breadth) of the same specimens (MM; FF): Forearm: 58 (56 - 60); 57.8 (54 - 60.5); Skull: 23.1 (22.5 - 23.7) X 13.4 (13.1-13.9); 22.7 (21.9 - 23.3) X 13.2 (12.6 - 13.7)

This large series of specimens, all taken the same day at the same locality, and also all fully adult, is especially interesting from the wide range of color variation it presents, which, as shown by the skulls, is wholly independent of age, and probably of sex, although of the 16 specimens in the red phase 11 are females and 5 are males, and none of the males are nearly as red as are the majority of the red phase of the females. The dark phase, on the other hand, includes 11 males, while only 8 females can be assigned to it; and only two of the dark males are strictly referable to the norm of the dark series of females, the, others, being distinctly intermediate between the dark and red phases.

The *dark phase* may be described as follows: Upperparts, in general effect, washed with drab-brown, lighter on the neck and shoulders, whitish prevailing on the sides of the shoulders; fur at extreme base dusky, with a broad intermediate zone of whitish, the tips of the hairs dark drab-brown, giving a dark brown superficial tone to the dorsal aspect. The extent of the dusky tipping varies greatly in different specimens, and maybe almost absent over the shoulders and especially on the sides of the shoulders,

giving there a prevailing whitish tone. In general the white middle zone of the fur shows more or less at the surface. Underparts uniform dingy pale buff with a faint superficial wash of yellowish. Basal portion of the fur very pale brown, showing more or less through the pale buffy tips.

Red phase. Upperparts cinnamon-brown, often darkening on the middle of the back to nearly chestnut-brown. Fur at extreme base slightly darkened, the broad middle zone, pale cinnamon, the tips of the hairs dark ruddy brown; sides of shoulders light yellowish white. The underparts vary in different specimens from pale buffy to deep reddish ochraceous; in average female specimens, pale ochraceous. This is the 'red' phase as

p. 434

shown in females; the males in the red phase are much less rufous, both above and below, the upperparts being of a much darker and less reddish tone, and the ventral surface is seldom brighter (yellowish buff).

Many of the males and some of the females are so nearly intermediate between the two phases that it is difficult to assign them satisfactorily to either. None of the specimens is young enough to indicate the character of the immature or juvenile pelage.

Hipposideros abæ is allied to the *H. caffer* group, from which it differs in considerably larger size, and lighter and more buffy underparts. *H. caffer centralis* occurs with *H. abæ* at the type locality of the latter. Average length of forearm in *H. abæ* (35 specimens), 58 mm.; of *H. caffer centralis*, 50; total length, *H. abæ*, 101, *H. c. centralis*, 92. Skull, *H. abæ*, 23 X 13.3; of *H. c. centralis*, 18.5 X 10.

Hipposideros braima Monard, 1939

p. 73

Collection: N° 602 F ad., Bagingara.

Description. Très petite: espèce à longue queue du groupe de *caffer-beatus-nanus*.

Feuillet nasal (Fer-à-cheval] assez large (5 mm) muni sur les côtés de deux feuillets accessoires (largeur avec ces feuillets: 6 mm). Partie dressée aussi large que le fer-à-cheval avec ses feuillets latéraux, à marge supérieure en arc surbaissé, presque horizontale, sans trace de sillons et de crêtes verticaux. Ïmmédiatement derrière le feuillet vertical, un petit sac frontal muni d'une touffe de poils noirs, à ouverture transversale; il est à présumer qu'il est mieux développé chez les mâles. Oreilles courtes mais larges, du type de *caffer* ou de *fuliginosus*. Marge interne d'abord

p. 74

très convexe, s'approchant beaucoup du feuillet nasal: puis à peu près droite et horizontale (l'animal en position verticale). Pointe de l'oreille en angle droit. Marge externe formant dès l'origine un large lobe convexe (antitragus) à peine séparé de la conque par une légère sinuosité concave: puis convexe, enfin concave vers la pointe de l'oreille. Celle-ci dirigée en arrière.

Membranes normales naissant de l'extrémité du tibia. Fémur et tibia proportionnellement allongés; pied étroit, plus long que le pouce. Queue allongée, la dernière vertèbre libre. Membrane interfémorale en forme d'arc.

Pelage complètement noirâtre.

[table removed - eds.]

On voit par ces dimensions que les caractères principaux de notre nouvelle espèce sont l'allongement de la queue et des membres postérieurs:
nanus ALLEN, *beatus* AND., *braima* n. sp.
Longueur de la queue mm.: 22, 20.5 - 22, 26
" du tibia: 16.5, 15.2 - 16, 18
" du pied: 7.9, 7.8 - 8.5, 9

En outre l'avant-bras est proportionnellement plus court, les doigts ayant des dimensions comparables.

Le crâne n'a pas été tiré de notre unique exemplaire.

p. 76

Mœurs. L'espèce vivait en compagnie de nombreux *Nycteris* de diverses espèces dans le comble de la maison que le Régulo de Sama met à la disposition de ses hôtes, à Bagingara. Mais elle y était beaucoup moins nombreuse que les *Nycteris* et deux individus seulement furent capturés, le second ayant réussi à s'enfuir.

Notre exemplaire femelle porte, immédiatement en avant de l'éminence sexuelle, deux petits appendices, de signification douteuse, qu'on signale parfois dans les femelles de ce genre

---

Hipposideros caffer niapu J.A. Allen, 1917

p. 431

Type, No. 49414 (alcoholic), M ad., Niapu, Belgian Congo, Jan. 27, 1914; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig, No. 2322.

Similar in general coloration to *H. caffer centralis*, but much larger; it has a dark phase and a rufous phase, like the other forms of the *caffer* group.

Type (in rufous phase), upperparts uniform chestnut-brown; underparts cinnamon-brown; ears and membranes dark brown.

In the dark phase the upperparts are hair-brown, below lighter, with the tips of the hairs lighter than the basal fur. Most of the specimens are in the dark phase, which is similar to the corresponding phase of *H. caffer centralis* and *H. abæ*, but none of the specimens in the rufous phase approach nearly to the intensity of coloration seen in many examples of either of these forms.

Measurements: Type, total length, 88; head and body, 58; tail, 30; tibia, 21.8; foot (c.u.), 10.8; ear, 11.2 X 14.6. Forearm, 54.5. In the ten topotypes (including; type) the forearm averages 54.7 (53-56).

Skull (type), total length, 20.3; condylobasal length, 17.8; zygomatic breadth, 10.6; mastoid breadth, 10.2; interorbital breadth, 2.9; maxillary breadth, 6.8; breadth at base of canines, 4.8; maxillary toothrow (c-m^3), 6.6; length of mandible,

p. 432

12.4; mandibular toothrow, 7.2. Four male topotype skulls (including type), total length, 20.1 (19.8-20.3); zygomatic breadth, 10.5 (10.3-10.0); interorbital breadth, 2.9 (2.8-3); length of mandible 12.4 (12.2-12.5).

H. caffer niapu seems clearly to represent a large race of the *caffer* group, larger than any hitherto described. In Andersen's table of measurements of the forms of the *caffer* group, based on 98 specimens (including 75 skulls), the maximum length of the forearm is given as 53.8 for 24 specimens of *centralis*, as against 54.7 in 10 specimens of *niapu*, while the maximum in 40 specimens of typical *caffer* is 51.8. He gives (l. c., p. 270) the average forearm length for 40 specimens of *H. caffer caffer* as 48.6, and for 50 specimens of *centralis-guineensis* (which do not differ in size) as 50.6, as against 54.7 in 10 specimens of *niapu*, the latter exceeding the *centralis-guineensis* series by 4 mm. The skulls bear out the evidence of larger size for the *niapu* series, in which the average total length of the skull is 1 mm. greater than in the *centralis-guineensis* series, which is equal to the average difference between the latter and typical *caffer*.

H. c. niapu is represented by 10 adult specimens (6 males, 4 females), all from the type locality, and all collected the same day. It is clearly specifically different from the much larger *H. abæ* described below from a series of 35 skins and skulls, all from Aba, and all collected also during one day.

Hipposideros camerunensis Eisentraut, 1956

p. 526

Material: 4 Exemplare

Buea, 29. April 1954, 2 MM (505, 510), 2 FF (506, 511).

Die hier neu beschriebene Art, die in 4 in den wesentlichen Merkmalen übereinstimmenden Exemplaren vorliegt, ist am nächsten verwandt mit *H. cyclops* und gleicht ihr in den äußeren Merkmalen, zeichnet sich aber durch ihre bedeutende Größe aus, die durch keinen gleitenden Übergang mit den für *cyclop*s vorliegenden Maßen verbunden ist. Man könnte vielleicht die Ansicht vertreten, daß die neue Form nur eine Unterart von *cyclops* darstellt, und zwar in diesem Fall eine Gebirgsform, doch gibt als Fundort für *H. cyclop*s DOBSON "Cameroon-Mountains" und MATSCHIE (1891) ausdrücklich Buea an, von wo auch die vorliegenden Stücke stammen, so daß eine artliche Trennung als gegeben erscheint. Es liegt hier ein ähnlicher Fall von Größendifferenz zweier nächstverwandter Formen vor, wie wir ihn z. B. von *Nyctalus noctula* und *Nyctalus lasiopterus (maximus)* kennen. Wie weit die neue Form in Kamerun und darüber hinaus verbreitet ist, wissen wir nicht. Die 4 vorliegenden Exemplare wurden in einer Höhle oberhalb des Eingeborenen-town Buea gefangen.

Hipposideros camerunensis besitzt wie *H. cyclops* ein außerordentlich dichtes und wolliges Fell. Oberseits ist der Grundton schwärzlich, doch gewinnt das Fell durch die grauweißlichen Haarspitzen einen graumelierten Ton. Am Unterarm, der oberseits bis zur Hälfte dicht behaart ist, nehmen diese Haare eine bräunliche Färbung an; auch am Vorderkopf ist das Fell etwas mehr graubräunlich getönt. Die Färbung der Unterseite ist eine Nuance heller als die der Oberseite und geht in den vorderen Partien ein wenig in Grau, an den hinteren in Braun über. Auch hier sind die Haare am Ende heller als am Grunde. Der Unterarm ist auf der Ventralseite in seinem proximalen Drittel schwach behaart. Flughäute und Ohren sind bräunlich-schwarz. Das Plagiopathagium schließt den Metatarsus der 1. Zehe völlig

p. 527

mit ein und inseriert ein Stück oberhalb des proximalen Endes des 1. Zehengliedes. Der Schwanz ist relativ kurz. Der letzte Wirbel steht frei aus der Flughaut.

Der Schädel von *H. camerunensis* ist nicht nur absolut, sondern auch relativ länger als der von *cyclops*. Die Gegenüberstellung der Körper- und Schädelmaße läßt den Größenunterschied zwischen beiden Arten deutlich erkennen (vgl. auch Abb. 6). Der Hinterfuß ist gegenüber dem von *cyclops* relativ klein.

Der Nasenaufsatz zeigt im wesentlichen die gleiche Form wie bei *cyclops* und ist durch den keulenförmigen Fortsatz in der Mitte des oberen Nasenblattes ausgezeichnet (Abb. 7). Die Breite des unteren Nasenblattes (Alkoholstück 511 F) - ohne die sekundären Seitenlappen - beträgt 14.8 mm, die des oberen Nasenblattes 10.1 mm gegenüber 12.9 und 9.4 mm bei *cyclops*. Der sich hinter dem Nasenblatt longitudinal öffnende Drüsenschlitz läuft am unteren Ende in eine mäßig lange Zunge aus. Die MM besitzen einen mit langen borstenartigen rotbraunen Haaren besetzten Analdrüsensack, der sich unmmittelbar über dem After nach außen öffnet und mit der Afteröffnung zusammen in einen kloakenartigen, von der Hautfalte überdachten Vorhof mündet. Außerdem öffnet sich ein kleiner Drüsengang separat im Zentrum der Hautfalte nach außen. Wie bei *cyclops* kann der Drüsensack ausgestülpt werden. Die FF besitzen Afterzitzen, die bei dem einen Tier nur klein, bei dem anderen dagegen von

p. 528

[table removed - eds.]

ansehnlicher Länge sind. Die Vaginalgegend ist vorn und seitlich mit starren borstenartigen Haaren besetzt.

Die Zahnformel (vgl. auch Abb. 8) lautet: $^{1-1-2-3}/_{2-1-2-3} = 30$. Der 1. obere Prämolar ist sehr klein und völlig nach außen gerückt, so daß sich Caninus und 2. Prämolar fast oder ganz berühren. Der 2. Prämolar ist sehr kräftig entwickelt und überragt die Spitzen der Molaren. Die unteren Incisivi sind dreigelappt. Der 1. Prämolar ist nur etwa $^1/_3$ so hoch wie der 2. (bei *H. cyclops* erscheint er etwas höher).

Die kurze Zeit in Gefangenschaft gehaltenen Tiere waren außerordentlich bissig.

Der Typus (M, Tagebuch-Nr. 505, Katalog-Nr. s 194) und die 3 Paratypen befinden sich im Staatlichen Museum für Naturkunde in Stuttgart

---

Hipposideros Commersoni mostellum Thomas, 1904

p. 385

Size small, as in *Commersoni*. Supplementary leaflets four, with rudiment of a fifth. General colour whitish, the brown Y-shaped marking of the back well defined; under surface creamy whitish, a brown line across each shoulder separating off a white patch at the insertion of the antebrachial membranes.

Skull and teeth as in true *Commersoni*, the cheek-teeth conspicuously smaller than in *gigas*.

Dimensions of the type (measured in skin): -

Forearm 92 mm.

Skull: length from cingulum of canine to back of occipital crest 32; basal length to cingulum of canine 26.5; zygomatic breadth 18; mastoid breadth 15; upper cheek-teeth, front of p^4 to back of m^3 8.4; front of lower canine to back of m_3 13.

p. 386

Hab. (of type). Tana R., British East Africa. Other specimens from Zanzibar.

Type. Male. B.M. no. 89.3.8.3. Presented by H. C. V. Hunter, Esq.

Hipposideros curtus G.M. Allen, 1921

p. 194

Hipposideros curtus sp. nov.

Type. - A female in alcohol, 19305, Museum of Comparative Zoölogy, from Sakbayeme, Cameroons. Rev. George Schwab, collector, 1920.

Description. - A small species, about the size of *H. beatus*; female without the frontal glandular sac; tail very short, barely exceeding the extended femur; wings from the distal end of tibia; calcar short, about one half the length of tibia; thumb markedly small and weak as contrasted with *H. beatus* and *H. caffer guineensis*; forearm about as in the latter but wings shorter, the combined length of metacarpal III and its proximal phalanx exceeding the forearm measurement by only 1 mm. as against 6 mm. in the two other species; metacarpals III and V subequal, IV a trifle longer, whereas in the two contrasted species metacarpals III and IV are about equal, the fifth shorter. Ears noticeably larger than in either *H. beatus* or *H. caffer guineensis*; tibia longer than in the former but shorter than in the latter.

The noseleaf is essentially similar in *H. beatus* and *H. caffer* but in the new species is of a very different appearance. The horseshoe is noticeably broader and thicker, with a slight median emargination anteriorly, the edges of which are a trifle upturned; the small cushion-like expansion of the nasal septum, nearly obsolete in the two other species, is here considerably developed, and, with the small projections at the outer border of the nasal openings, forms a partial roof over the nares.

The erect "sella" is slightly thickened, densely covered with short stiff hairs, more as in *H. beatus* rather than nearly naked as in *H. caffer*. The posterior crescent is simple and evenly convex in outline, and is divided by three vertical ridges on its anterior face. There are two lateral accessory leaflets at each side of the horseshoe, but these are very small and poorly developed.

p. 195

the outer one a mere wart and so concealed by the hair of the lip that is not easily made out; the larger supplementary leaf is only about half the latéral extent of the horseshoe, instead of nearly as long, as in *H. caffer* and *H. beatus*.

The color is not definable from the alcoholic specimen, but seems to be a uniform dark smoky brown.

Skull shows no striking peculiarities. Contrasted with that of the other two species mentioned, it more resembles that of *H. caffer guineensis* in that the width across m^3 about equals rather than exceeds the length of the maxillary tooth row; it differs from both in having more terete upper incisors, their outer sloping border without indication of the notch obviously present in the two other species; p^3 is in contact with canine and p^4, very small but barely external to the median axis of the tooth row; upper canine with a minute posterior basal cusp; lower canine very slender, nearly equalled in height by p_4; sagittal crest weakly developed, extending to the back of the parietals; nasal inflation prominent.

Measurements. - Length (circa) 67 mm., tail from anus 17, tibia 20, with the foot 27, ear from meatus 17.5, width of ear 15, calcar 10.5, forearm 47, third metacarpal 32.5, with proximal phalanx 48, fourth metacarpal 35, with proximal phalanx 45.5, fifth metacarpal 33, with proximal phalanx 45, greatest width of horseshoe 6.5, of posterior crescent 7.5.

Skull: total length 17.5 mm., zygomatic breadth 9, width outside m^3, 5.8, upper maxillary teeth 5.7, lower tooth row i_1 to m_3, 6.8.

Remarks. - Externally this small species is at once distinguishable from *H. beatus* and *A. caffer guineensis*, of similar size and inhabiting the same region, by its very short tail which barely exceeds the extended femur, by its much larger ears, by the short calcar combined with the long slender leg, and by the shorter fingers in comparison with the forearm. The noseleaf is very different, with its broad horseshoe, emarginate anteriorly, reduced

p. 196

supplementary lappets, expanded internarial septum, and hairy sella. These characters will also serve to distinguish it from *H. nanus*, of the Belgian Congo, apparently a close ally of *H. beatus*. For additional notes on the type of *H. nanus*, as well as for carefully executed drawings of its noseleaf, thanks are due Mr Herbert Lang of the American Museum of Natural History.

Hipposideros gigas niangaræ J.A. Allen, 1917

p. 438

Plate LI, Fig. 1.

Type (and only specimen), No. 49103, F ad., skin and skull, Niangara, Uele district, Belgian Congo, June 2, 1013; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 2069.

A small member of the *H. gigas* group. Dorsal hair-brown Y-patch of short

p. 439

dense fur well defined; upperparts anterior to the Y-patch with the fur much longer and looser and of a pale brownish gray, the extreme tips of the hairs, particularly on the posterior third of this area, whitish; still paler on the top and front of the head; sides of, the head lighter than the top, and joined by a narrow still lighter band enclosing the nose-leaf area; sides of back grayish posteriorly, like the anterior back, separated from the Y-patch by a whitish transverse band about 13 by 6 mm. in extent; a patch of clear white on the sides beneath the junction of the propatagium with the body and extending slightly in front of it, bounded ventrally by a band of dark hair-brown fur, a lateral extension of the dorsal Y-patch; general color of underparts yellowish gray, with a broad median band of dusky gray, the fur darker basally; ears, feet and membranes blackish. Ears long and tapering, the extreme tip slightly rounded. Membranes attached about 5 mm. above tarsal joint. Supplementary leaflets three, well-defined.

Collectors' measurements: Total length, 137 mm.; head and body, 107; tail, 30; foot, 25; ear (from outer base), 35.

Forearm (in skin), 104; third metacarpal, 72; tail, 30; lower leg, 40.5; breadth of nose-leaf, 11.7.

Skull, total length, 35.3 (39.8); zygomatic breadth, 20 (22,2); mastoid breadth, 15.8 (18.2); maxillary breadth, 14 (14.2); antorbital breadth, 11 (11); across cingula of canines, 10.5 (11.6); mandible, 24.4 (27.8); upper teeth, 13,5 (13.8-14.5); lower teeth, 15.5 (16-16.3).

The single specimen, of *H. niangaræ* is a fully adult female, with a strongly developed sagittal crest, but the teeth are not appreciably worn. It has the coloration and general characters of *H. gigas*, from which it differs in much smaller size, the forearm measuring only 104 mm. as against 108-116 mm. given by Andersen (*l. c.*, p. 48) for 6 specimens of *H. gigas*; while the total length of the skull is 35.3 as against 39.8 given by Andersen for *gigas*, with other skull measurements proportionally less.

The type locality of *H. gigas* is the Benito River in Angola, and the 8 specimens cited by Andersen are likewise all from Angola. The type, and apparently the only recorded specimen, of *H. gigas gambiensis* is from Gambia, in the same general region. On

the other hand the type of *niangaræ* is from the Uele district of the Belgian Congo, a region of quite different physical conditions and more than a thousand miles westward.

Hipposideros gigas viegasi Monard, 1939

p. 70

KNUD ANDERSEN: Ann. Mag. Nat, Hist, 7. 17. 1906. p. 42 (sur *H. gigas*)

Collection: N^{os} 908 à 926, 19 MM et FF; en plus 14 crânes de MM et FF; Madina Boé.

Les *Hipposideros* du groupe *commersoni* ont été revises par KNUD ANDERSEN dans le travail cité plus haut; il en distingue trois espèces et deux sous-espèces: *commersoni typicus* GEOFFROY, *commersoni marunqensis* NOACK, *thomensis* BOCAGE, *gigas typicus* WAGNER, *gigas gambiensis* KNUD ANDERSEN.

L'examen de notre abondant matériel, auquel il faudrait joindre une cinquantaine d'exemplaires que nous avons refusés ou qui se sont montrés trop détériorés pour la préparation, nous a démontré qu'il s'agissait d'une nouvelle sous-espèce de *gigas*, très nettement caractérisée par sa coloration, son dimorphisme sexuel, la brièveté de la queue et le faible développement de l'uropatagium. Tous nos exemplaires, sans aucune exception et sans atténuation montrent ces caractères distinctifs avec une grande netteté.

Description. Couleur: les mâles, plus grands que les femelles, plus fortement armés et plus agressifs, ont tous une couleur d'un beau jaune, parfois plus pâle, parfois plus vif; les oreilles, les appendices nasaux, les membranes sont brunes. Il n'y a pas trace des détails de coloration que donne KNUD ANDERSEN comme caractéristiques de *gigas gambiensis*: le dessin dorsal foncé en Y

p. 71

n'existe pas et ne laisse pas deviner sa prêsence; la tête a la même coloration que le dos, un peu plus claire seulement; pas trace non plus de poils bicolores: ils sont launes de la base à la pointe; le dessous est de même couleur que le dessus; pas trace encore d'une ligne claire longitudinale de chaque côté du dos, ni de tache blanche à l'insertion du propatagium (toutefois, à cette place, le jaune est plus vif). Il ne s'agit pas non plus d'une "russet phase" dont le style est le même que dans *gigas*, mais où le poil est fortement lavé, de roux.

Les femelles, plus petites, ont une coloration si différente qu'on pourrait les prendre au premier abord pour une autre espèce. La teinte jaune des MM est remplacée par un orangé extrêmement vif, même ardent. Aucune trace de tache en Y, de raie claire, de poils bicolores, de touffe blanche aux épaules, de différence entre le dos et la face ventrale, entre la tête et le tronc.

Le second caractère de notre sous-espèce est la réduction de la queue et de l'uropatagium qui en est la conséquence. Les individus de *commersoni* et *gigas* que nous avons examinés et qui proviennent des Musées de Bâle et Genève ont une queue longue de 30 mm et plus; ANDERSEN donne 34.7 à 35.5 (*commersoni*) et 31 à 39 (*gigas*). Nos exemplaires ont tous la queue du tiers plus courte, mesurant environ 20 mm seulement rarement plus; le nombre des vertèbres n'a pu être comptés, car nous n'avons pas conservé les corps, mais il nous a paru réduit à 4 ou 5? La queue est plus courte que la moitié du fémur et dépasse un peu l'uropatagium.

Le fer-à-cheval nasal est bien conformé; il est large de 11 à 12 mm, donc plus petit que dans *gigas gambiensis*; il y a trois folioles supplémentaires bien conformées et une quatrième rudimentaire.

L'oreille est du type de *gigas*, relativement petite et pointue.

Le crâne, qui chez les vieux mâles, est plus grand que dans *gigas gambiensis*, lui ressemble parfaitement. Les canines sont très longues, de section triangulaire, chaque face sillonnée, avec un faible tubercule accessoire postérieur. La première prémolaire est petite, arrondie, rejetée en dehors de la ligne dentaire, coincée dans l'angle formé par la canine et la seconde prémolaire. Celle-ci tranchante, plus élevée que la première molaire. Les deux premières molaires sont normales, la dernière réduite. Les crêtes

p. 72

sagittales et lambdoïdes sont extrêmement saillantes, la première presqu'aussi haute que la boîte crânienne dans certains exemplaires. Incisives inférieures trifides, canines triangulaires, les prémolaires et molaires comme dans *gigas*.

Cette nouvelle et remarquable forme de Chiroptères est dédiée à M. CARVALHO VIEGAS, gouverneur de Guinée.

[table removed - eds.]

Distribution géographique. Les espèces et sous-espèces du groupe de *commersoni* se distribuent selon le schéma suivant:

Gambie: *gigas gambiensis*
Guinée portugaise: *gigas viegasi*
Angola, fleuve Muni, Benguela: *gigas typicus*
S. Tomé: *thomensis*
Tanganyika, Moçambique, Brit. East Afr., Zanzibar: *commersoni marungensis*
Madagascar: *commersoni typicus*

Mœurs. Ces chauves-souris nous furent apportées un soir à notre campement du Boé par un indigène qui en avait rempli trois

p. 73

sacs. Nous n'avons pas compté le nombre des individus, mais il pouvait y en avoir en tout une centaine. Féroces et agressives, leur maniement n'était pas sans danger. L'heure étant très tardive et mes boys absents, je me suis fait aider par l'indigène. Nous en attachâmes une partie aux branches avoisinantes, en laissâmes quelques-unes dans leurs sacs et en libêrames une moitié environ. Celles qui étaient renfermées dans les sacs se battirent toute la nuit en poussant des sifflements aigus; elles finirent par se tuer mutuellement et furent pour la plupart inutilisables à cause des blessures qu'elles s'étaient faites. Il n'était pas question de les conserver en alcool; l'épaisse couche de graisse dont elles étaient toutes munies, eût rendu impossible la pénétration du liquide et la bonne conservation des sujets; la préparation des peaux fut rendue répugnante et difficile par la même raison.

Ces Chiroptères vivaient en grande société dans les trous des arbres de la forêt du Boé, toutes au même endroit. L'indigène qui nous les a amenées a dû épuiser la colonie, dans l'espoir d'une plus forte récompense. Les individus libérés s'enfuirent immédiatement et s'allèrent loger dans l'épais bosquet où j'avais établi mon campement. Toutefois. je n'en vis plus trace les jours suivants, et il est possible qu'ils aient, à la manière des pigeons voyageurs, rejoint leur station d'origine

---

Hipposideros jonesi Hayman, 1947

p. 71

Type. - B.M. No. 47.629, collector's number 42, F in alcohol, collected with two other FF, B.M. Nos. 47.627, 47.628, at Makeni, Sierra Leone (in cave), 12 December, 1946.

Diagnosis. - A medium-sized *Hipposideros* (forearm 48 mm.), distinguished by the combination of very large ears with a very distinct form of nose-leaf, in which the internarial septum is greatly expanded and the posterior transverse leaflet is greatly lengthened (see figure). Skull of the *H. bicolor* type, with mastoid-breadth-considerably exceeding zygomatic breadth.

