Nez simple; chanfrein méplat.
Oreilles larges, isolées et latérales ; oreillon intérieur.
Membrane interfémorale moyenne.
Queue longue, à demi enveloppée, et libre au-delà.

OBS. On n'en connoît que la seule espèce publiée par Daubenton, sous le nom de rat-volant.

Myopterus albatus Thomas, 1915

p. 469

A large whitish and white-winged species with the upper body-colour arranged in a lineated pattern.

Size large, the forearm about half as long again as in *M. whitleyi*, and rather larger than that of *M. daubentoni* would be if in the same relative proportion to the skull (that is to say, about twice the length) as in *M. whitleyi*. Fur soft and fine, hairs of shoulders about $4^1/_2$ mm, in length, of lower back $3^1/_2$. Fur not extending at all on the membranes, and stopping on the lower back a little way short of the tail, just as in *M. whitleyi*. General ground-colour above drabby brown ("dusky drab"), the hairs white at their bases, brown terminally; but on the median area of the nape, from occiput to withers, and along two broad lines running down the back on each side from the withers, the white extends nearly to the tips of the hairs, so as to show through above, and to form broad whitish lines, the brown along the side of the body and that in the middle line from the withers backwards, therefore, appearing as three broad brown longitudinal lines separated by whitish. Fur of whole of under surface pure creamy white, sharply contrasted on the sides of the neck with the brown of the upper surface. Wing-membranes white throughout, except that by the side of the body which is spotted with brown granules, just as in *M. whitleyi*; interfemoral membrane brown. Upper surface of forearms, digits, legs, and feet also brown.

Ears apparently similar in structure to those of *M. whitleyi*, separated in the middle line, their inner keels low and little developed. Tragus short and broad. Nasal septum without a mesial ridge, clothed with fine whitish hairs. Edges of lips with a close mixture of spoon-shaped and normal bristle-hairs. Lips practically without wrinkles. Wings to the distal end of the tibiæ.

Dimensions (measured on the skin): -

Forearm 55 mm.

Head and body (probably stretched) 84; tail 40; ear (dry) 19; third finger, metacarpal 54.5, first phalanx: 19.5, second phalanx 19.5; fifth finger, metacarpal 35, first phalanx: 15; hind foot (c. u.) 13.

Hab. R. Welle. Collected by M. Hutereau.

p. 470

Original number 17. Congo Museum, no. 2911.

The coloration of this beautiful bat is quite unique, but of course it assimilates, in the brown upper and white lower surface, with that of *M. daubentoni* and *whitleyi*.]

Myotis blythii punicus Felten, 1977

p. 39

Holotypus: SMF 44104, M ad.; Höhle El Haouaria, Cap Bon, Tunesien; NAGEL, SCHUBERTH & VESMANIS leg. 25.III.1971. S + A.

Paratypen: SMF 18946-52, 18955-64, 22214, 22217-20, 43386-92, 43961-68, 44097-103, 44618; 6 M, 39 F vom gleichen Fundort.

Weiteres Material: Die auf S. 31 angeführten Exemplare von anderen tunesischen Fundorten, aus Algerien und Marokko.

Diagnose: In den Schädelmaßen (Mittelwerte; s. Tab. 14) meist größer als *omari* und *oxygnathus*. Mittelwerte von Länge, Breite und Kronenfläche (= Länge X Breite) des M^2 deutlich größer als bei *omari* und *oxygnathus*. Jedoch Breite C^1-C^1 (Alv) im Mittel so groß wie bei *oxygnathus* und deutlich kleiner als bei *omari*.

Myotis Bocagei cupreolus Thomas, 1904

p. 407

Essential characters as in true *M. Bocagei*, but the colour much darker, owing to only the terminal millimetre instead of 2 - 3 mm. of the dorsal hairs being reddish; the reddish is also of a more coppery tone. A blackish patch at the base of each humerus. Under surface dark smoky brown, the hairs being dark smoky with brownish tips; inguinal region not or scarcely lighter. In true *Bocagei* the under surface is pale buffy brown.

Dimensions of the type: -

Forearm 39 mm.

"Head and body 60"; "tail 40" ; "ear 15."

Skull: greatest length 15.

Hab. Efulen, Bulu Country, Cameroons.

Type. Male. B.M. no. 3.2.4.6. Collected 14th August, 1901, by Mr. G. L. Bates.

Myotis Hildegardeæ Thomas, 1904

p. 209

A beautiful and brightly coloured species allied to *M. Bocagei*.

Size medium. Ears small, narrow; inner margin evenly convex, tip very narrowly rounded, outer margin concave above, convex below, a marked angular antitragal lobule at the outer base thickly covered with fur. Tragus rather short, its inner margin slightly but evenly convex, its greatest breadth opposite the lower third of its inner margin, whence it slopes evenly to the narrow but not sharply pointed tip; basal lobe large, rounded. Feet large; wings to the metatarsi; calcars long, reaching nearly three-fourths towards the tip of the tail and ending in a distinct lobule.

Fur soft, thick and fine; hairs of back about 5 - 6 mm. in length. Wing-membranes naked, except for a few hairs on the under surface between the humeri and the flanks. Interfemoral furry above at the base, a narrow band passing outwards behind the legs nearly halfway down the tibise. Top of toes hairy.

General colour of upper surface bright "tawny-ochraceous," the head rather paler than the back. Individually the hairs are blackish brown for about 2 mm. at their bases, then pale tawny, darkening to their tips. Below the general colour is "pinkish-buff," the hairs blackish at their bases. Membranes dark throughout, contrasting strikingly with the bright colour of the body.

Skull considerably larger than in *M. Bocagei*, broader and lower than in *M. Goudoti*. Small upper premolars in the tooth-row, subequal in horizontal section, and less unequal in height than usual.

Dimensions of the type (measured in skin): -

Forearm 37 mm.

Head and body (c.) 53; tail 37; ear (dry) 13; tragus on inner edge (dry) 4.6; thumb clear of membrane 5; third finger, metacarpus 35, 1st phalanx 15.5, 2nd phalanx 10.7; fifth finger 53; tibia 17; foot from back of calcar (c. u.) 9.8; calcar 17.

Skull: greatest length 15.2; basal length 11.3; breadth of brain-case 8; front of canine to back of m^3 5.7.

Hab. Fort Hall, Kenya District. Alt. 4000 feet.

Type. Male. B.M. no. 3.3.2.2. Original number 115. Collected 17th Oct., 1902, by Mrs. Hinde. Two specimens.

This very beautiful bat I have much pleasure in naming in honour of its discoverer Mrs. Hildegarde Hinde, to whom

p. 210

the British Museum is indebted for so many interesting Chiroptera and Rodentia.

M. Hildegardeæ is readily distinguishable from any of its allies by its striking coloration, as it is far brighter in tone than either *M. Bocagei* or *M. Goudoti*, the species most similar to it.

Myotis morrisi Hill, 1971

p. 43

(Plates i, 2 (a, b))

SPECIMEN. HOLOTYPE. B.M. 70.488. Adult female. A flat, card-mounted skin with skull; collector's number A107. "Forward Base Three", mouth of Didessa River, Blue Nile Gorge. 10° 05' N, 35° 38' E, alt. c. 1,000 m. 28 August 1968.

OTHER MATERIAL: none.

TAXONOMIC NOTES. DIAGNOSIS. Similar to *Myotis tricolor* (Temminck, 1832) of eastern Africa but differing from this species in its generally more orange dorsal coloration; unicolored and not bicolored ventral pelage; elongate, narrower skull with uninflated braincase and supraorbital region, the braincase shorter, more globular and markedly narrower than in *M. tricolor*, the rostrum proportionately longer and less broadened than in that species. Dentition less massive than in *M. tricolor*; second upper premolar (pm^3) relatively larger and incompletely intruded from the toothrow; second lower premolar (pm_3) relatively larger, not compressed between pm_2 and pm_4; posterior upper premolar (pm^4) with narrower lingual shelf, separated from the lingual shelf of m^1 by a wider interspace.

DESCRIPTION. Of moderate size (length of forearm 45.4) for the genus; anterior margin of ear smoothly convex, posterior margin concavely emarginated in its distal half, the proximal half convex. Tragus long, its length equal to one half of the length of the ear, tapered, with slender, rounded tip directed slightly posteriorly; anterior margin faintly convex, especially distally, posterior margin concave distally, convex proximally, slightly serrated, a small rounded lobe at base beneath an acute, angular emargination just below widest point of tragus. Wing inserted at base of first toe; calcar strongly developed, extending along

almost one half of the posterior margin of the tail membrane; no obvious post-calcareal lobe. Pelage woolly, dorsally overall orange brown, individual hairs tricolored, the basal quarter blackish brown, most of remainder creamy white, hairs tipped terminally with bright orange brown. Dorsal pelage extending narrowly on to the wing membrane and on to the tail membrane for nearly one half of its width. Ventral pelage unicolorous dull creamy white, tinged faintly with brown on chin and flanks. Wing membrane generally black but antebrachium and endopatagium pale orange yellow, a narrow band of the same colour extending across the membrane immediately behind the forearm; anterior edge of membrane and area between first and second metacarpals and tail membrane similarly coloured. Tibia flanked by a narrow band of orange hairs on wing membrane and a wider band of similar hairs on tail membrane. Toes with a sparse covering of long orange hairs.

p. 44

Skull (Plates 1, 2(a)) elongate, the braincase not especially inflated; rostrum narrow, the supraorbital region not expanded, the supraorbital ridge forming an uninterrupted curve; a shallow, narrow median rostral depression. Narial emargination narrow, V-shaped posteriorly, its apex rounded. Palate long, narrow, anterior palatal emargination rounded posteriorly, extending almost to a line joining the centres of the canines; narrow post-palatal extension; shallow basioccipital pits. Inner upper incisor (i^2) longer than wide, bicuspid, with strong angular anterior cusp; smaller posterior cusp extending for two thirds of the height of the anterior cusp. Outer upper incisor (i3) wider than long, bicuspid, closely appressed to inner tooth, cusps lying transversely to line of toothrow. Outer cusp the larger, rising from a narrow cingulum shelf to a height equal to that of the posterior cusp of inner tooth; supported internally by a smaller secondary cusp for two thirds of its height, the tooth somewhat hollowed internally, separated from the canine by a short diastema. Anterior upper premolar (pm^2) about as high as i^3, a little larger at base, in contact with canine, a slender pointed cusp with wide, strong cingulum. Second upper premolar (pm^3) rising slightly above cingulum of pm^2, slightly less than one half its basal area, visible externally, a simple cusp rising from a narrow cingulum, slightly intruded from row but separating pm^2 and the posterior upper premolar (pm^4), in contact with these teeth. Posterior upper premolar (pm^4) with strong cusp and short, narrow lingual shelf with a wide interspace, separating it from the lingual shelf of the first upper molar (m^1). Lower incisors imbricated, first (i_1) and second (i_2) with four cusps, outer cusp of i_1 incipient, of i_2 well developed but lower than inner cusps. Lower premolars not especially compressed: second (pm_3) rather more than one half the height of anterior tooth (pm_2) and approximately one half its basal area, in contact with pm_2 and posterior lower premolar (pm_4), but not compressed or displaced, its length and width equal. The measurements of the new species are compared with those of *M. tricolor* in Table 4.

REMARKS. In some respects *M. morrisi* resembles *M. bocagei* but is larger, has unicolored and not bicolored ventral pelage, a relatively longer rostrum lacking supraorbital inflation, narrower narial and anterior palatal emarginations and relatively narrower palate. Dentally the two species are closely similar but the teeth of *M. morrisi* are more generally massive than are those of *M. bocagei* and *M. morrisi* lacks a protoconule on the anterior ridge of the first and the second upper molars (described in *M. bocagei* by Harrison (1964b: 135).)

Tate (1941 : 539) reviewed the subgenera of *Myotis* and (p. 552) referred *tricolor* to the subgenus *Selysius*. However, both *tricolor* and *morrisi* approach the subgenus *Chrysopteron* in dichromatic wing pattern, although this is less evident in *tricolor*, and in the presence of four lobes on the inner (i_1) and second (i_2) lower incisors, but retain a relatively high braincase and concave frontal profile. I have much pleasure in associating with this new species the name of my co-author, Dr. Pat Morris, of Royal Holloway College, University of London, in recognition of his many services to the study of the Ethiopian fauna while with the Great Abbai Expedition.

p. 45

[table removed - eds.]

p. 46

COLLECTION AND FIELD NOTES. The specimen was caught by Messrs. Yalden, Largen and King of the Great Abbai Expedition, using a hand-held mist net. The bat was flying after dark over the river Nile, near its north bank, at a height of about one metre. The surrounding habitat comprises mainly maize plots and thick bush. The specimen was photographed whilst still alive (Plate 2 (b)).

N[ycteris] albiventer Wagner, 1840

p. 439

Die weißbäuchige Hohlnase.

N. supra dilute brunea, pilis basi alibidis; subtus pulchre alba, pilis basi brevissime griseis.

Aus dem frankfurter Museum hat schon for längerer Zeit das unferige vier Exemplare einer Hohlnase erhalte, die, den äußern Formverhältnissen nach, mit den Beschreibugen von *N. thebaica* übereinkommen, fo daß man sie unbedenklich dieser Art zuzählen könnte, wenn nicht in der Färbung ein Unterschiedsich ergäbe. Die Oberseite ist nämlich zwar ebenfalls lichtbraun, wie bei jener Art, aber die Unterseite ist nich aschgrau, sondern rein weiß, wobei die hellbraune Farbe der Oberseite nur die Spitzen einnimmt, während die viel längere Wurzelhälfte graulichweiß ist, was am Hinterhalfe am hellsten ausfällt. Aufder Unterseite ist blos der kurze Wurzeltheil etwas graulich, so daß die graue Farbe auf der Oberfläche gar nicht sichtlich wird; an dem einen Exemplar sind aber die Haare des Unterleibs, fast ihrer ganzen Länge nach, durchaus weiß. Der Anfang des Oberarms und der Flügelansaß am Leibe ist oben braun, unten weiß behaart. Backenzähne sind jederseits $^4/_4$ vorhanden. Ob ich diese weißbäuchige Hohlnase mit Fug und Recht von der graubäuchigen *N. thebaica* als selfständige Art trennen darf, muß ich der Beurtheilung Deren überlassen, welche Gelegenheit haben, die Geoffroy'sche Art zu vergleichen.

Die zweifarbige Hohlnase.

N. fusca, subtus sordide albida, pilis omnibus basi nigro-schistaceis, auriculus amplissimis.

? *Nycteris capensis*. SMITH zool. journ. IV. p. 434 - SMUTS mamm. cap. p. 7.

Von Ecklon ist uns ein ausgestopftes Exemplar zugekommen, daß vielleicht zu *N. capensis* gehören könnte; indeß ist die Ohrlänge des unserigen beträchtlicher, auch Smith's Angabe der Färbung so ungenau, namentlich von der Zweifarbigkeit der Haare sogar keine Rede, daß ich es nicht wagen mag, selbiges mit *N. capensis* zu identifiziren. Die Formenverhältnisse sind die der vorigen Art; auch die Furche an der Spitze des Unterkiefers scheint nicht zu fehlen; die breite abgerundete Klappe ist and ihrem obern Ende mit Haaren gewimpert. Der leßte Schwanzwirbel vor der

footnotes:

20) Smith's Diagnose lautet: N. cervice et dorso nigro-fuscis, colli lateribus sordide albis, pertibus inferioribus subcinereis, membranis rubro-fuscis; apice tragi semicirculari cum crista villi albescentis. Die Eindigung des Schwanzes ist nur schwach gabelig, der leßte Wirbel kurz. Die Höhe der Ohren außen vom Pelze bis zur Spiße giebt er aus $^7/_8$", die Breite über $^6/_8$ an, die Länge über 2"; als Heimat das Innere von Südafrika und die Ostküste.

21) Smith stellt noch eine Art als *N. affinis* auf: "N. cervice et dorso rubro-fulvis, colli lateribus rubro-albis, .. terge aurium subrufa; partibus inferioribus fulvo-albis; membranis nigro-fuscis; dentibus primoribus maxillae in paria dispositis." Die beiden Paare der obern Schneidezähne sind durch einen deutlichen Zwischenraum getrennt; die Endigung des Schwanzes ist stark gegabelt, der leßte Wirbel einer der längsten. Die Länge des Körpers ist 2", die Ohren ziemlich länger und breiter als bei *N. capensis*. - Smuts hält dies *N. affinis* mit Unrecht für identisch mit *N. thebaica*; viel eher könnte mit leßterer *N. capensis* zusammen gestellt werden. Färbung, wie die Stellung der obern Schneidezähne deuten auf eine eigne Art hin; vielleicht möchte sie aber auch mit *N. hispida* zusammen gehören.

p. 441

Spalte ist einer der kleinsten. Die Farbe der Oberseite ist im Allgemeinen ein etwas rußiges Relkenbraun, derUnterseite schmußig weiß, wobei alle Haare, welche sehr lang sind, in ihrer ganzen Wurzelhälfte schieferschwarz sind. Die Ohrwurzel ist hinten und an den Seiten mit weißen Haaren beseßt. Die Wangen sind bräunlich; ein großer brauner Fleck finded sich unten an der Einlenkung der Flügel, während weiterhin die Behaarung an dem Anfang de Oberarms und an dem Flügelansaß am Leibe weißlich, oben braun ist. Die Flughäute und Ohren sind dunkelbraun. Die Heimath dieser Art ist die Südspiße von Afrika.

p. 34

Die Originaltype von *N. Adovanus* des Stuttgarter Museums gehört nach Professor Peters zu *N. Schlieffenii*, der, wie es scheint, in Kordofan heimlich ist.

p. 35

Ich gebe hier die nach dem Thiere im Fleisch von mir entworfene Beschreibung wörtlich aus meinem Notizbuch;

Im Oberkiefer $^2/_2$ echkzahnartige Schneidezähne, unten $^3/_3$, deren jeder oben dreispitzig; der obere, dem Eckzahn zunächststehende, sehr Klein, wohl abortiv. Ohren start von halber Kopflänge, ihre Außenseite ziemlich gradlinig; Tragus schmal, gegen die Augen zu nach vorwärts geneich; Nasenlöcher etwas rührig, auswärts und vorwärts gerichtet; Wangen vor den Augen wulstig aufgetrieben; Schwanz bis zum sehr rudimentären Spitzglied von der Schenkelhaut eingeschlossen; der lange Sporn trägt einen äußeren Hautlappen; die Schenkelflughaut reicht bis zum Fersengelenk, die Bauchflughaut dagegen noch weiter am Fuß herab; Obersiete der Füße, Ohren und Flughäute schwärzlich, die letztere mit deutlichem, aber feinem, weißem Saum; Gesicht und Oberseite bräunlich mausfarben; Unterseite graulichweiß; *Patagium interfemorale* mit regelmäßigen

Querreihen von weißen Haaren auf der Unterseite; ist aber auch äußerlich spärlich behaart; Nägel weißlich. Körperlänge bis zum After 1" 7‴. Schwanz von After bis zum Spitze 1" $2^1/_2$‴. Vorderarm 1" 1‴.

Das beschriebene, den Zahnverhältnissen nach jüngere Thier wurde von uns im November am Asam-Fluß bei Adowa in Tigrié erbeutet.

Vorkommen: In Nord-Afrika, besonders Aegypten, in Gesteins- Mauer- und Baumritzen (Zelebor). Originalexemplare: in der Sammlung des k. Hofnaturalienkabinets zu Wien, des Hrn. Zelebor, des Prof. Dr. Kolenati in Brünn, Parasiten u. z. 1. Körperhautschmarotzer: Ichoronyssus foveolatus Kolen. Die grubentragende Schmutzmilbe. 2. Ohrmuschelschmerotzer: Otonyssus orthotrichus Kolen. Die geradborstige Ohrmilbe. 3. Flughautschmarotzer: Monostaspis hexastigma Kolon. Die sechsgrubige Einschildborstenmilbe.

Anhang. Mit V. macuanus Peters (Säugeth. Mossamb. 61. Taf. 16. Fig, 1.) hat unsere Art keine Aehnlichkeit, da bei macuanus der Tragus oben erweitert und die Flugweite = 0.36 ist; eben so wenig mit V. Rüppeli Fischer (Synops. 108), bei dem die Ohren rund sind, und die Flugweite = 0.193 beträgt. Bei V. nanus Peters(63. Taf, 16. Fig. 2.) ist der Aussenrand des Ohres gebuchtet, und beide oberen Schneidezähne gleich lang, Flugweite 0.22. Sundevall's V. subtilis hat zwar oblonge ganzrandige Ohren, aber einen kurzen halb ovalen Tragus. Smiths Mammal. Cap. 107 V. platicephalus hat eine an der Rückenseite bis zur Hälfte behaarte Schwanzflughaut, und eine Flugweite von 0.23. Temmink's (Monogr. Mamual. II. 309) und Smiths (Illustrat. S. Afrik. Tab. 51.) V. minutus hat den innern obern Schneidezahn zweispitzig, sonst wäre er in der Grösse und Ohrbildung unserem ziemlich ähnlich, doch ist das Patagium bei ihm nicht weiss gesäumt. Smith's V. hesperida, 211 hat auch mit unserem hinsichtlich der Grösse viel Aehnlichkeit, aber eine schwarze Schnauze. Vesperugo Kuhlii Natterer hat 6 untere Schneidezähne und 8 Gaumenfalten, Vesperugo ursula Wagner dagegen einen winkelig vorspringenden Spornlappen und Haftlappen an den Fusskrallen, Vesperugo marginatus Cretschmar in Rüppel's Atlas 74 Tf. 29 Fig. a. hat zwar den weisscn Saum an der Flughaut, aber eine Flugweite von 0.22, und wird von dem

p. 79

kritischen Chiropterologen Prof. Blasius selbst als Synonym zu V. Kuhlii Natterer gezogen, daher hier ein Verkennen nicht wohl denkbar ist. Er wäre einzureihnn zu Vesperugo albolimbatus Cretschmar, V. subtilis Sundevall und V. hesperida Smith

---

Neoromicia Roberts, 1926

p. 245

Neoromicia gen. nov., type *Eptesicus zuluensis* Rbts.

Since describing *E. zuluensis* in these *Annals* (x, p. 60, 1924), I find that the species ill fits the genus *Eptesicus*, and there being no other to which it can be referred, I have no option but to place it in a new genus as above. It differs from Eptesicus in having the cranium slightly raised above the leve1 of the muzzle, as in *Pipistrellus*, from which it differs in having no small upper premolar. In examining the generic arrangement of these little bats, I find it advisable to recognize other genera. Thus, while *Glischropus*, to which I tentatively refer *P. nanus* (Peters), has much in common with the typical *Pipistrellus*, it has a lighter skull,

and might therefore be removed if necessary, though it would seem to represent the genus in S. Africa. *Romicia* Gray, type *R. kuhli* (Kuhl), has the heavy skull of *Pipistrellus*, but the upper incisors as in neither, the outer one very small, much less than half the height of the inner, instead of being nearly as high. *Neoromicia* comes nearest to *Romicia*, but lacks the small upper premolar. *Pipistrellus rusticus* (Tomes), which is commonly associated with the above-mentioned genera, has really nothing to do with them and in the shape of the skull shows affinity to *Eptesicus*, from which it differs in its smaller size and presence of the small upper premolar. I therefore place it in a new genus *EPTESICOPS*, type *V. rusticus* Tomes. With this last genus I tentatively associate *Vespertilio subtilis* Sundeval.