Description. - Ears very large, length from meatus 23 - 23.5 mm., greatest breadth 20 - 21 mm., rounded, with a small fold on the lower part of outer margin. Nose-leaf quite distinct in form, characterised by (a) the wide main horseshoe with broad free margin, covering the whole of the muzzle, and having no median emargination, (6) the single wide lateral leaflet, (c) the greatly expanded internarial septum, which is developed into a broad fleshy oval pad, with slight median longitudinal groove, concealing the nares from view, (d) the wide sella with slightly undulating upper margin and with four small warts on the upper part of the anterior surface, and (e) the greatly lengthened posterior leaflet with strongly curved upper margin and having on its basal portion

p. 72

three weak vertical ridges dividing the basal portion into four shallow cells. The visible portion of this posterior leaflet occupies one-third of the total length of the whole nose-leaf. All surfaces of the nose-leaf are well haired. The measurements of the nose-leaf of the type are: greatest length from anterior margin of horseshoe to upper margin of posterior leaflet 15; breadth of horseshoe and of posterior leaflet 8; breadth of internarial septum 4.7, length 3. (All measurements in millimetres.)

The thumb is weak, metacarpals III. and V. subequal, IV. slightly longer. Legs are long, with wing attached at end of tibia. Terminal tail vertebra free of membrane.

There is no frontal sac in the three females examined.

p. 73

The colour above is a uniform smoky brownish grey, the hairs being dark basally, with pale grey median zone, and terminally as described. Below the general colour is paler, the hairs being without the terminal smoky zone.

Skull and teeth: the skull has the general proportions of a typical member of the *H. bicolor* group, particularly in the wide expansion of the brain-case and narrow zygomatic breadth. The upper incisors are slightly bilobed, upper canines with weak basal cusp, the small p^2 separating and in contact with canine and p^4. Lower incisors are trilobed, canines slender, p_2 well developed and about half the height of p_4.

Measurements of type and two paratypes (latter in parentheses). - Head and body 52 (52, 53), tail 25 (22, 27), hind foot 7.5 (8, 7), ear-length from meatus 23 (23, 23.5), ear, greatest breadth 21 (20, 20), forearm 48 (49, 48), tibia 22 (22, 22), metacarpal III. 35 (35, 36), metacarpal IV. 36 (36, 38), metacarpal V. 34 (33, 35) ; skull of type and one paratype, greatest length 18.2 (19.1), condylobasal length 17.2 (17.4), palatal length 7 (6.9), mastoid breadth 10 (10), zygomatic breadth 8.5 (8.3), interorbital breadth 2.8 (2.9), breadth across canines 3.6 (3.8), breadth across m^3-m^3 6 (5.9), upper tooth-row c-m^3 6 (6.2), height of rostrum 5 (5.2), height of cranium from bulla 7.7 (7.5), manidbular length 10.9 (11.7).

Remarks. - *Hipposideros jonesi* stands apart from any of the groups defined and keyed by Tate (1941). Although in size and form of ears and in mastoid breadth exceeding zygomatic breadth it approaches the *bicolor* group, in other respects, such as the well-developed single lateral leaflet and absence of frontal sac it differs widely from that and the other groups. The expanded internarial septum is far better developed than in *H. curtus* from the Cameroons (breadth 4.7 against 1.7), and the greatly developed posterior leaflet removes it from other groups.

Hipposideros lamottei Brosset, 1985

p. 548

Parmi les Chiroptères collectés au Nimba figurent six spécimens se rapportant à une forme d'*Hipposideros* apparemment inédite que nous décrirons ci-après comme *Hipposideros lamottei*, en hommage à M. Lamotte qui organisa la mission au Nimba.

Type M ad. - collect.: Brosset, Pierre Richaud, déc. 1983, Muséum de Paris, CG 1984-487.

Cotypes 2 M, mêmes date et provenance, Muséum de Paris, CG 1984-488 et 489; 1 F et 1 M, mêmes date et provenance, Mus. de Genève; 1 M ad., déc. 1983, grotte de Blandé, Mus. de Genève.

Matériel de comparaison: 5 *Hipposideros ruber*: 1 M et 2 F ad., Mus. de Genève; 1 M CG 1984-490 et 1 F CG 1984-491, du Mus. de Paris. Tous provenant de la grotte de Blandé (collect. Lamotte-Aellen 1963 et Brosset 1983).

Diagnose.

Hipposideros de taille moyenne, du groupe *caffer-ruber*, plus grand que *caffer* et différent de la sous-espèce sympatrique de *ruber*, *H. ruber guineensis*, par des dimensions corporelles plus grandes et un crâne plus petit; autres différences concernant les oreilles, la feuille nasale, la forme du crâne et les dimensions des dents.

p. 549

Morphologie externe de *H. lamottei*.

Ressemble à celle des autres *Hipposideros* du groupe *caffer-ruber*. Diffère de *ruber* par des oreilles plus courtes de 2 mm; le processus postérieur de la feuille nasale forme un bourrelet rectiligne se terminant par un angle presque droit aux extrémités (Fig. 1), sa longueur étant égale ou supérieure à la largeur de la feuille nasale (inférieure chez *ruber*). Toutes les dimensions corporelles

[Table removed - eds.]

dépassent celles des formes décrites du groupe *caffer-ruber* (Tabl. 1). Présence d'un sac frontal chez les deux sexes. Pelage brun (rougeâtre chez les adultes de *ruber guineensis*.

p. 550

... corporelles, toutes les dimensions du crâne sont inférieures chez *lamottei* à celles relevées chez la forme sympatrique de *ruber* (Tabl. 2). Le crâne de *lamottei* est plus étroit et d'apparence

[Table removed - eds.]

p. 551

générale moins robuste. La distance entre C^1-C^1 et M^3-M^3 est plus faible, d'où un palais plus étroit chez *lamottei*. Le profil de la capsule crânienne présente une dépression caractéristique en son milieu, alors que celle de *ruber* réalise une courbe assez régulière (Fig. 2). La denture est considérablement plus faible chez *lamottei*.

p. 552

Cette forme a peut-être été déjà collectée au Nimba, où d'importantes séries d'*Hipposideros* ont été constituées (Verschuren, 1976; Wolton et al, 1982), mais elle n'aurait pas été distinguée de *ruber guineensis*. Peut-être s'agit-il d'une espèce montagnarde, encore qu'elle soit présente à Blandé, à 500 m d'altitude.

Répandus dans l'ouest du Maroc et toute l'Afrique tropicale, les *Hipposideros* du complexe *caffer-ruber* sont probablement les mammifères les plus nombreux du continent africain, et aussi les mieux représentés dans les collections scientifiques. Cependant, l'individualisation des espèces de ce groupe, composé de populations géographiques variables, est très compliquée, et la systématique en serait à reprendre à l'aide de critères de distinction non exclusivement morphologiques: étude des formes sympatriques et allopatriques, des caractères chromosomiques, de l'écologie et du comportement.

La validité d'une distinction spécifique entre *caffer* et *ruber*, fondée sur des caractères ténus et géographiquement variables, avait été mise en doute (Aellen et Brosset, 1968) jusqu'à ce que Adam et Hubert (1972) aient montré qu'au Sénégal les deux formes vivent en association dans de mêmes gîtes, ce qui prouve leur isolement génétique. L'extension à d'autres régions de l'étude des formes sympatriques du complexe *ruber-caffer* permettrait probablement d'isoler d'autres espèces, non décrites ou considérées comme des sous-espèces de *ruber* ou de *caffer*.

Observations "in natura".

Cinq spécimens d'*H. lamottei* furent capturés près du Pierre Richaud (1 450 m), un autre à la grotte de Blandé (500 m). Ces deux cavités sont distantes de 6 km à vol d'oiseau.

La grotte de Blandé est située au pied du Mont Nimba, près de Ziéla, dans une vallée encaissée, en forêt dégradée. Elle se présente comme un abri sous roche assez vaste, se prolongeant au fond par un réseau dé galeries et sous-bassements exigus. Ces galeries étaient connues pour abriter une colonie d'*Hipposideros ruber* (Aellen, 1963). Nous y avons capturé 3 représentants de cette dernière espèce et 1 *H. lamottei*. Une colonie de *Rousettus aegyptiacus* qui habitait le porche de Blandé

(M. Lamotte, *viva voce*), n'a pas été revue en décembre 1963, bien que de nombreuses traces témoignent de sa présence récente.

La galerie de mine de la face N.E. du Pierre Richaud, où furent collectés 5 spécimens, dont le type de *H. lamottei*, s'ouvre sur une pente abrupte, dépourvue de végétation arbustive. La galerie, creusée dans le minerai de fer, est rectiligne, haute et large d'environ 2 m, profonde d'environ 100 m. La colonie d'*Hipposideros* comptait 130 individus, en majorité du type brun (non rouge, comme *ruber*). Dix individus, examinés à l'extérieur, répondaient au type *lamottei*. Les deux sexes étaient représentés (5 M - 5 F) mais il n'y avait aucun jeune ni aucune femelle visiblement gravide. Le cycle de reproduction est probablement boréal. 4 *Lissonycteris* cohabitaient avec ces *Hipposideros*.

Hipposideros langi J.A. Allen, 1917

p. 434

Text Figs. 4-6.

Type, No. 49098 (skin and skull), M ad., Avakubi, Jan. 24, 1914; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 2481.

A large species, with long, soft, woolly pelage, allied in general features to *Phyllorhina cyclops* Temminck.

p. 435

Upperparts, in general effect, blackish grizzled with white, the pelage being brownish black at base and apically with a narrow subapical zone of white; head grayish brown, much lighter than the back; with dusky eyerings; underparts uniform dusky brown, the tips of the hairs lighter, giving a decidedly grayish general effect, considerably lighter than the back. Proximal half of forearm heavily furred. Ears and membranes naked, blackish brown, the wing and leg bones and the feet much lighter than the membranes, especially on the ventral aspect.

Ears narrow and attenuate, tapering apically to a sharp point. Interfemoral membrane deeply hollowed; tail very short, about one-third of the length of head and body, the terminal vertebra free. Thumb short. A large frontal sac in both sexes, lined with silky straight hairs, wholly white, or white at base with light brownish tips. When the sac is everted these white hairs form a conspicuous white tuft. A glandular pouch is present in males just in front of the anus, lined with long, rusty brown bristly hairs, which when the pouch is everted form a conspicuous tuft, the hairs being more or less obvious even when the pouch is not everted. The females appear to lack the anal pouch, but have in its place a pair of elongated nipple-like papillæ, usually clubshaped or thickened apically. Those are conspicuous in alcoholic specimens and usually readily observed in dry skins. They are situated about 5 mm. apart and have a length of about 8 mm.

Nose-leaf very broad (about 20 mm. wide); posterior leaflet narrow (about 10 mm. wide), with a narrow central point 2 mm. high and 0.5 mm. wide. The nostrils are enclosed posteriorly and laterally by a fleshy conch-shaped border. There is a prominent fleshy knob at the posterior border of the nose-leaf, and two supplemental leaflets, the inner strongly and the outer weakly developed.

p. 436

Type, total length (collectors' measurements), 114 mm.; head and body, 87; tail, 27; foot, 20; ear, 33.
Collectors' measurements of 4 adults (3 females and the male type), total length, 113 (110-116); head and body, 85.5 (83-87); tail, 28 (27-30); foot, 19.5 (19-20); ear, 33.8 (33-35).

Forearm in 10 specimens (6 skins and 4 alcoholics), 68 (66.2-68.8).

Type skull, total length, 28.1; condylobasal length, 25.1; zygomata breadth, 14.0; mastoid breadth, 12; interorbital breadth, 2.8; breadth at base of canines, 8.4; maxillar breadth; 10.7; maxillary toothrow (c-m^3), 10.1; length of mandible, 18.6; mandibular toothrow (c-m_3), 10.0.

Six adult skulls (5 females and the male type), total length, 28.4 (28-29); condylobasal length, 25.2 (24.5-25.7); zygomatic breadth, 15.4 (14.9-15.9); mastoid breadth, 12.1 (11.8-12.4); interorbital breadth, 2.9 (2.8-3.1); breadth at base of canines, 7.8 (7.2-8.4); breadth of rostrum (at point of greatest inflation), 8.2 (8-8.5); maxillar breadth, 11 (10.7-11.3); maxillary toothrow (including canine), 10.1 (9.8-10.4); length of mandible, 19 (18.4-19.4); mandibular toothrow (including canine), 11 (10.9-11.2).

P^2 is minute, and stands outside of the toothrow, the cingula of the canine and p^3 being in close contact.

Posterior border of palate broadly U-shaped, with a slight median point, and extends to a line passing through the posterior border of m^2.

Represented by 14 specimens, of which 5 are alcoholic, collected as follows: Avakubi, 4, of which 3 were taken Jan, 24-26, 1914, and 1 in October, 1913; Niangara, 2, Dec. 3 and 6, 1910; Medje, 7, April 27 and Sept. 3, 1910; Niapu, 1, Oct. 28, 1914. Two of the Medje specimens are half-grown young, and two others are young

p. 437

adults, not fully mature as regards size. The others are fully adult, all with perfect skulls except the Niapu specimen, of which the skull is too much broken for measurement.

The specimens represent two seasonal periods, April, and September-January. The April specimens (from Medje), in worn pelage, are browner and the light tips of the hairs are stained faintly yellowish in contrast with the clear blackish brown ground-color and whitish hair-tips of the Septem-

p. 438

ber-October and January specimens. That the difference is probably purely seasonal is indicated by a Medje specimen taken in September, which is dark with white hair-tips, like the October-January specimens from other localities.

In its soft woolly pelage and other external features *Hipposideros langi* appears to resemble closely *Phyllorhina cyclops* Temminck, from the Boutry River, Guinea, but it is a much larger species and darker in coloration, being blackish brown with white hair-tips instead of dull brown with yellowish hair-tips. *H. cyclops*, however, appears to be little known, the only original references to it being Temminck's description and Dobson's account, based on two specimens, including one from the Cameroon Mountains, the other without definite locality. Neither of these descriptions is very satisfactory, the character of the skull not being mentioned in either. Dobson's measurements indicate a total length of about 93 mm., and Temminck's a total length of about 89 mm., as against an average of 113 mm. for 4 specimens of *H. Langi*. Dobson gives the length of the forearm as 62.2, as against an average of 68 in 10 specimens of *H. langi*. Temminck gives the length of the forearm as 38 mm. ("antibrachium 1 police 7 lignes"), which is obviously an error (possibly a misprint for 2 pouces 6 lignes = 63 mm.). The type localities of the two forms are widely separated. Dollman, however, has recorded two specimens from Avakubi (Rev. Zool. Africaine, IV, fasc., 1, 1914, p. 70), as "*Hipposideros cyclops*, Temm.," which probably are referable to the present form.

H. langi differs greatly from all the African species of the genus *Hipposideros* except *cyclops*, from which it is distinguishable by much larger size and darker coloration.

Hipposideros marisae Aellen, 1954

p. 474

TYPE. - M adulte, collection personnelle; n° original 400; Duékoué (Côte d'Ivoire), rocher de la Panthère Blanche, 13.5.1953.

DIAGNOSE. - *Hipposideros* de petite taille (avant-bras 41 mm.), voisin de *curtus* du Cameroun (avant-bras 44-47 mm.) dont il a les mêmes proportions externes, mais s'en distinguant par la feuille nasale plus petite qui ne possède qu'une seule foliole secondaire très rudimentaire (deux dans *curtus*) et par la forme du crâne dont la largeur zygomatique est subégale à la largeur mastoïde, alors que cette dernière est plus grande chez *curtus*.

DESCRIPTION. - Les oreilles sont grandes, presque aussi larges que longues, bien séparées sur le sommet de la tête, de même forme que chez *curtus*, c'est-à-dire que le bord interne est régulièrement convexe; le sommet à angle droit est arrondi et le bord externe présente une échancrure à 1.5 mm. du sommet; le lobe antitragal est séparé du pavillon par une deuxième échancrure moins importante; à ce niveau, il n'y a pas de pli interne ("internal fold") comme chez les espèces du groupe *bicolor*, auquel la nouvelle espèce pourrait s'apparenter.

Le sac frontal est très net et s'ouvre transversalement à 1 mm. en arrière du processus postérieur de la feuille nasale.

Celle-ci est du type *curtus* et ne diffère essentiellement que par ses dimensions nettement inférieures: la largeur du processus postérieur représente le 13 % de l'avant-bras pour 16-16.5 % chez *curtus*. Il n'y a qu'une seule foliole secondaire très petite et peu visible; en réalité, il s'agit plutôt d'une verrue allongée que d'une vraie petite feuille.

p. 475

Les plis palataux sont au nombre de six; les trois premiers sont nettement courbes et les trois derniers presque droits; le 3^{e} est situé entre les dents P^4-M^1, le 6^{e} au milieu de M^2.

L'aile présente les mêmes proportions que celle de *curtus*. Les métacarpes III et V sont subégaux, le IV ^{e} légèrement plus long.

Les tibias sont longs (44 % de l'avant-bras), de même que les pieds (env. 18 % de l'avant-bras). La queue est remarquablement courte (48 % de l'avant-bras) et libre sur les deux derniers millimètres.

Le patagium est inséré à l'extrémité distale du tibia, comme chez *curtus*.

La coloration est très uniforme: gris foncé dessus et dessous; les oreilles et le patagium sont brun-noir; la feuille nasale est noirâtre sur les bords et au processus postérieur, brun clair au processus médian (selle).

La forme générale du crâne est la même que chez *curtus* et bicolor. On peut remarquer la petitesse du rostre et la grande largeur zygomatique: le renflement nasal (mesuré au-dessus de l'insertion antérieure des arcades zygomatiques) n'est que le 46 % de la largeur zygomatique, alors que chez *curtus*, il représente le 54 % et chez *bicolor* le 50 %. Ce faible renflement nasal donne au crâne un profil supérieur peu concave, au-dessus des orbites. Les bulles tympaniques sont relativement petites. La largeur mastoïde est légèrement inférieure à la largeur zygomatique. La crête sagittale est faiblement développée.

Les dents ne présentent aucune particularité et sont tout à fait comparables à celles de *curtus*. Les incisives supérieures sont simples, sans trace de lobe postérieur et la couronne est dirigée vers l'intérieur. La canine est nettement séparée de la 2^{e} prémolaire (P^4) par la 1re prémolaire (P^2) qui est très petite et située au bord externe de la rangée dentaire. La dernière molaire

(M^3) est réduite dans les mêmes proportions que chez les espèces du groupe *bicolor* et chez *curtus*. Les incisives inférieures sont tricuspides, I_1 chevauchant I_2. La canine est étroite et la 1re prémolaire inférieure (P_2) mesure environ la 1/2 de la hauteur de la 2e (P_4).

REMARQUES SUR LA POSITION SYSTÉMATIQUE DE *H. marisae*. - Cette nouvelle espèce n'entre dans aucun des groupes définis par

p. 476
[Tables removed - Eds.]

p. 477

TATE (1941). Elle se rapproche le plus de *curtus* du Cameroun, que son descripteur, G. M. ALLEN (1921) compare à *beatus* et *caffer guineensis*. TATE place *curtus* dans le groupe *caffer* qu'il fait dériver du groupe indo-australien *galeritus*. Cependant, j'ai déjà attiré l'attention sur les affinités possibles de *curtus* avec le groupe indo-australien *bicolor* (AELLEN, 1952).

Il semble bien que l'on ne peut pas admettre *curtus* dans le groupe *caffer*. TATE a principalement étudié les rapports entre les formes orientales du genre *Hipposideros*; il dit précisément (1941, p. 353): "African species of *Hipposideros* haven been studied only in order to learn their relationships to Oriental species. No study bas been made of sub-relationships within African groups, such as *caffer* and its allies."

Dans le tableau comparatif suivant, je résume les principaux caractères distinctifs de *marisae*, de *curtus* et des espèces des groupes *bicolor* et *caffer*. Le groupe *galeritus*, duquel le groupe *caffer* semble dérivé, présente généralement les caractères indiqués ci-dessous pour *caffer*.

Avec ces données, on se rend compte que les espèces *marisae* et *curtus* s'écartent notablement du groupe *caffer*; elles de rapprochent beaucoup du groupe *bicolor*, mais les différences me

p. 478

[table removed - eds.]

p. 479

semblent suffisantes pour justifier la création d'un nouveau groupe qui est ainsi défini:

Groupe *curtus*, n. gr.

Oreilles grandes (40-45 % de la longueur de l'avant-bras), plus longues que larges, à bord externe concave sans pli interne à la base. Sac frontal présent chez le mâle, parfois absent chez la femelle (type de *curtus*). Feuille nasale de taille variable, mais présentant une cloison internariale élargie, claviforme; 1 ou 2 petites folioles secondaires. IVe métacarpe plus long que les IIIe et Ve. Indice de largeur 19-22, indice digital 1.15-1.17. P^2 petite, située au bord externe de la rangée dentaire, séparant C de P^4.

Hipposideros nanus J.A. Allen, 1917

p. 434

Type No. 49426 (alcoholic), F ad., Faradje, Uele district, Belgian Congo, Oct, 24, 1912; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1689.

A very small species of the *H. beatus* type.

Upperparts dusky brown, the hairs dark at base and tips with a broad median zone of white; underparts lighter, the hairs with grayish tips; ears and membranes dark brown.

Total length, 68 mm.; head and body, 46; tail, 22; forearm, 43.4; third metacarpal, 31; tibia, 16.5; foot, with claws, 7.9; ear, length, 9.2, width, 12; greatest breadth of horseshoe, 5; of posterior leaf, 5.5.

Skull, total length; 16.2 (16.8) ; zygomatic breadth, 8.2 (9.7); mastoid breadth, 8.5 (9.2); maxillary breadth, 5.5 (7), breadth at base of canines, 4.5 (4.3-4.7); mandible, 9.5 (10.7-11.3); upper toothrow (c-m^3), 5.2 (5.9-6.2); lower toothrow, 5.7 (6.2-7).

Represented by only the type.

Hipposideros nanus is nearly related to *H. beatus* Andersen (*l. c.*, p. 279), from near Benito River, Guinea, and may be considered as its geographical representative in the Uele district of northeastern Belgian Congo.

Hipposiderus beatus K. Andersen, 1906

p. 279

Smaller than *H. caffer*, with very short tail and tibia. Skull small and very broad-jawed.

In all forms of *H. caffer* the maxillary width (across the antero-external corners of m^3) is practically equal to the length of the maxillary tooth-series; in *H. beatus* the former is markedly greater than the latter (7 mm. as against 5.9-6.2); the great maxillary width, combined with the small size of the skull, makes the cranium of *H. beatus* easily distinguishable from that of any race of *H. caffer*. The zygomatic width is larger than the mastoid width, as in *H. c. centralis* and *guineensis*.

The teeth are of the same size as in the small-toothed *H. c. typicus*. The dentition, although in all essential respects

p. 280

as in *H. caffer*, seems to be a trifle more advanced: p^2 is in all the three specimens examined exceedingly small, so small indeed as to be very easily overlooked.

Externally this bat is readily distinguished from *H. caffer* by its small size and very short tail and tibia (see measurements below, p. 282). The wing-membrane is inserted on the middle or distal part of the metatarsus or on the base of the phalanges; in *caffer* it is never produced further backwards than the base of the metatarsus, and this but very rarely.

Type: - F ad. (in alcohol). 15 miles from Benito River; Feb. 1899. Collected by G. L. Bates, Esq. Brit. Mus. no. 0.2.5.45. - A second specimen (Brit. Mus. no 5.5.23.11), also obtained by Mr. Bates, is from Efulen, Cameroons. A third specimen +, from Mt. Coffee, Liberia is preserved in the Washington Museum (no. 83857) ++.

Judging from this, *H. beatus* is distributed over the countries bordering the Gulf of Guinea, from Benito River to Liberia. This it inhabits the same region as the large-skulled and large-toothed *H. c. guineensis*.

* Dention in 76 skulls of *H. caffer* (all races): - p_3 always wanting. p_2 and p_4 never separated; in 10 specimens in simple contact, in 66 overlapping each other at bats. p^2 always external to the series and always easily observable. Upper canines and p^4 in 21 specimens distinctly separated; in 39 extremely slightly separated or almost in contact; in 3 completely in contact on one side of the jaw only, in 13 on either side.

+ For the loan of this specimen I am indebted to the Authorities of the United States National Museum. It is one of the *Hipposiderus caffer* mentioned by Gerrit S. Miller in his paper on a collection of small mammals from Mount Coffee, Liberia (Proc. Wash. Acad. ii (1900) p. 647; forearm 42 mm.).

++ A fourth specimen, not examined by me, is in a Continental (probably Swedish or German) Museum: - In his "Säugethiere aus Kamerun, West-Afrika" (Bih. Kgl. Svenska Vet.-Akad. Handl. xxiii. Afd. iv. no. 1, p. 18; 1897) Dr. Yngve Sjöstedt gives some external measurements of 10 "*H. caffer*"; no. 1 is Sundevall's type, from Port Natal; nos. 2-8 and 10, all from Cameroon, are probably *H. c. guineensis*; no. 9, also from Cameroon, with the forearm measuring 44 mm., the tail 24, and the tibia 16, is undoubtedly a *H. beatus*.

Hipposiderus caffer centralis K. Andersen, 1906

p. 277

Large-toothed, large-skulled, and broad-jawed.

The skull is larger and in every respect more heavily built than in the typical form. The zygomatic width is almost invariably slightly larger than, or at least equal to, the mastoid width, which gives the skull in upper view a very characteristic aspect as compared with that of *H. c. typicus*. The maxillary width is markedly larger: 6.8-7.1 mm., as against 6-6.2 in the typical form; in conformance with this the width across the canines and the anteorbital width are slightly larger. The teeth are considerably larger, the mandible longer.

Externally, this form is *on an average* larger than *H. c. typicus*, but the difference is practically far less well marked than in the skulls and teeth (for details, see *H. c. typicus*). The colour of the fur, both in the dark and red phase, is darker than in the typical form, but lighter than in *H. c. guineensis* (see this latter, below).

Type: - M ad. (skin). Entebbi, Uganda. Presented by F. J. Jackson, Esq. Brit. Mus. no. 99.8.4.8.

26 specimens have been examined, from: - Takaungu, Mombasa, British East Africa (4); Dar es Salam, German East Africa (1); Zomba, Nyasa (1) §; Entebbi, Uganda (9); Stanley Falls, Upper Congo (3); Leopoldville, Lower

p. 278

Congo (2)*; Wathen, Lower Congo (1); 75 miles up the Congo River (4)*; Caiala, Bihé, Angola (1)+. - 16 skulls, from all the localities enumerated.

According to this, *H. c. centralis* is distributed in a broad belt across the Equatorial region of Africa, from British and German East Africa and Nyasaland in the East, through Uganda and the whole of the Congo Valley, to the western coast of the continent; like the typical form it extends to Angola.

Hipposiderus caffer guineensis K. Andersen, 1906

The extreme in the maxillary width of the skull and the intensity of the colour of the fur.

The skull and teeth of this form are of the same size as in *H. c. centralis*; but the maxillary width on an average decidedly larger: 7-7.7 mm., as agains 6.8-7.1.

External dimensions as in *H. c. centralis*.

The colour of the fur is markedly darker than in any other race: - Back approaching "seal-brown," base of hairs scarcely lighter; upperside in front of the shoulders "hair-brown," base of hairs next to "bistre"; underside dull "drab," base of hairs next to "bistre." - I have seen no very young specimens of this form.

Also the red phase is darker than in the other races: - Upperside "cinnamon-rufous," in some individuals so dark as to approach "chestnut"; underside "cinnamon-rufous" or "hazel." Different at a glance from the corresponding phase of the typical form.

Type: - F ad. (skin). Como River, 70 miles from Gaboon, almost sea-level; June 3rd, 1897. Collected by G.L. Bates, Esq. Brit. Mus. no. 97.12.1.11.

27 specimens examined, from: - Como River (4); Gaboon (1); Benito River (4); Fernando Po (9)++; Cameroon Mts. (1); Efulen, Bulu Country, Cameroon, 1500-1800 ft. (4); Old Calabar (1); Mt. Coffee, Liberia (3) §. - 23 skulls, from all the localities enumerated.

According to this, *H. c. guineensis* is distributed from

p. 279

Como River westwards, through the countries bordering the Gulf of Guinea (including the island of Fernando Po), at least as far as Liberia.

Hypsignathus H. Allen, 1862

p. 156

Head large, massive. Face greatly developed, anterior portion humped. Nose very high, blunt, corrugated. Nostrils produced; opening laterally; bounded internally and inferiorly by a projection of the coriaceous membrane, which by its continuation externally forms a lateral fold. This expansion, after descending from the posterior part of the nostril to the lip, runs along the line of the upper jaw, forming the outer wall of a distinct groove, the inner wall of which is made by the true lip. Just as this remarkable membrane turns down from the anterior nares, it also extends forward, clearly defining the boundaries of the snout. From the lower anterior part of each nostril a leathery ridge extends to the mouth. These divide the muzzle into three distinct sulci. The chin is peltated, and indistinctly divided into halves by a mesial line. Ears small, naked, without tragus and tufted at base. Wings thrown very far back. Basal joint of thumb small. Index finger clawed. Interfemoral membrane small, ecaudate. Lower incisors closing anterior to the upper.

Dental Formula, m $^{3}/_{5}$, c $^{1}/_{1}$, i $^{4}/_{4}$, c $^{1}/_{1}$, m $^{3}/_{5}$ = 28.

Skull remarkably high. Nose broad at summit, occasioned by the development of the nasal bones. Extending from the canines to near the top of the face is an irregular ridge for the insertion of the curious nasal membrane already noticed. The infra-orbital foramen opens posteriorly to the entire dental series. The skull is broader between the eyes than in other Pteropines. Post-orbital processes stout, short and pointed outwards and backwards. Cranium small, comprising but a third of the entire head. A parietal crest is present for about two-thirds its length, when it abruptly terminates at the apex of a small triangle which is formed by the want of approximation of the hinder

p. 157

portion of the temporal fossæ. Occipital ridge well marked and leaning backwards. Foramen magnum orbicular. Palatal bones united with the deeply arched mouth by a greater angle than that of *Pteropus*. The foramen incisivum is cordate.

The *lower jaw* is flattened and irregular, depressed at symphysis. The two halves unite at a less acute angle than in *Pteropus*. The coronoid process is low, and the angle which it forms with the alveolar ridge is so slight that the distance from the top of the process to the last molar is equal to one half the distance from the same point to the small pre-molar. The condyloid process is about one-half the distance between the base of the jaw and the top of the coronoid.

The superior incisors are small unicuspid, regular and separated from one another. The distance between the canines and the laterals is greater than the distance from one incisor to another. The canines are slender, convex anteriorly, point slightly backward, and, when the jaws are closed, nearly touch the plane on which the skull rests. The first molar is pointed; the second and third are much alike, the posterior being smaller and less trenchant, the external cusp being the larger.

The inferior incisors are small, separated, the space between the centrals exceeding that between the laterals. The canines are smaller and blunter than those above, and lean strongly backwards. The premolar, which is absent above, is here present; it is very minute, shaped, like an incisor, is nearer the canine than the second molar, is directed backward and outward, and, when the jaws are closed, is observed to be placed *anterior* to the superior cuspidatus. The first and second molars assume the carnivorous type; the second has two cusps divided as usual by a longitudinal groove; the third and fourth have their cusps much worn, the latter being little more than flattened tubercles.

As mentioned above, the articulation is curious; the inferior incisors close in front of the superior, so as to completely hide them.

Kerivoula africana Dobson, 1878

p. 335

Ears and tragus almost quite similar to those of *K. hardwickii*, but longer than the head; thumb shorter; wings from the base of the toes.

The fur extends upon the base only of the interfemoral membrane and along the legs to the backs of the feet; a few fine hairs extend along the calcanea and margin of the interfemoral membrane, but not so thickly as to form a fringe. The face is nearly naked between the eyes, but long hairs arise from the glandular eminences in front, and also form a fringe along the margin of the lips.

On the upper surface the fur is dark brown at the base, the extremities greyish brown; beneath similar, but paler.

Inner upper incisor on each side long, with a distinct outer cusp; outer incisor unicuspidate, exceeding the outer cusp of the inner incisor, and nearly equalling that tooth in vertical extent. First upper premolar smaller than the third and equal to the second premolar; lower premolars equal.

Length (of the type, a M, preserved in alcohol), head and body 1".35, tail 1".35, head 0".5, ear 0".5, tragus 0".3, forearm 1".1, thumb 0".2, third finger 2".15, fifth finger 1".6, tibia 0".45, calcaneum 0".5, foot 0".25.

Hab. East coast of Africa (Zanzibar).

Type in the collection of the Paris Museum.

This is the smallest species of *Kerivoula* as yet described. It resembles *K. hardwickii* very closely in general form, but may be at once distinguished by the upper incisors.

Kerivoula argentata Tomes, 1861

p. 32

In the Proceedings of this Society for 1858 I described at some length the peculiarities of the present group of Bats, giving my reasons for regarding these peculiarities as generic. All that was stated respecting the several species then enumerated may with equal exactness be said of the present one; and I may add that I have since that time again examined the fine collection of Bats in the Leyden Museum, and that, with the exception of identifying my specimens of *K. papillosa* with the *Vespertilio papillosus* of M. Temminck, and examining a specimen of my *K. ærosa*, labelled "Gorontalo," I saw nothing which in any way either confirmed or modified my previous opinions of the genus.

The present species is of larger size than either of the African species before described, fully equal in size to the *K. papillosa*, and in the colour of its fur it differs from all the other species.

Compared with the African species which it most nearly resembles, it possesses some of the characters of both *K. lanosa* and *K. ærosa*.

The top of the head is elevated in about the same degree as in *K. ærosa*; and it greatly resembles this species in the shape of the muzzle and the distribution of the hair on the face; but in the shape of the ears it approaches more nearly to *K. lanosa*, differing from it only in having the inner rounded margin toward the top of the ears more prominent even than in that species. The tragus is remarkably narrow, and tapers evenly to an exceedingly acute point; near the bottom of its outer edge is a narrow notch, or rather slit, and below it a small and pointed process, which is placed, in fact, immediately above what may be called the foot-stalk or narrow root of the tragus. Inside the ear, and vertically beneath the tragus, is a well-defined fleshy tubercle, of a flattened form, and about one line in length.

In the quantity and distribution of the fur on the membranes, this species is intermediate between *K. lanosa* and *K. ærosa*, but it has fewer adpressed hairs on the wings than either. The fur of the back extends on to the membranes of the flanks a little, and on to the interfemoral membrane in a scattered manner, but more thickly on to the tibiæ and feet, especially on to the latter, which are well clothed. Beneath, it extends a little on to the membranes near the sides of the body. The *os calcis* is well clothed with short adpressed hairs; and between it and the tail-tip the membrane is fringed with closely-set hairs, which curve downwards and have a comb-like appearance, as in *K. lanosa*.

The fur is everywhere long and silky; that of all the upper parts is of four colours - at the root very dark grey for a fourth of its length, then yellowish, passing into a pale but bright rust-colour, and the tips of the hairs of a shining and silvery white. There is very little variation in the colouring of the different parts of the upper surface. Beneath, the fur is unicoloured and dirty-white, on the sides of the neck and on the cheeks-tinged with rust-colour.

The teeth, as far as may be gathered from inspection without re-

p. 33

moving the skull from the specimen, are like those of *K. lanosa*, the upper incisors being, as in that species, nearly of the same length. The outer incisors in the lower jaw have the singular and prominent cusp, which I have mentioned as peculiar to the genus, quite as much developed as in any of the species.

Hab. "Otjoro, December 1st, 1859. Female."

Kerivoula brunnea Dobson, 1878

p. 334

Ears slightly shorter than the head, laid forwards the extremities do not extend quite to the end of the muzzle; ear-conch very similar in outline to that of *K. picta*; tragus with a slight indication of a lobe at the base of the outer margin, which, however, is not succeeded by an emargination, and the projection opposite the base of the inner margin is obtuse.

Fur, above, yellowish brown, the basal half of the hairs very dark brown or black; beneath paler or grayish brown, the base of the hairs also dark-coloured; very long and dense, covering nearly half the upper surface of the interfemoral membrane, and extending along the legs to the backs fo the feet; the posterior margin of the interfemoral membrane has a comb-like fringe of curved hairs of equal length, as in *K. picta* and *K. lanosa*. Membranes dark brown.

Upper incisors nearly equal in length and in cross section, the inner incisor on each side with a small postero-external basal cusp visible from the front; of the lower incisors the outer on each side has a blunt cusp rising considerably above the others; second upper premolar slightly smaller than the first, with a more oblique cusp inclined forwards.

Length (of a not full-grown M), head and body 1".5, tail 1".9, head 0".55, ear 0".5, tragus 0".35, forearm 1".3, thumb 0".25; third finger - metacarp. 1".25, 1st ph. 0".65, 2nd ph. 0".8; fifth finger - metacarp.1".2, 1st ph. 0".4, 2nd ph. 0".3; tibia 0".55, foot 0".3.

Hab. Uncertain.

This species is at once distinguished by the very dark colour of its fur, by the comb-like fringe along the interfemoral membrane behind, and by the large size of the upper outer incisors.

P. 335

The type specimen has suffered from long soaking in weak alcohol, which has denuded it of much of its fur, and it is possible that the anterior extremities may have had short hairs clothing them as *K. lanosa*, especially as some hairs are found still adhering to the outer margin of one wing.

A. M (not full-grown), al. Madras or South Africa. Sir A. Smith [P.].

Kerivoula cuprosa Thomas, 1912

p. 41

A small speckled brown species with short incisors.

Size decidedly less than in the related species *K. ærosa* and *lanosa*. Fur soft and fine (hairs of back 6 - 6.5 mm. in length), extending on to the forearm, thinly along the pollex and terminal part of the third digit, and down the upper side of the legs on to the feet; proximal part of interfemoral thinly haired, naked distally, the hinder margin with a

p. 42

number of fine hairs not forming a fringe; under surface of legs and interfemoral nearly naked. General colour above dark bistre-brown, the tips of many of the hairs conspicuously contrasted silvery buff, those on the forearms, rump, and hind limbs more ochraceous buff; under surface duller brown, the bases of the hairs dark slaty, the tips of some of the hairs whitish.

Ears of medium length, anterior border strongly convex, posterior with a sharp concavity just below the tip. Tragus long, curved outwards, its base with a, small lobule externally succeeded above by an emargination.

Upper incisors unusually short, their enamel-covered portion but little longer than the projecting part of their root, the inner one bicuspid, its posterior cusp as thick as and half the height of the anterior. Outer incisor also bicuspid, owing to its basal ledge being raised up postero-internally as a second cusp half the height of the main cusp. Middle premolar about two-thirds the height and area of the anterior one. Outer lower incisors tricuspid, the outer cusps half as large as the median one. Middle lower premolar rather smaller than the subequal first and last.

Dimensions of the type (the starred measurements taken in the flesh by the collector): -

Forearm 32 mm.

Head and body *45; tail *45; ear *13.5; tragus on inner edge 5.5; third finger, metacarpal 3.1, first phalanx 15; lower leg and foot (c. u.) 21.

Front of upper canine to back of m^3 5.1; front of lower canine to back of m_3 5.5.

Hab. Bitye, Ja River, S.E. Cameroons. 2000'.

Type. Adult male. Original number 564. Collected 17th October, 1911, by Mr. G. L. Bates.

This well-marked species resembles *K. ærosa* in colour, but is much smaller, the forearm of that animal being 37 mm. in length. By the characters used in Dobson's synopsis it comes nearest to *K. lanosa*, but differs both by size and colour, and, as from every other, by its peculiarly short and deeply bicuspidate upper incisors. At Bitye Mr. Bates also obtained the little *K. muscilla* and an additional specimen of *K. smithii*, described by me in 1880. The latter is slightly larger than *K. cuprosa* and has practically unicuspid outer lower incisors.

Kerivoula harrisoni Thomas, 1901

p. 802

Most nearly allied, according to the characters used in Dobson's synopsis, to *K. lanosa* A. Smith, but considerably smaller. Fur very long, soft, and woolly, the hairs of the back about 9 mm. in length. Muzzle thickly hairy. Back of ears hairy, except at the edges, these and the whole inner surface practically naked. In shape the ears are very much as in *K. lanosa*; their inner margin slightly convex below, more strongly so above; tip inconspicuous, behind and below the level of the most convex point of the anterior edge; below the tip a marked concavity, after which the hinder edge is evenly convex to its base. Tragus, so far as can be seen in the dried skin, very like that of *K. lanosa*; its basal lobe small.

Fur of back not extending on to the wing-membranes, but the interfemoral is clothed basally with scattered long hairs; the legs are thickly clothed down to the toes; the upperside of the tail is well haired to the tip, and the interfemoral membrane has a thick fringe of hairs along its posterior edge. The forearm is irregularly tufted with line golden hairs, which are Continued on the thumb to the base of its claw, and again along the final edge of the second digit, edge of wing-membrane, and terminal part of third digit to the extreme tip of wing.

The general colour of the back is a dull "old gold," the woolly hairs being blackish basally, then dull huffy orange with their tips blackish, longer hairs tipped with silvery yellow. The hairs on the legs, feet, tail, and calcars, like those on the forearm, golden yellow, but the interfemoral fringe is a dull pale brown. Belly-hairs blackish basally, dull buffy white terminally.

Skull very fine and delicate, on the whole very like that of *K. brunnea* Dobs., though the nasal notch is not so deep.

Upper outer incisors nearly as long as the inner ones, the former with a low postero-internal secondary cusp, the latter with a posterior one at about the level of the tip of i^2.

Forearm 31.5 mm. Front of canine to back of m^3 5.2.

Hab. Walamo, between Lakes Suai and Margherita, N.E. Africa. Alt. 6700 feet.

Type. B.M. No. 0.11.4.1. 21st February, 1900. Collected and presented by Mr. J. J. Harrison.

No species hitherto described can be confused with *K. harrisoni*. *K. lanosa*, is larger and of a different colour; *K. smithi* has no interfemoral fringe; *K. ærosa* has minute outer incisors; and *K. brunnea* and *K. africana* have the same teeth unicuspidate, and the tragus of a different character.

Kerivoula harrisoni bellula Aellen, 1959

p. 221

Type. - M adulte, en alcool. Adiopodoumé, près d'Abidjan, Côte-d'Ivoire, 20.7.1953; coll. V. Aellen, n° orig. 622. Muséum d'Histoire naturelle de Genève, n° 965.38.

p. 222

Matériel examiné. - De la Côte-d'Ivoire, j'ai rapporté un autre spécimen provenant aussi d'Adiopodoumé, 21.12.1953, leg. U. Rahm (F n° 965.39 Mus. Genève). Les exemplaires suivants ont encore été examinés :

1 M subadulte, Hill-Town, Du Queah River, Libéria, 25.2.1887. Musée de Leyde. Signalé par JENTINK (1888) sous le nom de *Kerivoula africana*.

1 M; 1 ?, Ntronang, Ghana, 2.9.1945. British Muséum n° 46.118 et 46.119.

1 M, Mukonje, Cameroun anglais, 1905. Musée zoologique de Strasbourg, n° 20g. Signalé par AELLEN (1957) sous le nom de *Kerivoula* sp.

1 F, Pawa, district Kibali-Ituri, Congo belge . Musée royal du Congo belge, Tervuren n° 15729. Indiqué par SCHOUTEDEN (1944) sous le nom de *Kerivoula ? argentata*.

Diagnose. - *Kerivoula* de petite taille (avant-bras de 28,5 à 33 mm) à frange interfémorale très nette. Les premières incisives supérieures (I^1) sont bicuspides. Le rostre est long, c'est-à-dire que la rangée dentaire C-M^3 est égale ou plus longue que la largeur maxillaire (M^3-M^3). Diffère de *K. h. harrisoni* par ses oreilles qui sont plus longues: 11 à 12,5 mm au lieu de 8,8 mm; le tragus est plus long également: 5,8 à 6,5 mm au lieu de 5,3 mm.

Remarques. - Depuis quelques années, j'ai entrepris la révision des formes africaines du genre *Kerivoula*. Cette étude m'amène à croire que *K. lucia* Hinton n'est qu'une forme
de *K. harrisoni* Thom. et non de *K. lanosa* (A. Smith), comme le pensent ROBERTS (1936) et ELLERMAN, MORRISON-SCOTT et HAYMAN (1953). En effet, chez *K. harrisoni* et *K. lucia*, le rostre est relativement long (C-M^3 = ou > M^3-M^3) et les premières incisives supérieures (I^1) sont bicuspides, alors que chez *K. lanosa*, le rostre est court (C-M^3 = ou < M^3-M^3) et les premières incisives unicuspides [1].

K. harrisoni n'est connu que par la description originale de THOMAS (1901), basée sur l'examen d'un seul spécimen (British

p. 223
Muséum n° 0.11.41, peau sèche). Il existe au British Muséum un second spécimen, provenant de Taveta, Kenya (n° 9.6.12.18, en alcool), dont M. R. W. Hayman m'a aimablement communiqué les principales mensurations.

K. lucia, par contre, est mieux connu; j'en ai examiné une demi-douzaine d'exemplaires du SE du Congo belge, du Ngamiland et du Natal. Très semblable à *K. harrisoni*, il n'en diffère guère que par une oreille et un tragus plus longs, des proportions légèrement différentes du crâne.

Si mes conclusions sont correctes, la répartition géographique de *K. harrisoni* se présenterait ainsi:

K. h. harrisoni: Ethiopie, Kenya.

K. h. lucia: SE du Congo belge, N Rhodésie, Nyasaland, Ngamiland, Natal.

K. h. bellula: région forestière du Libéria à l'E du Congo belge: Libéria, Côte-d'Ivoire, Ghana, Cameroun, Congo belge.

Description. - Les oreilles mesurent de 11 à 12,5 mm; le tragus de 5,8 à 6,5 mm au bord interne. Le lobule de la base du bord externe du tragus, qui sert de principal caractère dans le synopsis des espèces de DOBSON (1878), semble variable d'un spécimen à l'autre: chez le type, il est à peine indiqué, alors que chez le paratype, provenant du même lieu, il est petit, mais bien marqué; il est présent sur les spécimens du Cameroun et du Congo, peu marqué chez celui du Libéria, à peine indiqué ou absent chez ceux du Ghana. Les avant-bras, les doigts et les jambes sont de dimension et de proportion semblables à celles de *harrisoni* et de *lucia*. L'avant-bras est peut-être à peine plus court: *bellula*, moyenne 6 spécimens: 30,75 mm; *lucia*, moyenne 8 spécimens: 31,33 mm; *harrisoni*, moyenne 2 spécimens: 31,55 mm. La frange interfémorale du bord libre de l'uropatagium est très bien marquée, comme d'ailleurs chez *harrisoni* et *lucia*.

La coloration n'offre rien de particulier pour un *Kerivoula*. Les descriptions qu'en donnent THOMAS (1901) et HINTON (1920) s'appliquent presque mot pour mot au type de *bellula*. Le dessus est gris clair un peu brunâtre; les poils sont gris souris à la base, brun très clair au sommet; beaucoup présentent une

p. 224

pointe blanc brillant, ce qui donne un reflet argenté surtout visible au niveau des jambes. Les avant-bras, le pouce, le deuxième doigt, la base du métacarpe du cinquième, les jambes, les pieds et la plus grande partie de la queue sont couverts de poils plus ou moins longs de couleur jaune paille; ces poils sont particulièrement longs sur les jambes et donnent à celles-ci un reflet doré. Il y a quelques longs poils épars sur la moitié proximale de l'uropatagium. Le dessous est assez semblable au dessus, mais moins brunâtre; le reflet argenté s'étend surtout à la poitrine; les avant-bras, les doigts, les jambes et la queue sont nus; il y a quelques poils très courts, groupés par deux ou trois, sur les lignes glandulaires transversales de la moitié proximale de l'uropatagium. Les oreilles sont brun clair, un peu translucides; la moitié basale et le tragus sont crème. Les glandes faciales, bien que recouvertes de poils, sont très apparentes et de couleur orange vif; cette couleur est due à leur sécrétion grasse.

Les premières incisives supérieures (I^1) sont bicuspides; la pointe postérieure atteint presque la hauteur de la seconde incisive. Celle-ci mesure environ les quatre cinquièmes de la première, en hauteur. La première incisive inférieure est quadricuspide, la seconde tricuspide, la troisième tricuspide avec la pointe médiane plus développée que les latérales. Ces caractères dentaires se présentent, non seulement chez le type, mais aussi
chez tous les *K. h. bellula* examinés.

Dans le tableau de mesures suivant, j'ai indiqué, à titre de comparaison, celles du type de *K. h. harrisoni* et d'un autre spécimen du Kenya (mesures communiquées par R. W. Hayman) et les minima et maxima de *K. h. lucia*, déduits des données de la littérature et d'examens personnels.

A l'échelle spécifique, *K. harrisoni* se distingue des autres *Kerivoula* africains à frange interfémorale nette par les caractères de la clé suivante:

1. Taille grande: avant-bras + troisième doigt de 109 à 128 mm. Long. totale du crâne (aux incisives) de 15 à 16 mm. I^1 unicuspide (parfois une deuxième pointe postérieure basse). M^3-M^3 généralement > C-M^3. --> *argentata* Tomes

p. 226

- Taille moyenne ou petite: avant-bras + troisième doigt de 88 à 106 mm. Long. totale du crâne de 12,7 à 13,6 mm. --> 2

2. I^1 bicuspide. Rostre long: C-M^3 généralement > M^3-M^3. --> *harrisoni* Thom.

- I^1 unicuspide. Rostre court: M^3-M^3 généralement > C-M^3. --> 3

3. Taille moyenne: avant-bras de 30 à 35,5 mm. Troisième doigt de 65 à 72 mm. Long. totale du crâne de 13,2 à 13,6 mm. --> *lanosa* (A. Smith)

- Taille petite: avant-bras de 29 à 31 mm. Troisième doigt environ 60 mm. Long. totale du crâne 12,7 mm. --> *muscilla* Thom.

Kerivoula lucia Hinton, 1920

p. 240

Kerivoula lucia, sp. n.

Type. - An adult male collected at N'dola on Sept. 26, 1919 [by Capt. Guy C. Shortridge (see page 239)]; original number 472. No other specimen seen.

p. 241

This species closely resembles *K. lanosa* in general appearance, but it is distinguished by its rather smaller size, smaller and less hairy ears, greyer colour, and by some characters of the skull.

Size small, forearm 30.5 mm. Fur on body and top of head very long, dense, and woolly, closely resembling that of *lanosa* in quality. Cheeks in front of ears nearly naked. Ears very sparingly haired on outer surface, nearly naked within. Forearm, thumb, and outer edge of dorsal surface of wing clothed with tufts of hair; upper surface of tibia, hind foot, and tail similarly clothed. Interfemoral membrane with tufts of hair along the veins on dorsal surface, similar but smaller tufts of hair on ventral surface; with a well-developed posterior fringe. Ears smaller than in *lanosa*, with a somewhat deeper, though narrower, lateral emargination towards the tip; tragus normal.

General colour of back between "sepia" and "dusky drab," passing to a light grey on top of head and muzzle. Dorsal hairs with slaty bases, mostly with long yellowish-brown tips; in many the tips are silvery, and these silver tips produce a quite conspicuous "lining" on the back and rump. Under surface silvery grey, darkened irregularly by the partly visible slaty bases of the hairs. Hairs on forearm, wings, legs, tail, and the upper surface of the interfemoral membrane yellowish; those on the ventral surface of the membrane are silver.

Skull about as large as that of *K. lanosa*, from which it is distinguished by its relatively narrower brain-case, more boldly convex frontal region, narrower rostrum, and more nearly parallel tooth-rows, the width between the outer borders of the last molars markedly less in proportion to the width across the canines. Dentition not essentially different. Outer upper incisor about three-fourths the height of inner incisor, rather stouter than the latter in cross-section, and with a well-developed internal basal cusp. Inner incisor with a posterior secondary cusp, the summit of which is a little less lofty than the outer incisor. Middle upper premolar smaller in cross-section than the anterior premolar.

Collector's measurements (taken on the flesh). - Head and body 39 mm.; tail 40; hind foot 6; ear 12.

Wing-measurements (from skin). - Forearm 30.5; third digit, total length 66, its metacarpal and phalanges 1 and 2 being respectively 32, 16, and 18; fifth digit 46.5, the metacarpal and phalanges being 30.5, 9, and 7.5.

Skull measurements (those of 7.1.1.538, a cotype of *lanosa*, being added in parentheses for comparison). - Greatest length 13 (13.4); condyle to canine 11.5 (11.5); canine to m^3 5.1 (5.2); width across canines

p. 242

3 (3.2); width across outer .borders of m^3-m^3 5.1 (5.5); zygomatic breadth 7.7 (7.9); interorbital breadth 3 (3) ; width of brain-case 6.6 (7.1).

This pretty little bat is named in honour of Miss Wilson, to whom I am indebted for much intelligent assistance.

Kerivoula muscilla Thomas, 1906

p. 294

Kerivoula muscilla, sp. n.

Size very small. Ears short, laid forward in the spirit-specimen they barely reach to the tip of the muzzle; their breadth equal to their length; inner margin strongly convex, outer with a well-marked emargination above, convex below. Tragus as in Dobson's second group, a small basal lobule present, very much as in *K. Smithii*; inner margin evenly convex, outer slightly concave. Limbs short, less strikingly delicate than usual; upper surface of forearms and proximal part of the digits and of hind limbs and feel clothed with fine golden-brown hairs. Wings to the base of the toes. Posterior edge of interfemoral with a fringe of short curved hairs growing from its under surface. Prepuce tufted with long hairs.

Fur long, brownish grey above and below, so far as can be made out on a spirit-specimen.

Inner upper incisors slender, practically unicuspid, a rudiment of a secondary cusp present about halfway up the hinder aspect; outer incisors long, nearly as long as the inner ones, each with a minute external basal secondary cusp. Two small upper and three lower premolars subequal *inter se*.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 27 mm.

Head and body 37; tail 33; head 14; ear 10; tragus on inner edge 6; third finger, metacarpus 26.5, first phalanx 13.5, second phalanx 15; lower leg and hind foot (c. u.) 17.5; calcar 16.

Hab. Ja River, Southern Cameroons.

Type. Adult male. Collected 22nd December, 1905, by Mr. G. L. Bates. One specimen.

This little *Kerivoula* is readily distinguishable from any African species hitherto described by its small size, the presence of an interfemoral fringe, and its long outer incisors. Dobson's *K. Africana* agrees with it in some respects, but is said to have a tragus as in *K. hardiwickei* and ears "longer than the head"*.

* By this expression Dobson appears always to have meant that the ears when laid forward extended beyond the tip of the muzzle.