Neoromicia vansoni Roberts, 1932

p. 15

A small form similar to *N. zuluensis* and its allied forms in colour and general characters, not so small as *pusillus* Noack, but smaller than *zuluensis* Roberts. Colour above tawny olive for the terminal part of the hair, dark slate basally, the hairs rather long and soft, about 7 mm, in

p. 16

length on the middle of the back; these hairs extend slightly on to the membrane at the sides and interfemorally; face and throat like the back, but remaining under parts white, these hairs dark slate for the basal two-thirds. Skull rather lighter than in *capensis*.

Type: T. M. 6553, adult F, Zweizwe Waterhole north of Tsotsoroga Pan, Northern Bechuanaland, 7th July, 1930, No. 882, Vernay-Lang Kalahari Expedition. Length of head and body 38, tail 36, hind foot (c.u.) 5.6, ear 10. Skull: canines to occiput 12.2, zygomatic width 7.3, width of brain case 6.1, of palate across outside of m^2 4.5, length of upper tooth row (c-m^3) 4, of mandible 8.2 mm.

Noctula Bonaparte, 1837

Noctula ??

La presente specie, che a prima giunta crederesti il giovane del *Pipistrellus serotinus*, appartiene certamente al suo medesimo gruppetto di *Noctula* per l'encefalo molto depresso, per la gran disuguaglianza degl'incisivi, e per la forma del trago. Si distingue specificamente però dal detto *P. serotinus*, non solo per la piccola statura. ma per la tinta altresì del vello, i cui peli son bicolori, e per l'acutezza delle orecchie; carattere questo che unito a quelli del cranio serve a non farla confondere col *Pipistrellus vispistrellus*, col quale ha più simile il colore. Le vien da noi dato il nome di *Alcythoe*, la più solenne delle tre suore, nella cui denominazione conviene anche Ovidio, che nelle altre da Eliano discorda.

Nyctalus verrucosus Bowdich, 1825

p. 36

… and, that the bat is more than specifically distinct from all those which have, as yet, been described, for it has four pointed incisors above (two by the side of each canine, with a large interval between), and six small incisors below, with three indentations in each. It forms a new sub-genus between *pharopus* and *cephalotes*, and may be named, *nyctalus verrucosus* [h].

Footnote:

[h] Νυκταλος, noctem amans. *Suid : de Diogen. Cyn*. The lower canines have a heel. The muzzle and *oreillettes* are simple; the ears are equal to the depth of the head in length, and present clusters of orange warts on the outer part, and a few within. It has a nail, and extra joint to the forefinger; three joints to the middle finger, two to the others. The interfemoral membrane (not notched, but triangular) reaches to within one line of the end of the tail, which is within it: - width, from the tip of one wing to the other, 11 $^3/_4$ in., from the muzzle to the tip of the tail 4 $^1/_4$ in., colour, dusky brown.

Nycterikaupius Menu, 1987

p. 108

(Second Ensemble dentaire)

(Pl. 4, fig. 1)

Origine du nom: du grec *Nycteris* (chauve-souris) et de J. Kaup, mammalogiste allemand. Il est établi en hommage à ce dernier pour ses travaux sur les Vespertilionidae.

Espèce-type: "*Eptesicus*" pumilus GRAY, 1841.

Le genre *Nycterikaupius* est odontologiquement homogène, et notre investigation est

p. 109

limitée à cette seule considération. Il est vraisemblable que ce taxon fera plus tard l'objet d'une révision, et que les raisons de le scinder seront autres que celles liées aux structures dentaires. Il semble prématuré de s'engager présentement dans cette démarche, qui nous obligerait à utiliser d'autres méthodologies que l'odontologie. Cette probable mise au point comporte d'ailleurs un préalable: la révision des types spécifiques et leur comparaison avec les pièces muséologiques, afin de limiter la confusion qui règne actuellement à ce niveau.

Diagnose odontologique:

I1/: première voie évolutive; types B' et B" (I,80);
I2/: type B (I,84); processus de régression engagé;
C. sup.: type B (I,91) très modifié; la crête mésiale s'estompe, elle laisse place à un arrondi antérieur; la face plane interne devient moins importante; par ailleurs pas de renfort sur la face interne, comme cela est le cas sur les dents du type C (I,91);
P2/: type B (I,99) quand la dent est présente;
P4/: type D (I,102), dent morphologiquement fluctuante;
M1/-M2/: type A (I,112) peu souvent; type B (I,114) communément; dans les deux cas la partie linguale de la dent est fluctuante;
M3/: intermédiaire entre les types A et B (I,122);
I/1-I/2-I/3: nombreux intermédiaires entre les morphologies B et C (I,86-87); disposition imbriquée ou non;
C. inf.: type B1 (I,96);
P/2: type B (I,106);
P/4: type B (I,108); fusion des racines parfois amorcée; type uniradiculé quelquefois réalisé (I,111) ;
M/1-M/2: myotodontes (I,119);
M/3: myotodonte, types B et C (I,124-125).

Composition spécifique du genre *Nycterikaupius* gen. nov.: *brunneus; capensis; inexpectatus; matroka; melkorum; nasutus; pumilus; rendalli; somalicus; tenuipinnis*. Cette liste n'est pas limitative

---

Nycteris æthiopica Dobson, 1878

p. 165

Ears as in *N. javanica*, but the tragus is narrower and more curved inwards (Plate XI, fig 3).

Fur, above, brown, paler at the base of the haris; beneath, the chest and abdomen vary in colour from yellowish white to pure snow-white.

Upper incisors bifid; the second lower premolar as large as in *N. hispida*, standing in the tooth-row, but drawn half inwards.

Length, ear 1".15, thumb 0".6; third finger - metacarp. 1".4, 1st ph. 1", 2nd ph. 1".15; fourth finger - metacarp. 1".5, 1st ph. 0".55, 2nd ph. 0".5; fifth finger - metacarp. 1".55, 1st ph. 0".55, 2nd ph. 0".6; tibia 0".85, foot 0".45.

Nycteris æthiopica guineensis Monard, 1939

p. 66

Collection: N^{os} 282 F, 283 M, 284 M, 285 F, 319 M, Mansoa.

Cette nouvelle sous-espèce fait partie du groupe *æthiopica*, mais diffère du représentant occidental du groupe, *macrotis* DOBSON par la taille des oreilles et la forme du tragus; de *æthiopica* DOBSON, elle diffère par la longueur du tibia.

Description. Oreille: grande et large, moins grande toutefois que dans *macrotis*, plus longue que la tête; les deux oreilles se touchent sur la ligne médiane du crâne par un petit lobe accessoire, visible de derrière, mais sans se souder. Tragus de *æthiopica*, marge interne concave, sommet arrondi, marge externe convexe sur toute sa longueur, lobe accessoire replié en avant. Appendices nasaux: lobes supérieurs arrondis en croissant; lobes moyens larges et arrondis; lobes inférieurs dépassant peu les moyens en arrière et seulement légèrement échancrés; fosse postérieure profonde, sans crête médiane; lobe postérieur très proche du lobe interne des oreilles. Membranes normales. Tibias plus longs que dans *æthiopica* et *macrotis*.

Pelage: noirâtre sur le dos, la base des poils claire. Faces ventrales blanchâtres; côtés du museau, nombreux poils des lèvres, base des oreilles par derrière blancs. Membranes noirâtres.

Crâne: incisives supérieures bifides, séparées par paires au milieu. séparées aussi des canines. Deuxième prémolaire inférieure petite, située à peu près dans la ligne dentaire, légèrement en dedans. Pointes accessoires des canines supérieures basses. Des-

p. 67

sin formé par les naso-frontaux terminé en arrière par un arc en ogive, les expansions latérales larges.

[table removed - eds.]

Nycteris æthiopica guineensis f. aurantiaca Monard, 1939

p. 68

Collection: N° 717 M, Pitche.

Cet unique exemplaire possède tous les caractères de *guineensis* et des mensurations comparables: longueur du corps 56 mm; queue 53; oreille, marge externe 30; avant bras 49; doigt III, 36, 26, 26; doigt IV, 40, 14, 13; doigt V, 42, 13, 14; tibia 25; pied 12. Seule la couleur diffère: elle est d'un bel orangé, avec les pointes des poils plus foncées sur le dos, de même teinte sur le ventre. Le museau et la base des oreilles, par derrière sont blancs. Les appendices nasaux ont la même forme que dans *guineensis*. Une autre forme orangée de *Nycteris* a été signalée: *Nycteris thebaica aurantiaca* DE BEAUX, dans la colonie du Kenia. Les mêmes altérations de couleur se trouvent dans d'autres genres, tels que *Hipposideros, Mops*, etc.

Nycteris aethiopica luteola Thomas, 1901

p. 30

Similar to the typical form in essential characters, but slightly larger, with longer posterior extremities, and of more yellowish coloration.

Fur soft, fine, and straight, the hairs of the back about 9 millim. in length, considerably longer than those of true *æthiopica*. Humeri and proximal halves of forearms clothed with fur, which also extends on to the wing-membrane. Base of interfemoral membrane and proximal halves of femora also hairy. Below, the fur extends further back on the wing-membrane, but less on the interfemoral than above.

General colour above dull buffy, not far from Ridgway's "clay-colour," browner posteriorly and on the humeri. Individually the hairs are glossy buff, with brown tips. Below, the colour throughout is clear buff, very near Ridgway's pl. v. fig. 13.

Ears and tragus as in true *æthiopica*. Forearms rather longer; tail, lower legs, and feet decidedly longer.

Skull similar to, but rather larger than, that of true *æthiopica*.

Dimensions of the type (in skin): -

Forearm 56 millim.

Tail (vertebræ) 57; lower leg and foot, including claws, 36.

Skull: greatest length from occiput to tip of canines 22.2;

p. 31

zygomatic breadth 13; breadth of frontal shield 7.8; upper tooth-row, from front of canine to back of $m.^3$, 7.5.

The measurements of an adult spirit-specimen are given by Dobson (P. Z. S. 1879, p. 718) under the name of *N. æthiopica*. In that specimen the tail is 59 millim. long and the lower leg and foot 37, just about the same as in the type. On the other hand, in a series of true *æthiopica* from Shendy, Soudan, therefore practically topotypes, the tail does not exceed 53 millim., and the lower leg with foot 33 millim., these measurements being very uniform in all.

Hab. Kitui, British East Africa, alt. 3500 feet. Another specimen from Zanzibar.

Type. Female. B.M. no. 1.5.6.4. Collected 14th February, 1901, and presented by S. L. Hinde, Esq.

The original series of *N. æthiopica*, from Kordofan, consists of three faded skins, with imperfect skulls; but fortunately, just as Mr. Hinde's specimen needed determination, the Museum has been presented by Messrs. N. C. Rothschild and A. F. R. Wollaston with a very nice set, both skins and spirit-specimens, from Shendy, on the Upper Nile, and these have enabled me to satisfy myself as to the constancy of the distinguishing characters of the new form.

As already indicated, the example from Zanzibar, referred to by Dobson (P. Z. 8. 1879, p. 718), proves to belong, as might be expected, to *N. æ. luteola*.

Nycteris affinis A. Smith, 1829

p. 434

Nycteris affinis, mihi.

N. cervice et dorso rubro-fulvis; colli lateribus rubro-albis; a tergo aurium subrufa; partibus inferioribus fulvo-albis; membranis nigro-fuscis; dentibus primoribus maxillæ in paria dispositis.

Neck above and back reddish brown or tawny, sides of neck before wings reddish white; behind ears somewhat rufous; beneath tawny white, membranes blackish brown. Incisors of upper jaw in pairs which are separated from each other by a distinct open space immediately in the front of the jaw. Length from nose to root of tail, two inches; ears rather longer and broader than in the last species; tragus short, and its apex semicircular; termination of tail deeply forked, with the last vertebra but one the longest.

The arrangement of the incisors of the upper jaw, the marked difference in respect to the last joint but one of the tail, added to the

p. 435

depth of the fork, and the greater proportion of transverse veins, in the portion of the interfemoral membrane connected with the joint named, tend, with other characters, to estabhsh this as a distinct species from the last.

Nycteris angolensis Peters, 1871

p. 903

(Fig. 5.)

Durch die Güte des Hrn. Barboza du Bocage habe ich verschiedene Exemplare einer *Nycteris* zur Untersuchung erhalten, welche ich für identisch mit *N. fuliginosa* aus Moçambique gehalten habe. Eine genauere Untersuchung hat mir aber gezeigt, dafs, obgleich sie in der Färbung mehr mit dieser letztern übereinstimmt, sie durch die Entwicklung des kleinen zweiten untern falschen Backzahns und auch durch eine etwas geringere Länge des Sporns der *N. thebaica* näher steht und dafs sie von dieser nur durch eine etwas stärkere Entwickelung dieses äufserst kleinen

p. 904

Zalmes von ihr verschieden ist. Der Tragus zerfällt, wie gewöhnlich, in zwei Abtheilungen und die obere abgerundete Abtheilung hat, wie bei *N. thebaica* und *capensis*, den vordern Rand convex.

Diese Art ist in Caconda, Biballa und Rio Coroca VOn Hrn. Anchieta gefunden worden

Nycteris arge Thomas, 1903

p. 633

Allied to *N. thebaica*, but with much smaller tragus.

Size medium. General colour dark brownish above and below. Nose-leaf of normal structure, but unusually thickly

p. 634

hairy. Ears of average size, the projecting lobule at their outer bases very strongly developed, inverted, deeply concave externally, convex internally. Tragus with its free portion, as in *N. thebaica*, expanded above and convex on its inner margin, but the free portion itself is barely one third its size in the allied species, the distance from its inner base to its tip considerably less than the distance from the same point to the base of the outer margin.

Upper incisors deeply bifid; second lower premolar nearly half the size of the first, in the tooth-row.

Dimensions of the type (measured in spirit): -

Forearm 45 mm.

Head and body 52; tail 48; lower leg and foot (s.u.) 32.5; head 21.5; ear 28; inner margin of tragus 2.5.

Hab. Efulen, Cameroons.

Type. Adult male. Collected by Mr. G. L. Bates. Two specimens.

This *Nycteris* is readily distinguishable by the extremely small size of the free portion of the tragus, which is otherwise similar in shape to that of *N. thebaica*.

Nycteris avakubia J.A. Allen, 1917

p. 426

Type (and only specimen, in alcohol), No. 49403, M ad., Avakubi, Belgian Congo, September, 1913; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 2623.

A member of the *N. hispida* group, intermediate in size between *N. hispida* and *N. grandis*. Upper incisors trifid, p_4 large, fully one third the size of p_3, and similar to it in general form. Coloration not distinctive, but very dark including ears and membranes, in the single specimen in alcohol.

Total length, 137 (150, 144.7); head and body, 63 (--, 71); tail, 65 (70, 73.7); ear, 25 (32, 30,5); forearm, 51 (59.5, 57); third finger, metacarp, 40 (44, 43.2); tibia, 30 (25.5, 31.8); foot, 12 (18.5, 15.2); calcaneum, 20 (23, 22.9).

Skull, total length, 22.4; zygomatic breadth, 12.9; upper toothrow (c-m^3), 7.7; length of mandible, 15.1; lower toothrow (c-m_3), 8.4.

Represented only by the type (in alcohol) taken at Avakubi.

Nycteris benuensis Aellen, 1952

p. 53

COLLECTION

2 exemplaires.

N° 1481 a (type) M ad., 1481 b (tête seulement), Rei Bouba, 16.9.1947.

DESCRIPTION

Caractères externes. - D'allure générale, cette nouvelle espèce est semblable à *nana nana*. Les mesures externes sont un peu plus fortes que chez cette dernière. L'oreille et la feuille sont comme chez *nana nana*. Le lobule de la base du bord externe est grand, presque plat, beaucoup moins concave que chez *nana* ou *arge*. Le tragus est falciforme; le bord externe est convexe; le bord interne est sinueux, concave à la base, convexe au sommet; la partie libre est égale à la moitié de la longueur totale (fig. 12, p. 50). La queue est relativement plus courte que chez *nana nana*. Le pelage s'étend sur le 1/3 basal de l'avant-bras, à la face supérieure, un peu moins dessous.

Coloration. - La teinte générale est gris brunâtre, légèrement plus clair à la face inférieure et à la base des oreilles. Les oreilles et le patagium sont bruns.

Crâne. - Il ne présente aucun caractère particulier.

Dentition. - Les incisives supérieures sont à peine bifides, probablement très usées. La 2^{me} prémolaire inférieure est dans la rangée dentaire; elle est petite et atteint juste le talon de la première prémolaire dans un des spécimens (N° 1481 a), elle est encore plus petite dans l'autre.

N. benuensis est voisin de *nana*, mais s'en distingue principalement par la forme du lobule du bord externe de l'oreille et par la taille de la 2me prémolaire inférieure.

BIOLOGIE

Les deux exemplaires obtenus par la Mission Suisse ont été apportés par un indigène en même temps que des *Rhinolophus foxi*. Mais, il n'est pas certain que ces deux espèces aient été trouvées ensemble.

Nycteris Capensis A. Smith, 1829

p. 434

Nycteris Capensis, mihi.

N. cervice et dorso nigro-fuscis, colli lateribus sordido-albis; partibus inferioribus subcinereis: membranis rubro-fuscis; apice tragi semicirculari cum cristâ villi albescentis.

Neck above and back blackish brown, sides of neck dirty white, below cinereous white with shades of blackish; membranes reddish brOwn; height of ears without from fur to tip, $^7/_8$ of an inch, width better than $^6/_8$; tragus short, apex semicircular and its upper edge clothed with a tuft of long, white, woolly fur; termination of tail but slightly forked, last vertebra but one if any thing the shortest. Length from nose to root of tail, better than two inches; expanse of wings, ten inches. Found in the interior parts of South Africa as well as upon the Eastern coast.

Nycteris damarensis Peters, 1871

p. 905

(Fig. 7.)

Aus dem Damaralande haben das Berliner, das Stockholmer und das British Museum Exemplare einer *Nycteris* erhalten, welche der *capensis* Smith äufserst nahe steht, durch die ganz schneeweifse Unterseite, ohne bräunliche Schattirung an der Seite der Brust vor der Schulter, auffällt und sich durch eine etwas stärkere Entwickelung des kleinen zweiten untern falschen Backzahns auszeichnet. Ich lasse dieser Art den Namen, unter welchem sie im British Museum und in dem Catalogue of Mammalia von 1843 (p, 24) aufgeführt ist, obgleich sie niemals beschrieben wurde.

Nycteris Daubentonii E. Geoffroy Saint-Hilaire, 1813

p. 19

Pelage roussâtre; blanc-sale sous le ventre. Oreilles oblongues.

p. 20

Vesp. hispidus. SCHREB., pl. 56.

HABITE le Sénégal.

Nycteris fuliginosa Peters, 1852

p. 46

Tafel X.

N. fuliginosa, subtus ex griseo fuscescens; alis nigris; pilis cervicis, laterumque colli in basi albis, reliquis in basi nigroschistaceis; auriculis dimidio capite longioribus.

Lonqitudo tota 0,120; caudae 0,055; antibrachii 0,045; volatus 0,300.

Habitatio: Africa orientalis, Boror, 17° Lat, Austr.

Die Ohren sind aufserordentlich lang, entfaltet um die Hälfte länger als breit und um ebenso viel länger als der Kopf, über der Stirn durch eine niedrige wulstige Hautfalte verbunden, von elliptischer Gestalt, oben an der Vereinigung der verdickten bogenförmigen Ränder stumpfwinklig zugespitzt, am vorderen Rande und an der Basis mit wolligem weifslichen Haar bekleidet, am übrigen Theil mit zerstreuten Härchen bewimpert. Der Tragus ist durch einen hintern Einschnitt in zwei Lappen getheilt; der obere Lappen ist eiförmig, länger als breit, am obern Rande mit einem Haarbüschel geziert; der Antitragus ist abgerundet, deutlich vom hintern Ohrrande abgesetzt und verlängert sich nach vorn durch eine Hautfalte über die Schläfe. Der hintere Ohrrand spaltet sich, wie bei allen andern Arten, in eine innere nach dem Gehörgang gerichtete Lamelle und in den äufsern mit dem Antitragus verbundenen Theil. Die Augen sind klein und stehen in der Mitte zwischen dem Schnauzenende und der Wurzel des vorderen Ohrrandes. Die Schnauze ist stumpf und abgerundet; die Maulöffnung ist bis unter die Basis der Nasenklappe gespalten, und an den Seiten in einem nach unten flach convexen Bogen geschwungen. Der Rand der Oberlippe ist vorn ein wenig vorstehend und verdickt. Die Unterlippe zeigt eine mittlere breite dreieckige sich nach unten verschmälernde Furche, die zu beiden Seiten durch einen wulstigen Rand, nach oben hin durch eine warzige Erhöhung begrenzt ist. Die Bildung des Nasenbesatzes, die Furchung des Kinnes und die Bildung der Lippen zeigt nichts von den andern Arten Abweichendes. Die Schleimhaut des Gaumens bildet sechs Querfalten. Die Behaarung des Körpers ist sehr reich, an der Rückseite doppelt so lang wie am Bauche. Sie erstreckt sich aber über die Flughäute nicht weiter als bei *Nycteris thebaica*, Geoffroy, etwas über die Hälfte des Oberschenkels, an der Bauchseite etwas weiter als an der Rückenseite. Die Verhältnisse der Gliedmafsen gehen aus den unten angeführten Mafsen hervor, sie zeigen nichts Eigenthümliches. Das letzte Schwanzglied ist bei verschiedenen Exemplaren von verschiedener Länge, bald äufserst kurz, bald länger, immer aber viel kürzer als die beiden Zweige des Endknorpels zusammengenommen.

Die Farbe der Rückenseite ist rufsbraun, die Bauchseite grau mit einem bräunlichen Schein. Die Haare des Nackens und der Halsseiten sind am Grundtheile weifs, die übrigen schwarzgrau, schieferfarbig. Die Flügel und Ohren erscheinen blauschwarz, bei durchfallendem Schein haben sie eine Beimischung von Braun. Bei jungen Individuen ist die Farbe etwas

p. 47

heller, immer aber noch viel dunkler als bei den verwandten Arten. Die Nägel sind von weifser Hornfarbe.