Kerivoula nidicola zuluensis Roberts, 1924

p. 61
Kerivoula nidicola zuluensis subsp. nov.
In dimensions almost identical with a specimen of *K. nidicola* from Boror, and therefore larger than *K. lanasa*, but in colour much darker, the underparts of body being smoky greyish white, instead of buffy white, the upper parts darker, buffy brown instead of golden buffy as in *nidicala*. In *K. lanosa* the subterminal coloration of the hair is of a reddish brown, merging into the dark basal colour, whereas in *nidicala* the dark base of the hair is well defined from the subterminal golden buffy, which occupies the greater part of the hair; in *zuluensis* the dark base is even more pronounced, owing to the presence of a buffy line immediately above it, this becoming darker towards the tip of the hair, which becomes brown and produces a general dark effect. The hair of the back is long, as in *lanosa*, about two millimetres longer than in *nidicola*. White tips to the hairs of the back are present as in the other species.
Type: Adult male, T .M. No.3025, taken from the nest of a weaver bird, together with two companions, on the White Umfolosi River, Zululand, on July 17th, 1922.

Kerivoula phalæna Thomas, 1912

p. 281

A small pale brown species with subequal incisors.

Size as in the smallest members of the genus. Fur long soft, and fine; hairs of back about 7 mm. in length. General colour above uniform pale reddish brown - like "Mars-brown" of Ridgway, but much paler; the hairs of this color all through, except that on the posterior back they have inconspicuously darker bases. Extreme tips of some of the rump-hairs silvery buff. Under surface similar but rather paler, and with more blackish at the bases of the hairs. Membranes and wings almost naked, the base and edge of the interfemoral with thinly scattered hairs, not forming a fringe, the upper surface of the legs thinly hairy, the feet well haired.

Ears with inner margin strongly convex, a distinct concavity below the tip. Tragus slender, straight, a well-marked projection at its outer base, succeeded above by an emargination, above which there is again a projecting point, forming the broadest part of the tragus; in front of the middle of the base there is a wart clothed with long hairs, forming a loose tuft; a particularly prominent tragoid projection present facting the tragus on the inner side of the outer base of the ear.

Skull very light and delicate, with narrow brain-case. Upper incisors subequal in length, the outer rather shorter, and practically unicuspid, a smalle secondary cusp at the extreme posterior base of the inner one and at the internal base of the outer. First and second lower incisors tricuspid, third with a single large rounded cusp with minute anterior and posterior secondary cusps.

Dimensions of the type (the starred measurements taken in the flesh): -

Forearm 29.5 mm. (28 mm. in the male).

Head and body *33; tail *40; ear *13; third finger metacarpus 29.5, first phalans 12.5; lower leg and foot 18.8.

Skull: greatest length 12.1; basi-sinual length 9.1; zygomatic breadth 7.1; breadth of brain-case 6.1; front of upper canine to back of m^3 5.1

Hab. Bibianaha, inland of Denkwa, Gold Coast. Alt. 720'.

p. 282

Type. Adult female. B.M. no. 12.6.20.3. Original number 224. Collected 24th April, 1912, and presented by Dr. H. G. F. Spurrell. Male and female skins, female and young in spirit examined.

This delicate little *Kerivoula* belongs to Dobson's second group of the genus, and would seem to be allied to *K. lanosa* and *smithii*, but is markedly smaller than either.

Perhaps its nearest relative is the Kamerun *K. muscilla*, Thos., which is, however, distinguishable by its more inflated brain-case and its interfemoral fringe.

Læphotis Thomas, 1901

p. 460

Most nearly allied to *Vespertilio*, but the ear and tragus enlarged as in *Histiotus*.

Skull, as compared with that of the allied form, long and narrow, flattened above, very smooth and little ridged, the crests scarcely perceptible. Palate narrow, its posterior part unusually produced backward. Bullæ rather large.

Dental formula as in *Vespertilio*.

Upper incisors close to canines, instead of being well separated from them, the tip of the lower canine biting on to the top of, or outside, the outer incisor, instead of between it and the upper canine. In correlation with this the lower canine is unusually short and feeble, its length from cingulum to tip not exceeding the outer horizontal length of m^1. Detailed proportions of teeth as described below.

Type and only species *Læphotis Wintoni*

Laephotis angolensis Monard, 1935

p. 45

Voir *A. M. N. H.* 7, VII, 1901, p. 460.

Le genre *Laephotis*, créé par THOMAS sur une espèce du British East Afrrca, est voisin d'*Eptesicus* et en diffère surtout par les oreilles très grandes, plus longues que la tête et par quelques détails de dentition: les incisives supérieures externes placées tout près de la canine, la canine inférieure vennant buter contre elles au lieu de se placer dans l'intervalle qui les sépare de la canine. Le crâne est allongé et étroit, aplati, lisse, les crêtes à peine perceptibles. Le palais est étroit, sa partie postérieure remar-

p. 46

quablement prolongée en arrière, L'espèce type, *L. wintoni*, mesure 37^{mm} d'avant-bras.

Du Tyihumbwé, nous avons rapporté une Chanve-souris qui nous parait appartenir à ce genre. Elle possède la dentition d'*Eptesicus* mais se distingue à première vue par la grandeur des oreilles, plus longues que la tête. Les détails de la dentition sont ceux de *Laephotis*, les incisives supérieures, les canines correspondent à ce qui a été rappelé plus haut. Malheureusement le crâne a été cassé, et je n'ai pu en vérifier l'aspect et la grandeur des bulles auditives. Les détails de forme et de coloration correspondent en partie, si bien que nous pensons avoir à faire à une forme voisine; de taille un peu plus faible.

Voici du reste la description détaillée.

Pelage de couleur foncée dessus, la base des poils noirâtre, la pointe brune; poils de 6^{mm} de longueur. A la face ventrale, la couleur est plus claire, la base des poils toujours foncée mais la pointe blanchâtre. Région pubienne blanche. Les membranes sont presque nues en dessus, sauf dans le voisinage immédiat du corps. En dessous, il y a des poils blancs vers le corps et le long de l'avant-bras. Dans la partie interfémorale, il y a quelques poils dessus et dessous, surtout dans le voisinage de la queue.

Oreilles grandes, triangulaires en forme générale, les deux bords supérieurs, en position normale, placés sur une même ligne horizontale. Marge antérieure munie d'un repli bien développé, long de 5^{mm} et formant un angle droit avec la marge, qui est un peu convexe. Pointe de l'oreille arrondie. Bord externe replié, le pli rectiligne, donnant la forme triangulaire générale; marge à peu près droite. Antitragus en demi-cercle, séparé de la marge externe par une profonde incision. Tragus grand, à marge interne bien concave, à sommet arrondi, ayant son maximum de largeur un peu au-dessus du point de la base interne. Sa marge externe commence par un petit lobe arrondi en cornet, séparé de la partie supérieure par une échancrure arrondie, l'un des oreillons présente en outre une petite échancrure triangulaire au dessus du lobe basal; mutilation? La longueur de l'oreille, comptée de l'angle antérieur

p. 47

de l'antitragus est de 18^{mm}; la largeur est de 12^{mm} (mesurée sur l'oreille aplatie); le tragus mesure 5.5^{mm} sur sa marge interne.

Ailes normales; métacarpes III à V égaux; dernière phalange du troisième doigt terminée en T. La membrane s'insère à la base du cinquième orteil. Eperon long de 15^{mm} environ; un lobe éperonnier arrondi bien développé et, en plus, à l'extrémité de l'éperon un très petit lobe supplémentaire. Extrême pointe de la queue dépassant la membrane. Celle-ci d'une couleur générale brune, mais une très étroite bordure blanche du cinquième doigt à la cheville.

Le crâne cassé ne permet pas une description générale. L'échancrure palatale nous parait normale et non étroite, comme dans *wintoni*; elle atteint en arrière le niveau postérieur de la canine; le palais est allongé et profondément concave. Les incisives médianes sont convergentes et munies d'une petite pointe supplémentaire près de leur extrémité; le cingulum forme, derrière la dent, un petit tubercule. Les incisives externes sont placées très proches des canines, qu'elles ne touchent cependant pas; les canines inférieures viennent buter contre une concavité de celles-là. La canine supérieure est bien développée; la première prémolaire, grande, touche la canine; les deux premières molaires sont normales, avec les tubercules bien développés; la dernière branche de W de la dernière molaire manque et la crête se termine par un tubercule. Dents mandibulaires normales; la dernière molaire comptant un petit tubercule postérieur, donc six au total.

Dimensions: avant-bras 35[mm]; métacarpes 34; doigt III 62; tibia 14; pied 6; queue 38; tête et corps 50.

Cette forme diffère de *wintoni* par une taille plus petite, par les oreilles moins développées et d'une forme un peu différente.

Localité: Tyihumbwé, septembre 1932; une femelle

Laephotis botswanae Setzer, 1971

p. 260

Holotype: Adult female, skin and skull, U.S. National Museum no. 425349, from 50 mi. W, 12 mi. S Shakawe, Botswana. Obtained 24 May 1967 by S. W. Goussard, original no. 691.

Referred Specimens: British Museum (Natural History) 55.1134 and BM(NH) 55.1135 from Solwezi Boma, Zambia, obtained 28 April 1952 by W. H. F. Ansell; BM(NH) 57.436 and BM(NH) 57.438 from Mumene, 40 km. E Elizabethville, Congo (Kinshasa), obtained 28 December 1955 by the Hygiene Service of the Congo.

Measurements: The measurements of the holotype are: Total length 96; length of tail 41; length of hind foot 8; length of ear from notch 21; length of forearm (dry) 37.3; greatest length of skull 14.5; greatest breadth across zygomatic arches 8.3; least postorbital breadth 3.4; greatest breadth of braincase 7.0; depth of braincase 4.7; length of maxillary toothrow 4.7; postpalatal length 5.2; breadth of palate across M^2-M^2 5.4; breadth of palate across C-C 4.4.

Diagnosis: Upper parts near Buffy Brown; flight membranes near Clove Brown; underparts somewhat paler than dorsum, individual hairs black at base (5 mm), a narrow band (1 mm) of pure color and tipped (2 to 3 mm) with buffy. Ears moderate in size; tragus and antitragus moderately developed. Skull average in size for the genus; relatively narrow; rostrum relatively long and narrow; zygomatic arches fragile;

p. 261

[table removed - eds.]

p. 262

toothrows diverging slightly posteriorly; palate markedly arched dorsally; auditory bullae moderately sized.

Comparisons: From *Laephotis wintoni* as known by a specimen in the Royal Ontario Museum (ROM 36368) from Namanga, Kenya, *L. botswanae* differs in lighter color throughout; smaller ears; somewhat shorter forearm; and smaller, less curved tragus. The skull is smaller in all respects; auditory bullae smaller; palate more concave; upper toothrows more divergent posteriorly; and bony palate less projecting posteriorly.

Laephotis botswanae differs from the holotype and paratype of *L. namibensis* in smaller size; darker color; markedly smaller ears and tragus; and in having a shorter forearm. The skull is markedly smaller with a broader, shorter rostrum; occipital region more rounded; palatal region shorter, broader and more concave; auditory bullae less inflated; and foramen magnum markedly smaller.

Compared with *Laephotis angolensis* as known by a specimen from 35 mi. E Dande, Angola (AMNH 87244), *L. botswanae* differs in somewhat paler color; larger ears; and longer forearm. The skull is markedly larger; rostrum more massive; occipital crest less projecting posteriorly; palate broader but not as deeply concave; upper toothrows more divergent posteriorly; and auditory bullae, relatively as well as actually, smaller.

Remarks: With the recognition of these two new taxa, four species are now known in the genus *Laephotis*. There is reasonably close relationship between *L. wintoni* and *L. botswanae* but the relationship of *L. angolensis* and *L. namibensis* with the others is somewhat obscure.

When the skulls are arranged according to their greatest length, *namibensis* is largest, followed by *wintoni, botswanae*, and finally *angolensis*. The same applies when greatest breadth of braincase is examined; *wintoni* is the largest, *namibensis* next, followed by *botswanae* and *angolensis* (Table 1).

Forearm measurements are rather distinctive for *L. namibensis* and *L. angolensis*, the measurement of the former being over 38 while the measurement of the latter is not known to exceed 33. The same measurement overlaps between L. botswanae and L. wintoni. If, however, one adds to the preceding differences, the size and configuration of the tragus (Fig. 1), *L. wintoni* and *L. namibensis* show the closest relationship while *L. angolensis* and *L. botswanae*, which might possibly occur together, show striking differences in the tragi.

If one assumes *L. namibensis* to be the most specialized in shape and size of the ears; shape and size of the tragus; size of the auditory bullae; and in the shape and size of the rostrum; one is tempted to group the other taxa on the same morphological bases. When this is done it seems reasonable to place *L. wintoni* and *L. namibensis* as being closely allied, even though they are separated from each other by some 24° of latitude and some 30° of longitude. The other two species, occupying this hiatus of latitude and longitude can be readily separated on the basis of length of tragus, length of forearm and greatest length of skull. It would seem

p. 264

that an arrangement from least to most specialized based on several morphological features *L. angolensis* might be the least specialized; *L. botswanae* next with *L. wintoni* and *L. namibensis* in that order.

Peterson (MS, 1971) suggests that the populations of *Laephotis* represented by specimens from Botswana, Zambia and the southeastern Congo (Kinshasa) might represent a new species if female specimens of true *L. wintoni* were known. I suggest that since the holotype of *L. angolensis* is a female and that the measurements of a single male of the same taxon from 35 km. E Dande, Angola (AMNH 87244) show no real differences, there is no significant sexual variation involved. Examination of the external and cranial measurements of the series of specimens in the British Museum from Mumene, Musonge, Congo, as presented by Peterson, reveals that sexual variation is slight but that females do average a bit larger than males.

Laephotis namibensis Setzer, 1971

p. 259

Holotype: Adult female, skin and skull, U.S. National Museum no. 342152, from Namib Research Station, Gobabeb, South West Africa; obtained 22 November 1963 by Ronald E. Cole, original no. 270.

Specimens examined: Two from the type locality.

Measurements: The measurements of the holotype with those of a female paratype (USNM 342153) in parentheses are: Total length 106 (104); length of tail 47 (46); length of hind foot 8 (8); length of ear 25 (24); length of forearm (dry) 38.2 (38.6); greatest length of skull 16.5 (16.5); greatest breadth across zygomatic arches 9.0 (-); least postorbital breadth 3.2 (3.6); greatest breadth of braincase 7.5 (7.6); depth of braincase 4.7 (4.9); length of maxillary toothrow 4.9 (5.0); postpalatal length 5.9 (6.0); breadth of palate across M^2-M^2 5.2 (5.4); breadth of palate across C-C 4.0 (4.0).

p. 260

Diagnosis: Upper parts Light-Drab; flight membranes near Olive Brown; underparts noticeably paler than dorsum, individual hairs black at base, a narrow band (1-2 mm) of pure color (near Light-Drab), and tipped (2-3 mm) with white. Ears exceptionally large; tragus and antitragus well developed. Skull large for the genus; relatively long and narrow; upper toothrows nearly parallel; palate relatively long and narrow; auditory bullae remarkably inflated ventrally.

Comparisons: Compared with the holotype of *Laephotis wintoni, L. namibensis* is markedly paler in color; markedly larger ears, especially across the base (10.9 dry); and markedly larger tragus. The skull is longer; the postorbital constriction is less; the braincase is somewhat more domed; the auditory bullae are more inflated; the zygomatic arches are more markedly bowed dorsad; and the maxillary toothrows are more nearly parallel.

From a specimen of *Laephotis angolensis* from 35 km. E Dande, Angola, in the American Museum of Natural History (AMNH 87244), *L. namibensis* differs in markedly larger size; paler color; and strikingly larger ears. The skull, in all respects is decidedly larger and more robust.

Remarks: These specimens were taken in a mist net over a water hole in the bed of the Kuiseb River near the Namib Desert Research Station.

The name proposed for this new taxon is in reference to the Namib Desert of South West Africa.

Læphotis Wintoni Thomas, 1901

p. 460

Size rather less than in *Histiotus velatus*; general appearance very much as in that species, although the ears are not so large. Fur close and fine, the hairs of the back about 6 - 7 millim. in length. General colour above coppery brown, the basal halves of the hairs sooty, the terminal halves clear

p. 461

coppery or cinnamon (Dr. Hinde speaks of the colour as "bronze"). Under surface paler brown, the tips of the hairs becoming almost white in the pubic region.

Fur above not extending on to arms or wing-membranes, though there are a few fine hairs on the thumbs; but the legs are clothed as far as the knee, the backs of the feet are finely hairy, and the basal half of the interfemoral is thinly covered with fine and inconspicuous hairs. Below the wing- membranes are finely clothed nearly as far outwards as a line from the elbow to the knee, but the interfemoral membrane is more nearly naked than above. No trace of an interfemoral fringe.

Ears large, much larger than in *Vespertilio*, but not so large as in *Plecotus, Otonycteris*, or *Histiotus*; not connected across the forehead with each other. Inner margin with a distinct basal fold, ending below in a narrow lobe; its basal third is strongly convex forward, so that the basal line is at right angles to the upper two thirds, which are very slightly convex and pass gradually into the rounded tip; outer margin nearly straight above, slightly convex below; antitragus low, half-oval, marked by a distinct notch behind. Tragus unfortunately damaged in the type on both sides, but enough is left to show that it is long, broad at base, with a slightly concave inner margin and a broadly rounded tip.

Wing of normal Vespertilionine proportions, the metacarpals of the third, fourth, and fifth digits approximately equal in length. Insertion of wing-membrane at base of the digits, so far as can be made out in the dry skin. Calcar reaching about halfway towards the tip of the tail; postcalcaneal lobule present, but very narrow. Tip of fourth finger T-shaped, or even slightly spatulate. Membranes and ears uniformly brownish grey, except that the wing-membrane from the tip of the fifth finger to the ankle is edged with whitish.

Skull very thin and papery, long and narrow, low, smooth, and scarcely ridged at all. Nasal notch comparatively shallow. Intertemporal region not strongly constricted, the intertemporal but little less than the interorbital breadth. Palatal notch penetrating to the level of the middle of the canines. Palate narrow, the greatest breadth across the outer corners of m^2 going nearly three times in the total length of the skull; its posterior part produced behind the molars a distance equal to the combined lengths of p^4 and m^1.

Upper incisors slightly convergent, of about the same relative proportions as in the Serotine, the inner one long, with a secondary postero-external cusp near its tip and a small

p. 462

postero-internal cingular cusp at its base; outer incisor quite small, its main cusp about half the height of the inner incisor, also with a small internal basal cusp. Large premolar pressed close up against the back of the canine; last upper molar triangular, with a well-developed posterior lobe, in correspondence with which the talon of the last lower molar is large and tricuspid. Lower incisors trifid, overlapping; anterior lower premolar about one half the height and one fourth the area in cross-section of the posterior one.

Dimensions of the type (measured in skin): -

Forearm 37 millim.

Head and body (approximate) 50; ear (dry and no doubt contracted) 21; tragus, length on inner edge 6.3, breadth basally 3.5; metacarpus of third finger 35; first phalanx 13; tibia 13.5; hind foot, s. u. 7, c. u. 7.7; calcar (c.) 15.

Skull: greatest length 15.7; basipalatal length in middle line 12.8; interorbital breadth 5; intertemporal breadth 3.6; breadth of brain-case 7.8; palate length 6.6. Front of lower canine to back of $m._3$ 5.6.

Nab. Kitui, British East Africa. Altitude about 3500 feet.

Type. Male. Original number 64. Collected 7th January, 1901, by Dr. S. L. Hinde.

I have ventured to name this interesting bat in honour of my friend Mr. W. E. de Winton, to whose labours on the small mammals of Africa all naturalists, and I especially, have been so constantly indebted for assistance.

Lavia frons affinis K. Andersen and Wroughton, 1907

p. 138

Diagnosis. - Average size smaller.

Details. - Comparative measurements are given above under *L. frons frons* (p. 139).

Type. - M ad. skin. Kaka, White Nile. Collected by R. M. Hawker, Esq. B.M. no. 1.8.8.3.

Specimens examined. - 8 (7 skins) and 6 skulls, viz, White Nile (5), Lake No (1), Lado (1), Wadelai (1).

The British Museum possesses a somewhat damaged skull without skin from Cape Coast Castle (Gold Coast) which seems to belong to this race, and Miller's specimen of "*L. frons*". referred to above under *L. f. frons* (p.
139) appears also to belong to the present race; so it is possible that the range of *affinis* extends westward to the coast.

Lavia rex Miller, 1905

p. 227

1892. *Megaderma frons* True, Proc. U.S. Nat. Mus., XV, p. 469, October 26, 1892 (part).

Type from Taveta, German East Africa. No. $^{18993}/_{38197}$, United States National Museum. M adult (in alcohol). 1889. Dr. W. L. Abbott.

Characters. - Like the West African *Lavia frons* (Geoffroy) but considerably larger (forearm 60 instead of 56, mandible 17.8 instead of 15.2), and with disproportionately heavier teeth.

Color. - (Skin of topotype, No. 18,992, not sexed): Fur everywhere drab-gray (that of belly a little darker than that of back) tipped with ochraceous-buff. On middle of back and neck and on posterior half of belly the ochraceous-buff is so inconspicuous that it

scarcely modifies the ground color, but on face, sides of neck, entire chest and throat, and along border of interfemoral membrane it strongly predominates. At shoulder the wood-brown fades to buffy white, forming an inconspicuous light shoulder-spot. The type does not appear to differ appreciably in color from the dry specimen, though it has been subject to the action of alcohol for more than fifteen years.

Ears, membranes, etc., - Probably not different from those of *Lavia frons*. Dr. F. W. True has already noted the peculiar broadened, serrated form

p. 228

of the secondary lobe of the tragus in the type specimen as compared with that figured by Dobson and represented by a Sierra Leone specimen in the United States National Museum. In the skin from Taveta this lobe has a form intermediate between the others and closely resembling that of *Lavia frons* as figured by Geoffroy. The variation is probably individual.

Skull and Teeth. - As compared with those of an adult male *Lavia frons* from Sierra Leone (No. 38,196, United States National Museum) the skull and teeth of *Lavia rex* are readily distinguishable by their uniformly greater size and massiveness. In actual form of either skull or teeth there are no striking differences between the two species; but the larger animal has the audital bullæ relatively larger and the interpterygoid space narrower, while the teeth, particularly the upper canines and upper molars, are very considerably increased in size.

Measurements. - Type: Head and body, 70 (69);** tibia, 34 (29); foot, 16 (15); forearm 60 (56); thumb 14 (11); second finger, 62 (55); third finger, 110 (105); fourth finger, 78 (72); fifth finger, 83 (75); ear from meatus, 43.6 (40); ear from crown, 39 (33); width of ear, 28 (26); tragus, 29 (25); noseleaf, 22 (22); greatest width of noseleaf (flattened), 16 (16). Skull: Greatest length, - (23); basal length, - (18); basilar length, - (16), median palatal length, 6.6 (4.8); greatest palatal width including molars, 9.2 (8.2); distance between tips of upper canines, 5.4 (?); mandible, 17.8, (15.2); maxillary toothrow, 9.2 (8.2); mandibular toothrow, 11 (9).

Footnote:
** Measurements in parentheses are those of an adult male of *Lavia frons* from Sierra Leone (No. $^{11539}/_{38196}$, United States National Museum).

Leiponyx Jentink, 1881

p. 60

Muzzle as in *Pteropus*. Nostrils slightly projecting, rather deeply emarginate between. Upper lip with a distinct vertical groove in front.

Index finger without a claw. Metacarpal bone of the middle finger smaller than the index finger. Wings from the sides of the back and from the base of the first toe. Tail short, for its greater part free from the membrane.

Dentition. Inc. $^{2-2}/_{4}$, c. $^{1-1}/_{1-1}$, p.m. $^{2-2}/_{2-2}$, m. $^{2-2}/_{3-3}$ = 32.

Leiponyx büttikoferi Jentink, 1881

p. 60

Ear longer than the muzzle (the distance between the tip of the nose to the foremost corner of the eye). Earconch with a rounded tip, the outer margin in its upper part concave, convex further on, inner margin slightly curved. Shoulder-glands absent in the female, the single specimen we possess.

The palate-ridges are seven in number; the first four are undivided; the first is nearly straight and placed between the canines, the second is slightly curved and placed immediately behind the first premolars, the third ridge is broader than the second and unites the second premolars; the fourth again is more arched and unites the space between the two molars on each side. The three remaining ridges form oval elevations on each side resembling those in *Epomophorus comptus*. They are succeeded by ill-defined semicircular toothed lines similar to the same parts in *Epomophorus franqueti*.

The four unicuspidate upper incisors are placed at a distance from the canines, in pairs, with a rather wide space between those pairs. The foremost incisors are the smallest. The lower incisors are also unicuspidate and nearly equal in

p. 61

size and placed in a semicircular row between the smooth canines. The canines in the upper and lower jaw are followed at a small distance by the little developed first premolars, which are separated from the much stouter second premolars by a rather large interval. The third premolar in the lower jaw is separated by a space nearly as large as the interval between first and second premolar. This is the most developed premolar, not in vertical extent but in circumference. Molars very small, slightly raised above the level of the gum, especially the lower molars.

Fur short, yellowish brown, darker on the head. Ears and wings blackish brown. Claws black, strongly arched and acutely pointed.

Measures of the single specimen. (mm)

Head and body: 195.
Tail: 13.
Tail free from membrane: 7.5
Ear: 25.
Thumb with claw: 46.
Forearm: 125.

Hab. Liberia, St. Paul's River (Millsburg).

Liponycteris Thomas, 1922

p. 266

WHEN, in 1915, I wrote my "Notes on *Taphozous* and *Saccolaimus*", and recognized the latter as a distinct genus from the former, as had Hollister previously under another name, I did not sufficiently weigh the characters which separate *Taphozous nudiventris* and its allies from the typical members of *Taphozous*.

On reconsidering the subject, I now think that these remarkable half-naked bats should be separated as a distinct genus from the ordinary hairy species, and would suggest that the whole group might be synoptically arranged as follows: -

A. Bullæ imperfect, the inner side of each incomplete. A radio-metacarpal pouch.

a. Frontal concave; upper profile of brain-case rising from it in a strong curve. Occipital "helmet" scarcely developed. Body haired as usual..... I. *Taphozous*, Geoff.
Genotype: *T. perforatus*, Geoff.

b. Frontal almost flat, the cranial profile scarcely rising above it behind. A strongly developed occipital helmet.

p. 267

Body partly naked behind, both above and below ..... II. *Liponycteris*, gen. nov.
Genotype: *L. nudiventris* (*T. nudiventris*, Cr.).

B. Bullæ perfect internally. No radio-metacarpal pouch. Body hairy..... III. *Saccolaimus*, Less.
Genotype: *S. saccolaimus* (*T. saccolaimus*, Temm.).

Besides *nudiventris*, *Liponycteris* would contain only *kachhensis* and its two subspecies - *magnus*, Wettstein (1914, syn. *babylonicus*, Thos., 1915), and *nudaster*, Thos.

Lissonycteris angolensis goliath Bergmans, 1997

p. 46

Rousettus (Lissonycteris) angolensis; Harrison, 1960: 65, 1961: 287; Meester et al., 1986: 30.

Rousettus angolensis; Fenton, 1975; Hutton, 1986: 227.

Rousettus angolensis angolensis; Smithers et al., 1976: 42, 1983: 65 (in part: records from Zimbabwe and Mozambique).

Rousettus (Lissonycteris) angolensis angolensis; Hayman et al., 1971: 12 (in part: records from Rhodesia); Smithers et al., 1979: 27 (in part: not the record from the Haroni/Lusitu River confluence); Koopman, 1994: 20 (in part: the record from Zimbabwe).

Material examined

ZIMBABWE. Holotype specimen: 1 F, skin, skull, 19-III-1970, Gleneagles, Inyanga, collected by M. Stuart Irwin and party (NHMBZ 59831; field number T1854); paratype specimens: 4 MM, 1 imm. M, 2 FF, 1 imm. F, skins, skulls, same data as für

holotype specimen (HZM 16.7321, field number GNA/MP 1; NHMBZ 59826/29, -32/33 & ZMA 24.719, field numbers T1848/50, -52/53, -55/56).

Other material: Umtali: 1 M, skin, skull, 18-VI-1960, R. H. Smithers (HZM 15.3219).

Referred material (not examined)

MOZAMBIQUE.

(Western boundary of Vila Pery District, 1832Bd, 1832Dc, 1833Cc.)

ZIMBABWE.

(Birchenough Bridge at Sabi River.)

Diagnosis: As for the species, but with large body, skull, and teeth dimensions, with fal ranges of 81.9-87.5 in 4 MM and 82.1-89.6 in 3 FF and gsl ranges of >= 43.3-46.0 in 4 MM and >= 42.2-45.8 in 3 FF, and (antero-posteriorly) lang cheek teeth with rather distinct heels anterior and posterior to the outer cusps.

Measurements: Table 3. Same ratios are:

rl MM 37.2 -38.0 % of gsl (n = 2),
FF 38.2 % of gsl (n = 1);
C^1-C^1 MM 17.4 -20.4 % of gsl (n = 2),
FF 19.0 % of gsl (n = 1);
M^2-M^2 MM 29.1 -30.1 % of gsl (n = 2),
FF 29.4 % of gsl (n = 1).

Distribution: Fig. 5.

Related species: See the account of the typical subspecies.

Remarks

Taxonomy: The seven known localities are all in or near the border area of Zimbabwe and Mozambique, between 18 and 20 30 S and at a distance of about 1000 km from the nearest known populations of *L. a. ruwenzorii*. Ansell (1967, 1974) recorded representatives of the species, here included in *ruwenzorii*, from extreme northwest Zambia and, in 1978 the same author remarked that, apart from northeast Zambia it was perhaps unlikely to occur elsewhere in the

p. 47

[table removed - eds.]

country. Other *ruwenzorii* specimens are known from southeast Zaïre (fig. 5). With fal ranges of 72.3-84.4 in MM and 72.8-83.0 in FF and gsl ranges of 39.3-43.8 in MM and 39.1-43.2 in FF, *ruwenzorii* averages very distinctly smaller than *goliath*. No fruit bats have been recorded from the northeast zone of Zimbabwe (Bergmans, 1988, fig. 1), and the new subspecies' characteristics strongly suggest its prolonged isolation from the Central and East African populations of *angolensis*. Apart from its larger size, its premolars and molars, especially P^3, P^4, M^1 and P_4, M_1 and M_2, are relatively longer, with in lateral view more distinct heels anterior and posterior to the outer cusps, which themselves are relatively obtuse. The difference in size between M^1 and M^2 is generally smaller than in the smaller subspecies *smithii* and *petraea*. As a consequence of the longer cheek teeth, the interstices between them are relatively short.

Harrison (1960), who described the first specimen of *Lissonycteris angolensis* from this region, already remarked on its exceptional size when compared to specimens from Kenya, and re-

p. 48

frained from describing a new subspecies only because of the limited material. Smithers et al. (1979) gave same rounded measurements of specimens from Zimbabwe but did not comment on them.

The palatal ridge pattern has been preserved only in the specimen from Umtali and is typically 3 + 4 + 2.

Distribution and geographical variation: Harrison recorded a specimen from Umtali (= Mutare; square code 1832Dc, or 1832D3), Zimbabwe. Smithers et al. (1976) recorded specimens from along the western boundary of Vila Pery District in Mozambique. They did not mention specific localities (nor where their specimens have been deposited), but on their map the squares 1832Bd, 1832Dc, 1833Cc and 2032Bb have been marked. (From the localities mentioned in their gazetteer, only Machipanda corresponds with 1832Dc and Chemezi with 1833Cc.) Smithers et al. (1979) added Birchenough Bridge on Sabi River (1932Cd) and Gleneagles (1832Bd), both in Zimbabwe, as collecting localities for *Lissonycteris angolensis*. They also mentioned material from the Haroni/Lusitu River, but this actually represents *Myonycteris relicta* Bergmans, 1980 (see present paper).

The distribution appears to be confmed to the escarpment region in the border area of Zimbabwe and Mozambique, between 17 and 21 S, with known occurences from between 200 and 500 m (Birchenough Bridge) to 1800 m (Gleneagles). Smithers et al. (1979) reported that the specimen from Umtali had been taken in an old, established suburban garden with trees and shrubs, where it was feeding on guavas among many *Epomophorus wahlbergi* (Sundevall, 1846), but that two of the other localities were associated with evergreen forest (one of these probably the Haroni/Lusitu River confluence from where the species was incorrectly recorded). According to White (1983) the localities are all associated with forest mosaics, forest transitions or

woodland: 2 are in Undifferentiated Afromontane vegetation (type 19a), 1 is in Drier Zambezian miombo woodland (dominated by *Brachystegia* and *Julbernardia*) (type 26), 1 in *Colophospermum* mopane woodland and scrub woodland (type 28), and 3 in either type 19a, or 16, or 26, in which l6(a) is East African Zanzibar-Inhambane coastal mosaic. Its restricted distribution would suggest that geographical variation within this subspecies is unlikely.

Etymology: The specific epithet *goliath* has been chosen in honour of Dr. David L. Harrison, who would have 'mastered' this Goliath long ago if he had had more specimens. Of course, it also refers
to the subspecies' exceptionally large dimensions.

Rousettus aegyptiacus aegyptiacus (not of E. Geoffroy-St. Hilaire, 1810); Dorst *et al.*, 1972: 394 (in part: the specimens from 10 km from Agaro and from Ghimbi).

Rousettus aegyptiacus (not of E. Geoffroy-St. Hilaire, 1810); Largen et al., 1974: 228 (in part: the records from 10 km from Agaro and from Ghimbi).

Rousettus angolensis; Largen *et al.*, 1974: 229, 255.

Rousettus angolensis ruwenzorii; Largen *et al.*, 1974: 230.

Material examined

ETHIOPIA. Holotype specimen: 1 M, alc., skull, 10/13-VI-1968, 10 km from Agaro, at the road to Jimma, J. Dorst and party (MNHN CG 1972-482; field number 4017); paratype specimens: 5 MM, 2 imm. MM, 1 F, 2 imm. FF, alc., skulls, same data as holotype specimen (MNHN CG 1972-482, field numbers 4018/19, -24, -27, -32, -44/46, -51 and ZMA 25.180, field number 4050).

Other material: Didessa River: 1 F, 2 MM, alc. (BMNH 71.2446/47, 72.638). Ghimbi: 1 imm. M, 2 imm. FF, alc., 27/30-IX-1971, J. Dorst and party (MNHN CG 1984-2074/76). Nur Moha-med Cave: alc. material (BMNH).

Referred material (not examined)

ETHIOPIA. Didessa: 2 specimens, alc., 1-1972, J. S. Ash (USNM 497488/89); 1 specimen, 25-1-1973, J. S. Ash (USNM 497490).

(Doki River Bridge.)

Diagnosis: As for the species, but with small average body and skull dimensions, with a fal range in 8 MM' of 72.7-76.3 (mean 74.2) and in 2 FF 71.7-73.5, and a gsl range in 6 MM of 38.5-41.3 (mean 39.7), and (antero-posteriorly) short and low canines and cheek teeth, the latter with relatively long outer ridges.

Compared with *L. a. angolensis* and *L. a. ruwenzorii*, smaller average body and skull dimensions and (antero-posteriorly) relatively shorter upper canines and shorter and lower upper cheek teeth with longer and more diverging outer cusps, or ridges, and P^4 and M^1 more squarish; larger lower cheek teeth equally low and also with relatively lang outer cusps. Compared with *L. a. smithii*, slightly larger in average body and skull dimensions, upper incisors narrower and not sharply curved backward, upper and lower cheek teeth with relatively lang outer cusps, P^4 with a well-developed inner cusp.

Measurements: Table 2. Some ratios are:
rl MM 37.1 - 38.3 % of gsl (n = 6);
C^1-C^1 MM 17.9 - 18.7 % of gsl (n = 5);
M^2-M^2 MM 27.3 - 30.5 % of gsl (n = 5).

Distribution: Fig. 5.

Related species: See the account of the typical subspecies.

Remarks

Taxonomy: The Ethiopian populations of *L. angolensis* are geographically nearest to those in South Sudan, at a distance of about 600 km, identified as *L. a. ruwenzorii* and including the largest specimens of that subspecies: the fal range in 8 MM is 76.5-84.4 and in 8 FF 76.5-80.9; the gsl is c. 41.2 in 1 M and 40.1-41.3 in 3 FF.

The next nearest subspeciesis *L. a. angolensis*, possibly represented at about 1500 km to the West, in the northern Central African Republic (fal of 1 M 74.4, of 1 F 75.1; Schlitter et al., 1982), and still further west in Cameroun where specimens average larger (fal range in 4 MM 73.4-80.0 and in 12 FF 74.5-83.0; gsl in 1 M 42.1 and in 4 FF 38.7-40.5) and, like *ruwenzorii*, differ in teeth morphology. In overall size *L. a. petraea* comes nearest to *L. a. smithii*, but it is separated from this by *L. a. angolensis* and differs in teeth morphology. The cheek teeth in the new subspecies show specific trends in their development. They are relatively weak by being shorter and lower, and at the same time retain long outer ridges (or cusps) instead of the short, more pointed cusps in the other sub-

p. 45

[table removed - eds.]

species, and the inner cusp in P^4 is less obsolete than in *smithii*. The overall weakening of the dentition may indicate that this subspecies represents an old branch of the species, while the long outer ridges, which are probably a primitive character, may have persisted as an adaptation to specific food sources.

The palatal ridge pattern in *petraea* is 3 + 4 + 2 in nine, and 4 + 3 + 2 in two (including the holotype) out of 11 specimens. The sixth ridge is much reduced in two specimens. The specimen with field number 4018 has an M^3 measuring 0.9 x 0.95 on the left side, and the one with number 4024 an M^4 of 1.0 x 0.9 on the right side.

Distribution and geographical variation: The six known localities are all in or near montane rain forest in the southern Ethiopian highlands, at both sides of the Central Rift, with altitudes between 1190 and 2600 m (only of Doki River Bridge no attitude is known). Of the six localities, three are in East African evergreen and semi-evergreen bushland and thicket, two in

p. 46

Undifferentiated Afromontane vegetation, and one in Undifferentiated Ethiopian woodland (types 38, 19a and 29b in White, 1983). The distribution area is separated from the areas of the subspecies *ruwenzorii* and *angolensis* by less favourable and probably uninhabitable vegetation types: towards the west mainly by a Transition from undifferentiated Ethiopian woodland to Acacia deciduous bushland and wooded grassland, and Edaphic grassland in the Upper Nile basin (types 35b and 61 in White, 1983), and towards the south mainly by Somalia-Masai *Acacia-Commiphora* deciduous bushland and thicket (type 42 in White, 1983).

With the exception of the type series, the samples are insufficient to establish possible geographical variation.

Four specimens were infested with typical examples of the nycteribiid fly *Dipseliopoda biannulata* (Oldroyd, 1953).

Etymology: The new subspecies has been named in honour of Dr. Peter J. H. van Bree, former Curator of Mammalogy of the Institute for Systematics and Population Biology (Zoölogisch Museum) of the University of Amsterdam, under whose guidance the author laid the basis for his studies of African fruit bats. The names Peter and *petraea* are both derived from the Greek petra, in its meaning of rock in the metaphorical sense of a solid and trustworthy basis, but also referring to the subspecies' apparent confinement to the tormented relief of the Ethiopian plateau.

Macronycteris Gray, 1866

An updated description is given by Foley *et al.* (2017: 10).

Megaloglossus Pagenstecher, 1885

[Eds.: This is from Jahrbuch der Hamburgischen Wissenschaftlichen Anstalten, 1885, 2: 125 - 128. This paper has the same title as the one in Zoologischen Anzeiger, which is generally considered to be the original description]

p. 126

Megaloglossus: Schwanz mit zwei gegen das Os sacrum und unter einander beweglichen, aber gänzlich versteckten Wirbeln, der zweite verkümmert, Flughaut mit 2 Fältchen von der Basis der zweiten und der dritten Zehe.

In dem einen Merkmal vermittelt also die Gattung *Megaloglossus* zwischen *Macroglossus* und *Melonycteris*, im anderen eutfernt sie sich weiter von *Macroglossus* als *Melonycteris*. Sie nähert sich in der Anordnung der Gaumenfalten, indem die zwei letzten gespalten sind, mehr *Melonycteris*.

Es ist nicht unwarscheinlich, daß auch die neue Art allein in ihrer Gattung steht und man wird dann Gattungscharakter und Artcharakter vielleicht überhaupt nicht zu trennen in der Lage sein. Jedenfalls wird man für jetzt über das obige mit Sicherheit nicht hinaus gehen können.

Nach nachfolgender Tabelle hält die neue Art in der Größe die Mitte zwischen *Macroglossus minimus* Geoffr. und *Melonycteris melanops* Dobs.

Macroglossus minimus M incl. Schwänzchen; *Megaloglossus Woermanni* F; *Melonycteris melanops* M
Körperlänge von Nasenspitze an: 82 mm; 90 mm; 120 mm
Länge des Schädels: 26; 29; 38
Entfernung von Augenmitte bis Schnauzenspitze: 12; 25; 19.5

p. 127

Entfernung von Augenmitte bis zum unteren Winkel der Ohröffnung: 12; 11; 16.5
Länge der Zunge: 21; 28; 28
Höhe der Ohröffnung: 12; 13; 16
Vorderarm: 38; 45; 62
Daumen mit seinem Metacarpus: 15; 19; 25

Dritter Finger: 70; 80; 130
Fünfter Finger: 55; 56; 85
UnterSchenkel: 17; 20; 28
Fuß ohne Sporn: 10,5; 12; 18

Rechnet man alle genommenen Maße jeder Fledermaus zusammen und dividirt durch die Zahl der Maße, so hat *Megaloglossus* das 1.21, *Melonycteris* das 1.54 fache von *Macroglossus*. Über diesen Durchschnittsfaktor gehen bei *Megaloglossus* hinaus die Zunge mit 1.83, die Schnaunze mit 1.33 und der Daumen mit 1.26, bei *Melonycteris* der dritte Finger mit 1.85, der Fuß mit 1.71, der Daumen mit 1.66, der Unterschenkel mit 1.65, der Vorderarm mit 1.63. *Megaloglossus* ist hiernach die größzungige Macroglosse und zum Klettern gut geeignet. Der Fersensporn ist größer als hei *Macroglossus*.

Was die Zähne betrifft, so hat die neue Fledermaus die Formel der beidcn anderen Gattungen:

$^{2+3+1+4+1+3+2}/_{3+3+1+4+3+3}$

Die oberen Schneidezähne sind fast aequidistant, in der Mitte wenig weiter von einander entfernt, die Krone der unteren ist in zwei körnerartige Lappen getheilt, der obere Eckzahn hat, wie bei den anderen Gattungen die vordere Rinne, in welcher der untere gleitet. Der erste obere Lückzahn ist vom Eckzahn deutlich getrennt, wie bei *Macroglossus*, während er bei *Melonycteris* dichter an diesen rückt. Die beiden folgenden Lückzähne sind im vorderen Theile gut entwickelt und etwas hakig gespitzt, während bei *Macroglossus* der vordere, hakige Teil früh abschleift und bei *Melonycteris* der Zahn mehr im Ganzen und plumper sich zuspitzt. So ist namentlich der zweite obere Lückzahn recht kräftig. Die Jochbogen sind weniger nach außen gedrängt als bei *Macroglossus* und setzen sich vorne etwas höher an.

Die Umrandung der Naslöcher steht im ganzen minder vor als bei *Macroglossus*. Die Naslöcher werden theilweise überdeckt von einem

p. 128

deutlichen Zipfel des oberen oder inneren Randes. Die Oberlippe ist breiter, plumper als bei *Macroglossus*, ihre Mittelkerbe eher tiefer.

Die Zunge, indem sie die gleiche Länge hat, wie die des erheblich größeren *Melonycteris*, auch ähnlich breit und dicker, viel massiger als bei *Macroglossus* ist, hat mich zu der Gattungsbenennung *Megaloglossus* veranlaßt. Sie ragt schon heim ungeborenen Jungen aus dem Munde hervor. Ihr Mittelfeld mit einem Pflaster von Platten, jede mit drei nach hinten gerichteten Zähnen, hat fast die Ausdehnung wie bei *Melonycteris*, namentlich eine größere Breite als bei *Macroglossus*. Haar dicht, weich, dunkler als bei *Macroglossus*, umbra-braun, auf der Unterseite graubraun, Flughäute dunkelbraun. Zitzen groß, an den Brustseiten, ungefähr in der Höhe des Ellenbogens.

Nach dem um unser Museum, insbesondere für west-afrikanische Thiere, so hoch verdienten Herrn *Adolf Woermann* habe ich diese Fledermaus *Megaloglossus woermanni* zu nennen mir gestattet. Sie wird als ein Beweis einer gewissen alten Faunalbeziehung zwischen westafrikanischen und malayischen Gegenden betrachtet werden können, wie er ähnlich in den anthropomorphen Affen vorliegt, hier mit einer Ausdehnung nach Polynesien, wie sie für Fledermäuse möglich ist. Wahrscheinlich wird sich das Thierchen weiter verbreitet finden, da die westnfrikanische Fauna sich von der ostafrikanischen im allgemeinen erst am Tanganika-See und Albert-Nianza trennt.

Megaloglossus woermanni Pagenstecher, 1885

p. 245

Fruchtfressende langzungige Fledermäuse sind bisher nicht weiter westlich als im Himalaja gefunden worden. Unser Museum hat eben eine solche durch Herrn Soyaux von Ssibange-Farm in Gabon erhalten. Diese große Veränderung in unserer thiergeographischen Erfahrung berechtigt zu einer vorläufigen Mittheilung. Unser Thierchen gehört in die zweite Gruppe der Macroglossen bei Dobson: Zeigefinger mit Nagel, Zwischenkiefer vorn verbunden. Sie hat das volle Gebiß mit $^{2}/_{2} + {}^{1}/_{1} + {}^{3+2}/_{3+3}$ jederseits. Wäre nicht *Melonycteris* von *Macroglossus* geschieden, so hätte man diese Art auch unter *Macroglossus* lassen können. Wie in der Größe, so vermittelt sie mit einem Theile der Eigenschaften zwischen diesen beiden Gattungen; mit einem Theile aber entfernt sie sich weiter von *Macroglossus* als *Melonycteris*. Der Schwanz, bei *Melonycteris* fehlend, hat hier zwei Wirbel, bei *Macroglossus* drei. Die Flughaut am Fuße bei *Macroglossus* von der vierten Zehe, bei *Melonycteris* von der dritten entspringend, thut dies hier mit Bändchen gleichmäßig von der dritten und zweiten. Die Schnauze ist eher noch einfacher als bei beiden Gattungen; der zweite Lückzahn ragt oben und unten über das Niveau der übrigen: zwei hintere Gaumenfalten sind getheilt, wie bei *Melonycteris* während sie das bei *Macroglossus* nicht sind. Da die Zunge so lang ist wie bei dem erheblich größeren *Melonycteris melanops* Dobson, *alboscapulatus* Ramsay und zugleich breit, schlage ich den Gattungsnamen *Megaloglossus* vor.

Die Art ist dunkelbraun, am Leibe etwas heller, Gesammtlänge von der Schnauze zur Schenkelhaut 90, Unterarm 45, dritter Finger 80 mm.

Die genaue Beschreibung und Abbildung behalte ich mir vor für die Beilagen des Jahresbeiichts über das Museum für 1885.

Micropteropus Matschie, 1899

p. 57

Subgen. *Micropteropus* Mtsch, subgen. nov.

Die Entfernung zwischen dem vorderen Augenwinkel und der Nasenspitze ist ungefähr so gross, wie die Breite des Gesichtes an den Mundwinkeln. Der Gaumen trägt keine Querfalten, sondern eine nach vorn gegabelte Längsfurche in der Mitte, deren Ränder in dem nicht gegabelten Theile von 4 sehr dicht aneinander stehenden, mehr oder weniger deutlichen Höckern bcsetzt sind. Die Lippe ist nicht gefurcht. Der Schwanz ist kaum zu fühlen. Auf dem Plagiopatagium durchschneiden weniger als 32 Fascien den vom Ellenbogen zur Spitze des fünften Fingers verlaufenden Strang. Die Reihe der Molaren ist viel länger

p. 58

als die Entfernung zwischen den Spitzen der oberen Caninen; der letzte obere Molar reicht weit über das Foramen infraorbitale nach hinten. Der knöcherne Gaumen ist ungefähr wie bei *Epomops* gebildet. Der Unterarm ist höchstens 60 mm lang.

Typus: *Ep. pusillus* Ptrs.

Hab. West-Afrika: Ober- und Nieder-Guinea, Congo-Gebiet, Seeen-Gebiet, Bongo im Gebiet des Weissen Niel.

Micropteropus intermedius Hayman, 1963

p. 100.

(Fig. 8)

Type: F adult, 5060, in alcohol. Dundo, Lunda. N.E. Angola. Collected June or July 1953 by Dr. A. DE BARROS MACHADO. Brit. Mus. No. 62.2073.

Native name. - *Tshingunzu* (tshokwe).

Diagnosis. - Larger than *M. pusillus*, with forearm 59 to 63.5, thus falling within the bodily size range of *M. grandis* SANBORN, but cranial measurements notably less, particularly in the rostrum, palate and tooth row. Palatal ridges five (six in *M. grandis*), the first undivided, the remaining four paired, widely separated anteriorly, converging posteriorly so that the last pair are almost in contact, so that the pattern is quite distinct from the two parallel rows of divided ridges in *M. grandis* (see fig.). The number of ridges is as in *M. pusillus*, but the clear separation into distinct pairs is as in *M. grandis*, so that it can be said that not only the skull size but the palate ridge pattern indicates that this species is intermediate between the two other forms in this genus. Principal measurements of the type; forearm 63.5; skull greatest length 33.2, upper toothrow 10.4. (For full comparative measurements see table).

General description. - In all external characters closely akin to other *Micropteropus*. General colour dull brown above, hairs pale for two-thirds their length with dark brown tips. Ventral colour paler. The whole impression is of an animal darker than *M. grandis*. At the anterior and posterior borders of the ears are the normal Epomophorine pale tufts. The interfemoral membrane is well haired. Skull with rostrum less elongate than in *M. grandis*. Teeth slightly built.

The discovery that three distinct species of *Micropteropus* are sympatric at Dundo is of special interest, as until 1950, when SANBORN described *M. grandis*, the genus had been believed monotypic. The new form, *M. intermedius*, is quite clearly intermediate in character between *M. pusillus* and *M. grandis*, and one effect of its discovery is that the generic distinction of *Micropteropus*, as defined by ANDERSEN (1912), is no longer so clearly recognisable as compared with *Epomophorus*. The strong shortening of the rostrum in the type species of the genus, *M. pusillus*, is not matched in either *M. grandis* or *M. intermedius*, in both of which the rostrum is longer in relation to total skull length, and the highly specialised palate ridges of *M. pusillus* lead, in *M. grandis* and *M. intermedius*, to a type which, while still peculiar, is approaching that found in *Epomophorus*. Thus it can be said that these two species tend to link *Micropteropus* with *Epomophorus*.

In this connection it may be mentioned that although the smallest *Epomophorus, E. labiatus minor* DOBSON, has closely similar overall measurements to *Micropteropus grandis*, its very distinct palatal ridges (the first four undivided), together with its longer narrower rostrum and longer, narrower teeth, remove any possibility of confusion.

p. 101

[table removed - eds.]

Mimetillus thomasi Hinton, 1920

p. 240

Mimetillus thomasi, sp. n.

Type. - An adult female, collected at N'dola on Oct. 4, 1919 [by Capt. Guy C. Shortridge (see p. 239)]; original number 481.

This interesting bat, represented by a single specimen, is distinguished from its West-African relative, *M. moloneyi*, chiefly by its larger size, duller colour, and still flatter skull.

General outward appearance and all the essential characters of the genus as in *moloneyi*. Size larger, the forearm measuring 31 instead of 27 - 29 mm. Third digit of wing relatively a little longer, its total length equalling 165 % (instead of 146 - 159 %) of the length of the forearm. Fur on back slightly longer. General colour, above and below, dark brown, deepening almost to black on head, dull, lacking both the gloss and the deep chestnut tinge seen in *moloneyi*.

Skull considerably larger (condyle to canine 14.1, instead of 13 mm.), with the characteristic depression and flattening of the brain-case even more pronounced than in *molouneyi*; interorbital region relatively broader. Dentition without especial peculiarities.

External measurements (taken in flesh by collector). - Head and body 56 mm.; tail 38; hind foot 7.5; ear 13.

Measurements of wing (made on skin). - Forearm 31; third digit, total length 51, its metacarpal and phalanges 1 and 2 being respectively 32.5, 9, and 9.5; fifth digit 36, its metacarpal 29.5. Revilliod's index of width 49.

Skull. - Extreme length 14.6; condyle to canine 14.1; canine to m^3 5.2; width of brain-case in mastoid region 9.5; median occipital depth 4.7; interorbital breadth 5.3; breadth across preorbital swellings 8; width across outer borders of m^3-m^3 7.8.

Mimetillus moloneyi was originally described from Lagos by Mr. Thomas. Many specimens were collected subsequently in Fernando Po; and we have lately received an example from Sierra Leone, collected by Mr. Willoughby P. Lowe. Hitherto no representative of the genus has been found inland or away from the West-African coast. Captain Shortridge's discovery in Rhodesia is therefore of considerable interest. I have great pleasure in naming the second species of this genus in honour of Mr. Oldtield Thomas, to whom I am indebted in so many ways.

Miniopterus Bonaparte, 1837

Miniopterus

In description of *Vespertilio emarginatus*:

Introducendoci ora nel sottogenere *Vespertilio*, il cui tipo inevitabile è il *V. murinus*, L. lo vediam corrispondere a quella sezione de Vespertìlìoni detta de' Murinoidi da Federico Cuvier, e tanto distinto dai nostri *Pipistrelli*, che se non si frapponesse il nuovo sottogenere *Miniopterus* lo riguarderemmo come genere confacendoci agli epistolari desiderii del dottissimo prof. Savi.

Miniopterus africanus Sanborn, 1936

p. 111

Type from Sanford's Ranch, Mulo, northwest of Addis Ababa, Shoa District, Ethiopia. Altitude 8,000 feet. No. 28769 Field Museum of Natural History. Adult female. Collected October 25, 1926, by A. M. Bailey. Orig. No. 73.

Diagnosis. - In general like *natalensis* but much larger. Skull and teeth larger. Zygomatic width greater than mastoid width.