Der Schädel und das Gebifs zeigen dieselbe Form wie von *Nycteris thebaica*; auch in den relativen Verhältnissen finde ich keinen bemerkenswerthen Unterschied. Der untere zweite kleine Lückenzahn ist bei allen Exemplaren vorhanden, und ein ganz wenig gröfser als bei den jungen ägyptischce, denen er im späteren Alter zu fehlen scheint. Die Zahl der Wirbel ist constant an mehreren Skeleten 35: hiervon sind 7 Halswirbel, 10 Rückenwirbel, 6 Lendenwirbel, 5 Kreuzbeinwirbel und 7 Schwanzwirbel.

Die Zunge ist ganz gleichumäfsig von kleinen platten Schüppchen bedeckt, welche auf der Grundhälfte etwas weniger gedrangt stehen, und nahe der Basis zeichnen sich zwei von einer ringförmigen Vertiefung umgebene Wärzchen durch ihre Gröfse aus. Die Speiseröhre geht, sobald sie das Zwerchfell durchbohrt hat, in einen sackförmigen rundlichen Magen über, der sich durch eine geringe Abschnürung von dem etwa 120 Millmeter langen Darm scheidet, welcher einfach, nach mehreren Windungen, in das etwas erweiterte Rectum übergeht. Die Luftröhre macht unter dem Kehlkopf zwei seitliche Anschwellungen und enthält bis zu ihrer Theilungsstelle 23 knorpelige Halbringe. Die Lungen bilden jederseits nur einen unregelmäfsig quadratischen Lappen. Die Nieren sind ungelappt, bohnenförmig. Die Nebennieren haben eine platte Gestalt und sind sehr klein. Die Gestalt der Milz ist zungenförmig. Die Hoden liegen aufserhalb der Bauchhöhle. Die Ruthe enthält in ihrer Endhälfte einen 3 Mm. langen Knochen, der mit einer breiten, ausgehohlten Basis dem Ende der Corpora cavernosa aufsitzt. Die Hörner am Uterus des Weibchens sind sehr lang.

Ich fand diese *Nycteris* nur ein einziges Mal, aber in grofser Anzahl, in einem dunkeln Raume meiner Wohnung, welcher durch einen Schornstein mit der freien Luft in Verbindung stand. Es war dies im März 1846, in Boror, etwa 12 Meilen nordwestlich von Quellimane. Diese Thiere nähren sich wol nur von Insecten, obgleich die Einwohner ihnen Schuld geben, dafs sie das Fleisch in den Vorrathskammern angreifen. Wenigstens fand ich nur Theile von Insecten in ihren Verdauungsorganen. Die Eingebornen nennen diese Fledermaus *nantûtu*.

Nycteris capensis und *Nycteris affinis* sind nur nach Smiths kurzen Diagnosen bekannt; hiernach unterscheidet sich die erste von vorstehender Art durch rothbraune (rubrafusca) Färbung der Flughäute, schwache Gabelung des Schwanzes und die im Verhältnifs zum Länge gröfsere Breite der übrigens kürzeren Ohren (Länge $^7/_8$ Zoll, Breite $^6/_7$ Zoll); die zweite ist ganz anders gefärbt "cervice et dorso rubro-fulvis, colli lateribus rubro-albis; a tergo aurium subrufa; partibus inferioribus fulvo-albis: membranis nigro-fuscis;" und soll die oberen Schneidezähne paarweise getrennt haben. Aufserdem wird zwischen beiden Arten noch eine Verschiedenheit in der Kürze oder Länge des letzten Schwanzgliedes gesucht, was nach meine Beobachtungen bei einer und derselben Art variirt, *N. discolor*, welche ich durch die zuvorkommende Güte meines hochverehrten Freundes A. Wagner vergleichen konnte, hat eine breitere Ohrklappe und verhältnifsmäfsig breitere Ohren, aufserdem ist die Farbe des Thieres und der Flughäute viel heller braun. *Nycteris hispida*, Schreber, ist oben röthlichbraun, unten gelblich weifs. *Nycteris thebaica*, Geoffroy, hat kürzere und verhältnifsmäfsig breitere Ohren, die Ohrklappe ist breiter und abgerundeter, die Farbe der Rückenhaare ist an der Basis schmutzig weifs, und der zweite kleine untere Lückenzahn ist ganz nach innen gedrängt und fällt bei den älteren Individuen aus. *Nycteris javanica*, Geoffroy, ist durch ihre Gröfse, durch die roströthliche Farbe und die Gröfse des zweiten untern Lückenzahns hinreichend von allen anderen Arten unterschieden.

Nycteris Geoffroyi Desmarest, 1820

p. 127

(Non figuré dans l'Encycl.) *Description d'une chauve-souris étrangère*, Daub. Œuvres de Buffon, descripr. du cabinet, n. DCDX et DCDXI. - *Nyctère de la Thébaide*, Geoff. Mém. de l'Instit. d'Egypte, hist. nat. tom. 2. pl. 1 et 2.

CAR. ESSENT. *Oreilles très-grandes; opercules des environs des narines assez développés et en spirale; lèvre inférieure ayant une forte verrue à son extrémité, située entre deux bourrelets alongés, non réunis et en forme de V; pelage d'un gris-brun en dessus; gris plus clair en dessous*.

DIMENS. Longueur du corps mesuré en ligne droite, depuis le bout du museau jusqu'à l'origine de la queue: 1 pouc. 10 lig.

- de la tête, depuis le bout du museau jusqu'à l'occiput: 1 pouc. 10 lig.

- de la fosse du chanfrein: 5 lig.

Largeur des opercules: 1 ?/?

Longueur des oreilles: 11 lig.

Envergure des ailes: 9 pouc.

Longueur du pouce de l'aile: 5 ?/?

- de la queue: 1 pouc. 11 lig.

DESCRIPT. Tête grosse, fort prolongée en avant; crâne volumineux, très-arrondi en arrière; museau renflé; bouche très-fendue; lèvre supérieure haute et très-entière; lèvre inférieure comme bifurquée, et offrant deux bourrelets ou replis de la peau épais et nus, formant un angle entr'eux, et étant séparés par un sillon qui se prolonge sous la mâchoire; un tubercule entre-deux, formant la terminaison de la lèvre; canines assez fortes; incisives très-petites et bilobées ou trilobées; langue alongée, arrondie au bout, et ayant sa surface parsemée de petits grains élevés qui paroissent être des papilles cornées extrèmement fines; nez très-compliqué, composé, 1°. des deux ouvertures nasales fort rapprochées et situées à la partie antérieure d'une grande fosse du chanfrein qui se porte depuis le haut de la lèvre jusqu'à la base du crâne proprement dit; 2°. d'un repli mince de la peau, recouvert de poil, bordant extérieurement, cette fosse, et ne s'apercevant que lorsqu'on le soulève avec l'extrémité d'un instrument aigu; 3°. de deux replis plus minces, longitudinaux, sans poils, situés parallèlement l'un à l'autre dans le fond de la fosse du chanfrein; 4°. de deux espèces de pièces de

p. 128

forme arrondie, un peu en spirale, tenant au repli extérieur de la peau, et recouvrant en partie le milieu de la fosse du chanfrein, mais non les ouvertures des narines, qui sont situées en avant; oreilles placées à peu près au tiers postérieur de la longueur de la tête, d'une hauteur presque double de la sienne, ayant l'ouverture de la conque de forme ovale oblongue, dirigée en avant et les contours entiers; les bords internes des deux oreilles étant assez rapprochés l'un de l'autre, et même réunis sur le front par une perire cloison membraneuse, transversale; bords externes commençant sur les côtés de la tête et fort bas, où ils forment un assez grand repli; conque velue près de la tête, n'offrant en dehors qu'un seul pli droit, partant de sa base et se portant presqu'à son extrémité, et assez près du bord externe, ce pli étant indiqué par une nervure saillante postérieurement, et garnie d'une seule rangée de petits poils disposés comme des cils; des poils rares sur les deux faces de la conque, et dont les bulbes forment autant de points moins transparens que le reste de la membrane; oreillon petit, appliqué au bord interne du dedans de la conque, de forme arrondie ou en cuiller, et étant deux fois aussi large que haut, sa face antérieure érant velue; yeux petits, une fois plus près de l'oreille que de la pointe du museau; cou court, mais bien marqué; corps très-épais et très-musculeux antérieurement; ligne moyenne du dos entre les épaules, offrant un sinus longitudinal très-profond; poitrine très-renflée et très-large; ventre mince; ailes grandes et larges; pouce grêle avec un ongle foible; muscles des avant-bras très-forts; membrane interfémorale très-ample, soutenue par des osselets cartilagineux presqu'aussî longs que la jambe, et embrassant la queue, qui est formée de sept vertèbres, et terminée par un cartilage en forme de T, dont les branches partent à droite et à gauche de l'extrémité de la dernière; pelage doux et fin, brun en dessus et gris-brun clair en dessous.

Nota. Telle est la description détaillée d'un nyctère qui nous a été rapporté du Sénégal par M. Huzard fils, habile médecin vétérinaire. Ayant comparé ce cheïroptère avec le nyctère de la Thébaïde de M. Geoffroy, nous n'avons pu trouver de caractères distinctifs assez tranchés pour l'établir en titre d'espèce; mais les proportions de diverses parties de son corps nous ont présenté quelques différences que nou relaterons ici.

Nycteris Geoffroyi Var. Senegalensis Hartmann, 1868

p. 44

N. Geoffroyi Desm. (Mumm. p. 127, 190). Var. *Senegalensis* (das.). Sennar.

Nycteris grandis Peters, 1865

p. 358

In der Färbung und Behaarung ganz mit *N. fuliginosa* übereinstimmend, aber beträchtlich gröfser, indem sie selbst noch *N. javanica* an Gröfse übertrifft. Die Ohren sind so lang wie der Kopf. Die vier oberen Schneidezähne sind dreilappig und der zweite untere falsche Backzahn ist zwar klein, indem seine Gröfse kaum ein Drittel des vorhergehenden Zahns ausmacht, aber er ist nicht von vorn nach hinten zusammengedrückt. Auch bei dieser grofsen Art habe ich vergeblich nach einer ??bula gesucht.

Länge vom Hinterhaupt bis Ende der Schenkelflughaut ungefähr 0^m,110; Länge der Schenkelflughaut ungefähr 0^m,0??, Kopf 0^m,029; Ohr 0^m,029; Vorderarm 0^m,055; Tibia 0^m,0??; Sporn 0^m,023.

p. 359

Aus Guinea; dem einzigen getrockneten Exemplar, welches sich im Reichsmuseum zu Leiden befindet, ist der Schwanz ausgezogen, so dafs sich die Länge desselben nicht genau bestimmen läfst.

Nycteris intermedia Aellen, 1959

p. 218

Type. - F adulte, en alcool. Adiopodoumé, près d'Abidjan, Côte-d'Ivoire, 20.7.1953; coll. V. Aellen, n° orig. 623. Muséum d'Histoire naturelle de Genève, n° 923.94.

Matériel examiné. - Trois paratypes ont encore été obtenus en Côte-d'Ivoire, à Cosrou (W d'Adiopodoumé) le 24.7.1953 (2 F, n^{os} 923.95 et 923.97 Mus. Genève) et le 19.8.1953 (F n° 923.96). Je rapporte, d'autre part, à cette espèce le spécimen n° 277 de la Mission scientifique suisse au Cameroun, que j'avais déterminé *Nycteris nana* et dont la forte taille m'avait déjà intrigué (AELLEN, 1952).

Diagnose. - *Nycteris* de petite taille (avant-bras 37 mm) voisin de *N. nana* (Anders.) et de *N. arge* Thom., c'est-à-dire à P_4 grand (égal ou supérieur à la moitié de P_2) et à I^1 bifide; de proportions très semblables à *N. arge*.

Description. - Par tous ses caractères, cette nouvelle espèce est voisine de *N. nana* et *N. arge*. Les oreilles ont la même proportion que chez ces derniers, c'est-à-dire qu'elles mesurent environ les 60 à 75 % de la longueur de l'avant-bras. La profonde poche située à la base externe de l'oreille (lobe antitragal) est présente comme chez *N. nana, arge* et *major*. Le tragus est de forme semblable chez les quatre spécimens: type liguli-pyriforme; le bord interne est droit ou légèrement convexe, le bord externe est généralement échancré au milieu, parfois presque droit. Le patagium est inséré environ au milieu du métatarse, alors que chez *N. nana* et *N. arge*, il est fixé au tiers distal du métatarse, presque à la base de la première phalange. Le tibia est de même proportion que celui de *N. arge*; il dépasse la moitié de la longueur de l'avant-bras (plus court chez *N. nana*).

La coloration du spécimen type était la suivante, au moment de sa capture: sommet de la tête et dos brun un peu roussâtre; cou et surtout base externe des oreilles brun fauve; sur le dos les poils sont bruns de la racine à la pointe, au cou ils sont gris blanchâtre à la base et brun fauve au sommet. La face ventrale présente la même coloration que le dessus. La feuille nasale est

p. 219

brune; les côtés du museau brun clair, les oreilles et le patagium brun foncé.

Le crâne est de forme générale très semblable à celui de *N. arge*. La largeur zygomatique représente les 56,8 à 58,6 % (moy. 57,45) de la longueur totale du crâne (chez *N. arge*:
moy. 58,6 %, chez *N. nana*: moy. 55 %). Les premières et secondes incisives supérieures (I^1 et I^2) sont bicuspides. La deuxième prémolaire inférieure (P_4) atteint la moitié ou les deux tiers de la hauteur de la première prémolaire (P_2); en
aucun cas, elle n'arrive à la hauteur de la pointe antéro-interne de la première molaire.

Remarques. - La répartition géographique de *N. intermedia* englobe très probablement toute la zone forestière du golfe de Guinée. Connu jusqu'à présent seulement en basse Côte-d'Ivoire et dans le S du Cameroun, ce Chiroptère a peut-être été signalé par quelques auteurs sous le nom de *N. nana* ou éventuellement de *N. arge*. Du fait qu'il cohabite avec ces deux espèces, on doit le considérer comme espèce autonome et non comme sous-espèce de l'une ou l'autre.

De taille exactement intermédiaire entre *N. nana* et *N. arge*, il fait partie d'un groupe de *Nycteris* qui demande une nouvelle définition. Mon intention, dans ce court article descriptif, n'est pas de faire l'historique du genre *Nycteris* et de ses divisions subgénériques. Cependant, je rappellerai qu'ANDERSEN (1912) a proposé un arrangement des espèces de Nycteris en quatre groupes constitués comme suit:

1° groupe **javanica**: *javanica, tragata* (espèces indo-malaises);
arge, nana, major (espèces africaines);

2° groupe **hispida**: *hispida, aurita, grandis*;

3° groupe **aethiopica**: *aethiopica, macrotis*;

4° groupe **thebaica**: *thebaica, revoili, capensis, damarensis, gambiensis*.

Si l'on considère seulement le premier de ces groupes, on constate que l'une des espèces se sépare nettement des autres par ses incisives supérieures tricuspides: il s'agit de *N. javanica* (cf. ELLERMAN ET MORRISON-SCOTT, 1953). Les autres espèces

p. 220

ont toutes les incisives supérieures bicuspides. Dès lors, il me semble nécessaire de créer un nouveau groupe qui se trouve défini dans la clé suivante. Le nom de l'espèce la plus anciennement décrite a été choisi pour désigner ce groupe:

1. P_4 grand (égal ou plus grand que la moitié de P_2). --> 2

- P_4 petit (plus petit que la moitié de P_2. --> 3

2. I^{1-2} bicuspides (I^2 parfois tricuspide). --> groupe **arge** gr. nov.

- I^{1-2} tricuspides. --> groupe **javanica**

3. I^{1-2} bicuspides. --> 4

- I^{1-2} tricuspides. --> groupe **hispida**

4. Tragus semi-luné. --> groupe **aethiopica**

- Tragus pyriforme (partie libre plus étroite à la base). --> groupe **thebaica**.

Clé des espèces du groupe arge:

1. Avant-bras de plus de 39 mm. Long, du crâne dépassant 19 mm. --> 2

- Avant-bras de moins de 38 mm. Long, du crâne inférieure à 19 mm. --> 4

2. Rangée dentaire supérieure C-M^3 de plus de 8 mm. Avant-bras de 46 mm environ. --> *tragata* Anders. 1912

- Rangée dentaire supérieure C-M^3 inférieure à 8 mm. --> 3

3. Avant-bras de 47,3 à 50 mm. Long, du crâne de 20,9 à 22,4 mm. Oreilles mesurant les 50 à 65 % de la longueur de l'avant-bras. --> *major* Anders. 1912

- Avant-bras de 39,5 à 46 mm. Long, du crâne de 19,3 à 20,9 mm. Oreilles mesurant les 63 à 77 % de la longueur de l'avant-bras. --> *arge* Thom. 1903

4. Avant-bras de 36,5 à 37 mm. Long, du crâne de 18 à 18,7 mm. Tibia plus long que la moitié de la longueur de l'avant-bras. --> *intermedia* sp. nov.

- Avant-bras de 32 à 36,2 mm. Long, du crâne de 15,9 à 16,6 mm. Tibia plus court que la moitié de la longueur de l'avant-bras. --> *nana* Anders. 1912

Dans le tableau de mesures suivant, j'indique à titre de comparaison les minima et maxima pour *N. nana* et *N. arge*.

p. 221

Ces derniers chiffres ont été publiés par divers auteurs et sont complétés par des mensurations personnelles et inédites.

Nycteris intermedia (923.94 F type, 923.95 F, 923.97 F, 923.96 F); *N. nana* (min - max); *N. arge* (min - max):

Avant-bras: 37, 37, 37, 36.5; (32 - 36.3); (39.5 - 46)
3e doigt, métacarpe: 29.5, 30, 30, 29.5; (25 - 28.5); (30 - 36)
" 1re phalange: 19, 19.5, 18.5, 18.5, (15.5 - 16.5); (20 - 23.1)
" 2e phalange: 23, 22.5, 23, 23; (18); (25 - 27)
4e doigt, métacarpe: 31.5, 33.5, 33, 32.5 (27.5 - 29.7); (33 - 38.2)
" 1re phalange: 10.5, 11, 10.5, 10; (9); (11 - 13.4)
" 2e phalange: 9, 9, 9, 9.5; (8); (11 - 13.2)
5e doigt, métacarpe: 32, 34, 33.5, 32.5; (27 - 30.3); (35 - 38.6)
" 1re phalange: 10, 10.5, 10.5, 10; (9); (11.5 - 13.8)
" 2e phalange: 11, 11, 11.5, 11.5; (9); (12.5 - 14.5)
Tibia: 21, 21, 21, 21; (14.5 - 17.3); (22 - 24.5)
Pied (avec griffes): 9, 9, 9, 9.5; (6.5 - 8); (9.5 - 11)
Queue (de l'anus): 53, 51, 52, 53; (38 - 44); (50 - 60)
Oreille (longueur): 24, 23.5, 24, 24; (17 - 21); (25 - 32)
Tragus (bord interne): 2.1, 2.2, 2.2, 2.3; (1.7); (2.5)
" (bord externe): 5.4, 5.3, 5.5, 5.5; (3.2); (6.2)

Crâne:
Long, totale (à la canine): 18.7, 18, 18.3, 18.2; (15.9 - 16.6); (19.3 - 20.9)
" condylobasale: 16, 15.2, 15.7, 15.7; (13.4 - 13.9); (16.8 - 18.2)
" losange nasal: 8, -, 8.1, 7.2; (6.8); (9.2)
Larg. losange nasal: 7.8, -, 7.1, 6.6; (6.3); (7.4 - 7.8)
" zygomatique: 10.7, 10.3, 10.4, -; (8.6 - 9.5); (11 - 12.6)
" mastoïde: 8, 8.1, 7.8, -; (7.2 - 8); (8.6 - 9.6)
" C-C (externe): 4.6, 4.3, 4.5,-; (3.7); (4.7 - 5.2)
" M^3-M^3 (externe): 6.9, 6.5, 6.8, -; (5.5); (7.4 - 7.7)
Long, rangée dent. C-M^3: 6.4, 6.1, 6.3, 6.1; (5 - 5.7); (6.7 - 7.3)
" mandibule: 12.3, 12, 12.3, -; (9.8 - 10.7); (12.9 - 14)
" rangée dent. C-M_3: 6.9, 6.4, 6.8, 6.7; (5.6 - 5.8); (7.3 - 8.2)

Nycteris labiata Heuglin, 1861

p. 5

Fissura frontis membranis utrinque quatuor ornata, quarum superiore biloba; labro trisulcato, labio bipartito; gastreo, pileo naribusque albidis; regione ophthalmica, fronte, cervice et dorso murinis; colli lateribus humerisque intense griseo-rubente indutis; auriculis pallide fuliginosis, minutissime nigro-marginatis; patagiis nigricantibus.

Auf der gespaltenen Nase vier Hautfalten; die Oberlippe als eine ihrem Rande parallele Querfalte aufgetrieben, welche jederseits in der Eckzahngegend durch eine Furche gespalten ist; die Unterlippe in der Mitte einfach getheilt und die ganze Schnauze dicht und ziemlich kräftig und lang behaart - Ohren sehr gross und breit, elliptisch, am Innenrand fein und mässig lang behaart; *Tragus* klein und gerundet, letzterer sowie die Aussenseite des Ohrenrandes mit kleinem Lappen; Gaumenfalten sechs, die vorderste ungelheilt, zwischen ihr und der nächstfolgenden in der Gaumenmitte eine sticknadelkopfgrosse Warze; Schwanz sehr lang, an der Spitze getheilt und mit den Gabelgliedern einen

p. 6

Theil des untersten Randes des *Patagium interfemorale* einfassend; die Lippen sind nackt fleischfarb, ins Gräuliche mit feinen violetten Punkten besetzt - Zahnsystem regelmässig; oben je zwei, unten je drei Schneidezähne. Die Länge der Ohren ist bei verschiedenen Individuen ziemlich verschieden: die mittlere durchschnittliche Länge 1" 1‴ französ. Mass auf 9‴ Breite; Körper 2" lang, Schwanz 2", Flugweite 10"-11".

Ein Exemplar zeigt auf Rücken und Schultern einfach mausgraue Färbung ohne Beimischung von röthlichgrau.

Nycteris macrotis Dobson, 1876

p. 80 (footnote)

Length (of an adult M preserved in alcohol), head and body 2".25, tail 2".4, head 0".85, ear 1".4, tragus 0".3 x 0".18, forearm 1".9, thumb 0".5, second finger 3".6, fourth finger 2".8, tibia 0".95, caleaneum 0".75, foot and claws 0".4.

Hah. Africa (Sierra Leone).

Type in the collection of the British Museum.