Color. - Type, general color above very light Fuscous, bases of hairs Fuscous with light tips. Chin and throat dark where worn.

p. 112

Rest of under parts light, hairs Fuscous basally with gray tips. A few light gray hairs in pubic region.

A male and female topotype are practically like the type. Three other female topotypes have the head and shoulders near Natal Brown and the back near Clove Brown, some hairs with gray tips. The under parts are as in the type but browner.

Skull. - Large, with zygomatic width greater than mastoid width. Sagittal crest low. Teeth large.

Measurements. - Type and topotypes: forearm 50.4 (48.4 - 50.5). Skull: greatest length 16.9 (16.6 - 17); condylo-basal length 16.1 (16 - 16.5); palatal length 7.8 plus (8.2 - 8.8); interorbital width 4.2 (4.1 - 4.2); zygomatic width 9.4 (9 - 9.5); mastoid width 8.9 (8.7 - 9.1); width of brain case 8.3 (8.4 - 8.5); width across canines 5 (5 - 5.1); width across m^2-m^2, 7.1 (6.9 - 7.1); upper tooth-row c-m^3, 6.6 (6.4 - 6.6); lower tooth-row c-m_3, 7 (7 - 7); length of mandible 12.5 (12.2 - 12.7). Two alcoholic specimens from Kenya Colony: forearm 49.6 - 49.7; second digit metacarpal 45.9 - 45.9; third digit metacarpal 45.6 - 46.5, first phalanx 11.4 - 11.8, second phalanx 32.1 - 33.5, tip 6 - 6.5; fourth digit metacarpal 44.8, first phalanx 9 - 9.4, second phalanx 17 - 17.1; fifth digit metacarpal 40.6 - 41, first phalanx 9.8 - 10.6, second phalanx 7.6 - 7.6. Tibia 21.3 - 21.5; foot 11 - 11.

Specimens examined. - Type and five topotypes (six skins with five skulls) and two specimens in alcohol from Ulukenia Hills, Kenya Colony (U. S. Nat. Mus. Nos. 166595 - 96).

Remarks. - The large size and the color added to the more widely expanded zygoma will separate this form from all other African *Miniopterus*. Heuglin (Reise in Nord. Afrika, 2, p. 32, 1877) records a *Miniopterus* from Lake Tana which was identified by Peters as *M. dasythrix* of south and southwest Africa. His specimen may belong here but it is not recognizable from the description.

Miniopterus breyeri Jameson, 1909

p. 471

Miniopterus breyeri, sp. n.

I name this bat after my friend and former colleague Dr. H. G. Breyer, Chairman of Senate of the Transvaal University College, who accompanied me on the last of my collecting-expeditions in the Transvaal, when the series under description were captured.

It differs so markedly from the form inhabiting eastern South Africa that it requires a name to itself.

I may here say that it is probable that all the South African *Miniopteri*, with the exception perhaps of *M. minor*, Peters, will prove to be geographical subspecies of *M. schreibersi*, a form originally described from Southern Europe.

Sclater's 'Fauna of South Africa' treats the common South-African *Miniopterus* as *M. schreibersi*, but this form, which is of a light grey colour, does not appear to extend into South Africa at all.

Description. - Size as in *M. natalensis*, but lighter in colour. The hairs on the dorsal surface are reddish brown or reddish grey, the tips with a slight tinge of red-gold. On the ventral surface the tips of the hairs are rather lighter, becoming almost white in the pubic region.

The bases of the hairs are never black, as in *M. natalensis*.

Dimensions of the type: -
Head and body 56 mm.; tail 53; ear 11 tragus 6; forearm 46.

Type F. No. 398 (B.M. no. 9.7.2.6).

These examples were found in the great cave at Gatkoppies, in the Waterberg District of the Transvaal. There must have been many hundreds in one small chamber, the roof of which was black for many yards with a continuous cluster of bats.

All the examples examined were females.

Miniopterus breyeri vicinior J.A. Allen, 1917

p. 450

Type, No. 49019, M ad., skin and skull, Aba, northeastern Belgian Congo, Dec, 16, 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1770.

Differs from *M. breyeri breyeri* in slightly smaller size and in the absence of white on the pubic region.

Upperparts dark drab, the hairs unicolor from base to tip; underparts paler, grayish drab, the hairs dark brown basally with grayish brown tips; the pubic region fulvous; ears and membranes dark brown. Limb bones ventrally light yellow brown; calcar yellowish white.

Wing membranes attached at or slightly above ankle; no post-calear lobe. Ears very small, uniformly convex on outer and upper border, posterior border nearly straight. Tragus long, narrow, with parallel edges, 4.8 mm. long by about 1.5 mm. wide.

Collectors' measurements of type: Total length, 100 mm.; head and body, 52; tail, 48; foot, 11; ear, 11. Forearm (from skin), 43.2; third metacarpal, 40; tibia, 28; foot, 8.8; ear, length, 6.5, width, 7.5.

Skull (type), total length, 14.8; zygomatic breadth, - ; breadth of braincase, 7.5; interorbital breadth, 3.8; maxillar breadth, 5.6; breadth at base of canines, 3.8; maxillary toothrow (with canine), 5.1; length of lower mandible, 10.4; height at coronoid, 3.2; lower toothrow, 6.3.

Represented by 17 specimens (skins and skulls), all adult, and all taken at Aba, Dec. 10, 1911.

Collectors' measurements, 8 males and 8 females (MM; FF): Total length: 101 (94-105); 103 (96-108); Head and body: 54.5 (51-59); 54.0 (50-57); Tail: 46.3 (43-49); 49.0 (46-50); Foot: 10.6 (10-11); 10.5 (10-11); Ear: 10.6 (10-11); 10.7 (10-11).

p. 451

Forearm, from skins, same specimens, M 43.6 (42-44.7), F 44.2(43.4-44.9).

Skull, 5 males, 6 females: Total length, M 14.6 (14.3-15), F 14.7 (14.4-14.9); breadth of braincase, M 7.4 (7.2-7.6), F 7.5 (7.3-7.7).

The present form is similar in general coloration to *M. breyeri breyeri*, from the Waterberg District of the Transvaal, with two topotypes of which the present series has been compared. The pubic region is pale fulvous, however, instead of white, and the average size is considerably less, the forearm in *breyeri* having a length
(3 specimens) of 46 mm. and in *vicinior* (16 specimens) 43.5, the largest specimen of the latter being smaller than the smallest of the *breyeri* specimens. Jameson gives the length of the skull in *breyeri* as 15.5; the average in *vicinior* is 1 mm. less, only one in a series of 12 skulls reaching 14 mm.

M. breyeri vicinior is readily separable from the *M. natalensis* group by its paler, much browner coloration and by other features, as shown by direct comparison with typical *natalensis* and with topotypes of *natalensis arenarius*.

Miniopterus fraterculus Thomas and Schwann, 1906

p. 162

M. 1073, 1077. F. 1079. Knysna

Closely similar in every respect to *M. dasythrix*, agreeing with that species absolutely in colour, even to the peculiarity in the respective coloration of the two sexes. Thus the back of the male is smoky blackish, the head and whole of the under surface dark brown (darker than Prout's brown); the female is dark brown above and below, rimmed with black along the hinder part of the back. But the skull and teeth are very markedly smaller and the forearm rather shorter; though the latter is not so much shorter than in *dasythrix* as might have been expected from the difference in the skulls.

Dimensions of the type, the starred measurements taken in the flesh: -

Forearm 43.7 mm. (other specimens, M 43, F 44).

*Head and body 54 mm.; *tail 53; *ear 9; *tragus 4; third finger 79; lower leg and foot (c.u.) 27.5.

Skull - greatest length 14.7; basal length in middle line 11.2; breadth of brain-case 7.5; height of brain-case from basion 6.3; palate length 5.7; front of canine to back of m^3 5.5; greatest breadth of palate, including molars, 5.6; front of lower canine to back of m_3 5.7.

Type. Male. B.M. No. 5.5.7.18. Original number 1073.

Taken 3 October, 1905.

"In cave on sea-coast."

Like as all the eight specimens of *Miniopterus* found at Knysna are to each other in most respects, we have come to the conclusion that they cannot be referred to one species, as in size they fall into two groups, without intermediates. We have therefore described the smaller form as new, while the larger, as already noted, may be referred to *M. dasythrix* Temm.

"Fairly common. *Miniopteri* were taken in both the caves where *Rhinolophus augur* and *Rousettus collaris* were secured." - *C.H.B.G.*

Miniopterus gleni Peterson, Eger and Mitchell, 1995

p. 128

(MMAD, fig. 60 et 61)

Holotype: Royal Ontario Museum (ROM) 42567, mâle adulte, crâne et peau récoltés le 9 mai 1967 dans une grotte marine entre Sarodrano et Saint-Augustin, à 20 km au Sud de Tuléar.

Description. - Pelage long, soyeux, sombre; poils du dos longs de 7 à 8 mm: Bnun Girofle à Brun Foncé (Ridgway 1912); poils du ventre longs de 5 à 6 mm, couleur générale un peu plus pâle que sur le dos. Oreilles basses, arrondies, à large teagus uniforme (fig. 60). Museau large et poilu. Crâne grand et large avec la boîte crânienne haute, longue et arrondie (fig. 61). Formule dentaire I 2/3, C 1/1, P 2/3, M 3/3.

Diagnose. - Le plus grand des *Miniopterus* malgaches. Diffère de *M. inflatus* d'Afrique (*M. i. inflatus*, MIIN; *M. i. rufus*, MIRU) par les tibias nettement plus longs; les 3ème et 4ème métacarpiens nettement plus longs (3DME et 4DME), la calotte crânienne plus haute (HBC), le rostre plus large (ROSW et CCUP); les rangées dentaires (M^3-M^3) et C-M^3) plus longues et plus larges et par le plus fort rétrécissernent post-orbital (POC). Il diffère de *M. africanus* (MXAF) par le tibia significativement plus court, le 5e métacarpien plus court (5DME), la plus grande largeur du rostre (ROSW, M^3-M^3, CCUP), la plus grande longueur du palais (PALL et PALN). mais la partie post-palatale plus courte (PPL). la plus grande largeur de la rangée dentaire (C-M^3) et de la mandibule (MANL). Le tableau 26 permet de comparer *M. gleni, M. inflatus* et *M. africanus*. *M. gleni* est significativement différent

[table removed - eds.]

p. 131

des autres *Miniopterus* malgaches par tous les caractères, sauf celui de la première phalange, qu'il partage avec *M. majori* (MSMD).

Distribution. - Répandu dans la plus grande partie de Madagascar, et, en particulier, dans les régions côtières.

Nous avons étudié 77 spécimens de cette espèce.

MADAGASCAR NORD: Cap Diégo (ZMK).

MADAGASCAR-EST: 20 km au N.-O. de Maroantsetra. - 40 km au N.-O. de Maroantsetra (MNHN et FMNH).

MADAGASCAR CENTRE: Maninday (ROM). - Beroroha (BMNH).

MADAGASCAR SUD-OUEST: Sarodrano, Saint-Augustin, 20 km au S. de Tuléar (ROM).

Variation systématique. - Etant donné que l'analyse multivariable ou univariable n'a pas permis de trouver de différences entre les populations du Nord-Est et celles du Sud-Ouest, traitées séparément, l'ensemble de l'échantillon malgache a été regroupé en un seul OTU.

Les mesures sur le terrain des exemplaires capturés par nous dans le Sud-Ouest malgache, de l'holotype * et des valeurs moyennes et extrêmes de huit mâles et de quatorze femelles étaient les suivantes:

Poids: 15*, mâle 14.25 (11 - 16); femelle 13.6 (11 - 17).
Longueur totale: 124*, mâle 120.4 (110 - 126); femelle 117.6 (112 - 126).
Longueur de la queue: 56*, mâle 55.2 (53 - 57); femelle 55.2 (51 - 60).
Longueur du pied: 11*, mâle 11.4 (11 - 13); femelle 11.3 (10 - 13).
Longueur de l'oreille au-delà de l'entaille; 15*, mâle 15.0 (14 - 16); femelle 14.8 (14 - 16).
Envergure alaire: 358*, mâle 356.0 (344 - 360); femelle 356.7 (342 - 369).

Les longueurs de l'avant-bras, du tibia et les mesures du crâne de l'holotype et les statistiques basées sur une série de 58 *M. gleni* (MMAD) figurent tableau 26.

Biologie. - On trouve, nichant avec *M. gleni*, dans la region de Saint-Augustin, les espèces suivantes: *M. majori, M. manavi, Triaenops furculus, Myotis goudoti* et *Otomops madagascariensis*. On l'a trouvé en association sympatrique avec *M. fraterculus*; dans des grottes à 20 km au N.-O. de Maroantsetra en juin 1936 (MNHN à Paris). Sur la base des données actuelles, *M. gleni* n'a pas été trouvé associé à *M. manavi* dans la région centrale, dans la savane de l'Ouest ou à la Montagne d'Ambre. A Madagascar, le même gîte est souvent partagé par deux ou quelque fois trois espèces de *Miniopterus*.

Miniopterus inflatus Thomas, 1903

p. 634

Colour of *M. scotinus*. Size larger than in *M. Schreibersi*.

Fur of back about 4 mm. in length, its texture about as in *M. scotinus*, not extending on the interfemoral or wing-membranes except close to the sides below. Colour uniform dark "seal-brown" above, rather paler below. Ears and membranes black.

Skull markedly larger than in *M. Schreibersi*, therefore still more exceeding that of the similarly coloured *M. scotinus*.

Dimensions of the type: -

Forearm 46 mm.

"Head and body 65; tail 48; hind foot 7; ear 11" (*G. L. B.*).

Skull: greatest length 16.7; basal length in middle line 12.3; front of incisors to back of m^3 7.8

Hab. Efulen, Cameroons.

Type. Adult skin (male). B.M. no. 3.2.4.8. Collected 24th July, 1901, by Mr. G. L. Bates.

This *Miniopterus* is at once distinguishable from *M. Schreibersi* by its dark colour and large head, and from *M. scotinus* and *M. Newtoni* by its much larger size.

Miniopterus inflatus villiersi Aellen, 1956

p. 890

?*Miniopterus inflatus* J. ALLEN, 1917; SANBORN, 1936; HAYMAN, 1954.

8 spécimens, n° 54-1-1 (type) à 54-1-8. 3 M. 5 F. Grotte du Marché, Dalaba, 16-4-1954.

Aucun *Miniopterus* n'est signalé jusqu'à présent en A.O.F. En effet, MONARD (1939), VEIGA-FERREIRA (1949), CANSDALE (1948), ROSEVEAR (1953), etc. n'en citent pas. Ce genre n'a pas été trouvé plus à l'Ouest qu'au Cameroun anglais où SANBORN (1936) indique "*M. inflatus*".

Avant d'examiner ces spécimens de Guinée française, j'avais déjà été surpris de constater que divers auteurs rapportaient à *inflatus*, avec quelques doutes d'ailleurs, des Chauves-Souris de taille nettement inférieure.

P. 891

Grâce au matériel rapporté par J. L. PERRET du Cameroun français, je suis maintenant en mesure de confirmer la diagnose de *inflatus* de THOMAS (1903). En effet, je possède 6 spécimens de Nkoétyé, près d'Ebolowa, qui correspondent parfaitement à *inflatus*, en particulier par leurs grandes dimensions. Ce sont presque des topotypes, puisque la localité typique de *inflatus* est Efoulen, situé à quelque 90 km. à l'Ouest de Nkoétyé, dans le même biotope.

Je suis persuadé que les "*inflatus*" de J. ALLEN (Thysville, Bas Congo), de SANBORN (Mont Cameroun) et de HAYMAN (Thysville: Kakontwe; Mont Homa, Congo belge) appartiennent à une autre forme. Les spécimens de Guinée française semblent correspondre à ces derniers et je propose de les nommer *Miniopterus inflatus villiersi*. Il sera peut-être permis d'élever cette forme au rang spécifique, s'il s'avère qu'elle cohabite avec *M. inflatus* typique.

TYPE. - M ad., grotte du Marché, Dalaba, Guinée française, 16-4-1954, collecté par A. VILLIERS. N° du collecteur 2839. N° 54-1-1 des collections zoologiques de l'IFAN, Dakar. 7 paratypes don't 2 M et 5 F.

DIAGNOSE. - *Miniopterus* de taille moyenne, voisin de *inflatus* du Cameroun, mais s'en distinguant par un avant-bras, un pouce et des mesures crâniennes plus petites.

DESCRIPTION. - La coloration de la fourrure est brun noir uniforme. Le patagium et les oreilles sont brun grisâtre. L'extrémité distale du tragus est blanche, dépigmentée; ce caractère s'est révélé constant chez les 8 spécimens.

Le crâne présente la particularité d'avoir la largeur zygomatique plus grande que la largeur mastoïde, ce qui distingue cette nouvelle forme de tous les autres *Miniopterus* africains, à part *africanus* (1) et *rufus* (2). SANBORN (1936 : 111) dit que *inflatus* a des largeurs mastoïde et zygomatique subégales ou que la première est plus grande que la seconde. Ce caractère n'est pas signalé dans la description originale et les auteurs subséquents qui citent *inflatus* n'en parlent pas non plus. Chez les *inflatus* typiques rapportés par J. L. PERRET, la largeur zygomatique est nettement plus grande que la largeur mastoïde.

P. 892

Dans le tableau suivant , on trouvera les mesures de la nouvelle, forme et, à titre de comparaison, celles de *inflatus* typique.

[Table removed - eds.]

Les "*inflatus*" mesurés par J. ALLEN, SANBORN et HAYMAN sont, tout à fait comparables à nos *inflatus villiersi*:

avant-bras : (A) 44.2 - 46: (S) 42.2 - 45.4; (II) 44.4 - 44.6;
crâne. Long. Tot.: (A) 15.3 - 15.9; (S) 15 - 15.3;
- larg. Zygom.: (A) 8.6 - 8.7;
- rang. Dent. I-M^3: (S) 6.9.

p. 893

ECTOPARASITES. - 4 spécimens d'une nouvelle espèce de Nyctéribiidé ont été pris sur ces *Miniopterus*. Cette espèce sera décrite par O. THEODOR sous le nom de *Nycteribia exacuta*, dans son prochain article sur les Nyctéribiidés éthiopiens.

Un spécimen de *Raymondia huberi* FRAUENF. examiné par B. JOBLING a également été trouvé, de même que quelques Acariens non encore déterminés.

Miniopterus Majori Thomas, 1906

p. 175

Size large, slightly exceeding that of the largest South-African members of the genus. Fur fairly long, hairs of back about 6 mm. in length. Colour dark glossy black, with a slight brownish suffusion, the head not or scarcely lighter than the back; the hairs black for their basal half, then dull yellowish brown, their terminal fourth glossy black. Under surface little lighter, the ends of the hairs dark brown instead of black. Fur extending slightly on to interfemoral membrane both above and below.

Dimensions (see below).

Hab. Madagascar. Type from Imasindrary, N.E. Betsileo. Other specimens from Vohimar.

Type. Adult female. B.M. no. 97.9.1.33. Original

p. 176

number 457. Collected 3rd July, 1895, by Dr. C. I. Forsyth Major, after whom the species is named.

This large Malagasy *Miniopterus* differs from *M. dasythrix*, Temm., its South-African ally, by its glossy black colour and the dull yellowish rings on the dorsal hairs, that animal being of a "noir mat," as stated in the original description, confirmed by fresh specimens recently received from Knysna (Rudd Collection).

Miniopterus manavi Thomas, 1906

p. 176

Size small, much smaller than in *M. Majori*, which occurs in the same localities. Fur of medium length, hairs of back about 5 mm. Fur of body extending thinly over nearly half the upper surface of the interfemoral membrane and on the proximal fourth below. General colour blackish, not so glossy as in *M. Majori*, the hairs blackish for two thirds their length, with dull brown tips. Under surface similar, but rather paler.

Some specimens are dull reddish throughout, representing a rufous phase of the species.

Skull comparatively small and delicate, with a smooth and narrow brain-case.

Dimensions (see table below).

Hab. Madagascar. Type from Imasindrary, N.E. Betsileo. Other specimens from Vinanitelo.

Type. Male. B.M. no. 97.9.1.37. Original number 453. Collected 3rd July, 1895, by Dr. C. I. Forsyth Major.

This is the bat called by Dobson *Miniopterus scotinus*, Sund., but Sundevall's species has a forearm 44 mm. in length, and differs also by its much paler colour and its African habitat. *M. Majori* again was referred by Dobson to *M. Schreibersi*, from which, to use his own words, it "only differs in colour and in the forearm being constantly longer."

Peters's *M. minor* is presumably nearly related to *M. manavi*, but from its continental habitat (Zanzibarà) is no doulbt specifically distinct.

Dimensions of the two *Miniopteri* above described: -

	M. majori; *M. manavi* mm
Forearm:	46.3; 39.2
skull:	
Greatest length:	15.5: 13.8
Basal length in middle line:	12; 10.4
Front of canine to back of m^3:	6.4; 5.0
Breadth of palate outside m^2:	6.6; 4.9
Front of lower canine to back of m_3:	6.7: 5.4

p. 177

The difference in size between these closely allied species affords an instance of the curious tendency of Chiroptera to sort themselves into couples, a larger and a smaller form of so many different groups being often found, as in this case, inhabiting the same locality.

Miniopterus minor Peters, 1867

p. 885

In der Färbung, dem Ansatz der Flughäute, der Bildung der Spornen u. s. w. mit *Miniopterus Schreibersii* übereinstimmend, aber beträchtlich kleiner als diese Art.

Totallänge 0^m,086; Kopf 0^m,0153; Ohr 0^m,010; Schwanz 0^m,042; Vorderarm 0^m,037; Mittelfinger 0^m.072; Tibia 0^m,014.

Ein einziges ausgewachsenes Männchen von der Küste von Zanzibar.

Miniopterus minor griveaudi Harrison, 1959

p. 192

in honour of its discoverer, M. Paul Griveaud.

Type: Adult female. Grande Comore Island, Comoro Islands, Indian Ocean. 10 August, 1958. Obtained by M. Paul Griveaud. In my collection, No. 3.2803.

Description: Differs from *Miniopterus minor* Peters in the decidedly narrower braincase and rostrum of the skull (See Photo) and also in colour, being a darker shade of brown on the back and belly. It differs from *Miniopterus minor manavi* only in colour,

there being two colour phases in that form, either blackish on the back or dull reddish, as described by Thomas (1906). The dorsal surface of the Type of *M. minor griveaudi* closely approximates to Bison (Plate .... Maerz and Paul, 1950). On the belly it is slightly

p. 193

paler brown but again darker than the examples of *M. m. minor* and different from both colour phases of *M. m. manavi*.

Measurements of the Type: Forearm 37.8, hind foot 7.2, ear 7.8 mm.

Cranial measurements (in mm.): Condylobasal length 13.1, zygomatic breadth 6.7, interorbital constriction 2.9, breadth of the braincase 6.2, mandible 10.5, maxillary dentition c-m^3 5.0, mandibular dentition c-m_3 5.4, width of the palate from the external alveoli across m^2-m^2 4.9.

Remarks: In contrast to the material of *M. m. manavi*, the paratypical series of *M. m. griveaudi* are very uniform in colour and the five paratypes, three of which are now in the Museum d'Histoire Naturelle, Paris, differ little from the Type. At this stage little definite can be stated about the exact shade of colour found in *M. m. minor*, which was not described in detail by Peters and the two examples here recorded had been immersed for a short while in alcohol and their tint may thus have been slightly altered, but it is clearly different. However, all three skulls of *M. m. griveaudi* which have been examined differ strikingly from *M. m. minor* in their narrvow, delicate braincases, whilst the difference in colour from

p. 194

M. m. manavi is equally striking. It is interesting to note that the fur of the body extends thinly over the proximal half of the upper surface of the interfemoral membrane in all the examples of *M. m. manavi* in which this character can be ascertained, as stated by Thomas in his description. In two of the three examples of *M. m. griveaudi* this part of the membrane is naked, while in one it is haired thinly as in *M. m. manavi* but less marked. In the case of the two examples of *M. m. minor* both have a thin hairy covering of this part of the interfemoral membrane. It is clear therefore that this character does not distinguish the Madagascar form specifically, but that it is of some value in subspecific determination. No differences in dentition have been noted.

The measurements of all the material examined are tabulated below, compared with those of the Type of *M.minor* after Peters.

[table removed - eds.]

Miniopterus natalensis arenarius Heller, 1912

p. 2

Æquatorial Broad Winged Bat

Type from the Guaso Nyuki, Northern Guaso Nyiro River, British East Africa; adult female; No. 181811, U.S. Nat. Mus.; collected by Edmund Heller, October 4, 1911; original number, 4413.

Characters. - Size of *natalensis*, but color paler, pelage shorter; the skull with broader brain-case and with inner incisor greatly exceeding outer in size.

Coloration. - Dorsal color seal-brown, the head darker, clove-brown, and the rump lighter walnut-brown, the hair only slightly darker at the base; underparts washed with drab-gray, the hair basally dark slaty; ears and membranes blackish, the latter narrowly white bordered.

Measurements. - Head and body, 55 mm.; tail, 47; hind foot, 9; ear, 11; forearm, 45.

p. 3

Skull: Greatest length, 14.8; condylo-incisive length, 14.3; basilar length, 11: zygomatic length, 5.6.; upper cheek teeth, 4.8; condylo-incisive length of mandible, 10.9; coronoid-angular depth of mandible, 3.5.

The type was secured in a large crevice among granite boulders on the summit of a small kopje. One other specimen was shot at dusk among some acacia trees in the same vicinity.

Miniopterus Newtoni Bocage, 1889

p. 198

De la taille à peu-près du *M. scotinus*. Pelage d'un beau brun-marron, plus pâle, tirant au roux, sur la partie inférieure de l'abdomen; membranes alaires et caudale noires. Museau court, glanduleux, ayant de chaque côté de la face, au-dessous de l'œil, un sillon horizontal profond. Oreilles beaucoup plus courtes que la tête, d'une forme à peu-près quadrangulaire, à contour supérieur droit; tragus allongé, étroit, arrondi à la pointe. Ailes se prolongeant jusqu'à l'extrémité inférieure de la jambe. Pieds longs et étroits. Queue entiérement comprise dans la membrane interfémorale, de la même longueur que la tête et le tronc réunis. Une bande étroite de poils, de la couleur du dos, sur la face dorsale de la membrane alaire, limitée en dehors par une

ligne tirée du tiers supérieur de l'humerus au milieu du fémur; en dessous tout l'espace compris entre l'humerus et le fémur est revêtu de poils plus clairsemés; la membrane interfémorale nue sur ses deux faces.

Tête et corps 45 mm., queue 43 mm., tête 16 mm., oreille 95 mm., tragus 45 mm., avant-bras 39 mm., pollex 5 mm., 3^{e} doigt - metac. 34 mm., 1^{e} phal. 10 mm., 2^{e} phal. 28 mm., jambe 16 mm., pied 9 mm.

Nos individus de St. Thomé me semblent bien distincts du *M. scotinus*, de Madagáscar et de la côte orientale d'Africa, le seul avec lequel il serait possible de les confondre, par son système de colora-

p. 199

tion et surtout, par une disposition tout-à-fait différente des poils sur les membranes alaire et interfémorale. Je suis arrivé à cette conclusion non pas par suite d'une comparaison directe des deux especes, car le *M. scotinus* ne se trouve pas représenté dans nos collections, mais en me servant de la description de cette espèce, publiée par M. Dobson dans son *Catalogue des Chiroptères du Muséum Britannique*. "Le *M. scotinus*, suivant cet auteur, est d'un brun-roux ou brun-foncé, presque noir, avec les parties inférieures d'une teinte plus pâle. En dessus l'aile porte une bande distincte de poils courts entre le coude et le coude-pied, tandis que l'espace compris entre la moitié externe de l'humerus, le tibia et le genou est presque entiérement nu; la moitié de la membrane interfémorale est couverte de poils courts et clairsemés, qui forment aussi une bande sur le bord interne de la jambe jusqu'à la base du calcanéum".