Nycteris madagascariensis G. Grandidier, 1937

p. 353

Vient de la vallée du Rodo; il y en a deux exemplaires dans nos collections. Bien que représenté par de nombreuses espèces dans toute la région chaude, de l'Ancien monde, des îles de la Sonde au continent africain, ce type de chauve-souris n'a pas encore été signalé à Madagascar; nos spécimens bien que présentant tous les caractères du genre, diffèrent des *Nycteris* connus jusqu'ici par leurs proportions, et la teinte de leur fourrure notamment de *N. hispida, javanica, arge* et *angolensis* avec lesquelles *N. madagascariensis* y a quelques points de ressemblance; nous devons cependant les considérer comme les types d'une espèce nouvelle.

Le pelage est très clair, gris brun sur le dos et gris ardoisé clair sur le ventre; les oreilles qui sont à peu près de la longueur de la tête et très développées sont glabres, le tragus est arrondi et très petit, les pieds sont grisâtres. La queue qui est très importante et qui est complètement prise dans la membrane, se termine par une petite vertèbre en forme de T et non pas en pointe comme chez la plupart des *Nycteris*.

Le crâne montre tous les caractères de ceux des *Nycteris* avec sa dépression naso-frontale qu'entourent des expansions osseuses foliacées; il est cependant remarquablement fort et puissant en, proportion des dimensions des deux exemplaires de nos collections qui sont des adultes approximativement de même taille, l'un est une femelle, peut-être en état de gestation.

Voici les dimensions moyennes de ces deux chauves-souris:

Envergure 260 mm.; longueur totale 99 mm.; corps 45 mm.; queue 54 mm.; hauteur de l'oreille 27 mm.; largeur de l'oreille 18 mm.; hauteur du tragus 3 à 4 mm.; avant-bras 51 mm.; partie inférieure de la jambe 24 mm.; pouce 16 mm.; 2^{e} doigt 63 mm.; 3^{e} doigt 85 mm.; 4^{e} doigt 70 mm.; 5^{e} doigt 71 mm.

Crâne: longueur totale maximum 22 mm.; largeur zygomatique extérieure 13.5 mm. ; longueur C. m^3 8 mm.; Mâchoire inférieure: longueur maximum 14 mm.; longueur C. m^3 8 mm.

Nycteris marica Kershaw, 1923

p. 534

Nycteris marica, sp. n.

A large bat, equal to *N. grandis* in size, but with a smaller skull.

Colour drab-grey above and below, rather darker in the posterior dorsal region. Wing-membranes broccoli-brown. Lower surface of wing-membranes on each side of the body thickly furred to a distance of about 20 mm. from the body.

In the skull the fourth lower premolar is much larger than in *qrandis*, though not so large as in the *javanica* group.

Type. Adult. B.M. no. 23.8.2.1. Collected on 24th Jan., 1922.

Type-locality. Tindiga, Kilosa.

Measurements from the dried skin: -
Forearm 60 mm.; head and body 93; tail 70; ear 27;

p. 536

thumb 18.7; third finger, metacarp. 48, first ph. 32, second ph. 32; tibia and foot with claws 44.

Skull: greatest length to tip of canine 26; zygomatic breadth 16; breadth of frontal shield 10.2; p_4 comparatively large and standing in the tooth-row.

N. marica, a member of the *hispida* group, is, with *grandis*, larger than any other species in the genus. It differs from *grandis* in colour and in the smaller skull with the larger p_4.

Nycteris nana tristis G.M. Allen and Lawrence, 1936

p. 47

Type. Museum of Comparative Zoölogy, No. 31,156. An adult female, skin and skull, from Kaimosi, Kakamega district, Kenya Colony, collected by Arthur Loveridge, February 13, 1934.

Description. Compared with skins from Lolodorf, Cameroon, representing typical *N. nana* (type locality, Benito River, French Congo), the East African race lacks the warm russet coloration of the fur of both surfaces, and is instead a uniform dark drab gray both above and below. The fur is of the same color from tip to base except on the nape and expecially about the bases of the ears, where it is slightly paler, a soiled grayish, basally. On the membranes the fur extends out on the propatagium from the axilla to about the end of the first third of the fore arm, and on the plagiopatagium to a line joining the elbow and the first third of the tibia. On the uropatagium the fur extends out as far as a line connecting the proximal ends of the tibiae. On the under side the extent is about the same, except that it does not quite reach the knees.

Measurements. The specimen has practically the same dimensions as those of the West African race. The type measures: fore arm, 35.8 mm.; tibia, 15.7; foot, 6.5; tail (about) 45; thumb, 11.5; third metacarpal, 28.5; first phalanx, 16.5; fourth metacarpal, 29.7; fifth metacarpal, 30.3 mm.

The skull measures: greatest length, 16.6 mm.; basal length, 12.5; palatal length, 3.6; zygomatic width, 9.3; mastoid width, 8.0; width across frontal plate, 6.6; width outside last molars, 6.2; upper cheek teeth, 5.3; lower cheek teeth, 5.8 mm.

Remarks. Through the kindness of Mr. J. Kenneth Doutt, of the Carnegie Museum, we have had the loan of two specimens representing typical *Nycteris nana*, from Lolodorf, Cameroon. Both agree in their pronounced russet tint, contrasting with the dull gray hue of the

p. 48

eastern animal. It is a rather rare species, for, in addition to the original specimen from Benito River, it has apparently been recorded but twice: by Hollister, in 1918, who mentions two in the United States National Museum from Yala River, Kenya Colony, as forming a considerable extension of the known range into eastern Africa, and again by Cabrera and Ruxton (1926, Ann. Mag. Nat. Hist. (9), 17, p. 591), who had a specimen from Luluabourg, Belgian Congo, that flew into a room. The Cameroon specimens, referred to above, are now recorded for the first time.

Nycteris oriana Kershaw, 1922

p. 179

Nycteris oriana, sp. n.

F. 57, 312. Chiromo.

A member of the *æthiopica* group, with long ears and tail, approaching *N. luteola*, Thos., in size.

The body is clothed with long soft hairs, a dirty white colour on the dorsal surface for the greater part of their length, tipped with brown, the general result being a light pinkish brown. The hairs of the ventral surface are ecru-drab throughout their length. The edge of the wing-membrane from the ankle for about 21 mm. is fringed with light-coloured hairs. The shape of the tragus is as that figured by Dobson in the 'Catalogue of Chiroptera' for *N. macrotis*.

Type. Female. B.M. no. 22.4.2.5.3. Original number 312. Collected on June 7th, 1918, and presented by Mr. Rodney C. Wood.

Type-locality. Chiromo, Shiré Valley, Nyasaland.

Dimensions of the type: -

Forearm 53 mm.; head and body 67.5; tail 63; ear 33; thumb 15.2; third finger - metacarp, 44, 1st ph. 24, 2nd ph. 29; fourth finger - metacarp. 42.5, 1st ph. 16, 2nd ph. 15; fifth finger - metacarp. 45, 1st ph. 15, 2nd ph. 16.2; tibia 25; foot 11; tibia and foot (including claws) 37.

Skull: greatest length to tip of canine 22.3; zygomatic breadth 13.7; breadth of frontal shield 8.4; length of upper tooth-row 8.1; p_4 minute and internal to the tooth-row, not in it, as in *N. æthiopica* and *N. luteola*.

N. oriana does not appear to be nearly related to any of the species in the *æthiopica* group. In size it approaches *N. luteola*, Thos. (which Mr. Thomas now agrees should be elevated to specific rank), but differs widely from it in other respects, such as in the length of the fur (13 mm. in *oriana*,

p. 180

9 in *luteola*), and in its colour and texture, the dimensions of body and skull, the heavier dentition, the position of p_3, and the much larger frontal shield.

Nycteris pallida J.A. Allen, 1917

p. 425

(Type, No, 49144, M ad,, Faradje, Belgian Congo, March 1, 1912; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No. 1858.

A pale small form of the *N. hispida* group, differing strongly from typical *hispida* in its pale coloration and also slightly in smaller size.

Above, pale brown, the tips of the hairs on the lower back and sides pale fulvous; underpays grayish brown; head back to the ears very pale brown, in strong contrast with the body; a narrow whitish band bordering the nose pad in front and laterally; ears light brown terminally, much paler basally; membranes much paler than in *hispida*.

Collectors' measurements of type: Total length, 92; tail, 45; foot, 10; ear; 21 (in skin from anterior border, 15.5),

Additional measurements from type; Forearm, 39.5; tibia, 19; foot, 9.2. Forearm in 5 alcoholics (Faradje, 3, Vankerckhovenville, 2), 37.8 (36.5-39.5).

Skull (type), total length, 17.4; zygomatic breadth, 10.2; upper toothrow (c-m^3), 6.5; lower jaw, 11,8; lower toothrow, 6.8. Type and three topotypes, total length, 17.2 (16.9-17.4); zygomatic breadth (2 skulls), 10.2 (10.1-10.3).

Represented by 12 specimens (3 skins, 9 alcoholics, part immature), of which 8 are from Faradje, and 4 from Vankerckhovenville.

Present material indicates that *N. pallida* differs from *N. hispida*, its nearest ally, in much paler coloration, including especially the ears and membranes, and smaller size, averaging about 4 mm., less in the length of the forearm, with other measurements proportional. *N. pallida* is thus much smaller than *N. aurita* Andersen.

Nycteris poensis Gray, 1843

p. 24

Fernando Po Nycteris.

a. Africa, Fernando Po. - Presented by Capt. Edw. Downes, R.N.

Nycteris proxima Lönnberg and Gyldenstolpe, 1925

p. 1

A member of the *N. hispida*-group approaching in some respects to *N. grandis* PETERS, but differing in several dimensions.

Upper incisors trifid, p_4 in the tooth-row, smaller in size than the corresponding tooth of *grandis* but similar in shape to the same. The colour (in spirit) appears to be comparatively dark, a little paler below. Membranes and ears also dark.

p. 2

Type: M ad. coll. at Kartoushi, Sembiliki valley, $^{11}{}_3$ 1921 (orig. n:o 813).

Dimensions: forearm 58; third finger, metacarpal 38; third finger, first phalanx 27; tibia and foot with claws 39; tibia 25; calcaneum 19; tail 57; ear 30 mm. Tragus very hairy, almost lingulate, broadly rounded at the tip and of almost equal breadth along its whole length.

Skull: Greatest length to tip of canines 24; condyles to canine 20,5; zygomatic breadth 13,5; breadth of frontal shield 7; upper tooth-row, $c\text{-}m^3$ 8.9, length of mandible 16.5; length of lower tooth-row, $c\text{-}m_3$ 10 mm.

From *Nycteris avakubia* ALLLEN, 1917, the new species differs by its considerably longer forearm, somewhat shorter metacarpal of third finger and considerably shorter tail as well as its generally larger cranial dimensions. *N. grandis* PETERS and *N. marica* KERSHAW, 1923, are larger in every respect, the remaining species of this gronp are on the other hand much smaller.

Nycteris Revoilii Robin, 1881

p. 90

Oreilles beaucoup plus longues que

p. 91

la tête; tragus élargi en spatule à l'extrémité présentant un lobe externe arrondi, deuxième prémolaire inférieurs très petite et située dans la rangée dentaire; tête raccourcie (longueur 20^{mm}, largeur 12^{mm}); troisième phalange cartilagineuse du 5^{e} doigt ligre du côté externe; incisives supérieures séparées sur la ligne médiane. Couleur gris à peine centré sur le dos, blanchâtre sur le ventre.

Longueur totale 63^{mm}, queue 51^{mm}, bras 19^{mm}, avant-bras 44^{mm}, cuisse 22^{mm}, jambe 22^{mm}.

Nycteris Thebaicus E. Geoffroy Saint-Hilaire, 1818

p. 119

NYCTERE DE LA THEBAÏDE. *Nycteris thebaïcus*.

Planche I, N.° 2.

Les nyctères forment un genre très-différent des deux précédens.

C'est encore le même nombre d'incisives, mais non la même disposition: plus petites, sur-tout les inférieures qu'on distingue à peine à la vue simple, elles ne sont plus en haut (comme dans les makis) écartées par paire, mais garnissent, au contraire, sur une ligne continue, tout le bord de l'intermaxillaire.

Cet os, subordonné aux variations de l'organe de l'odorat, quoiqu'appuyé sur les maxillaires, jouit d'un mouvement propre; il est soulevé ou abaissé, oscillant comme sur un axe, par la lèvre supérieure, qui est d'une épaisseur et d'une consistance propres à l'entraîner: aminci à ses points d'articulation, il ne pouvoit participer à la fixité de toutes les autres parties osseuses.

p. 120

C'est sans doute parce que l'intermaxillaire est ainsi maîtrisé par les organes qui l'entourent, qu'il est très-petit: il ne fait pas de saillie au-delà des canines d'où il arrive que la mâchoire supérieure est plus courte que l'inférieure, et paroît comme tronquée; il en résulte aussi que les incisives des deux mâchoires ne se correspondent pas, et que posant à faux, elles n'usent point leurs sommets, lesquels restent à deux lobes en haut et à trois crénelures en bas.

Si l'on commence par examiner dans le crâne les fosses nasales des nyctères, on les juge d'abord sans profondeur, parce que les planchers qui en circonscrivent l'étendue sont très-bornés: le plancher inférieur ou la lame palatine ne se prolonge pas au-delà de la deuxième molaire, et l'externe ou les nasaux maxillaires sont des pièces réduites à des dimensions rudimentaires. Mais on prend, au contraire, une autre opinion de ces fosses nasales, en les voyant recouvertes le leurs parties molles. Les arrière-narines s'ouvrent beaucoup au-delà du point où se termine l'os maxillaire; et les méats extérieurs ont leurs larges entrées remplies et pour ainsi dire encombrées de lobes et d'appendices cutanés: un repli du derme naît du milieu de chaque conduit. On diroit que les conques nasales, en saillie chez les vespertilions, et dans une cavité chez les nyctères, ne sont devenues aussi voisines, et ne sont ainsi descendues dans une sorte d'en tonnoir, que parce qu'elles auroient été contractées, repliées sur elles-mêmes et tirées à travers le crâne. Un lobe qui a la forme d'une tête dé clou, et qui n'est autre que le cartilage de la narine, se voit de chaque côté, et concourt comme opercule, avec le repli intérieur, à fermer hermétiquement l'orifice nasal.

Il n'est pour cela besoin d'autre effort de la part de l'animal que de froncer toutes ces parties, et peut-être même de les abandonner à leur élasticité naturelle.

La cavité des narines se prolonge en arrière sur le chanfrein; première circonstance déjà remarquable. Mais ce qui ne l'est pas moins, c'est la grandeur et la forme canaliculée de cette dernière partie: elle donne aux nyctères cette physionomie sombre et farouche qui les caractérise.

Le chanfrein s'étend en effet au-delà de ses dimensions habituelles, et ce, au moyen de lames osseuses qui naissent des côtés de l'os coronal, et se réunissent au vertex: le canal ou fente longitudinale qui résulte de la saillie de ces crêtes, verse sur les narines; seule relation, en dernière analyse, que ces parties aient entre elles.

Cependant le chanfrein auroit-il subi ces étranges métamorphoses pour suppléer à la petitesse extrême des ouvertures nasales, et seroit-il une sorte d'entonnoir où se recueilleraient les fluides odorans? Les bords de la fente sont hérissés de poils longs et

abondans qui la remplissent; mais ce n'est pas quand les muscles labiaux soulèvent les opercules, détendent les plis intérieurs et entr'ouvrent les conduits nasaux: ces bords, par la tension de la peau, sont ramenés en dessus, te avec eux les longs poils qui les garnissent.

Des narines qui sont habituellement fermées, et qui, pour entrer en communication avec les corps ambians, exigent la volonté de l'animal et le jeu de quelques

p. 121

quelques muscles, fournissent sans doute une considération intéressante en elle-même.

Les nyctères ne peuvent manquer d'en tirer avantage; et il se trouve, en effet, qu'ils établissent leur demeure en des lieux d'où de fortes exhalaisons repousseroient d'autres animaux. Mais que la disposition des conduits nasaux son dans un ordre inverse pour les soustraire ainsi aux inconvéniens d'odeurs infectes, c'est ce que je n'ai pu croire. Cet arrangement suppose ailleurs une autre modification, et j'ai dû m'en proposer la recherche.

Le vol des chauve-souris a souvent ramené à l'idée de les comparer aux oiseaux; et l'on a trouvé que ceux-ci se distinguoient toujours par plus d'aisance et de grâces dans les allures, parce qu'indépendamment de plus de perfection dans les organes directs du vol, ils jouissent encore de la faculté de se gonfler d'air et de se rendre plus légers. En s'exprimant ainsi, on étoit loin de penser qu'on retrouveroit la même faculté dans les chauve-souris, dont en effet les fonctions pulmonaires sont si différentes de celles des oiseaux.

C'est toutefois ce que les nyctères m'ont montré, des vésicules aériennes semblables, encore plus grandes, et que l'animal remplit, quand il le veut et autant qu'il le veut. Mais, comme on le pense bien, les nyctères y portent l'air en vertu d'un mécanisme particulier, et au moyen d'une organisation qui, dans ses anomalies, dérive néanmoins du plan primordial et classique des mammifères.

On pressent peut-être déjà les résultats d'un mode si nouveau d'organisation; les moyens qui les donnent, sont d'une simplicité parfaite.

La peau n'a d'adhérence au corps qu'en quelques endroits, où elle est retenue par un tissu cellulaire très-lâche et très-écarté: l'air s'y introduit, et en séjournant ainsi, comme on le dit, entre cuir et chair, donne à l'animal l'apparence de ces veaux soufflés dans les boucheries. Il n'y a de brides aponévrotiques ou de tissu cellulaire que dans le voisinage des méats et sur les côtés du tronc: ainsi la peau se soulève entière sur le dos, à la poitrine et à l'abdomen; ce qui met les nyctères dans un bain d'air, ou, si l'on veut, dans une sorte de manchon que leur forme ce fluide élastique.

Jusque-là, quelque extraordinaire que soit un pareil fait, on ne voit pas qu'il soit en rien dérogé à l'essence du type des mammifères: il n'y est pas dérogé davantage quant aux moyens de souffler cette unique, mais bien vaste cellule.

Au fond de chaque abajoue est une ouverture de deux millimètres de large; et c'est tout simplement par-là que le sac aérien communique avec la bouche.

L'animal en ouvrant ses naseaux fait que l'air ambiant entre et gonfle sa poitrine: en abandonnant, au contraire, un moment après, toutes les membranes nasales à leur élasticité propre, et en tenant simultanément la bouche close, il force le gaz expiré à se rendre dans les abajoues, et de là dans le grand sac aérien.

Quoiqu'il y ait, à l'entrée de ce sac, un sphincter très-apparent, ce n'est pas lui, ou lui seul du moins, qui s'oppose au retour de l'air: il y a de grandes valvules, sur le cou et le dos, qui en sont chargées.

L'air ne suit de route qu'à partir du sphincter: il se rend, en passant,

p. 122

au-devant de l'oreille, dans le sinus du chanfrein, d'où il gagne le vertex, l'occiput, et le col supérieur: c'est là qu'il est versé dans le grand sac.

Ainsi, le nyctère se conduit exactement comme le tétrodon; il porte, à volonté, une gorgée d'air dans son sac, puis une seconde, et ainsi de suite. Il souffle comme nous pouvons le faire nous-mêmes, et de la même manière, avec cette seule différence qu'il souffle dans sa bouche, dont il tient la cavité sans issue à l'extérieur. Sa peau devient une véritable vessie, au-dedans de laquelle le tronc se trouve comme déposé. Les nyctères agissent presqu'à son égard de même que si elle étoit un hors-d'oeuvre, puisqu'ils la remplissent au point de lui faire prendre une forme sphérique. Dans cet état, tout l'animal ressemble à un ballon auquel on auroit attaché des ailes, une tête et des pieds.

Plus heureux que le tétrodon, qui ne recourt à la même industrie qu'en se réduisant à n'être plus qu'une masse inerte sur le miroir des eaux, il conserve toutes ses facultés, ou mieux il en augmente l'énergie, en devenant plus léger et susceptible de plus de vîtesse dans le vol.

J'avois cru apercevoir que les étranges anomalies des conduits olfactifs peseroient sur un autre système d'organe, et occasionneroient peut-être ailleurs d'autre changemens; et il se trouve en effet qu'un grand sac modifie, dans les nyctères, ou plutôt procure à leur organe respiratoire, un précieux appendice. Si cet appareil, qui est si bien adapté à ce système, n'est pas le motif des modifications des fosses nasales, et n'en donne pas une explication entièrement satisfaisante, du moins on ne sauroit nier qu'il n'y ait entre toutes ces parties des relations réciproques et nécessaires.

C'est aux différences que je viens de signaler que se borne l'énoncé des caractères distinctifs des nyctères: les dents canines et molaires de ces chauve-souris ressemblent à celles des vespertilions; il en est de même des viscères abdominaux.

Les tégumens offrent seulement plus d'étendue; les oreilles sont plus longues que la tête, sans que l'oreillon qui borde aussi le méat auditif soit agrandi en même proportion. Cette étendue se fait sur-tout remarquer entre les jambes, ou la membrane caudale surpasse dans ses deux sens la longueur de l'animal.

La dernière vertèbre de la queue est bifurquée; séparation singulière, puisqu'elle se trouve dans tous les nyctères, et n'existe dans aucun autre genre de chauve-souris.

On n'a fait mention que d'une seule espèce de nyctère, le campagnol-volant de Daubenton, dont Linnéus a fait son Vesp. hispidus. Le nyctère de la Thébaïde en diffère, ainsi qu'une autre espèce qui a été rapportée de Java, et qui m'a été remise par M. Leschenault

Les dimensions de ces chauve-souris forment un de leurs traits distinctifs: le nyctère de Daubenton a trente-huit millimètres de long, de la tête à la naissance de la queue; le nyctère de la Thébaïde cinquante-quatre, et celui de Java soixante-sept.

L'oreille a plus d'ampleur dans l'espèce d'Égypte, et le poil y est non moins long et touffu.

p. 123

Le pelage du nyctère de la Thébaïde est brun-clair en dessus, et cendré en dessous: c'est presque la même teinte dans le nyctère de Daubenton; mais elle passe davantage au roux sur le dos, et à un blanc sale sur le ventre, où se voit aussi un mélange de fauve: l'espèce de Java a les parties supérieures d'un roux-vif, et le poil inférieur cendré-roussâtre.

Le nyctère anciennement décrit avoit été rapporté du Sénégal: ainsi tout le genre habite les contrées chaudes de l'ancien continent.

Je présume qu'il en existe deux espèces au Sénégal; du moins Daubenton en a décrit deux variétés qui lui avoient toutes deux été données par Adanson: la seconde, qu'il ne constata que sur un individu desséché (voyez H. N. G., tome X, page 91), différoit de la première en ce que la couleur blanchâtre du dessous du corps étoit mêlée d'une teinte de cendré, et que la membrane des ailes n'avoit point de roussâtre.

J'ai sous les yeux le crâne et les principales parties osseuses du même individu; et ces parties ne s'accordent, ni pour les dimensions plus fortes, ni pour quelques détails de forme, avec les os, dans les nyctères de Daubenton et de la Thébaïde.

Nycteris villosa Peters, 1852

p. 48

Tafel XL.
N. colore corticinofusco, subtus ex qriseo fuscescente; alis fuscis; auriculis longitudine capitis, retro exisis, disjunctis; dentibus primoribus superioribus distincte trifidis; alis supra multo latius quam infra villosis.

Longitudo tota 0,094; caudae O,44; antibrachii 0,038; volatus 0,235.

Habitatio: Africa orientalis, Inhambane, 24° Lat. Austr.

Bei dieser kleinen ausgezeichneten Art sind die Ohren im Verhältnifs zu denen bei den andern Repräsentanten dieser Gattung sehr kurz, kaum so lang wie der Kopf; ihr äufserer

p. 49

Rand zeigt einen flachen Ausschnitt, und ihre inneren Ränder sind auf der Stirn nicht, wie bei allen andern Arten, durch eine Hautfalte miteinander verbunden; die Ohrklappe, welche ziemlich tief sitzt, ist an ihrer oberen Hälfte mit langen Haaren besetzt, verlängert, doppelt so lang wie breit. Der Nasenbesatz und die Bildung der Lippen zeigen nichts von den andern Arten abweichendes. Am Gaumen befinden sich sechs quere Schleimhautfalten; die erste ist grade und liegt zwischen den Eckzähnen; die zweite, welche V förmig ihre Mitte nach hinten in einem spitzen Winkel zurückgezogen hat, liegt zwischen den Lückenzähnen; die drei folgenden bilden in der Mitte einen stumpfen nach hinten gerichteten Winkel und haben ihre Lage zwischen dem ersten Paar der wahren Backzähne; die sechste und letzte grade erhebt sich zwischen den vorderen Enden des zweiten Paars der wahren Backzähne.

Die Behaarung des Ruckens ist beträchtlich länger als die der Bauchseite, und ein dichter Flaum setzt sich viel weiter als bei irgend einer andern Art über die Flughäute fort, so dafs die Schenkelflughäute bis zwischen den ersten zwei Fünfteln des Vorderarms und dem Unterschenkel, und die Schenkelflughaut über die Hälfte wollig erscheint. Auf der Bauchseite dehnt sie sich dagegen nicht so weit aus, während umgekehrt bei den andern bekannten Arten die Behaarung der Rückenseite die am wenigsten ausgedehnte ist. Die Bildung der Flughäute und Gliedmafsen ist dieselbe wie bei anderen Arten. Von den sehr langen Schwanzgliedern sind die beiden ersten von gleicher Länge, und die vier folgenden nehmen progressiv an Länge ab. Die Gabelung des Endknorpels übertrifft die Länge des damit verbundenen letzten knöchernen Gliedes.

Die Farbe der Oberseite its rufsig nelkenbraun, und die Haare sind hier in der Mitte weifslich, an der Basis schwarzbraun gefärbt. Die Bauchseite ist bräunlich weifsgrau, die Basis der Haare ebenfalls schwarzbraun. Die Ohren sind an ihrer äufsern Fläche bis zur Hälfte mit einer weifslichen Wolle bekleidet. Der Haaranflug der Bauchseite der Flügel ist weifslich. Die Flughäute und Ohren sind dunkelbraun, die Nägel weifs.

Der Schädel zeigt in seiner Form nichts Abweichendes. Die vier oberen Schneidezähne stehen zusammen, und sind, was ich bei keiner andern Art bemerken konnte, dreilappig, gröfser ab die sechs unteren, welche quer zum Rande des Kiefers gestellt sind. Der zweite untere kleine Lückenzahn ist mehr entwickelt wie bei den andern mir bekannten africanischen Arten und steht in der Reihe zwischen dem ersten Lückenzahn und dem ersten Backzahn. Die Zahl der Wirbel beläuft sich auf 35; darunter sind 7 getrennte Halswirbel, 10 Brustwirbel, 6 Lendenwirbel, 5 kurze Kreuzbeinwirbel und 7 Schwanzwirbel nebst dem knorpelichen gespaltenen Anhange. Das Brustbein, welches aus drei Stücken besteht, ist an seiner vordern Seite durch einen Längskiel ausgezeichnet, welcher bis auf die Pars xiphoidea herabgeht. Es befestigen sich fünf Paar Rippen an dasselbe, während die übrigen fünf als falsche Rippen zu betrachten sind. Der Magen ist sackförmig und geht in einen einfachen 85 Mm. langen Darm über. Die Leber zerfällt in drei Hauptlappen, in einen linken gröfseren und zwei rechte kleinere: zwischen und unter den letzteren liegt die birnförmige Gallen-

p. 50

blase. Die Milz, welche hinter dem linken Ende des Magens liegt, hat eine Länge von 6 Millim.; eine Breite von $1^1/_4$ Millim. Von den Nieren ist die linke gröfser als die rechte, $5^1/_2$ Millim. lang und 3 Millim. breit, von einfacher, bohnenförmiger Gestalt. Der ganze Kehlkopf ist nur zwei Millimeter lang; der Schildknorpel ist an seinem vorderen Winkel, der Ringknorpel längs der Mitte seiner hinteren Seite stark gekielt. Die Luftröhre bildet unter dem Kehlkopf eine ringförmige Auftreibung, und enthält bis zur Theilungsstelle 24 knorplige Halbringe. Die Lungen bestehen jederseits aus einem einzigen, unregelmälsig quadratischen Lappen. Das Herz hat eine eiförmige Gestalt, eine Länge von 7 und eine Breite von 4 Millimetern.

Mafse in Millimetern.
Ganze Länge in krummer Linie von der Schnauze bis zur Schwanzspitze: 94
Flugweite: 235
Länge des Kopfes: 18

Alle anderen bekannten Arten von *Nycteris* unterscheiden sich von dieser durch bedeutendere Körpergröfse, viel längere Ohren, geringere Behaarung der Flughäute und endlich durch die zweilappige Form der oberen Schneidezähne.

Das Material für diese Beschreibung besteht in einem einzigen Exemplar, einem Münnchen, welches in Inhambane, im 24° Südl. Br. gefangen wurde. Die Nahrung besteht dem Inhalte des Magens und Darms nach, ausschliefslich aus Insecten.

Nycteris vinsoni Dalquest, 1965

p. 256

Type. - Adult female, skin and skull, no. 18739, Walter W. Dalquest, Midwestern University Collection, taken on the south bank of the Save River, 212 km SSW Beira, Mozambique.

Diagnosis. - A very large *Nycteris*, similar in general proportions to *Nycteris thebaica* but larger and stouter. Forearm more than 50 mm and length of skull from canines more than 21 mm. Ears relatively short, probably less than 25 mm in life.

Comparisons. - This species needs comparison only with *Nycteris thebaica*, the only species of *Nycteris* ranging into southern Africa that is nearly as large. Fortunately two *Nycteris thebaica capensis* were taken in a hollow tree a few hundred yards from the site where the type and paratype of *N. vinsoni* were found. These *N. thebaica* are apparently typical and their measurements agree closely with those given by Roberts (1951). *N. vinsoni* differs from *N. thebaica* principally in its much larger size, more massive skull and heavier dentition but shorter ears. Both *N. thebaica* are in the gray color phase, while the type of *vinsoni* is in the orange phase. However, the paratype of *vinsoni* is of the gray phase.
The size difference between *thebaica* and *vinsoni* is too great to be individual variation within a species. The rostrum of *vinsoni* is 20 % heavier than that of *thebaica*, and the superorbital flanges overhang the orbits to a much greater degree; breadth across the flanges in *thebaica* is 6.8 mm versus 9.0 mm in *vinsoni*.

Measurements. - External measurements of the type are: total length, 125; length of tail, 55; length of hind foot, 13; height of ear from notch, 22. Cranial measurements are

p. 257

those used by Roberts (1951): length of skull from canines, 22.0; frontals to occiput, 17.3; zygomatic breadth, 13.3; braincase breadth, 10.0; width across upper M3's, 8.8; width across upper canines, 5.8; canine-upper M3 length, 7.8; height at bullae, 10.3; mandible length plus incisor, 15.0; canine to lower M3, 8.4; forearm length, 50.6. Every measurement exceeds, usually by a considerable margin, the maximum given by Roberts for *N. (thebaica) capensis*, as well as the measurements of the specimens of *N. thebaica* from the Save River.

Remarks. - The type and paratype were occupying a small hollow, not more than 6 inches in diameter, at the base of a large baobab tree. A fire was built at the base of the hollow and two bats were stupified by the smoke. One, in the gray color phase, fell into the flames and was so singed the skin could not be saved. The ears and membranes of the other, the type, were somewhat shrivelled. It is likely that the height of the ear in the living bat was greater than the 22 mm recorded, although some allowance was made for the shrivelling of the ear. In any event, the ear was much shorter than that of the *N. thebaica* (35 mm) taken nearby.

This species is named for Mr. Jerry Vinson, the sponsor of the Save River expedition.

Nycteris woodi K. Andersen, 1914

p. 563

A member of the *N. æthiopica* group (see Ann. & Mag. N. H. (8) x. p. 549, Nov. 1912), differing from the other representatives o£ the same group by its much smaller size and relatively longer ears, and from all other forms of the genus by having the fur of the underparts pure white, without any trace of darker bases to the hairs.

Forearm 42.5 mm.; ear from base of inner margin (relaxed) about 29. Skull, total length to front of canine 18.2; condylo-canine length 15.8; maxillary tooth-row (crowns) 6.

Type, skin and skull of an adult, Chilanga, N.W. Rhodesia, 4100', Nov. 1913, presented by R. C. Wood, Esq. B.M. 14.4.22.2.

Nycteris woodi sabiensis Roberts, 1946

p. 304

Differs from *Nycteris woodi* K. Andersen (*Ann. Mag, Nat. Hist.* (8), XIII, 563; 1913: Chilanga, Northern Rhodesia) in its longer ears (33 - 34 mm. as compared with 29) and in colour, having the underparts of body greyish white, browner on the sides, instead of pure white.

Measurements of the type: Head and body 49, tail 49, hind foot c.u. 9; ear 35, Forearm 40.5; 3rd finger metacarpal 33; 1st phalanx 21.5; 2nd phalanx 25; 4th finger metacarpal 35; 5th finger metacarpal 36. Tibia and foot (c.u.) 30.5. Skull, greatest length from canines 18 (in *woodi* 18.2); c-m^3 series 6 (in *woodi* 6).

Type: T.M. No. 8578, adult F, Birchenough Bridge, Southern Rhodesia. Also five others, adult and immature, collected at the same time.

Nycterops Gray, 1866

p. 83

NYCTEROPS. Ears separate, as long as the head. Africa.

N. pilosa

Nycticeius africanus G.M. Allen, 1911

p. 328

Type. - Skin and skull, male, no. 8272, M.C.Z., collected August 11, 1909, on the Meru River, British East Africa, by Glover M. Allen.

General characters.- A typical *Nycticeius*, slightly smaller and much paler than the *N. humeralis* of the southeastern United States, with shorter closer fur. Postcalcaneal lobe well developed.

Description. - Fur of the upper surface of head and body, short and close, about 4 mm. long on the lower part of the back, of a uniform pale wood-brown quite to the bases of the hairs; below cream-buff

p. 329

to the bases of the hairs. The muzzle in front of the eyes is nearly naked.

Wing membranes dark, and attached at the base of the first digit of the foot. Ears pale brownish. Hair of the body does not extend on to the interfemoral membrane. Calcar well developed with a conspicuous, low, rounded lobe at about 3 mm. behind the heel. Tragus with a distinct external basal lobe." Tip of tail free from the interfemoral membrane.

Skull. - The skull of the type is scarcely to be differentiated from that of the American species, *N. humeralis*, except by its slightly smaller size. The upper incisors, however, are set much more nearly at right angles to the long axis of the skull, so that viewed from above they hardly project beyond the premaxillae, whereas in *humeralis* they extend prominently forward.

Measurements. - The following measurements were taken in the flesh: total length, 85 mm.; tail, 35; hind foot, 6.5; tibia, 13; calcar, 17.5; ear, 12; forearm, 33. Third metacarpal, 29.7.

Skull: greatest length, 13.6; basal length, 10; palatal length, 5; interorbital width, 4; zygomatic width, 9.4; mastoid width, 8; upper cheek teeth, front of canine to back of m^3, 4.5; lower cheek teeth, 5.3; mandible, 10.2.

Remarks. - The discovery in East Africa of this genus hitherto known only from the southeastern United States and Cuba is one of the most important and interesting results of our expedition. Mr. Gerrit S. Miller, Jr., who examined the specimen, first called my attention to the fact that it is in all respects a typical *Nycticeius*, agreeing with the American species in all essential characters. The postcalcaneal lobe is well developed in the African but scarcely at all in the American bat, and the incisors of the former are less projecting, but otherwise they differ hardly at all except in color and size.

The single specimen on which this species is based was shot shortly after sunset as it was circling about in an open space among the ivorynut palms by the Meru River. The river here runs through a dry plain, and no doubt the pale coloration, of the species is due to the arid conditions under which it lives.

From a zoögeographic point of view the discovery of this genus in Africa is of extraordinary interest. Its case is somewhat paralleled by that of *Mormopterus* which occurs in Cuba, South America, Africa, and Madagascar. Possibly *Nycticeius* may yet be found to occur in South America.

Nycticejus eriophorus Heuglin, 1877

p. 34

Nycticejus eriophorus, Heugl. - Fitz. u. Heugl. Säugethiere p. 11.

Klein; die Ohrspitze scharf; der äußere Ohrrand bis tief unter den Mundwinkel herablaufend und hier eine scharfe Ecke bilbend; Tragus schmal, lanzettförmig, fast so hoch als die Ohrspitze; 8 bis 9 Gaumenfalten. Behaarung reichlich, lang, eigenthümlich gekräuselt; Oberseite hell erdgrau mit weißlichen Haarspitzen; Unterseite schmutzig weiß, Weichen mehr ins Braungrauliche; Flughaut braunschwärtlich. Körperlänge 1" 6"'. Kopflänge gegen 7"'. Außenrand des Ohres 6"' hoch. Schwanz 1" 3"'. Vorderarm 13"'. Mittelfinger 2" $4^1/_2$"'. Der vierte Finger 1" $11^1/_2$"'. Der fünfte Finger 1" 10"'.

Von dieser Art sammelte ich drei Exemplare im Belegaz-Thal zwischen Semién und Wogara in Abessinien ine. Sie befanden sich im Hängenest einer SperlingS ober WeBervogelart.

Nycticejus flavigaster Heuglin, 1861

p. 14

Supra brunneo-olivaceus, subtus pure sulfurcus; capitis lateribus nitide pistacino tinctis. Unguinibus podii postici virente griseis, apice intense-flava.

Das Ohr ist 7"' hoch, ziemlich breit und gerundet, mit an der Basis wagrecht abgeschnittenem Innenrande und tief herab und nach vorne gezogenem Aussenrande; hier hat letzterer einen halbkreisförmigen Lappen mit umgeschlagenem Rande. Der sichelförmige, $3^3/_4$"' hohe *Tragus* nach vorne gerichtet, mit halbzirkelförmigem Ausschnitt oder Klappe an der Oeffnung des Gehörganges.

p. 15

In der Ohrmuschel 5 - 6 undeutliche Querfalten. Nasenkuppe etwas aufgeworfen, die Nasenlöcher etwas röhrenförmig mündend und nach vorne und seitlich gerichtet; die Unterlippe schwach gespalten; die Gegend zwischen Auge und Nase aufgetricben, breit und stumpf, mit verhältnissmässig gröberen wenigen Haaren besetzt.

Zwei eckzabnartige Schneidezähne an dem Zwischenkiefer. Die vordere Spitze des ersten oberen Backenzahns auch kegelförmig und sehr verlängert.

Das unterste Daumenglied und der Sporn des Hinterfusses haben nach Aussen zu einen Hautrand.

Ohrmuschel schwärzlich-braun, fast nackt, an der Basis des Aussenrandes mit sehr feinen grünlichen Haaren bekleidet. Lippen schwärzlich fleischfarb; Flughaut fast schwarz und an der Innenseite des Oberarms, wie auf verschiedenen Partien der ganzen Innenseite mit feinen grünlich-gelben Härchen. Auffallend sind die licht-grüngelben Nägel der Füsse.

Am Schwänze, in den die Seitenfittige spitz verlaufen, nur das äusserste Glied, sowie eine feine, scheinbar nur aus Hautmasse bestehende Spitze frei. Diese freien Theile messen zusammen nur $2^1/_4$'''. - Körperlänge 2" 10'''. Schwanz 1" 9'''. - Flugweite 13". Ohrenlänge 7'''.

p.14
??

The ear is 7''' long, rather wide and rounded, with an on the base horizontally cut off inner margin and deep down and forwards drawn outer margin; the latter has a semicircular lobe with a turned edge. The sickle shaped, 3 $^3/_4$''' high tragus is pointed forwards, with as semicircular cutting or flap on the opening of the auditory canal.

P. 15
In the pinna there are 5 - 6 unclear ridges. Top of nose slightly raised, the nostrils somewhat pipeshaped ending and forwards and sideways pointed, the lower lip weakly split; the area between eyes and nose vigorous [?], wide and blunt, with proportionally larger fewer hairs.

Two canine like incisors in the middle jaw [actually "between jaw"]. The anterior tip of the first upper molar also cone shaped and extremely elongated.

The lower thumb part and the spur of the feet have on the outside a membrane.

Pinna blackish-brown, almost naked, on the base of the outer margin with very fine greenish hairs covered.

Lips blackish fleshcolour; wing membrane almost black and the inside of the upper arm, like various parts of the entire inner side with fine greenish-yellow small hairs. Remarkable are the light green-yellow nails of the feet.

On the tail, in which the "Seitenfittige" [???] tips develop, is only the extreme vertebra, as well as a fine, apparently consisting of only skin mass, tip free. These free parts together measure only 2 ¼ ''' - Length of body 2" 10'''. Tail 1" 9'''. Wingspan 13". Length of ear: 7'''

[Translated by Victor Van Cakenberghe, 2008]

Beschreibung.

Das von Raffinesque aufgestellte Geschlecht *Nycticejus* *) ist eine sehr wohl begründete, durch die Gleichförmigkeit in Schädel- und Zahnbildung aller Arten natürlich sich aufwerfende, vom *Genus vespertilio* zu trennende Gattung. Wir haben daher, um diese Ueberzeugung zu versinnlichen, nächst dem Schädel unseres hier aufgestellten Nyctic. leucog. (unter No. 1.2.) auch den Schädel des Nvctic. novemboracensis (unter No. 3.4.) abbilden lassen, welche in aller Hinsicht von gleicher Beschaffenheit sind. Die Zähne sind *dent. incis.* $^2/_6$. Die oberen 2 liegen dicht an den Eckzähnen, während sie

*) Von … Nacht und … ich tödte. Wir haben ganz willkührlich den Namen Nachtflatterer gewählt, anstatt einer gezwungenen Uebersetzung dieser Geschlectsbezeichnung.

p. 72

stark von Gestalt, nach innen convergiren und durch einen großen leeren Raurn getrennt sind. *Dent. canin* $^{1-1}/_{1-1}$, diese kehren ihre Spitzen nach außen. *Dent. Molares* $^{4-4}/_{4-4}$; diese bestehen aus einem vorderen falschen Backenzahn, so wie drei darauf folgenden normalen, wobei zu bemerken ist, daß der letzte der oberen Kinnlade als ein flacher, schmaler Zahnkörper, beinahe ganz transversal gestellt ist. Der digit. Index hat zwei Phalangen, der digit. medius vier und die übrigen drei. Da übrigens Herr Temminck in seinen *monographies de mammalogie* (siehe pag. 316.) eine umständliche Bearbeitung dieses in die systematische Darstellung der Säugthiere aufgenommenen Geschlechtes angezeigt hat, so haben wir uns nur auf diese wenigen Angaben von demselben beschränken wollen, um den Bemühungen unseres um die Naturgeschichte der Cheiroptern so sehr verdienten Freundes nicht von zugreifen.

Die Gesichtsfläche unseres Nyctic. leucog. ist nackt und fleischfarbig; die Ohren nackt und hellbraun; der Ohrdeckel von hinten nach vorn gerichtet; die Nase ziemlich wulstig, mit seitlichen runden Nasenlöchern. Auf der Stirne, dem Scheitel und dem

ganzen Oberkörper ist das Haar wollig, dicht, bräunlich von Farbe. Der ganze Unterkörper weiß, mit gelblichem Anflug. Die Flügelhäute röthlich braun, so wie die Intercrural-Membran, über welche das Schwanzende etwas hinausragt.

Vaterland. Kordofan.

Aufenthalt. Bewohnt die Höhlen den Adansonia, welche in Kordofan den Namen *Taboldi* führt und wurde am Brunnen Nedger gefunden. Heißt bei den Arabern *Abu Rigeh*.

Nycticejus murino-flavus Heuglin, 1861

p. 15

Similis N. flavigastro, sed minor; supra murino-olivaceus, subtus olivaceo-flavus; dentibus laniariis violascente tinctis.

Diese Art unterscheidet sich ausser durch die in der Diagnose bezeichneten Merkmale noch von *N. flavigaste*r durch viel breitere Nasengegend und etwas kürzere, mit einer stumpfen Spitze versehene Ohren. Ohr- und Zahnbildung ist im übrigen dieselbe. Körperlänge 2" 6'''; Schwanz gegen 2", Flugweite $11^1/_2$", Ohr kaum $6^1/_2$''' hoch. - Der olivengelbe Ton des Unterleibes ist an der Kehle und der Innenseite der Schenkel am intensivsten.