Miniopterus rufus Sanborn, 1936

p. 112

Type from Katobwe, 40 miles below Bukama on the Lualaba River, Tanganyika-Moero, Belgian Congo. No. 29416 Field Museum of Natural History. Adult male. Collected November 28, 1926, by J. T. Zimmer. Orig. No. 566.

Diagnosis. - About the size of *M. africanus* but with shorter forearm and tibia and of a reddish brown color.

Color. - Reddish brown, between Kaiser and Carob Brown (Ridgway, 1912), slightly lighter below. Hairs uniform to bases.

p. 113

Skull. - In general like *africanus* but narrower and with lambdoid and sagittal crests more developed and mandible heavier.

Measurements. - Forearm 47.4. Skull: greatest length 16.9; condylo-basal length 15.9; palatal length 8.7; interorbital width 4.1; zygomatic width 9.4; mastoid width 9.1; width of brain case 8.2; width across canines 5; across m^2-m^2, 6.7; upper tooth-row c-m^3, 6.4; lower tooth-row c-m_3, 7; length of mandible 12.8.

Remarks. - While there is but one specimen, the type, the character of the skull and the very different color seem to be of enough importance to separate this form from other African *Miniopterus*. There seems to be no red phase in this genus as in *Hipposideros, Myotis*, and others, but there has been another *Miniopterus* described which is of about this color, *M. ravus* Sody, of central Java.

Mops (Allomops) faradjius J.A. Allen, 1917

p. 476

Type, No. 49222, M ad. (in alcohol), Faradje, northeastern Belgian Congo, Nov. 1, 1913; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig, No. 3015.

Similar to *A. osborni* in general size and in coloration, but with a shorter forearm (44 instead of 49 mm.), a vestigial p^2 on the right side only, in the toothrow (visible only by aid of a strong lens), less developed sagittal and lambdoid crests (doubtless due to the fact that it is much younger than the type of *osborni*), darker upperparts and a more decided brownish band across the pectoral region.

Upperparts blackish brown, much darker than in *osborni*; underparts blackish brown along the sides and across the throat, forming a darker and broader pectoral band, the central area broadly whitish. Ears and membranes blackish, and in all other respects similar to those of *osborni*. The broad patch of glandular hairs between the ears deep black, fuller and longer than in *osborni* and covering the membrane connecting the ears, but not lengthened into a crest as in *Lophomops*.

Total length, 108 mm.; head and body, 76; tail, 32; forearm, 43.5; third metacarpal, 42.5; third finger, 82; ear from crown, 10; from notch behind antitragus, 17; expanse from tip to tip of both ears, 32.8; tibia, 15; foot, 9.

Skull, total length, 22.2; zygomatic breadth, 12.9; mastoid breadth, 11.5; breadth of braincase, 9.3; interorbital breadth, 4; maxillar breadth, 8.8; breadth at base of canines, 6.7; upper toothrow (c-m^3), 7.6; length of mandible, 14; angle to condyle, 4.5; depth at coronoid, 3.7; lower toothrow, 8,7; transverse extent of lambdoid crest at upper border, 6.7.

Represented by only the type, taken at Faradje, and labelled by the collectors

p. 477

as "from the; stomach of a *Machærhamphus* hawk." The specimen (preserved in alcohol) is practically uninjured for study.

As noted above, *Mops (A.) faradjius* closely resembles osborni, but it has a much shorter forearm; a slenderer body, and, though a male, is somewhat smaller in both external und cranial measurements. It is also markedly darker in general coloration. The type localities of the two forms (Kinshasa and Faradje) are far apart and in regions of widely different environment.

Mops (Allomops) nanulus J.A. Allen, 1917

p. 477

Type, No. 48864, M ad., skin and skull, Niangara, Belgian Congo, Dec. 12, 1910; Herbert Lang and James P. Chapin, American Museum Congo Expedition. Orig. No. 1318.

Similar in cranial characters and in dentition to *Mops (A.) occipitalis*, but much smaller and much lighter in coloration.

Upperparts cinnamon-brown; below with the whole median area lighter, the tips of the hairs dull gray with a slight yellowish or buffy tone, the sides much like the back but rather darker; extreme lower back naked or with only a slight pubescence; a thin fringe of bristly hairs from the posterior border of the dorsal pelage, the longer of these reaching to the base of the tail. Wing membranes from the sides of the back, light brown above, somewhat paler apically and on the lower surface. Interfemoral membrane palish brown above and below. Ears of medium size and thickness connected by a low membrane, from tho back of which (most prominent in males) is a tuft of lengthened hairs, as in its larger congeners; inner base of ears heavily furred and otherwise agreeing closely in form and structure with those of *occipitalis*. Tragus small, pointed, black. Antitragus of medium size, broad basally, convex on upper border. Tail short, rather more than the apical half free.

Skull and dentition similar to that of *A. occipitalis*.

Type, collectors' measurements: Total length, 82 mm.; head and body, 61; tail, 21; foot, 9; ear, 15. Forearm (from skin), 28.5. (The type is the largest of a series of 6 specimens.)

Type and 5 topotypes (3 males, 3 females), collectors' measurements: Males, total length, 78.7 (75-82), females, 76 (76-77); head and body, males 58 (56-61), females 55.7 (54-58); tail, males, 20.3 (19-21), females, 20 (19-21); foot, males 8 (7-8), females 9 (all 9); ear, males 15.5 (15-17), females 17 (16-18). Forearm (from skin), males 28.6 (28.3-28.7), females, 27.4 (27.3-27.0).

Skull (type), total length, 16.8; condylobasal length, 15.5; zygomatic breadth, 10.9; mastoid breadth, 9.6; interorbital breadth, 3.3; maxillar breadth, 7.3; breadth at base of canines, 3; depth (including pterygoids), 5.7; upper toothrow (with canine), 6.1; length of mandible, 11.2; height, angle to condyle, 3.5; depth at coronoid, 2.9; length of toothrow, 6.8.

Skull, type and 5 topotypes (3 males, 3 females): males, total length, 16.5 (16.0-16.8), females 15.4 (15.3-15.0); zygomatic breadth, males 10.3 (10.5-11), females; 9.9 (9.8-10). The females are thus smaller than the males, and they also lack the extreme development of the supraoccipital region shown by the males.

Represented by 7 specimens, all collected the same day at Niangara.

p. 478

This species is readily distinguished from all other known African mollosid bats by its extremely small size, aside from any other characters.

Although the premaxillæ are slightly emarginate behind the incisors, the other characters both external and cranial, agree completely with the larger forms here referred to *Allomops*, even in the sexual difference, and especially the sexual difference in the size of the lower premolar, p_2 being larger than p_4 in the males and smaller than p_4 in the females.

Mops (Allomops) occipitalis J.A. Allen, 1917

p. 474

Text Fig. 15

?Nyctinomus thersites THOMAS, Ann. and Mag. Nat. Hist. (7), XII, p. 364, Dec. 1903. Efulen, Cameroons.

Type, No. 48851, ad. M, skin and skull, Avakubi, Belgian Congo, Feb. 13, 1914; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 2487.

Pelage short, soft and velvety, about 1.5 mm. in length on the back to about 2.5 on the sides of the neck, throat, and sides of body below. External base of ears and whole space between them thickly covered with slightly lengthened glandular black hairs, which also cover tho back of the low connecting membrane, but do not rise much above it.

Fur of upperparts dark chocolate-brown; the sides of the back, the lower back from a line joining the hips posteriorly, and the hind limbs naked and blackish, the central furred portion of the back, from considerably in front of the shoulders to hips, of about

the same width as the naked area each side. A scanty fringe of long bristly hairs (blackish or mixed with a few whitish ones) from the hips, directed backward, the longest reaching to or beyond the middle of the uropatagium (scanty or nearly wanting in some specimens). Underparts blackish laterally, the median area buffy brown; a ventral area (corresponding ventrally with that of the lower back) and limbs naked, pale rusty brown (the denuded space much reduced in some specimens). Ears near together, blackish brown, united by a low membrane which extends forward as a swollen obtuse projection reaching nearly half-way to the nose; front and upper border of ears thickened, forming a sharp angle at the anterior inner border; tragus merely a minute dusky point, about 2 mm. in height; antitragus brownish, small, about 4 X 4 mm., bluntly convex above. Face naked, blackish; nostrils prominent, upper lip weakly corrugated; chin naked, brownish. Wings from middle of tibia. Forearm and membranes naked. Wing membranes above, including antebrachium, blackish brown, lighter, grayish brown apically; below simi-

p. 475

lar, the humerus and forearm whitish, in strong contrast with the membrane. Uropatagium dark brown and naked on both surfaces.

Collectors' measurements of type: Total length, 98; head and body, 68; tail, 30; foot, 11; ear, 18. Additional measurements from the skin: Forearm, 38; tibia, 15.5; foot, 10; ear from crown, 9; from notch behind antitragus, 16.

Collectors' measurements of 4 specimens (2 males, 2 females) from Medje (near type locality); Total length, 99 (98-101); head and body, 70 (68-73); tail, 29.2 (28-30); foot, 9.6 (8-11); ear, 18 (all 18). Forearm (from skins), 38 (36-39).

Measurements of the type skull: Total length, 20.4; condylobasal length, 18; zygomatic breadth, 12.7; mastoid breadth, 11.5; breadth of braincase, 9.5; interorbital breadth, 4.1; maxillar breadth, 8.2; breadth at canines, 5.8; depth (including pterygoids), 7.8; length of upper toothrow (c-m^3), 6.9; length of mandible, 13.4; angle to condyle, 4.5; depth at coronoid, 4; length of lower toothrow, 7.4 (Fig. 15).

Four skulls from Medje: Total length, 2 young adult males, each 91.8; 2 young adult females, 18.3, 18.8; zygomatic breadth (2 males, 1 female), all 12.5.

In the adult males the skull has the occipital region enormously developed, the lambdoid crest being high and broad with a marked backward overhang. In females and young males (subadult) it is much less developed. The mandible is noticeably massive in even young specimens.

Represented by the type, from Avakubi, and 6 specimens from Medje, of which 2 are about half grown and the others young adults, collected Sept, 15-16, 1910.

p. 476

Judging from the description, *Nyctinomus thersites* Thomas, greatly resembles the present species but whether they are identical cannot be satisfactorily determined without direct comparison of the types. The description of *thersites* makes no direct mention of the coloration of the underparts, which in *occipitalis* are very unlike the upperparts, the coloration of *thersites* being described as "Colour brownish chestnut, glandular hairs back of ears black." Other features mentioned point strongly to a form greatly resembling *occipitalis*. In *thersites* the premaxillæ are thus described: "Premaxillæ separated, but opening between them small," for which reason the species has been regarded as a *Nyctinomus*. In six skulls of *occipitalis* the premaxillæ are fully ossified in four of them and in the other two (one of them the type and the most mature specimen) there is a slight opening behind and between the incisors. In a skull of *A. faradjius* (the only one available for examination) the premaxillæ are fully ossified. In five adult skulls of the much smaller *A. nanulus* there is a very small opening at the inner base of the incisors in all, but in all other characters, external and cranial, including color pattern and femoral bristles, *nanulus* is obviously only the little brother of the three larger forms here referred to *Allomops*.

Mops (Allomops) osborni J.A. Allen, 1917

p. 473

Text Fig. 12-14, and 26.

Type, No. 49230, M ad. (in alcohol), Kinshasa (near Leopoldville), Belgian Congo, Dec. 22, 1914; cotype, No. 94244, F ad. (alcoholic), same locality and date. Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. of type 2570.

Upperparts dark hair-brown with a grayish sheen, the hairs whitish at extreme base; underparts, sides paler brown than back, the hairs grayish-tipped, the central area from chest posteriorly broadly white, throat and an indistinct pectoral band; grayish brown; wing membranes and limb bones above dark brown, below lighter, becoming whitish toward the body, including the propatagium and a narrow posterior edging; uropatugium dark brown above, whitish below; ears united by a deep band, the back of the membrane (in both sexes), covered with lengthened hair-brown hairs which barely reach its upper border (Fig. 14). Tragus minute; antitragus small (about 4 X 4 mm.), evenly rounded above. Sides of back, lower back and hind limbs above naked and dark brown; under side of limbs and anal region naked and yellowish white. Face dark brown; upper lip heavily corrugated. No gular pouch in either sex. Feet heavily clothed with spoon hairs (see Fig. 20, p. 556).

Total length, male type, 111.3, female cotype, 106.6; head and body, 73.5, 70, tail, 37.8, 36.6; forearm, 49, 47; third metacarpal, 47.2, 46.5; tibia, 17.5, 16.5; foot 10.5, 10.2; ear from crown, 8.5, 9; length from notch at posterior base of antitragus, 14.7, 12.5; expanse (tip to tip), 33.8, 32.

Skull in the old-adult male type with a highly developed sagittal crest, as in *Mollossus*, but differing from the latter in having also the lambdoid crest enormously developed, as in some other species of the *Mops* group. In the male type the sagittal crest has a height of 1.8 mm. and extends from the interorbital region to the lambdoid; in the female cotype neither the sagittal nor the lambdoid is more developed than in some species of *Nyctinomus* (e.g., *N. ochraceus* and *N. leonis*). Rostral and interorbital regions broad (as in other species of the group), the braincase wide and rounded; premaxillæ fully ossified; palate deeply concave; basisphenoid pits small and shallow; p^2 vestigial, on the outer edge of the toothrow and difficult to see without the aid of a strong lens. The type has only one upper incisor, the right having been lost in life, (Figs. 12 and 13).

Measurements of type (male) and cotype (female) skulls: Total length, M 22,9,

p. 474

F 20.7; condylobasal length, M 19.6, F 18.6; zygomatic breadth, M 13.4, F 12.6; mastoid breadth, M 12.2, F 11.8; breadth of braincase, M 10.4, F 9.9; interorbital breadth, M 4.4, F 4.5; breadth at base of canines, M 6, F 5.7; maxillary breadth (between outer borders of $m)^3$), M 9, F 9.2; depth of braincase medially (without the crest), M 7, F 6.8; upper toothrow (including canine), M 7.7, F 7.2; length of mandible, M 15, F 13.3; angle to condyle, M 5.2, F 4; depth at coronoid, M 4.2, F 3.4; lower toothrow (including canine), M 8.5, F 8.1. Height of sagittal crest in male, 1.8, in female, 0.5.

Represented by 2 alcoholic specimens, type (M) and cotype (F), collected at Kinshasa, 6 miles from Leopoldville, lower Congo, December 22, 1914.

The only species with which the present form needs comparison is *Mops (Allomops) faradjius*, which differs from it in smaller size, less highly developed sagittal crest, less concave palate, and in certain other features indicated under *M. (Allomops) occipitalis*.

Mops angolensis niveiventer Cabrera and Ruxton, 1926

p. 594

B.M. 2 M, 4 F (En maison.)

Type. Adult female, obtained in Saint Joseph de Luluabourg, April 16th, 1924. Collector's no. 409.

General colour dark vandyke-brown; under surface entirely pure white; without any buffy or brownish tinge.

p. 595

Dimensions of type: -

Head and body 72 mm.; tail 34; forearm 45; hind foot 11 ; ear 21.

Skull: condylo-basal length 19.3 ; zygomatic breadth 13.4; breadth of brain-case 10.5; upper tooth-row from canine 7.8; lower tooth-row from canine 9.2.

Specimens of *M. angolensis* from different parts of Africa appear to differ constantly among themselves by the coloration of the ventral surface. Those coming from the Angola coast have pale reddish-white bellie ; others from the Shire River (Portuguese East Africa) present also the lower parts strongly suffused either with brown or buff, while in specimens from Bagamoyo the belly is white only in the centre. These differences may be of subspecific significance; at least, we think it convenient to describe under a trinomial the form inhabiting the Lulua region, with its quite pure white underside.

In connection with *M. angolensis*, it is interesting to state that this specific name was given by Günther, and not by Peters as generally said. Peters described the typical Angolan bat in the 'Jornal' of the Lisbon Academy, vol. iii. 1870, p. 124, as "*Nyctinomus*, nov. sp.," the name *angolensis* being originally published, and wrongly attributed to Peters, by Günther in the 'Zoological Record' for 1870 (dated October 1871), p. 8, with the quotation of Peters's description as a basis.

Mops angolensis orientis G.M. Allen and Loveridge, 1942

p. 166

6 M 4 F (M.C.Z. 38826-35) Kitaya, T. T. 3.iv.39.

Type. Museum of Comparative Zoölogy No. 38829, an adult male, skin and skull, from Kitaya, Rovuma River, southeastern Tanganyika Territory. Collected by Arthur Loveridge, April 3, 1939.

Description. One of the stout-bodied forms with white underside, slightly smaller than *Mops (Allomops) angolensis osborni* of the Great Lakes region, to which it is related, and with the upper surface faintly tinged with tawny ochraceous instead of being uniform drabby brown; skull slightly smaller and with less development of the sagittal crest.

Distribution of the fur as in *M. a. osborni*, the wing above naked, but with a narrow line of whitish hairs on the anterior and posterior sides of the humerus; hind legs practically naked as well as the posterior part of the rump and the anal region, where,

however, minute scattered hairs are visible under a lens. Face, chin and ears blackish, with minute sparse hairs; toes with the usual longer stiff hairs as well as lateral hairs on outer edge of the first and fifth toes. Entire under surface of the body pure white to the edge of the membrane, with

p. 167

slight individual variation, so that in some specimens the sides of the neck are pale drab while in others this tint is more extensive, from the axilla back along the side halfway to the groin. Wings dusky brown, becoming whitish lateral to the forearm; this pale area varies individually but may extend to the tip of the third finger.

Measurements. The collector's measurements of the type are: head and body, 86 mm.; tail, 40; hind foot, 13; ear, 19; spread of wings, 340.

The cranial measurements of the skull of the type are: greatest length, 21.8 mm.; condylobasal length, 19.2; palatal length, 9.9; zygomatic width, 13.0; mastoid width, 11.5; width outside molars, 9.5; upper cheek teeth, 7.7.

In the adult-male skull the occiput is produced behind and squarely truncate, with a transverse angular crest, while the knife-like sagittal crest extends forward to the interorbital level. In the upper jaw the anterior premolar is minute and crowded into the outer angle between the canine and large premolar, which are in contact in their median line. In the lower jaw the anterior pair of incisors overlaps the posterior pair, and all four are bifid. In males the two lower premolars are of nearly equal height, but in females the anterior one is distinctly the shorter.

Remarks. The series is uniform in the decided tint of russet above instead of the dull drab of *osborni*, while the much clearer and more extensive white area of the lower side and the whitish wings, distinguish it further and altogether probably reflect the somewhat different climatic conditions of this part of the coast as compared with the Tana River and Lake region. The form, *Mops faradjius*, is a darker representative found in the northeastern Congo forest; probably all should be regarded as races of *M. angolensis*.

Habitat. These bats were roosting under the galvanized roof of the baraza house. I set up the net at 6.30 p.m.; the bats began emerging at 6.45 p.m. and by 7 p.m. I had removed ten of this species and one of the much smaller *C. limbatus*. Naturally their stomachs were empty, none of the females held embryos. The natives apply the same name *kiputiptiti* to them as for other small bats.

Mops angolensis wonderi Sanborn, 1936

p. 114

Type from Sotuba, 7 km. east of Bamako, French Sudan. No. 42138 Field Museum of Natural History. Adult female. Collected April 13, 1934, by Frank C. Wonder. Orig. No. 814.

Diagnosis. - Like *M. angolensis* but smaller and with lighter-colored under parts.

Color. - Type: upper parts dark brown, lighter on head and very strongly flecked with gray. A broad, almost hairless collar across shoulders. Below brownish gray on throat and chin; center of belly and sides of body from femur to groin white. Between these white areas, dark gray. Other specimens show more dark gray below and in one there is a rather spotted line of brown, but in all the sides of the body are white from femur to groin.

Skull. - Probably smaller than in *angolensis*, for which I can find no measurements, and shorter, with a narrower zygomatic width, and a much shorter lower tooth-row than in *M. a. niveiventer* Cabrera and Ruxton. Sagittal and lambdoid crests well developed and preorbital processes distinct. Anterior upper premolar minute.

Measurements. - Forearm 45.7 (44.8 - 48.5; 5 skins 44.8 - 47.8, 3 skeletons 46 - 47.5, one alc. 48.5). Skull: greatest length 20.9 (20.1 - 21.8); condylo-basal length 17.9 (17.9 - 18.8); palatal length 8.6 (8.6 - 8.8); interorbital width 4.5 (4.5 - 4.7); zygomatic width 12.6 (12.4 - 13.1); mastoid width 11.8 (11.7 - 12.2); width of brain case 10.4 (10.3 - 10.5); width across canines 6 (6 - 6.5); across m^2-m^2, 8.7 (8.6 - 9.1); upper tooth-row c-m^3, 7.3 (7.3 - 7.8); lower tooth-row c-m_3, 8 (8 - 8.6); length of mandible 13.5 (13.5 - 14.6). Measurements of alcoholic specimen: forearm 48.5; second digit 47.3; third digit metacarpal 50.9, first phalanx 22.9, second phalanx 23.6, tip 12; fourth digit metacarpal 49, first phalanx 20.5, second phalanx 18.8; fifth digit metacarpal 33.5, first phalanx 13.2, second phalanx 6.4. Ear, from meatus 15, from crown 12.6. Tibia 17.1, foot 13.

Mops chitauensis J.Eric Hill, 1937

p. 3

TYPE. - No. 88116, Amer. Mus. Nat. Hist.; M adult, skin and skull; from Chitau, Angola, alt., 4930 ft. Secured by the Phipps-Bradley Expedition, Mr. Lee S. Bradley, collector, orig. no. 676, February 10, 1933.

This species is known only from the type specimen.

GENERAL CHARACTERS. - A blackish brown, grizzled species of Mops; skull with high lambdoidal crest. Uropatagium reaches to heel, wing membrane attached to lower third of tibia.

COLORATION. - Upperparts near fuscous-black, shading into black on the head, grizzled with whitish hairs and tips; bases of hairs paler. Underparts dirty whitish. Wings darker than fuscous, as are the ears. Upper arms and legs pale.

SKULL. - Short and broad; supraoccipital region produced more than usual for *Mops*, but sagittal crest poorly developed.

DENTITION. - Upper incisors closely approximated, separated from canines by a gap. P^2 minute, situated laterally to axis of tooth row; P^4 and canine in contact medially. M^3 about half size of M^1 and M^2, with a V-pattern.

MEASUREMENTS. - Head and body, 75; tail, 41; forearm, 46.3; digit III, 47.0 X 19.4 X 19.9 X 8.4. Skull: greatest length, 23.3; basilar length, 17.6; palatilar length, 8.2; zygomatic breadth, 14.5; interorbital breadth, 4.5; mastoid breadth, 12.7; outside breadth across M^2 - M^2, 9.7; maxillary alveoli, 9.1; crowns P^4- M^3, 7.0; width M^1, 2.9.

Except for coloration, this species resembles the description of *Mops angolensis* (Peters). A specimen from Chitau, agreeing in color with Peters' description, collected by the Pulitzer Angola Expedition of the Carnegie Museum, has less extensive uropatagium and the wing membranes attach to the middle of the tibia. Cranially the occipital region is much less produced.

Mops congicus J.A. Allen, 1917

p. 467

Plate LV.

Type, No. 48893, F ad. (skin and skull), Medje, Belgian Congo, Sept. 8, 1910; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 966.

Above uniform deep chestnut-brown, the extreme base of hairs rufous; sides of back and lower back naked; below snuff-brown, passing into bister laterally, the extreme tips of the hairs on the middle area buffy; a naked band at base of uropatagium, continuous with the wholly naked hind limbs; wing membranes naked, blackish brown above, a little lighter brown below; interfemoral membrane naked, dull brown above and below. Ears joined by a low membrane, which extends forward as a protuberance in front of the ears; ears thick and leathery, black, with a strong frontal keel; tragus minute, difficult to distinguish in dry skins; antitragus small, low, evenly rounded above, about 5 by 3 mm. Face and chin naked, dark brown; nostrils prominently projecting; upper lip heavily corrugated; thumb with a conspicuous basal pad. A very small patch of fur near outer base of humerus, and a dense patch on inner upper border of ear; outer base heavily furred.

Collectors' measurements of type: Total length, 140 mm.; head and body, 91; tail, 49; foot, 17; ear, 22. Type and 12 adult topotypes; Total length, 138 (131-14x); head and body, 93.4 (86-100); tail, 45.3 (41-49); foot, 15.8 (15-17); ear, 22 (20-24). Additional measurements from skins: Type, forearm, 55; third metacarpal, 54; thumb (with claw), 9.3; foot, 15.8; length of ear on outer border, 19; breadth of ear near upper border, 9.5. Forearm, type and 14 topotypes, 55.8 (54.7-57.4).

Skull narrow and deep, heavily ossified; a low continuous median crest from front of interorbital constriction, joining the rather heavy lambdoid; preorbital process weak; braincase with a strong transverse preoocipital depression; basisphenoid pits very deep and large, circular in outline. Upper incisors slightly separated and parallel; lower incisors, middle pair bifid, the outer slender, posterior to the middle pair; canines not specially modified; first upper premolar minute, in the toothrow, separating the canine from p^4; first lower premolar about equal in size to the second.

Skull of type: Total length, 25; condylobasal length, 22.4; zygomatic breadth, 15, mastoid breadth, 13.2; interorbital breadth, 4.7; maxillar broadth, 10,3; breadth

p. 468

at canines, 8.7; breadth of braincase, 11.7; depth of braincase at condyles, 9.5, at bullæ, 10.7; upper toothrow (with canine), 8.9; length of mandible, 19.4; angle to condyle, 5.6; depth at coronoid, 4.6.

Skull, type and 11 topotypes (1 male, 10 females), total length, 25 (24.4-25.6); zygomatic breadth, 15 (14.5-15.0).

Represented by 15 specimens (of which 3 are alcoholic), all taken at Medje, September 1910.

Chærephon congicus is easily distinguished by its size, and dark coloration. The length of the forarm averages 56 mm. in a series of 12 adults, the skull 25, zygomatic breadth 15. It greatly exceeds the size of *C. angolensis* from which it also differs in other important characters. The forearm in *angolensis* is given by Peters as 48 mm., and by Dobson as 47 mm., while the average in *congicus* is 55.8. It differs from *C. midas* in being smaller (forearm 55.8, in midas 60.4), with much smaller ears and much darker coloration.

Mops niangaræ J.A. Allen, 1917

p. 468

Type (and only specimen), No. 48901, M ad. (skin and skull), Niangara, northeastern Belgian Congo, Dec. 12,1910; Herbert Long and James P. Chapin. American Museum Congo Expedition. Orig. No. 1313.

Similar to *M. congicus* but smaller and much paler.