Nur ein Exemplar, ein altes M, bei M'kullu an der abyssinischen Küste eingesammelt, wo wir diese Art übrigens in Gesellschaft von *Dysopes pumilus* öfter zu sehen Gelegenheit hatten.

p. 16

Auffallend ist der olivenbraune und gelbe Ton verschiedener ost- und südafrikanischer Schwirrmäuse, während die asiatischen Arten meist rostbraun oder rostgelb überflogen sind. *Nycticejus leucogaster*, Rüpp. aus Kordofan und dem südlichen Sennaar hat häufig einen gelblichen Anflug, bei *N. Nigrita* von Senegambien fehlt er auch nicht und bei *N. Dingani, N. planirostris* und *N. viridis* ist er vollends deutlich ausgesprochen. Möchte diese Färbung nicht durch äussere Einflüsse entstanden und etwa dem umstande zuzuschreiben sein, dass die Nycticejus-Arten meist hier hohle Bäume bewohnen, deren Holz entweder direct mechanisch färbende Eigenschaften besitzen, oder in welchen durch Verwesungsprocesse Humus-, Humin- oder ähnliche Säuren sich gebildet haben, die bei längerer Berührung, verbunden mit Feuchtigkeit, auf den feinen, sehr wenig Marksubstanz enthaltenden Pelz ähnliche Wirkung zur Folge haben? - Diese letztgenannte Species könnte möglicher Weise mit den vorhergehenden zusammenfallen; ein dieser Tage erlegtes Exemplar von *N. flavigaster* (kleiner und dunkler gefärbt) dürfte vielleicht den üebergang dazu bilden.

p. 15
This species distinguishes itself except by the in the diagnosis mentioned characters also from N. flavigaster by the much wider nose area and the somewhat shorter, ane ears with a blunt tip. Shape of ears and teeth is for the rest identical. Length of body 2" 6''', tail almost 2", wingspan 11 1/2 ", ear hardly 6 ½''' high. - The olive yellow tint of the belly is at the throat and inside of the thigh the most intens.

One single specimen, an adult M near M'kullu on the Abyssinian coast collected, where this species was frenquently observed together with Dysopes pumilus.

p. 16
Remarkable is the olivebrown and yellow tint in several east- and south-african bats, whereas the Asiatic species have primarily redbrown or russet-yellow glares. Nycticejus leucogaster Rüpp. from Kordofan and southern Sennaar has a yellowish spark, in N. Nigrita from Senegambia it isn't lacking either and in N. Dinganii, N. planirostris and N. viridis it is clearly prominent. Could if be possible that this colour is the result of external influences and attributed to circumstances, such as the Nycticejus species live mainly in hollow trees, whose wood has direct mechanical colouring properties, or in which decomposition processes result in humus, humin or similar acids, which as a result of extended contact, linked with humidity, might have such a result on the little marksubstance [???] containing pelage?
[I am not completely sure about the correct translation of this sentence, but my feeling is that Heuglin attributes the yellowish colour to external circumstances, e.g. colouring proporties of the wood directly or of their decay processes] This last mentioned species could possibly be identical to the previous one [=N. flavigaster]; a recently deposited specimens from N. flavigaster (smaller and darker coloured) could possibly be an intermediairy. - Translated by Victor Van Cakenberghe, 2008]

Nycticejus nidicola Kirk, 1865

p. 651

Nycticejus nidicola, sp. nov.

Fur brown; the base of the hairs blackish, beneath yellowish. Ears ovate, acute, with a well-developed rounded process at the front part of the outer or lower edge. Tongue linear lanceolate, acute, rather more than half the length of the ear. Face depressed, bristly. Wings elongate, thin, bald, rather hairy above and below, close to the body; forearm-bone nearly $1\ ^1/_2$ inch long; the thumb compressed, rather elongate, slender, of a single joint. Tail as long as the body. The interfemoral membrane very large, broad, with nearly regular, almost parallel, transverse muscular bands, which are hairy on the upper and lower surface. The spur elongate, strong, nearly as long as the foreleg and foot; the spur and the end of the membrane fringed with short, rather rigid hairs. The legs rather elongate; the lower part of the thigh slender; the shank slender, not quite half the length of the arm-bone; the toes moderate, slender, compressed, covered with short adpressed hairs.

Expanse of wings 10 inches, of forearm-bone 1.5 inch, of foreleg 8 inches, of foot 3 inches, of spur 9 $^{1}/_{2}$ lines.

Shupanga, near the Zambesi.

Four specimens were obtained ; they had taken possession of the nests of Weaver-birds (*Euplectes*). Having accidentally found a pair in one of these hanging nests; others were soon discovered in similar positions near by.

Nycticejus planirostris Peters, 1852

p. 65

Tafel XVII. Fig. 4

N. oliveofuscus, subtus flavidoalbus; auriculis capite tertia parte brevioribus, trago elongato, ensiformi; calcare crure longiore; rostro depressissimo; naribus in labii superioris margine positis.

Longitudo tota 0,120; autibrachii 0,052; caudae 0,055; volatus 0,340.

Habitatio: Africa orientalis, Tette, 17° Lat. Austr.

Die Schnauze ist breit und sehr platt, so dafs die Nasenlöcher ganz am vorderen Rande der Oberlippe ausmünden. Die Ohren sind um ein Drittel kürzer als der Kopf, eiförmig, am hintern Rande flach ausgeschnitten; ihr vorderer Rand bildet unten einen nach hinten vorspringenden Lappen, ihr hinterer Rand setzt sich über die Wange bis 4. Mm, hinter und unter dem Mundwinkel fort; der Tragus ist von sickelförmiger Gestalt, mit seiner Spitze nach vorn gekehrt, und halb so lang wie das Ohr. Die Schleimhaut des Gaumens bildet sieben Querfalten, von denen die beiden ersten grade und ungetheilt sind. Vor der Mitte der Unterlippe tritt die Schleimhaut in Form einer zweilappigen breiten Platte hervor. Der Körper ist dicht behaart, ohne nackte Stellen; die Haare sind an den Seiten der Brust am längsten, 15 Mm. lang. Die Flughäute sind sehr grofs, gehen bis zur Basis der Zehen herab und stehen uber der Lendengegend nur 9 Mm. von einander entfernt; neben den Seiten des Körpers sind sie dicht behaart, sonst auf der Rückenseite nackt; an der Bauchseite dagegen zeigt sich eine leichte wollige Behaarung auf der Halsflughaut, und langs des ganzen Vorderarms bis zum vierten Finger hin. Der Vorderarm reicht, neben dem Körper angelest, eben so weit wie das vordere Ende der Schnauze. Das Mittelhandglied des Daumens wird nach innen nur zur Hälfte, nach dem zweiten Finger hin ganz von der Flughaut umfafst. Die beiden letzten Glieder des Schwanzes. welcher den Unterarm an Länge ubertrifft, treten frei aus der Schenkelflughaut, deren Seiten durch lange Spornen gestützt sind, hervor. Nur das Anfangsviertel der Schenkelflughaut, besonders an der Bauchseite, ist leicht behaart, der übrige Theil nackt.

Die Farbe des alten Männchens ist an der Rückenseite dunkel olivenbraun, an der Bauchseite weifs mit gelblichem Anfluge, und vor dem Schultergelenk befindet sich ein grofser braunlicher Fleck. Die Flughäute und Ohren sind dunkler braun, die Nägel gelblich weifs.

Der Schädel zeigt nichts in seiner Form von anderen Arten dieser Gattung Abweichendes Gebifs $^{3\,2}/_{3\,2}{}^{1}/_{1}{}^{1}/_{4}{}^{1}/_{1}{}^{2\,3}/_{2\,3}$ = 30. Die Backzähne der *Nycticejus* unterscheiden sich in ihrer Gestalt sehr wesentlich von denen der eigentlichen Fledermäuse: die W Form der Schmelzfalte an den oberen Backzähnen ist wegen der Kleinheit des mittleren Winkels sehr undeutlich, so dafs auch statt fünf nur vier Höcker auf der Kaufläche hervorspringen, und die hintere Abtheilung

p. 66

der unteren Backzähne, welche bei den eigentlichen Fledermäusen die breiteste und gröfste ist, bildet hier nur ein schmales Anhängsel, welches kaum ein Drittel des ganzen Zahns ausmacht. Den ersten obern Backzahn mufs man seiner ganzen Bildung nach als Lückenzahn betrachten. Was das übrige Skelet anbelangt, so besteht die Wirbelsäule aus 39 Wirbeln; diese sind 7 Halswirbel, 12 Rückenwirbel, 5 Lendenwirbel, 5 Kreuzbeinwirbel und 10 Schwanzwirbel. Der Kiel des Brustbeins ist sehr niedrig und läuft oben vor dem Manubrium in einen dreieckigen Stachel aus. Das Wadenbein ist vollständig verknöchert.

Die vordere Hälfte der Zunge ist mit kleinen rückwärts gekehrten spitzigen Papillen bedeckt, welche in der Mitte gröfser und zwei- bis dreispitzig sind; auf der hintern Hälfte stehen linsenförmige rundliche Warzen und zwei grofse Papillae vallatae. Der Magen ist bohnenförmig und geht in einen einfachen 95 Mm. langen Darm über, welcher vor seinem Ende sehr erweiter erscheint. Die Leber ist rechts mit einem tiefen Einschnitte versehen, unter welchem hinten die kleine rundliche Gallenblase liegt. Die Milz ist platt, gestreckt, 8 Mm. lang und 2 Mm. breit. Die Nieren sind einfach bohnenförmig, 4, Mm. lang; die linke liegt viel tiefer als die rechte. Die Ruthe ist weich und häutig. Der Kehlkopf hat eine Länge von 5 Mm.; der Schildknorpe ist bandförmig schmal, der Ringknorpel hinten mit einer starken Crista für die Anheftung der Giefsbeckenknorpel versehen. Die Luftröhre ist allenthalben gleich weit und enthält his zum Spaltungsstelle 18 Knorpelringe. Die Lungen bestehen jederseits aus einem einzigen Lappen, die linke Lunge ist wegen des mehr nach links gerichteten Herzens etwas kleiner als die rechte.

Diese Art stammt aus dem Innern des Landes, aus Tette, ungefähr 120 Meilen von der Küste, im 17° Südl. Br.; das einzige Exemplar, ein ausgewachsenes Männchen, wurde im März 1845 im Fluge gefangen.

Mafse in Millimetern.

Lange der Wirbelsäule vom Atlas bis zum ersten Schwanzwirbel: 53; 47.

p. 65
???

The snout is wide and very flat, so that the nostrils are opening at the frontal edge of the upper lip. The ears are about one third shorter as the head; egg-shaped, at the posterior edge evenly cut (?), their anterior edge forms at the bottom a lobe pointing to the back, their posterior edge runs over the cheek up to 4 mm behind and under the corner of the mouth: the tragus is sickle-shaped, with its top pointed forward, and half as long as the ear. The mucous membrane of the palate forms seven ridges, of which both first are straight and undivided. In front of the middle of the lower lip, the mucous membrane forms a two-lobed wide plate. The body is densely haired, without naked patches; the hairs are the longest at the sides of breast, 15 mm long. The wing membranes are very large, run to the base of the toes and are in the lumbar region only 9 mm separated from one another; close to the body, they are densely haired, but on the backside they are naked; on the belly side there is a light woolly fur on the neck membrane, and along the entire forearm up to the fourth finger. The forearm, pressed against the body, reaches the top of the snout. The middle hand bone of the thumb is on the inner side up to half and to the second finger completely enclosed in the wing membrane. Both latter vertebra of the tail, which is longer than the forearm, are free of the tail membrane, which sides are supported by long spurs. Only the first quarter of the tail membrane, especially on the belly side, is faintly haired, the remaining part is naked.

The colour of the old male is on the back dark olive brown, on the belly white with a yellowish shine, and in front of the shoulder joint there is a large brownish spot. The wing membrane and the ears are dark brown, the nails are yellowish white.

The shape of the skull is not different from any other species in this genus. Dentition 3 - 2/3 - 2 1/1 1 - 1/4 1/1 2 - 3/2 - 3 = 30. The molars of Nycticejus can be clearly distinguished by their shape from the proper bats: the W form of the enamel of the upper molars is due to the small size of the middle corner very unclear, so that instead of five there are only four bends on the chewing surface,

p. 66
and the posterior part of the lower molar, which is the widest and largest in the proper bats, forms here only a narrow appendage, which barely accounts for one third of the complete tooth. The first upper molar should be considered false molar (?) due to its build. Concerning the remaining skeleton, the spinal column consists of 39 vertebras, which are 7 cervical vertebras, 12 back vertebras, 5 lumbar vertebras, 5 sacral vertebras, and 10 tail vertebras. The keel on the breastbone is very low and ends above in front of the manubrium (?) in a triangular sting. The fibula is completely turned into bone.

The anterior half of the tongue is covered with small backwards turned pointed papillae, which are largest in the middle and have two or three tips; on the posterior half there are lens shaped roundish warts and two large Papillae Vallatae. The stomach is bean shaped and runs into a simple 95 mm long intestine, which before its end seems much widened. The liver has on the right side a deep incision, under which posterior end a small roundish gall-blather is located. The spleen is flat, stretched out, about 8 mm long and 2 mm wide. The kidneys are simple bean shaped, 4 mm long, the left one situated much deeper as the right one. The rod [=penis?] is weak and skin-like (?). The larynx has a length of 5 mm, the thyroid is band shaped narrow, the ringcartilage (?) has at the back a strong crista for attaching the "Giefsbeckenknorpel" [no idea what this is, some sort of cartilage??]. The trachea is everywhere as wide and contains 18 cartilage rings to the split. The lungs have a single lobe on each side, the left lung is due to the left oriented heart slightly smaller than the right one.

This species came from the inside of the country, from Tette, about 120 miles from the coast, at 17° South; the only specimen, a fully grown male, was caught in flight in March 1845

Measurements in mm.

Total length from snout [=:nose] to tailtip: 120; 95
Wingspan: 340; 290
Length of head: 22 1/2; 20
Length of ear: 14; 11
Width of ear: 9; 7
Length of forearm: 32; 28
Length of upper arm: 52; 46
Length of thumb (Meta1, 1ph1, 1ph2): 3 1/2, 3. 1.Gl. 4, 4. 2.Gl. 2, 2): 9 1/2; 9
Length of second finger (Meta2, 2ph1): 47, 42 1/2. 1.Gl. 5 1/2, 4 1/2): 52 1/2; 47

Length of third finger (Meta3, 3ph1, 3ph2, 3ph3): 48 1/2, 43 1/2. 1.Gl. 18, 15. 2.Gl. 10 1/2, 11 1/2. 3.Gl. 7 1/3, 8 1/2): 84 1/3; 78 1/2
Length of fourth finger (Meta4, 4ph1, 4ph2, 4ph3): 46 1/2, 42 1/2. 1.Gl. 14, 11 1/2. 2.Gl. 8, 7 1/2. 3.Gl. 2, 2): 70 1/2; 63 1/2
Length of fifth finger (Meta5, 5ph1, 5ph2, 5ph3): 42, 39. 1.Gl. 8 1/2, 7 1/2. 2.Gl. 5, 5 1/4 3.Gl. 2, 2): 70 1/2; 63 1/2
Length of the upper leg: 19; 19
Length of lower leg [=Tibia]: 21; 19
p. 67
Length of entire foot: 10 1/2; 11
Length of tail: 55; 40
Length of spur [=calcaneum]: 20 1/2; 18
Length of skull: 19 1/2; 17 1/2
Length of the spinal column from Atlas to the first tail vertebra: 53; 47.

[Translated by Victor Van Cakenberghe, 2008]

Nycticejus Schlieffenii Peters, 1859

supra rufescens, subtus ex albo rufescens; alis fuscis.

Long. tota 0.075; cap. 0.015; aur. 0.013; tragi 0,005; caudae 0.032; antibr. 0.031; exp. alar, 0.200.

Nycticejus serratus Heuglin, 1877

p. 35.

Ziemlich groß; Kopf schmal und etwas zugespizt. Nasenlöcher klein, durch einen schwachen Spalt getrennt, der oben und unten sich erweitert und in seiner Mitte eine kleine aufgedunsene Membran zeigt; Unterlippe einfach gespalten, jederseits dieser Spalte in ein spitziges Läppchen herabgezogen; unter dem Kinn eine nackte, dreiseitige Vertiefung; Ohr klein, nach hitnten und aufwärts gerichtet, dreiseitig mit abgerundeten Ecken, innen, der Außenranb mit 5 bis 7 Querfalten, am Borderrand 6 bis 7 kerbenarttge Einschnitte; die Lappe an der Wurzer des äußeren Ohrflügels bogig bis gegen den

p. 36

Mundwinkel hin verlaufend; Tragus kürz, platt, oben mit einer rundlichen, blattförmig ausgebreiteten Spitze, Außenrand doppelt, Innenrand einfach eingekerbt; auf ber Kehlmitte ein kahter Fleck.

Im Oberkiefer 2 kleine, im Unterkiefer 2 + 2 ebenfalls kleine unb dreizackige Schneidezähne; die Eckzähne mit deutlichem Löcker an der Basis, also zweitheilig. Der kurze Schwanz theilweise vom Patagium interfemorale eingehüllt, jedoch seine Spitze frei. Zeigefinger eingliedrig, die drei folgenden dreigliedrig.

Olivenbräunlich ins Graue; Unterseite heller olivenbraun-grau; die Behaarung an der Spitze gelblich; Schnauze und äußere Fläche der Flüghäüte rußbraun, die unteren Theile der Spannhaut um die Schenkelgegend sowie der etwas aufgedunsene Seitenrand des Patagium gelblich ins Fleischrötliche; die ganze Innenseite der Spannhaut bläulichgrau bis graugrünlich, nach der Unterhälfte hin mehr ockergelblich genetzt; Ohr sehr wenig behaart; von einer Ohrbasis zur anderen führt ein etwaS obsoletes Halsband über die Kehle, dasselbe ist olivenbräunich, wie der Rücken. Körperlänge stark 3" 5"'. Schwanz 1" 2"'. Vorderarm 2" 6"' bis 2" 7"'. Flugweite fast 16". Ohrhöhe 8"'. Tragus $2^1/_2$"'. Sporn 9"'.

Ein jüngeres, kleineres Exemplar ist obenher dunkler umbra-braun ins Graue, am Unterleib mausgrau; im Ohr 10 bis 11 Falten.

Häufig im sogenannten Scherq el Aqabah, am Araschkol und den benachbarten Granitgebirgen.

p. 35.
Rather larger, head narrow and somewhat pointed. Nostrils small, separated by a faint groove, which above and below widens and has in its middle a small swollen membrane; lower lip wit a single split, on each side of the split with a pointed small lobe; below the chin a naked three-sided depression; ear small, backwards and upwards directed, three-sided with rounded corners, inside the outer margin has 5 to 7 ridges, on the border edge [??] 6 to 7 notchlike incisions; the lobe at the base of the outer earwing curved until near the corner of the mouth

p. 36
Tragus short, flat, open with a roundish, leaf shaped spread tip, outer margin double, inner margin once carved; on the middle of the throat a naked spot.

In the upper jaw 2 small, in the lower jaw 2 + 2 likewise smaller and trilobed incisors; the canines with an obvious humb at their base, also bilobed. The short tail partly enclosed in the interfemoral membrane, but its tip free. Index finger with one member, the three following with three.

Olivebrownish to greyish; lowerside brighter olivebrown-grey; the fur on the Tipps yellowish; snout and outer sides of the wing membrane russetbrown, the lower parts ot the wing membrane in the area of the thighs as well as somewhat swollen edge of the patagium yellowish to fleshreddish; the entire inner side of the wing membrane blueish-grey to greyish-greenish, towards the

lower half more ochre-yellowish netted; ear little furred, from one base of the ear to the other there is a somewhat obsolete collar over the throat, which is the same olivebrownish as the back. Length of body robust 3" 5"', Tail 1" 2"'. Forearm 2" 6"' to 2" 7"'. Wingspan almost 16". Height of ear 8"'. Tragus 2 ½ "'. Spur: 9"'

A young, smaller specimen is above dark umbra-brown to grey, on the belly mouse-grey; in the ear 10 to 11 ridges.

Common in the so-called Scherq el Aqabah, in Araschkol and in the neighbouring Granit mountains.

[Translated by Victor Van Cakenberghe, 2008]

Nycticejus viridis Peters, 1852

p. 67

Tafel XVII. Fig. 2.

N. olivaceoviridis, subtus viridiflavus; auriculis capite dimidio brevioribus, trago elongato; calcare crure breviore.

Longitudo tota 0,095; antibrachii 0,046; caudae 0,040; volatus 0,290.

Habitatio: Africa orientalis, Insula Mossambique, 15° Lat. Austr.

Mit breiter, dicker und wulstiger Schnauze, an deren vorderem Ende über dem Rande der Oberlippe die Nasenlöcher stehen. Die Entfernung der Nasenlöcher ist nicht ganz so grofs wie die Hälfte ihres Abstandes von den Augen. Die Ohren sind halb so lang wie der Kopf, oval, am hintern Rande oben schwach ausgeschnitten, an ihrer äufsern Fläche bis zur Hälfte dicht behaart. Der hintere Ohrrand geht nach vorn in einen Lappen über, der in gleicher Höhe mit dem Mundwinkel, 3 Mm. hinter demselben und durch eine warzenförmige Hervorra.ung von ihm getrennt; endigt. Der vordere Ohrrand endigt mit einem freien Lappen, welcher spitzwinkeling nach hinten vorspringt. Der Tragus ist sichelförmig, am vorderen Rande fast grade und mit seiner Spitze nach vorn und innen gerichtet. Schnauze und Kinn sind nur schwach behaart und mit grofsen warzigen Drüsenhervorregungen versehen. Die Schleimhaut der Unterlippe bildet vorn eine grofse, abgerundet viereckige, freiliegende Platte. Am Gaumen bemerkt man sieben Querfalten der Schleimhaut, von denen die erste grade, die zweite in der Mitte eingeknickt, die beiden folgenden tief V förmig zwischen die getheilte fünfte und sechste eingezogen sind, und die letzte und siebente mit ihrem stumpfen mittleren Winkel nach hinten vorspringt. Die Behaarung läfst am Körper keine Stellen unbedeckt, ist am Rücken, Halse und an den Seiten des Bauches gleich lang, etwas länger als in der Mitte des Bauches. Die Flughäute stehen in der Lendengegend viel weiter, 15 Mm., von einander ab, als bei der vorhergehenden Art, und gehen bis an die Basis der ersten Zehe herab. An der Rückenseite sind sie nackt bis auf den schmalen Saum, welchen die Ausdehnung der Körperbehaarung bedeckt; an der Bauchseite verdeckt langes zerstreutes Haar die Seiten bis zur Gegend zwischen Knie und Ellbogen, und eine noch viel spärlichere Behaarung macht sich an der Halsflughaut und längs des Unterarms bis zum vierten Finger bemerkbar. Das Ende des Vorderarms reicht bis zur Mitte zwischen Auge und Eckzahn. Das Mittelhandglied des Daumens ist nach innen nur zur Hälfte, nach dem zweiten Finger hin ganz von der Flughaut

p. 68

umsäumt. Der Schwanz, welcher kürzer als der Unterarm ist, steckt bis zur Spitze in der Schenkelflughaut, welche nur an ihrer Basis behaart erscheint.

Die Farbe der Rückseite ist ein schönes dunkles Olivengrün; die Haare der Bauchseite sind grünlichgelb. In Weingeist verändern sich diese Farben, so dafs das Grüne weniger hervortritt. Die Flughäute und Ohren sind braunschwarz, die Nägel weifs.