Upperparts uniform cinnamon-rufous, extreme base of hairs much lighter; underparts tawny-brown, lighter and more yellowish on the pectoral area; ears, membranes and the broad naked space along sides of back and posterior margin of body dark brown; ears not joined at base, thick, and otherwise as in *M. congicus*. A. large crown-patch of lengthened hairs, similar in color and texture to the surrounding pelage, but much longer, forms a broad, low crest covering the interaural portion of the head.

Collectors' measurements: Total length; 125 mm.; head and body, 91; tail, 34; foot, 13; ear, 22. Forearm (from skin), 52; third metacarpal, 52; foot, 13; ear from crown, 8.6; from notch at antitragus, 21; transverse breadth, 13.2; tragus very small, breadth at base and height about equal.

Skull, total length, 23.2; condylobasal length, 21.6; zygomatic breadth, 14.4; breadth of braincase, 11.1; interorbital breadth, 4.0; maxillar breadth, 9.8; breadth at base of canines, 7.1; upper toothrow (with canine), 8.2; length of mandible, 16; depth at condyle, 5.4; at coronoid, 4.5; lower toothrow, 9.4.

Mops niangaræ is structurally closely similar to *M. congicus*, but is smaller and much paler, and the ears are not joined by a membrane. The forearm is 4 mm. shorter and the cranial measurements are correspondingly less.

This is the only species of molossid bat in the present collection, numbering 19 species, in which the ears are not joined across the forehead by a strongly developed band, if we regard the high convex lappet between the ears, but not distinctly joined to them, in *Chærephon (Lophomops) abæ* as

p. 469

morphologically a connecting ear-band. In the present species (represented by the single type specimen) there is not even a vestigial band, but the position it should occupy if present is outlined by a line of slightly lengthened dark brown hairs, giving the visual effect of a vestigial band till it is carefully examined and found not to be a slight ridge of membrane.

Mops osborni occidentalis Monard, 1939

p. 78

ALLEN, LANG and CHAPIN: Bats From the Belgian Congo. Bull. Amer. Museum, 37, 1917. p. 473 (sur *M. osborni*)

Collection: N^{os} 215 à 227, 275. 13 MM, une F, Mansoa; 494 à 498, un M, 4 FF, Contubo-el; 775 à 780 et 788 à 790, 4 MM et 5 FF, Pitche. En tout 29 exemplaires,

Le sous-genre *Allomops* a été crée par ALLEN sur 4 espèces du Congo belge. Il est caractérisé par la forme du crâne, qui, chez les vieux mâles, présente une crête lambdoïde extrêmement saillante et prolongée au-dessus du trou occipital. Les autres caractères indiqués par ALLEN sont soit ceux du genre *Mops*, soit d'ordre plutôt spécifique. Le sous-genre *Allomops*, plus heureux que son voisin, *Lophomops*, subsiste, quoique la forme caractéristique du crâne n'apparaisse nettement que chez les vieux mâles.

Une description détaillée de *Mops (Allomops) osborni* nous a permis de conclure avec certitude que les *Mops* ramenés de Guinée où l'espèce est très abondante et forme même une véritable plaie dans les maisons européennes de Mansoa, Bafatá, Contubo-el, Pitche et certainement d'autres lieux encore, sont extrêmement proches de cette espèce. Nous ne notons guère, comme différence, que la petitesse du tragus qui ne mesure dans nos exemplaires que 3 X 3 mm, tandis qu'il en mesure 4 X 4 dans *osborni* typique, et la plus grande dimension de la queue, ordinairement 40 mm dans nos exemplaires contre 37 dans ceux du Congo. En outre, le pelage est un peu différemment réparti.

Description. Pelaqe d'une couleur gris-noirâtre sur le dos; il déborde légèrement sur la membrane qui, dans cette espèce, ne part pas des côtés du corps, mais prend son insertion sur la face dorsale, de sorte que par dessous, existent deux poches dépourvues de poils entre le corps et la membrane, côté dorsal. En vue dorsale,

p. 79

le pelage s'étend jusqu'à la base de la queue et sur les fémurs. Du côté ventral, la couleur est plus variable: les côtés du corps sont foncés, de même qu'une bande pectorale. Mais ces plages sombres ont des développements très inégaux d'un individu à l'autre, si bien que la face ventrale peut se montrer presqu'entièrenient blanche, ou entièrement foncée. La lèvre inférieure et le menton sont ordinairement noirâtres et tranchent parfois nettement sur la couleur de la gorge. Les membranes sont brunâtres par dessus, plus pâles par dessous: le propatagium, une plage s'étendant du radius et de l'humérus jusqu'au milieu du tibia et l'uropatagium sont blanchâtres. Une touffe de poils existe derrière le bandeau qui unit les deux oreilles; les pieds sont garnis de soies courbées, les lèvres de courts bâtonnets sensitifs, les deux glandes du menton d'un long poil chacune. Les membranes sont quasiment nues, surtout dessus; dessous l'uropatagium montre de fins poils blancs. Quelques longs poils naissent des fémurs, face dorsale, et se dirigent en arrière.

Le museau est très proéminent. dépassant de 7 mm la fente buccale; la lèvre supérieure est fortement plissée verticalement; les oreilles épaisses ont un antitragus séparé du pavillon par un sinus profond; l'antitragus lui-même est petit arrondi et mesure 3 X 3 mm.

Crâne. Il présente, très nettes, les caractéristiques du sous-genre: le développement postérieur de la crête lambdoïde. La dentition est celle de *osborni*, avec le caractère sexuel secondaire indiqué par ALLEN: la première prémolaire inférieure est aussi grande que la seconde chez les MM, plus petite chez les FF (ALLEN dit même: plus grande chez les MM, mais dans nos

exemplaires il y a très peu de différence). La première prémolaire supérieure est très petite et logée dans l'angle externe formé par la canine et la seconde prémolaire qui sont contiguës.

[table removed - eds.]

p. 80

Distribution géographique et mœurs. *Mops osborni* est connu par un mâle et une femelle, venant de Kinshasa, à 6 miles de Léopoldville (Congo belge). Nous ne savons s'il a été retrouvé depuis. Sa présence en Guinée portugaise, à l'extrême Occident du continent est très remarquable et laisse prévoir d'autres découvertes dans les espaces intermédiaires.

En Guinée portugaise, l'espèce pullule dans les établissements européens, à Mansoa (local des Postes), à Bafatá (Immeuble de la Compagnie française), à Contubo-el, dans toutes les maisons de commerce, à Pitche, dans la maison du poste. Elle y forme de vastes colonies dont l'épouvantable odeur musquée et douceâtre se perçoit à distance, surtout à la tombée de la nuit, et rend les habitations malpropres et même inhabitables. Elle préfère les habitations européennes aux indigènes, car la présence de combles au-dessus des plafonds lui assure la tranquillité.

Son vol est aisé et rapide: elle pousse, lorsqu'elle est dérangée, de petits cris aigus.

Mops osborni occidentalis f. fulva Monard, 1939

p. 80

Collection: N^{os} 228 à 237, 5 MM et 5 FF, Mansoa; 781 un M, Pitche.

En tous points semblables par la forme, la distribution du pelage. les dimensions, à *Mops occidentalis*, mais en différant par la couleur du poil. Le dos est brun vif, le ventre varie du brun plus clair au jaune ou à l'orange, avec le milieu du ventre plus clair. La bande pectorale est parfois indiquée. La lèvre inférieure est noirâtre; les membranes, les oreilles et le museau sont de la couleur des exemplaires gris.

Les dimensions du crâne N° 781 sont données plus haut

Mops trevori J.A. Allen, 1917

p. 469

Plate XLVIII, Fig. 2.

Type, No. 49250, F ad. in alcohol, Faradje, Sept. 29,1912; H. Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1954.

Pelage short, soft and fine, with the grayish sheen in certain lights seen in many other molossid bats.

Upperparts cinnamon brown, with the usual naked transverse zone across front of shoulders; underparts pale brown, darker on the sides and lighter medially, with the hairs of the pectoral region conspicuously tipped with grayish white; caudal end of body not denuded, but with the projecting bristly hairs seen in allied forms. Membranes and wing bones above blackish and naked, except for a small patch of short brown fur near tho center of the propatiigium; below much lighter and the wing bones whitish; naked portion of face and ears, and the naked hind limbs and tail blackish, interfemoral membrane above blackish, below much paler, as is also the ventral surface of the hind limbs. A low crest (the hairs about 5.5 mm. in length) arises from the back of the membrane connecting the ears and extends back over the front half of the interaural area and the basal half of the backs of the ears. The crest area is of the same color as the surrounding pelage.

Total length, 121.5 mm.; head and body, 82.3; tail, 39.2 (free portion 24); forearm; 53; third metacarpal, 53.5; thumb to base of pad, 8.4; tibia, 20; foot, 13.6; ear from notch, 20; breadth (near front border), 12; tragus minute, quadrate, 2 X 15; antitragus convex, broad at base and low, 6.5 X 4.

Skull, total length, 24.2; condylobasal length, 22; zygomatic breadth, 14.6; interorbital breadth, 5; mastoid breadth, 13.8; maxillar breadth, 10.4; breadth at base of canines, 7; upper toothrow (c-m^3), 8,6; length of mandible, 15.8; angle to condyle; 5.2; depth at coronoid, 4.5; lower toothrow, 9.7.

Represented only by the type.

Mops trevori is of nearly the same size as *M. congicus*, but it is slightly smaller in all measurements, except that the ears are larger. The coloration is radically different, the upperparts in *congicus* being deep chestnut, and dull cinnamon brown in *trevori*, with still greater difference in the color of the underparts. It differs from *M. midas* in much smaller size, while the color of both upperparts and the ventral surface in the two species is as different as between *trevori* and *congicus*. In cranial characters *trevori* is too different from either *congicus* or *midas* to render comparison necessary.

Mormopterus setiger Peters, 1878

p. 196

(Taf. 1. Fig.2.)

Kopf sehr platt und breit. Schnauze oben flach; in der Mitte ein wenig vertieft, kahl, mit ganz kurzen Härchen bekleidet, welche die Haut nicht verdecken. Nasenlöcher queroval, um mehr als ihren doppelten Durchmesser von einander entfernt und ummittelbar unter dem scharfen Endrande der Schnauze stehend; zwischen ihnen eine wulstige gelappte Längsleiste. Die breite wulstige, aber nicht quergefaltete Oberlippe ist jederseits mit vier bis fünf Längsreihen kurzer stachelförmiger dicker Borsten bekleidet, zwischen denen sparsame feine kurze und längere Härchen hervortreten. Die Unterlippe zeigt noch kürzere und schwächere sparsame Borsten und Haare. Die wulstigen Augenlider der kleinen Augen sind ebenfalls mit sparsamen Härchen bekleidet, welche sich nach oben und vorn zu einem grösseren Haufen zusammendrängen. Die Ohren sind dreieckig abgerundet und stehen weit von einander ab; die Ohrklappe ist im ganzen viereckig, am verdickten Endrande sparsam behaart.

Die oberen Schneidezähne sind deutlich zweispitzig, mit äusserer kürzerer Spitze. Sonst zeigt das Gebiss keine auffallende Verschiedenheit von dem der anderen Arten: $^{3\,1}/_{3\,2}{}^{1}/_{1}{}^{1\,1}/_{6}{}^{1}/_{1}{}^{1\,3}/_{2\,3}$.

p. 197

Der Körper erscheint plump und etwas platt. Kurze rostbraune, an der Basis etwas hellere Haare bedecken die obere Körperseite, die Halsseiten und die Seite der Brust und des Bauches; auch setzen sie sich noch auf die Basis der Lendenflughaut fort. Die Mitte der Brust und des Bauches ist von rostgelben noch kürzeren Haaren bekleidet, welche in der Analgegend die Haut durchsehen lassen. An der Kehle befindet sich eine Querfalte, welche in eine sackförmige Grube führt.

Der Schwanz ragt zur Hälfte aus der Schenkelflughaut hervor. Die langen Spornen sind sehnig. Die Gliedmafsen erscheinen im Verhältniss zu dem plumpen Körper kurz und gedrungen. Die Oberseite des Vorderarms und eines Theils der Finger ist durch zugespitzte Hautwarzen ausgezeichnet. An der Basis der Daumensohle befindet sich eine grössere, an der Basis der Fusssohle eine kleinere rundliche Wulst. Der Daumen und die Zehen sind durch sparsame lange borstige Haare ausgezeichnet. Die Flughäute sind ziemlich derbe, dunkelbraun, die Lendenflughaut am Rande weiss.

Aus Ndi (Taita).

Diese Art unterscheidet sich, abgesehen von ihrer viel plumperen Gestalt, den Lippenborsten, der warzigen Beschaffenheit der Oberseite der vorderen Extremität und der viereckigen Gestalt der Ohrklappe, sehr wesentlich von den anderen bisher bekannten Arten dieser Gattung durch die weit von einander abstehenden Ohren, welche bei jenen einander auf 2 bis 3 Millimeter genähert sind. In der Form der Ohren nähert sie sich mehr dem *M. jugularis* Ptrs., während *M. acetabulosus* Hermann (*D. natalensis* Smith) durch die zarte schlanke Gestalt und die sehr spitzen Ohren sehr verschieden erscheint.

Mormopterus Whitleyi Scharff, 1900

p. 569

Mormopterus Whitleyi

Three specimens of a bat, which I was unable to identify with hitherto published descriptions, were sent to me by Dr. J.C. Whitley from Benin City in West Africa. Before describing them I forwarded one of them to Mr. Oldfield Thomas, of the British Museum, who was good enough to confirm my opinion that it belonged to a new species. I have great pleasure therefore in naming the bat after its discoverer.

Dr. Whitley, and herewith give a description of its most salient external features.

Ears shorter than the head and approaching one another on the forehead to within 2 millim. Both the ears and their short tragus are rounded off above. The antitragus is well developed and separated posteriorly by a distinct notch. The extremity of the muzzle projects very much beyond the mandible, and the end of the nose is distinct from the upper lip. The nostrils open almost laterally. The upper lip is only very indistinctly folded and covered with thick bristles and fine hairs. On the lower lip the bristles are confined to the angle of the mouth, but the hairs extend all over it. The gular sac is small.

The dentition being $^{1}/_{3}$ $^{1}/_{1}$ $^{1}/_{2}$ $^{3}/_{3}$, *M. Whitleyi* diflfers from all other species of the genus in the possession of four lower incisors instead of the usual six.

The fur is dark brown above, the bases of the hairs being pale. The underside is of a light reddish-yellow colour. Nearly half the tail projects beyond the wing-membranes, which reach to the ends of the tibiæ.

The dimensions of the type, now in the British Museum (adult M in formalin), are: - Total length 81 millim.; head 22; body 30; tail 23; length of forearm 36, of lower leg 27.

The height of the ear is 15 millim., the width 10.

p. 570

Three other species of *Mormopterus* are known to science, viz., *M. albiventer, M. acetabulosus*, and *M. setiger*. The first of these is confined to Madagascar, the second has a •wide range from South-east Africa to Madagascar and Mauritius, while the last has been taken in German East Africa.

M. Whitleyi differs from *M. albiventer* in being somewhat smaller, in having a well-defined antitragus in the ear-conch, and from all the three in having only four lower incisors instead of six.

M. Whitleyi differs from *M. acetabulosus* and *M. setiger* in having the ears close together on the forehead, in the more regularly triangulate shape of the ears, and in the squareness of the tragus.

Finally, *M. Whitleyi* differs from *M. setiger* in being smaller and in having the tragus rounded off above.

Myonycteris leptodon K. Andersen, 1908

p. 450

Diagnosis. - m^2 about twice the bulk of p^1. Molariform teeth short and narrow. Forearm about 61-62 mm. Hab. Sierra Leone; Liberia.

Differential characters. - Skull similar to that of *M. wroughtoni*, but rostrum narrower in front (distance between inner bases of canines 3.3 mm., against 3.7-4 in *M. wroughtoni*

p. 451

and *torquata*), coronoid process higher and much slenderer. All molariform teeth conspicuously shorter and narrower than in the two other species of the genus: m^1, length 1.9 mm., against 2.2, breadth 1.3 mm., against 1.6-1.7; p_4, length 2.4 mm., against 2.7-3, breadth 1.7 mm., against 1.8; m^2 relatively of the same size as in *M. wroughtoni*, less reduced than in *M. torquata*. - Ears smaller than in the allied species, length from notch 14 mm., against 15-15.5 in *M. torquata* and 16.5-17.5 in *M. wroughtoni*; length of tibia and hind foot as in *M. wroughtoni*, but forearm, metacarpals, and phalanges somewhat shorter. Distribution and colour of fur as in the allied species.

Type. M ad. (skin and skull), Sierra Leone; presented by J. Hickman, Esq.; B.M. 91.2.13.1. - The species is represented in the Leyden Museum from Liberia.

Myonycteris relicta Bergmans, 1980

p. 173

Myonycteris relicta n. sp. (figs. 1-4)

Holotype: adult male, skin and skull, collected 30-VII-1978 by Mr. Robert N. Kyongo (field number RK 594), in the Shimba Hills, southeast Kenya (RMNH 27909). "Caught over water, about 1.20 m high, at about 10 p.m. local time, Mukanda River, Lukore area, Shimba Hills; along the river: big thorn trees and fig trees" (R. N. Kyongo in litt.).

Paratypes: adult male and adult female, in alcohol, skulls separate (and damaged to some extent), collected in January 1900 (collector unknown) at Ambangulu (5°5'S, 38°26' ?), Usambara Mountains, northeast Tanzania (ZMB 54936 and 54937, respectively

[Table removed]

p. 174

Diagnosis. - *Myonycteris relicta* is a large member of its genus (forearm lengths 69.3 - 75.1 mm and greatest skull lengths 36.4 - 39.2 mm in the three specimens known), with deflected facial axis, relatively slender rostrum, dental formula $^{2.1.3.2}/_{2.1.3.2}$, elongate teeth, and reduced M^2.

Description of holotype (notes concerning soft parts checked on paratypes). - Snout relatively long, with linear dorsal profile. Posterior part of head rather domed. Nose skin brown, nostrils pointed forward and outward, separated by a shallow but distinct groove. Chin pad narrow, notched at its proximal end in the median plane, with small and narrow offshoots along lower lips. Upper and lower lips quite thick, upper with a row of small pointed papillae on inner margin, extending backward from close behind the nose, lower with same from about halfway. Tongue with long and narrow field of toothed papillae on anterior part. Ears moderately long, anterior margin thickened, posterior margin convex with slight emargination just below tip; tip rather distinctly pointed; conchs darkish brown, with about ten transverse folds; antitragal lobe moderate, angular. Top and sides of head furred with soft woolly hair, very short and sparse near nose and somewhat longer and very dense backward from in between and under eyes, near Ecru-Drab, tipped with near Verona Brown on snout, forehead and cheeks, and with orange-brown on top of head. Same light short hair in zone along lower lip (centre of chin furred like ventral body side; see below). Sides of rostrum, a narrow zone around eyes, and lower lips furnished with additional, mostly dark brown, tactile hairs: many shorter ones, a few longer ones.

Dorsally, body densely furred with bicoloured hair (6-10 mm long), Light Cinnamon-Drab with Brüssels Brown to Tawny tips, the tips dominating the overall - light reddish brown - colour impression. Hair of same colours extending on arm, down to (and much shorter on) first half of forearm, on small areas of patagium in axillar region and below elbow, on hind legs almost down to ankles, and on adjoining parts of uropatagium, surpassing its caudal margin at either side of tail.

Ventrally, body covered with dense, short hair (length 3.5 - 5 mm), Fawn Colour with slightly darker bases; also on upper arm and proximal half of forearm, along upper legs to slightly below knee, and on proximal part of uropatagium. Holotype (and male paratype) with throat ruff of relatively coarse hair; foremost point of ruff on chin between mouth corners; ruff gradually widening to greatest width at throat level, with 'crowns' on shoulders, and ending on breast, about on level with antebrachial membrane insertion; ruff hairs with short thin bases and thick shafts, wavy and growing

p. 176

in clusters of about 12 in centre of ruff, but less coarse, less wavy and less obviously clustered towards ruff margins; ruff hairs in holotype from about Light Ochraceous Buff to Tawny Olive, with darkest hairs on chin. (Ruff colour in paratype ZMB 54936 very light, but possibly somewhat bleached.) Female paratype without ruff. Propatagium near furred part of arm, and endopatagium between furred part of arm and body, thinly covered with Fawn Coloured or in places weakly reddish brown hairs.

Wings rather large (see table 1 for proportions), darkish brown. Endopatagium attached near middle of first phalanx of second toe. Toes 'webbed' to middle of first phalanges. Calcar length about 7 mm. Caudal margin of stretched uropatagium almost linear between end of calcar and a point on the dorsal side of the tail at about 3 mm from its external base. Soft palatum not preserved in the studied specimens.

Skull (figs. 1 - 4) lightly built . Facial axis deflected. Alveolar line, if projected backward, passing slightly above upper edge of occipital condyle. Premaxillae slender, fused anteriorly (only clearly co-ossified in specimen ZMB 54937). Rostrum relatively long, with nearly linear dorsal profile. Lateral pair of frontal sinuses quite strongly inflated, medial pair somewhat less. Behind these, a third pair of externally slightly inflated interorbital sinuses, roundish in outline, in between postorbital foramina and not extending beyond postorbital constriction, well visible in holotype and male paratype, indistinct in female paratype. Postorbital processes well developed, slender. Postorbital foramina small, distinct. Braincase rather domed, inflated behind interorbital sinuses, somewhat constricted at level of posterior zygomatic arch insertions, elongated posteriorly. Temporal ridges distinct but weak, not fusing into a sagittal crest. Supraoccipital crest low. Zygomatic arches slender, curving down about as low as the alveolar line when viewed from the side . Orbit large. Tympanic bullae of moderate size (greatest length in specimen ZMB 54936 4.6 mm). Bony palate concave, with greatest depth at level of M^1; postdental margins rather straight and weakly converging backward.

Mandible delicate, with narrow rami and low coronoid processes; angle between alveolar line and anterior margin of coronoid process about 145°.

Upper incisors minute, with tips curved backward, crowded (distance I^1-I^1 slightly smaller than I^1-I^2); I2 at about 1 mm from canine. Upper canine short (reconstructed height from cingulum in specimen RMNH 27909 3.5 mm), with only weakly recurved tips; basal outline rectangularly ovate; antero-internal face flat or slightly concave, without longitudinal groove; anterior keel distinct, not sharp; labial face quite evenly rounded; posterior face sharply defined, narrow, concave; lingual face concave except in the middle,

p. 178

its orientation inward and backward, with trace of horizontal shelf at its base. Anterior upper premolar (P^1) small, about 2 to 3 times the bulk of an upper incisor, wider than long, with rounded anterior and flattish posterior face and an obtuse cusp. Second upper premolar (P^3) oblong, basal outline more or less triangular, with a pointed (outer) cusp just before the middle; lateral (outer) profile sub-triangular; with very weakly rounded labial face, obtuse anterior keel, rather flat antero-internal face and well-defined, slightly concave lingual (postero-internal) face; greatest width at level of keel separating antero-internal and postero-internal face; orientation of latter face either parallel with, or converging backward toward, labial face (thence the variable tooth outline). Third upper molar (P^4) oblong, subrectangular, with a pointed (outer) cusp before the middle; rather obtuse anterior (outer) and posterior outer ridges from cusp tip to cingulum; a weak commissure from tip to lingual side; antero-internal and postero-internal faces concave. First upper molar (M^1) essentially as P^4, but smaller and lower, with less rounded anterior side and strongly

reduced cusp. Second upper molar (M^2) small, ovate to triangularly ovate in outline, greatest width in front, even less differentiated than M^1, at some distance from posterior margin of anterior zygomatic arch insertion.

Lower incisors small, outer ones (I_2) slightly larger than inner ones (I_1); tips bicuspid, inner cusp the larger in both I_1 and I_2; distances I_1-I_1 and I_1-I_2 minimal, distance from I_2 to lower canine same or slightly larger. Lower canine short (height from cingulum in holotype specimen 1.8 mm); basal outline broadly ovate, with rather straight posterior side; tip hardly recurved, pointing outward; no distinct keels; antero-internal and labial faces rounded, lingual (postero-internal) face straight or concave, with a narrow shelf at its base. First lower premolar (P_1) relatively large; outline squarish or more rounded; cusp rather obtuse, separating rounded vertical antero-external face from sloping postero-internal face; latter ending almost horizontally. Second lower premolar (P_3) somewhat shorter than lower canine, with pointed cusp well in front of the middle; basal outline ovate (with truncated posterior side in holotype); labial face rather straight or weakly rounded; no anterior keel; antero-internal face rounded; posterior face somewhat concave, sloping, ending almost horizontally; postero-external longitudinal ridge distinct, obtuse. Third lower premolar (P_4) largest of all teeth; basal outline oblong, with about parallel labial and lingual sides and rounded anterior and posterior sides; the single cusp well in front of the middle, with ill-defined anterior keel and blunt postero-external ridge running from it; both labial and lingual faces weakly rounded and gradually passing into essentially round and sloping anterior face; postero-internal face an even,

p. 179

weakly concave slope without a clear horizontal posterior basal part. First lower molar ($?_1$) long, narrow, low; labial and lingual faces parallel; anterior and posterior faces somewhat truncated; outer longitudinal ridge higher than inner one (and with traces of antero-median cusp and commissure from cusp to lingual ridge in holotype); upper surface concave. Second lower molar (M_2) rectangularly ovate in outline, reduced, low, undifferentiated; surface flat or weakly concave.

Salient aspects of upper tooth rows when viewed from below (fig. 3) are the relatively heavy third premolars (P^4) and the more or less coulisse-like arrangement of second and third premolars and first molar, with longitudinal axes pointing forward - in the line of the row - but also somewhat inward; and of lower tooth rows when viewed from above (fig. 4) the large third premolars (P_4) and the absence of M_3.

Measurements: table 1. The only known weight is that of the adult male holotype: 48 g.

Myonycteris wroughtoni K. Andersen, 1908

p. 450

Diagnosis. - *m^2* about twice the bulk of *p^1*. Skull and teeth heavy. Forearm about 65-67 mm. Hab. Welle District, N.E. Congo.

Differential characters. - Skull larger and more heavily built than in *M. torquata**: total length 34 mm., against 31-31.8; rostrum longer and broader: from front of orbit to tip of nasals 10.5-10.7, against 9-9.2, lachrymal width (across lower edges of lachrymal foramina) 9.8-10 mm., against 8.8; length of combined orbital cavity and temporal fossa, measured on underside of skull from front of glenoid fossa to back of maxillary process of zygomatic arch, 10.7-11 mm., against 9-9.8 ; frontal region broader: interorbital breadth 6 mm., against 5-5.2. Cheek-teeth on the whole slightly broader; *m^2* less reduced in size, being about twice the bulk of *p^1* (in *M. torguata* subequal to *p^1*), actual length of tooth in two specimens 0.9 mm., against 0.5-0.7 in two *M. torquata*, breadth 0.6-0.7, against 0.4-0.5. - Wings, tibia, and foot conspicuously longer; forearm 65-67 mm. (57-60.5 in *M. torquata*), third metacarpal 44.5-45 (36-39), lower leg 25-25.5 (22), foot with claws 17-19 (14). Distribution and colour of fur as in the allied species.

Type. M ad. (skin and skull), River Likandi, Welle District, 18th April, 1906; Alexander-Gosling Expedition; B.M. 7.7.8.25. Two specimens examined.

Named in honour of Mr. R. C. Wroughton, who assisted in working out the mammals collected during the Alesander-Gosling Expedition.