Schädel und Gebifs stimmen aufser einem geringen Gröfsenunterschiede mit der vorigen Art überein, wie aus der Abbildung zu ersehen ist. Die Wirbelsäule besteht aus 7 Halswirbeln, 11 Rückenwirbeln, 4 Lendenwirbeln, 5 Kreuzbeinwirbeln und 9 Schwanzwirbeln, also aus drei, 1 Rücken-, 1 Lnhden- und 1 Schwanzwirbel, weniger als bei der vorigen Art. Die Eingeweide stimmen in ihrem Bau mit der vorigen Art überein, nur sind die Ringe der Luftröhre etwas zahlreicher, indem man deren 24 zählt.

Auch diese Art scheint selten zu sein, da ich nur ein einziges Exemplar, ebenfalls ein altes Männchen, von derselben erhalten habe, welches im Februar 1844 des Abends in einer Wohnung auf der Insel Mossambique gefangen wurde. Der Magen enthielt Skelettheile von Insecten.

Sie unterscheidet sich von der vorigen Art, abgesehen von der Färbung, durch kürzere Ohren, kürzere Spornen und kürzeren Schwanz, durch eine dickere Schnauze, etwas robustere Füfse, weiteren Abstand der Flughäute, viel schmälere Umsäumung der Spornen, und innerlich durch eine geringere Zahl der Wirbel und Rippen.

Scotophilus Dinganii (Smth, *Illustrations of the zoology of South Africa. Mammalia. Tab. 53*), welcher zur Gattung *Nycticejus* zu ziehen ist, scheint mir durch Folgendes von beiden Arten unterschieden zu sein: Die Ohren sind breiter als lang; die Nasenlöcher stehen näher beisammen; die Schnauze und Lippen sind dicker; die Flughäute gehen nur bis an die Fufswurzel herab; die unteren Schneidezähne sind zweilappig, während sie bei den beiden Arten aus Mossambique deutlich dreilappig sind; der Vorderarm ist viel länger, 2 Zoll 3 Linien oder 60 Mm., und die übrigen Mafse stimmen mit keiner von beiden, indem die ganze Länge der von *Nycticejus viridis* entspricht, der Schwanz aber in seiner Länge mit dem von *Nycticejus planirostris* übereinstimmt. Wie sich die Spornen und der innere Bau verhalten, namentlich, was die Zahl der Wirbel anbelangt, darüber gibt weder die Abbildung noch die Beschreibung Auskunft. Vielleicht gehört auch eine von Sundevall mitgetheilte Art von eigentlichen Fledermäusen, *Vesperugo Dinganii* (*Öfversigt af Kongl. Vetenskaps - Akademiens Förhandlingar*. 3. Jahrgang. 1846 pag. 119) hieher, aber ich wage es nicht, anzunehmen, dafs einem so ausgezeichneten Zoologen der Unterschied zwischen dem Bau der Zähne der eigentlichen Fledermäuse und der *Nycticejus* entgangen sei.

Die übrigen bekannten africanischen Arten wird man nicht leicht mit den von mir beschriebenen verwechseln können.

p. 67
Tafel XVII. Fig. 2.

N. olivaceoviridis, subtus viridiflavus; auriculis capite dimidio brevioribus, trago elongato; calcare crure breviore.

Longitudo tota 0,095; antibrachii 0,046; caudae 0,040; volatus 0,290.

Habitatio: Africa orientalis, Insula Mossambique, 15° Lat. Austr.

With wider, thicker, and more swollen snout, on which anterior end the nostrils are located over the edge of the upper lip. The distance between the nostrils is not entirely as large as half the distance between them and the eyes. The ears are half as long as the head, oval, on their posterior edge weakly cut (?), on their outer side up to their halve thickly haired. The posterior ear margin runs to the front in a lobe, which at the same height of the corner of the mouth, 3 mm behind the same and separated from it by a wart-like projection. The anterior ear margin ends with a free lobe, which turns forward with [or possibly "in"] a sharp corner. The tragus is sickle shaped, its anterior margin is almost straight and with its top directed to the front and inwards. Snout and chin are only weakly haired and with a large wart-like glandular projection. The mucous membrane of the lower lip forms a large, rounded four-sided, free-lying plate. In the palate there are seven ridges in the mucous membrane, from which the first almost, the second in the middle bent inwards, both following ones deep V shaped drawn between the split fifth and sixth, and the last and seventh with its blunt middle angle sticking out to the back. The pelage leaves no spot uncovered on the head, and is on the back, neck and sides of the bell evenly long, slightly longer as on the middle of the belly. The wing membranes are in the lumbar region much wider, 15 mm, separated from one another as in the previous species [=Nycticejus planirostris], and run to the base of the first toe. On the back side, they are naked to the very narrow border, which covers the extension of the body, on the belly side long, scattered hairs cover the sides to the area between the knee and the elbow, and an even more scarcer pelage makes itself visible on the neck membrane and along the forearm to the fourth finger. The end of the forearm reaches until the middle between the eye and the canine. The metacarpus of the thumb is on the inner side only until its halve and on the outer side entirely included in the wing membrane.

p. 68
The tail, which is shorter than the forearm, is enclosed until its tip into the tail membrane, which seems only haired on its base.

The colour of the back is a beautiful dark olivegreen; the hairs on the belly side are greenish-yellow. In spirit, these colours change, so that the green is less prominent. The wing membrane and the ears are brownish-black, the nails are white.

Skull and dentition agree with the previous species, except for a small size difference, as can be seen on the picture [I haven't seen any pictures of this]. The spinal column consists of 7 cervical vertebras, 11 back vertebras, 4 lumbar vertebras, 5 sacral vertebras, and 9 tail vertebras, so 1 back, 1 lumbar and 1 tail vertebra less than the previous species. The intestines agree in their build with the previous species, only the rings on the trachea are slightly more numerous, since there are 24.

Also this species seems to be rare, since I have only obtained one specimen, also an old male, from the same, which in February 1844 was captured in the evening in a house on Mozambique islands. In its stomach, there were skeletal parts of insects.

This species distinguished itself from the previous species, besides its colour, by the shorter ears, shorter spurs and shorter tail, by a thicker snout, somewhat more robust feet, larger distance of the wing membrane, much narrower edging of the spurs, and on the inside by the lower number of vertebras and ribs.

Scotophilus Dinganii (Smth, Illustrations of the zoology of South Africa. Mammalia. Tab. 53), which can be assigned to the genus Nycticejus, seems to be separated from these two species by the following: the ears are wider as long; the nostrils are closer together, the snout and lips are thicker, the wing membranes end at the base of the feet, the lower incisors are bicuspid, whereas they are in both species from Mozambique clearly tricuspid, the forearm is much longer 2 inches, 3 lines or 60 mm, and the other measurements do not agree with any of the other species, the total length agrees with the one of Nycticejus viridis [??? at least this is what I understood here ???], the tail however agrees with that of Nycticejus planirostris. How the spurs and internal built correspond, more specifically the number of vertebras, can not be determined from the picture nor the description. Possibly a species of proper bats reported by Sundevall, Vesperugo Dinganii (Öfversigt af Kongl. Vetenskaps - Akademiens Förhandlingar. 3. Jahrgang. 1846 pag. 119) might belong here, but I do not dare to accept that a so eminent zoologist might have missed the difference in the built of the teeth of the proper bats and Nycticejus.

The other known African species will hardly be confused with both described by me.

Nez confondu avec les lèvres; celles-ci largement -et profondément fendues.
Oreilles grandes, réunies et couchées sur la face; oreillon extérieur.
Membrane interfémorale moyenne et saillante.
Queue longue, à demi enveloppée, et libre au-delà.

OBS. Les espèces de ce genre sont le nyctinome d'Égypte, celui du Bengale, et le nyctinome de Bourbon.

Nyctinomus (Dysopes) ventralis Heuglin, 1861

p. 11

Vellere brevi, sericato, brunneo-rufo, subtus pallidiore; stria ventrali, lata, mediana, conspicua rubente-flava; fibrissis faciei obscure brunneis; fascia lata subbrachiali villosa pallide fulvescente; pilis digitorum (ciliis) podarii setosis, valde elongatis et unguines ex parte superantibus.

Nasenlöcher rüsselartig aufgetrieben, nach vorne durch eine schmale aber sehr deutlich ausgesprochene Leiste geschieden. Oberlippenrand hängend und faltig; auch das nicht sehr kleine Auge in einer langen, fast unter dem Ohre

p. 12

versteckten Querfalte, in welch letzterer vor dem Auge hin sich auch eine scharfe thränengrubenähnliche Furche befindet. Unterlippe ganzrandig, durch eine Querfurehe vom Kinn geschieden, an dessen Seiten zwei kurze Falten der Länge nach herablaufen. Gesicht im allgemeinen rauh und unbehaart, nur über der Nase bis zwischen den Ohren und um die Oberlippe stehen bürstenartige Haare, aus denen einzelne, theils über 2‴ lange Barthaare sprossen.

Die rundlichen breiten Ohren auf der Stirn durch eine niedrige, kurze Hautfalte verbunden und mit ihrem Aussenrande die Mundspalte fast erreichend; der genannte Rand an seiner Basis mit nach oben gerichtetem halbrundem Lappen; *Tragus* länglich-oval, niedrig, etwas tief in den Grund der Ohrmuschel herabgerückt, dort ebenfalls mit einem zum Verschlusse des Gehörgangs geeigneten Lappen. 8 - 12 Querfalten in der Ohrmuschel; die der faltigen Partie gegenüberstehende innere Längshälfte der Muschel innen gänzlich bis gegen den Rand, aussen mit einem schmäleren Streifen von Haaren bedeckt.

Gaumen mit 7 in ihrer Mitte getheilten Querfalten. Schneidezähne $^{1}/_{2}$, die oberen zwei ziemlich eng stehend und eckzahnartig verlängert, die unteren vier sehr klein und oben schaufelförmig und mit je einer Kerbe versehen. Obere Eckzähne normal, die unteren an der Basis der Krone je gegen den zunächst gelegenen Schneidezahn hin mit zackenförmig erweitertem Zahnkranz, so dass zwischen Schneide - und Eckzahn ein dritter abnormer Zahn zu stehen scheint. Der Zeigfinger besteht nur aus einer Phalange. Flughaut den Vorderfuss am Handgelenke umschliessend, letzteres mit kräftigem *Calcaneus*, der an seiner Basis nach aussen einen der Spitze zu immer schmäler werdenden Hautrand und eine Andeutung von nagelartiger Verlängerung hat. Zehenseiten und Nägelglieder mit weissen langen, halbrund gebogenen bürstenartigen, bis zu 2" langen Haaren besetzt. Das *Patagium interfemorale* sehr faltig und dehnbar, etwa $^{1}/_{3}$ des dicken, faltigen Schwanzes erreichend, von welcher Vereinigung aus sie die Spitze als Scheide einschliesst. Genannte Scheide sehr muskulös und sie kann an der Schwanzrübe weit auf- und abgeschoben werden.

Pelz kurz und sammtartig, ein 3‴- 5‴ breiter Streif von Behaarung zieht sich auf der Innenseite der Flughaut längs des ganzen Oberarms hin.

Ohr hoch: 9‴
Kopflänge: 1" 1‴.

Nyctinomus (Nyctinomus) tongaënsis Wettstein, 1916

p. 192

Aschgraue, mittelgroße Art, dem *N. aegyptiacus* Geoffr. am nächsten stehend, aber etwas größer. M mit Kehlsack, Ohren nicht durch ein Band verbunden, aber am Grunde zusammenhängend. Ohrmuschel sehr groß mit starkem Kiel, in ausgebreitetem Zustande ungefähr quadratisch, mit schwach konvexem Innenrande. breit abgerundetem Ende und zuerst geradem, dann stark konvexem Außenrand. Antitragus triangulär, oben stark abgerundet, durch einen tiefen Einschnitt vom Ohrrande getrennt. Tragus klein, breit und stumpf abgerundet, ungefähr rechteckig, Innenrand sehr stark konvex, Außenrand fast gerade. Oberlippe stark wulstig mit fünf bis sieben deutlichen Furchen. Oberseite hell aschgrau, das einzelne Haar dunkel "drab-gray", am Grunde

lichter, mit hellgrauer ("10. Gray") Spitze, Unterseite der Oberseite ähnlich, aber die Haarspitzen weißlich und der "drab"-farbige Ton lichter. Ein breiter Haarstreif auf der Unterseite der Flughaut entlang den Körperseiten graubräunlich-weiß, Kopf und Körp. 73 und 71, Schwarz 44 und 42.5. Unterarm 52 und 51, Ohrhöhe 23 und 22, Ohrbr. a. d. Basis 19 und 18, Traguslg. 6 mm.

Typen 2 MM, Tonga am oberen Weißen Nil, 16.IV.1914

Nyctinomus [(Mormopterus)] albiventer Dobson, 1877

p.733

Inc. $^{2}/_{6}$; Pm. $^{1-1}/_{2-2}$. Ears separate, tragus triangular.

(Subgen. *Mormopterus*, Peters.)

20. *Nyctinomus albiventer*, n. sp.

Ears triangular, shorter than the head, inner margins arising from distinct points of origin from the forehead; inner margin of the ear-conch almost straight, slightly concave in upper third, tip rounded off, outer margin straight; antitragus scarcely defined, separated posteriorly by a very shallow notch; tragus nearly as broad opposite the base of its inner margin as high, irregularly triangular, rounded off above, very similar in shape to that of *N. norfolcensis*, but less triangular and broader above, an obtuse projection about the middle of its outer margin. Extremity of the muzzle projecting very much beyond the mandible, the end of the nose very prominent and distinct from the upper lip, nostrils opening almost laterally. Sides of the upper lip with vertical grooves not well defined. Gular sac small.

Wings from the lower third of the tibiæ or from the ankles; fifth toe somewhat smaller than the first.

Dentition similar to that of *N. acetabulosus* (to be described), but the lower incisors are not crowded.

Fur, above, white at the base, the remaining part dark brown; beneath, the greater part of the chest and abdomen dirty white, the sides brown. Wing- and interfemoral membrane nearly naked; a narrow band of fur extends outwards behind the forearm and along the proximal third of the fifth metacarpal bone.

Length (of an adult ♀, the type): head and body 2"2; tail 1"25, tail free from membrane 0"7; head 0"85; ear 0"65, tragus 0"15; forearm 1"45; thumb 0"35; second finger - metacarp. 1"4, 1st ph. 0"55, 2nd ph. 0"35; third finger - metacarp. 1"4, 1st ph. 0"5, 2nd ph. 0"35; fourth finger - metacarp. 0"9, 1st ph. 0"35, 2nd ph. 0"15; tibia 0"4; foot and claws 0"3.

Hab. Madagascar.

Type in the British Museum.

Nyctinomus africanus Dobson, 1876

p. 348

Nyctinomus africanus n. sp.

Upper lip smooth, without vertical wrinkles. Ears from perfectly distinct points of origin though close together, their inner margins arising from the upper surface of the muzzle, though not so near the extremity of the muzzle as *N. Cestonii*; tragus somewhat similar to that of *N. Cestonii*, but longer, and the upper margin quite evenly rounded off; antitragus quadrilateral, the shortest side in front, the upper margin slightly concave.

Fur bright orange-chestnut above and beneath.

Incisors $^{2}/_{4}$; the lower incisors not crowded: premolars $^{2-2}/_{2-2}$; the first upper premolar very short and blunt, its base occupying the whole space between the canine and second premolar.

Length (of an adult male) 3.6 inches; tail 2.2; ear 1; tragus 0.3; forearm 2.5; thumb 0.4; second finger - metacarpal bone 2.4, first phalanx 1.1, second phalanx 1.3; fourth finger 2.4; tibia 0.75; foot and claws 0.45.

This species resembles *N. midas*, from North Africa, in size and in general appearance. The large tragus, however, at once distinguishes it from that species.

Hab. South Africa (Transvaal Republic). Type in the collection of the British Museum, presented by R. B. Sharpe, Esq.

Nyctinomus aloysii-sabaudiae Festa, 1907

p. 1

NYCTINOMUS ALOYSII-SABAUDIAE, nov. spec.

(diagnosi preventiva)

Orecchie grandi, arrotondate, riunite alla base del loro margine-interno da una spessa fascia cutanea, formante sulla sua parte anteriore una protuberanza carnosa, sulla parte anteriore della quale nascono radi peli setolosi. La carena interna è elevata, coll'orlo superiore ingrossato nella parte inferiore, e gradatamente assottigliantesi nella sua parte superiore.

L'antitrago è piuttosto alto, largo alla base, col margine interno obliquo e quasi rettilineo, col margine superiore leggermente convesso.

Il trago è assai piccolo, rivolto allo innanzi, col margine interno un po' concavo, e l'esterno convesso.

Il muso è troncato obliquamente. Il labbro superiore è molto ampio, solcato da profonde rughe, delle quali quelle sulla parte anteriore del labbro stesso sono leggermente oblique allo indietro, e quelle sulla parte posteriore, leggermente oblique allo innanzi.

La membrana alare è inserita alla metà della tibia sul lato anteriore; l'uropatagio comincia alla parte posteriore della tibia un po' al disotto del punto, dove è inserita la membrana alare.

La coda è compresa nell'uropatagio per un quarco circa della sua lunghezza.

p. 2

Il calcaneo è breve.

Il pelame è di colore castagno chiaro (*Russet* del Ridgway (*)) colla base dei peli di color fulvo chiaro.

Denti: Incis. $^{1}/_{2}$, Can. $^{1}/_{1}$, Premol. $^{2}/_{2}$, Mol. $^{3}/_{3}$.

Il cranio è mediocremente allungato. Il 1° premolare superiore è molto piccolo, situato nella linea dentale, in contiguità del canino. Gli incisivi inferiori sono bilobati. I canini hanno le basi vicine, più alte degli incisivi.

Le dimensioni dell'esemplare tipo della specie, una femmina di Toro sono le seguenti:

Lunghezza del capo e del corpo: mm. 69
" del capo: " 27
" dell'avambraccio: " 51
" della tibia: " 18
" della coda: " 42
" della porzione libera della coda: " 31.5
" delle orecchie, dall'intaccatura dell'antitrago all'apice: " 18
" del trago, dalla base del margine interno all'apice: " 2

p. 1

NYCTINOMUS ALOYSII-SABAUDIAE, nov. spec.

(preliminary diagnosis)

Ears large, rounded, join together at the base of their inner margin by a thick cutaneous band, forming on its front a fleshy protuberance, on the front of which grow sparse bristly hairs. The internal keel is elevated, with the upper edge enlarged in the lower part, and gradually tapered into its upper part.

The antitragus is rather tall, broad at the base, with an oblique and almost rectilinear internal margin, with a slightly convex upper margin.

The tragus is very small, facing forward, with a slightly concave inner margin, and a convex exterior.

The snout is obliquely truncated. The upper lip is very broad, furrowed by deep wrinkles, of which those on the front of the lip itself are slightly oblique to the back, and those on the back, slightly oblique to the front.

The wing membrane is inserted in the middle of the tibia on the front side; the uropatagium begins at the back of the tibia a little below the point, where the wing membrane is inserted.

The tail is included in the uropatagium for about a quarter of its length.

p. 2

The calcar is short.

The hair is light chestnut (*Russet* of the Ridgway (*)) with a light tawny hair base.

Teeth: Incis. $^{1}/_{2}$, Can. $^{1}/_{1}$, Premol. $^{2}/_{2}$, Mol. $^{3}/_{3}$.

The skull is slightly elongated. The 1st upper premolar is very small, located in the dental line, in proximity of the canine. The lower incisors are bilobed. The canines have bases close to each other, higher than the incisors.

The dimensions of the typical specimen of the species, a female from Toro are the following:

Length of head and body: mm. 69
" of the head: " 27
" of the forearm: " 51
" of the tibia: " 18
" of the tail: " 42
" of the free portion of the tail: " 31.5
" of the ears, from the indentation of the antitragus to the apex: " 18
" of the tragus, from the base of the internal margin to the apex: " 2

a, b. MF, Quibula, Angola, 1891. Anchieta; (alc. coll. d'Afr.).

c, d. MM, Galanga, Angola, 1893; Anchieta; (alc. coll. d'Afr.).

A presente especie foi ainda vista e estudada pelo professor Barboza du Bocage. Infelizmente, n'essa occasião, já a falta de vista principiava a difficultar sobremaneira os seus trabalhos de observação, e os preciosos apontamentos contendo a diagnose original d'esta nova especie extraviaram-se parece que de vez.

Procuraremos pela nossa parte evidenciar quanto possivel os seus caracteres, conservando-lhe a denominaçao especifica com a qual o illustre Professor a havia já determinado em homenagem a esse inolvidavel naturalista, a quem o Museu deve por assim dizer todas as riquezas que possue da nossa África occidental.

Descripção: - Orelhas separadas, muito redondas e bem desenvolvidas; anti-tragus elevado, carnoso e ovoide, separado da orelha por um sulco bem distincío; tragus mediocremente desenvolvido, um pouco anguloso; labio superior pouco rugoso proximo da commissura, mas profundamente nas proximidades das narinas; estas salientes; sacco gular indistincto; membrana da aza partindo do terço inferior da ítbia. O pello não muito abundante, curto, pardo escuro, ligeiramente mais claro e acinzentado no ventre, e amarellado no rebordo superior e anterior das orelhas. Membrana ante-brachial muitissimo curte, inerme pela parte inferior, coberta de curta e sedosa pubescencia pela parte superior; a inter-femoral, que é sustentada pelas fortes apophyses cartiliginosas do calcaneum, inerme pela parte superior, e apenas com alguns raros pellos proximo da cauda pela parte inferior; aquella que se estende dos membros anteriores e posteriores coberta em toda a volta do corpo pela parte inferior por uma larga faixa de pelles bastantes longos e um pouco mais claros que os do ventre. Estes pellos cobrem a região articular do autebraço bem como a do femur.

As membranas são bastante amplas e conservam approximadamente a côr geral do pello.

Os pés notavelmente guarnecidos de longos pello acinzentados.

Dentição: in. $^{1}/_{2}$ c. $^{1}/_{1}$ pm. $^{2}/_{2}$ m. $^{3}/_{3}$. Maxilla superior: incisivos mediocremente desonvolvidos, um pouco recurvados; caninos longos e quasi direitos; primeiro premolar pequenissimo, um pouco interior

p. 83

á linha normal e ao meio do espaço deixado entre o canino e segundo premolar, que ó beni desenvolvido; molares normaes. Maxilía inferior: incisivos biíobados; caninos bem desenvolvidos; primeiro premolar curto; segundo e molares normaes.

Paladar concordando com o typo do genero já exposto.

Dimensões: cabeça e corpo 70 mili.; cauda 40; parte livre 21; cabeça 24; orelha 19 (da base do anti-tragus á orla superior); tragus 5 X 2.3; ante-braço 51; pollegar 6; terceiro dedo: metacarpo 50; primeira phalange 20; segunda 24; quarto dedo: metacarpo 46; primeira phalange 17; segunda 10; quinto dedo: metacarpo 27; primeira phalange 14; segunda 7; tibia 17; pe 7.5.

Os doís exemplares de Galanga são de côr mais escura do que aquelles que vimos de descrever.

p. 82

The species presented was seen and studied by Professor Barboza du Bocage. Unfortunately, on this occasion, his lack of sight was beginning to greatly affect his observation work, and the precious notes containing the original diagnosis of this new species seems to have gone astray.

We searched on our part for as much evidence as possible for his/their characters, saving the names which the Professor had given in honour of this unforgettable naturalist, to whom the Museum must say all the riches that our Occidental Africa possess.

Description: Separated ears, rounded and well developed; high anti-tragus, fleshy and ovoid, separated from the ear by a distinct groove; underdeveloped tragus, slightly angular; upper lip slightly wrinkled near the commissura, but deep near the nostrils; protruding; distinguished gular pouch; wing membrane starting from the bottom third of the tibia. There is not an abundance of hair, it is short, dark brown in colour, lighter grey colour towards the belly, and yellowish by the upper edge and above the ears.

Anti-brachial membrane is very short, largely at the bottom, covered in short and silky pubescence hair on the top; the inter-femur, that is supported by the strong cartilaginous apophyses of the calcaneum, largely on the top part, and with a few rare hairs near the bottom part of the tail; those extending from the anterior and posterior of the membranes covers around the whole back of the body from the bottom with a range of long hairs and a little lighter than those of the belly. These hairs cover the joint region of the forearm as well as the femur.

The wing membranes are very large and are approximately the same colour as the hair.

The feet are notably trimmed with long grey hair.

Dentition: in. $^{1}/_{2}$ c. $^{1}/_{1}$ pm. $^{2}/_{2}$ m. $^{3}/_{3}$. Maxilla superior: poorly developed incisors, slightly curved; long and relatively straight canines; small first premolar, slightly inward.

The normal line goes until the middle of the space left between the canine and the second premolar, which is well developed; normal molars. Inferior maxilla: incisors are bi-lobed; canines well developed; first premolar is short; second premolar and molars are normal.

The palate corresponds with the general type already stated.

Measurements: head and body 70 mili.; tail 40; free part 21; head 24; ear 19 (from the base of the anti-tragus to the superior oral); tragus 5 x 2.3; forearm 51; thumb 6; third finger: metacarpal 50; first phalange 20, second 24; fourth finger: metacarpal 46; first phalange 17; second 10; fifth finger: metacarpal 27; first phalange 14; second 7; tibia 17; foot 7.5.

The two examples from Galanga are a darker colour than those we've been describing.

Mas adultus ex Angola. (Toulson)

Nyctinomus ansorgei Thomas, 1913

p. 318

Allied to *N. cisturus*, Thos., with which alone it shares a somewhat *Chærephon*-like shape of skull combined with typical *Nyctinomus* m^{3} and premaxillæ.

Size about as in *N. cisturus*; distribution of fur as in that species, except that the tail and interfemoral are less hairy; a partly naked patch on the crown behind the junction of the ears, and another across the nape just in front of the shoulders. General colour above dark chocolate-brown, the tips of the hairs paler. Below, succeeding the naked chin, the throat is blackish brown, considerably darker than any other part of the animal, and suggesting the blackish beard of certain species of *Taphozous*; chest and belly lighter brown, the tips markedly lighter than the bases, but not anywhere white. Ears of medium size, rounded; basal keel not specially thickened; antitragus triangular, rounded above, about half as high as long, separated behind by a deep notch. Tragus small, subquadrangular, very different from the triangular pointed tragus of *N. cisturus*. Tail apparently without special glands.

Skull on the whole very similar to that of *N. cisturus*, but rather larger throughout; upper profile not so convex in the frontal region. Teeth as in *cisturus*; anterior upper premolar in the tooth-row, not crowded, but just filling up the space between the canine and p^4. Lower incisors 4. Anterior lower premolar broader than the posterior.

Dimensions of the type (the italicised measurements taken in the flesh): -

Forearm 47 mm.

Head and body 70; tail 32; ear 19; tragus (dry) 1.5; third finger, metacarpus 46, first phalanx 18.6, second phalanx 19; fifth finger, metacarpus 28.

Skull: greatest length 19.2; zygomatic breadth 11.4; interorbital breadth 4.2; mastoid breadth 10.7; front of canine to back of m^3 7.4.

Hab. Malange, North Angola. Alt. 1150 m.

Type. Adult male. B.M. no. 10.4.8.4. Original number 5. Collected 17th February, 1908, by Dr. W. J. Ansorge.

The Angolan species described by Sr. de Seabra all have the low skull of typical *Nyctinomus, N. cisturus* being the only known species combining a high skull with the complete m^3 and divided premaxillæ which distinguish *Nyctinomus* from *Chærephon* and *Mops*. From *N. cisturus* the

p. 319

new species is readily recognizable by its dark beard and non-glandular tail.

Nyctinomus Bemmeleni Jentink, 1879

p. 125

Nyctinomus Bemmeleni , n. sp.

Dentition, Inc. $^{2}/_{4}$, c. $^{1-1}/_{1-1}$, p. m. $^{2-2}/_{2-2}$, m. $^{3-3}/_{3-3}$.

At a glance this species is distinguished from all the other species of the genus *Nyctinomus* by the length of the metacarpal bone of the third and the fourth finger, by the peculiar manner in which the interfemoral membrane and the wings are attached to the tibiae , and by the very long end of the tail free from the membrane.

Muzzle as in the other species; upper lip very expansible and thick, deeply grooved by vertical wrinkles.

Ears united by a low band in front, but connected by the bases of their inner margin, which form a sharp angle. Earconch triangular, rounded towards the tip, the inner and outer margins being oval. Tragus also triangular, very small. Antitragus well developed, broad, obtusely rounded towards the top, with a large base, separated from the earconch by a very deep notch.

The female possesses no gular sac.

p. 126

In the other species of the genus *Nyctinomus* the forearm always exceeds in length the metacarpal bone of the third and the fourth finger: in our species, however, the case is just the contrary, for the metacarpal bone of the third finger exceeds the forearm and that of the fourth finger equals the forearm in length.

Comparatively the tail is not longer than in the other species, but its part included in the interfemoral membrane is particularly short and therefore the free end of the tail is extraordinarily long.

In the other species of this genus according to rule the wings are attached to the outside of the tibiae or ankles, and the interfemorale membrane to the inside. Now in the species in question the wings and the interfemoral membrane proceed from the same point, to be found on the middle of the tibia just between the out and inside.

The thumbs, the first and the fifth toe are very thick; especially the latter, and further the other toes are ornated with long rigid, white colored, overhanging hairs - as commonly in the other species of this genus.

Fur dark smoke-brown above, yellowish brown beneath. Ears, wings and tail colored as the back.

Upper incisors well developed, close together, separated from the canines by a rather large interval. Lower ones very little, bifid, crowded. First upper premolar very small, acute, not filling up the space between the canine and second premolar: first lower premolar about half the size of the second premolar.

Type in the Leyden Museum.

Measures of the single specimen, being a female, preserved in alcohol.

Hab. Liberia.

Mr. A. A. van Bemmelen, Director of the Zoological Gardens at Rotterdam has been so kind as to present this curious Bat to the Leyden Museum: I therefore propose to name it in honor of its donor.

Nyctinomus bivittatus Heuglin, 1861

p. 13

Medius, auriculis apice vix rectangulare, fronte connatis; trago acuminato brevissimo; taenia frontale aures conjungente distinctissima, medio plica antice producta (projectione W-forme) - calcaneo indistincto, patagio interfemorale et lumbare circumdato; pollice intus disco orbiculare instructo; parte basale ($^1/_4$) caudae patagio vestita, antice pilis rigidiusculis. - Dent incis. Utrinque $^1/_2$, supra obtusis, subtus bi-cuspidibus minimis; caninis inferioribus apice vix cestiforme simpliciter incisa; molaribus utrinque duabus incurrentibus mandibulae. - Corpore supra obscure umbrino; pectore paulo pallidiore; abdomine fulvescente, regione femorale ferrugineo-ventre medio griseo indutis; vittis duabus occipitalibus albis; humeris, pectoris lateribus et regione subauriculare delicate albido stictis; labio maxillare, auriculis et patagio nigricantibus, mandibula pallidiore, vix carnicolore, nuda.

Dieser weitläufigen Diagnose habe ich beizufügen, dass die mittelgrossen Ohren 6 - 7 deutliche Querfalten zeigen; der Gaumen deren 5, und eine sechste minder entschiedene. Der sehr kurze, weit hinabgerückte *Tragus* mit seitwärts und nach aussen gebogener Spitze. Nasenlöcher wenig röhrenförmig aufgesetzt, seitlich geöffnet, durch eine kleine behaarte Furche getrennt. Die Lippen sehr faltig, die obere am Rande gekerbt; der Unterkiefer fast kahl und fleischfarb, weit zurücktretend, im Kinn mit rundlicher Vertiefung. Obere Eckzähne mit erhabenem Kronrande und einer die Spitze nicht erreichenden Furche auf der Vorderseite, die unteren mit starkem Höcker gegen die Schneidezähne hin und sie, an Grosse weil überragend. Im Unterkiefer kann ich 2 falsche Backen-

p. 14

zähne unterscheiden. Am Fusse reicht die Flughaut bis unter die Mitte der *Tibia*, der Schwanz fast zu $^3/_4$ frei, innen, so weit er im *Patagium interfemorale* steckt, wenig aber rauh behaart: letzteres ist heller als die übrige Flughaut, ins Bläulich-fleischfarbe spielend, innen dicht mit weisslichen Hautwärzchen besetzt; die Zehen mit borstigen Haaren auf dem Nagelgliede und Hände der innersten und äussersten. Die Flughaut in den Winkeln, die der Oberarm an seiner Basis mit ihr bildet, behaart. Auf der Vorder- und Hinterseite des Ohres etwa parallel mit seinem Innenrande ein behaarter Streif, der namentlich auf der Rückseite sehr deutlich ist und nach der Basis zu breiter wird. Am Daumenballen eine runde, etwas erhabene hornige Platte oder Scheibe. Occiput, Rücken, Kehle und Halsseiten umbrabraun, die beiden letzferen etwas heller; Unterleib bräunlich-grau, nach den Seiten etwas rost-röthlich angeflogen. Hinter der Ohrbasis längs des Ober- und Hinterkopfes jederseits ein schmaler, weisser Streif; Schultern, Brustseiten und Kehlmitte, sowie die untere Basis des Ohres fein weissgescheckt. Ganze Länge des alten M 4", davon kommen auf den Schwanz 1" 5"'; Ohr 8"' hoch, Vorderarm 1" 10"', Flugweite $12^1/_2$". Das F ziemlich schwächer. Ein jüngeres M ist auf der Oberseite mehr dunkel-rothlich-braun, die weissen Streifen an den Occiputseiten weniger deutlich entwickelt. Die unteren Eckzähne spitziger und an der Spitze selbst noch nicht gekerbt.

Diese Art trafen wir unfern Kérén mit einbrechender Dämmerung zuweilen zu 3 - 4 Individuen längs Regenbeeten und Hochbäumen hinziehend.

Nyctinomus Bocagei Seabra, 1900

p. 84

5 M, 1 F ad., Galanga, Angola. Anchieta; (alc. coll. d'Afr.).

Um grande numero de particularidades que procuraremos evidenciar distinguem esta especie de todas aquellas que temos observado e de que conhecemos a descripção. As orelhas obedecerem ainda aos caracteres do grupo das especies até aquí citadas e descriptas: separadas nas suas bases, opacas, com um engrossamento na sua base proximo da orla esterna, occupando o terço inferior d'esta e separada do anti-íragus por um profundo sulco. São bem desenvolvidas, de forma um pouco irregular, angulosas e guarnecidas anteriormente por uma serie rnuiío pronunciada d'aquellas lacineas tegumentares cuja ausencia citámos para, auxiliar a distincção do *Nyctinomus brunneus*. Anti-tragus pequeno, semi-ovoide como nas outras especiies; tragus quadrado e mais estreito. As rugas anteriores dos labios profundissimas, particularmente as duas medianas; as narinas salientes; sacco gular indistincto. Pello abundante, mesmo sobre as orelhas, que cobre em grande parte; pardo escuro sobre o dorso, pouco amarellado, e, segundo a re-

p. 85

gra, mais claro na região ventral. A sua distribuição sobre as membranas é semelhante áquella que temos observado nas outras especies, sómente é mais escasso na ante-brachial superior, nullo pela parte inferior d'esta, contrariamente á ínter-femoral, onde é bastante abundante pela parte inferior e quasi nullo pela parte superior, excepto junto á base da cauda. As apophyses cartilaginosas do calcaneum approximando-se notavelmente da cauda, que é delgada e curta. Os pellos que guarnecem os dedos nos pés estendendo-se sobre o rebordo da ínter-femoral até mais de metade da apophyse cartilaginosa do calcaneum, diminuindo gradualmente de comprimento.

Dentição: in. $^{1}/_{2}$ c. $^{1}/_{1}$ pm. $^{2}/_{2}$ m. $^{3}/_{3}$. Na maxilla superior os incisivos bastante convergentes; caninos bem desenvolvidos e pouco curvos; primeiro premolar muito pequeno e ao meio do espaço deixado entre o canino e o segundo premolar; este bem desenvolvido e excedendo notavelmente os molares, que são normaes. Na maxilla inferior os incisivos são bilobados e os restantes dentes não offerecem tambem nada de particular. O paladar concordando aínda com o typo generico.

Dimensões: cabeça e corpo 64 mill.; cauda 30; parte livre 13; cabeça 20; orelha (da base do anti-tragus á orla superior) 15; tragus 4 X 1.5; ante-braço 45; pollegar 4; terceiro dedo: metacarpo, 43; primeira phalange 18; segunda 22; quarto dedo: metacarpo 41; primeira phalange 14; segunda 10; quinto dedo: metacarpo 26; primeira phalange 12; segunda 6; tibia 13; pé 7.

Procurando ligar a todas as valiosas collecções do Museu de Lisboa o nome do seu Fundador, determinamos como fica esta nova especie.

p. 84

A large number of features were sought for evidence to distinguish this species from all those we have seen and whose descriptions we know. The ears still obey the characters of the group of this species which have been cited and described: separated at the base, opaque, with a thickening at the proximal base of the edge of the esterna, occupying a third of the lower esterna and separated from the anti-tragus by a distinct groove. They are well developed, somewhat irregular, angular and finished anteriorly by a series of many pronounced tegumental lacineas whose absence we have mentioned, assists in the distinction of *Nyctinomus brunneus*. Small anti-tragus, semi-ovoid like those in other species; square tragus and more narrow. The anterior wrinkles of the lips are deep, particularly the two medians; protruding nostrils; distinct gular pouch. A lot of hair, even on the ears, which covers the most part; dark brown on the back, yellowish, and, second to the rule,

p. 85

lighter on the ventral region. The distribution on the membranes is similar to that which we have observed on other species, only that it is scarcer on the top of the anti-brachial, no hair on the lower part, contrary with the inferior-femur, where there is an abundance of hair on the lower part and almost no hair on the top part, except near the base of the tail. The cartilaginous apophyges approaches noticeably from the tail, which is thin and short. The hairs which cover the toes of the feet extend over the inter-femoral rim to more than half of the calcaneum cartilaginous apophyse, gradually shortening in length.

Dentition: in. $^{1}/_{2}$ c. $^{1}/_{1}$ pm. $^{2}/_{2}$ m. $^{3}/_{3}$. On the superior maxilla the incisors are very convergent; the canines are well developed and slightly curved; first premolar is very small and until the middle of the space left between the canine and the second premolar; well developed and significantly exceeding the molars, which are normal. On the inferior maxilla the incisors are bi-lobed and the remaining teeth do not offer anything in particular. The palate corresponds with the genus type.

Measurements: head and body 64 mill.; tail 30; free part 13; head 20; ear (from the base of the anti-tragus to the superior edge) 15; tragus 4 x 1.5; forearm 45; thumb 4; third finger: metacarpal, 43; first phalange 18; second 22; fourth finger: metacarpal 41; first phalange 14; second 10; fifth finger: metacarpal 26; first phalange 12; second 6; tibia 13; foot 7.

Trying to connect all the valuable collections of the Museum of Lisbon to the name of its Founder, we determined how this new species fits in.

Nyctinomus brunneus Seabra, 1900

p. 83

a,b,c. 2 MM e 1 juv. Quissange, Angola, Anchieta; (alc. coll. d'Afr.).

A primeira vista distingue-se esta especie da precedente pela côr de um pardo muito escuro das suas membranas. Mais particularmente é assim caracterisada: orelhas separadas, redondas, *lisas no rebordo anterior e posterior*, ísto é, desprovidas d'aquella serie de pequenas lacineas tegumentares que caracterisam grande numero das especies d'este genero; anti-tragus semi-ovoide mediocremente desenvolvido, separado da orelha por um distincto sulco; tragus quadrado e bem desenvolvido; o

labio superior finamente rugoso proximo da commissura, seguindo-se-lhe tres pregas distinctas e irregulares nas proximidades das narinas; sacco gular do macho indinsticte. Membrana

p. 84

das azas partindo quasi do meio da tibia. Pello abundante, bastante longo, avelludado sobre o dorso, e mais particularmente o da cabeça, que se estende muito sobre as orelhas, onde toma uma brílhante côr de sepia; o do dorso e mesmo o da região occipital é mais claro em consequencia da côr amarellada das extremidades dos pellos; aquelles que cobrem aínda superiormente as azas junto ao dorso, bem como as membranas brachial e ínter-femoral, são como ñas orelhas de côr de sepia. Pela parte ventral é mais claro, mais acinzentado e mais grosseiro; notavelmente longo no pescoço, disíribuindo-se aínda ñas membranas tambem, bastante longo e abundante junto do ventre; na interfemoral menos abundante que nas especies já descriptas.

A dentição, muito semelhante á da especie precedente, distingue-se comtudo na maxilla superior pelos incisivos, menos desevolvidos, contrariamente aos caninos, muito mais longos que n'esta outra especie, e pela posição do primeiro premolar, que se encontra encostado ao segundo, ao passo que no *Nyctinomus Anchietæ* está ao meio do espaço deixado entre este dente e o canino. Na maxilla inferior os incisivos, em consequencia do pequeño espago que existe entre os caninos, acham-se irregularmente dispostos, mas symetricos; estes são bilobados como nas outras especies e em numero de quatro. O paladar concordando com o typo do genero já descripto.

Dimensões: cabeça e corpo 78 mill.; cauda 43; parte livre 26; cabeça 25; orelha (da base do anti-tragus á orla superior) 17; tragus 4.5 x 3.5; ante-braço 52; pollegar 5; terceiro dedo: metacarpo 56, primeira phalange 20, segunda 26; quarto dedo: metacarpo 52, primeira phalange 17, segunda 9; quinto dedo: metacarpo 30, primeira phalange 14, segunda 7; tibia 16; pé 7. Os pellos que guarnecem os pés são pouco abundantes e curtos.

p. 83

At first sight this species can be distinguished by the dark brown colour on its wing membranes. More particularly are the following characteristics: separated ears, round, *smooth at the anterior and posterior edge*, this is lacking from the series of small mucocutaneous lacineas which characterise a number of species of this genera; semi-ovoid anti-tragus which is underdeveloped, separated from the ear by a distinct groove; square tragus which is well developed; the lip is finely wrinkled near the commissura, followed by three distinct and irregular folds near the nostrils; the gular pouch of the male is distinct.

Membranes…

p. 84

of the wings start almost from the middle of the tibia. Abundant hair, very long, velvety on the back, more particularly that of the head, which extends over the ears, where the hair becomes a brilliant sepia colour; the hair on the back and occipital region is more clear in contrast with the yellow colour of the ends of the hair; those covering the wings and the back, as well as the brachial membranes and inter-femoral, are a sepia colour as in the ears. On the ventral part it is lighter, more greyish and coarse; noticeably longer on the neck, distributed on the membranes as well, very long and abundant together with the belly; less abundant on the inter-femoral than on species already described.

The dentition, very similar to that of the preceding species, distinguishes itself by incisors on the upper maxilla, less developed, contrary to the canines, much longer than the other species, and by the position of the first premolar, which is against the second, whereas in *Nyctinomus Anchietae* it is in the middle of the space left between this tooth and the canine. On the lower maxilla the incisors, in consequence with the small space between the canines, they are irregularly organised, more symmetrical; these are bi-lobed like in other species and in numbers of four. The palate corresponds with the type of genus described.

Measurements: head and body 78 mill.; tail 43; free part 26; head 25; ears (from the base of the antitragus to the superior edge) 17; tragus 4.5 x 3.5; forearm 52; thumb 5; third finger: metacarpal 56, first phalange 20, second 26; fourth finger: metacarpal 52, first phalange 17, second 9; fifth finger: metacarpal 30, first phalange 14, second 7; tibia 16; foot 7. There is not a lot of hair covering the foot, and these hairs are short.

Nyctinomus cisturus Thomas, 1903

p. 502

A medium-sized species, with imperfect premaxillæ, united ears, and a peculiar swollen gland at the base of the tail.

P. 503

Ears thin, united at their bases, but not forming a prominent folded lobe at their junction; their anterior edge evenly but slightly convex, not folded back, without minute warts; tip broadly rounded off; outer edge strongly convex; antitragus high, broadly triangular; keel low, not flattened or thickened externally; tragus minute, triangular. Lips with vertical wrinkles. Apparently no gular sac. Pad at base of thumb not specially large. Wings to the distal third of the tibiae, on their inner aspect. Tail involved in membrane for about three fifths of its length; at its base, on the upper surface, occupying the middle of the interfemoral area, there is a large glandular swelling, 8 millim. Long by 6 broad, covered with fine fur; this swelling is caused by the presence of a pair of glands, presumably of a scent-secreting nature, which open on the under surface of the interfemoral by two large mouths, each over 3 millim. In length, placed diagonally on the two sides of the tail some 5 millim. Behind the anus; the area round these mouths well covered with fine silky white hair; internally some sort of dark-coloured glandular secretion is present.

Colour above chocolate-brown, rather paler below, the tips of the belly-hairs greyish. Wings and interfemoral membranes above brown, below brown outside of the elbow, white near the body and on the interfemoral.

Skull rather small in proportion, smoothly rounded, a low median crest present running from the level of the intertemporal constriction to the occiput. Premaxillæ imperfect mesially, but the opening between them unusually small.

Incisors $^{2}/_{4}$, the upper slender, not far apart, nearly parallel. Anterior upper premolar small but not crowded, standing in the line of the tooth-row, its conical point higher than the cingula of the neighbouring teeth.

Dimensions of the type (measured in the flesh): -

Forearm 47 millim.

Head and body 63; tail 35; ear 15 ; tragus 1.3; height of antitragus 2.2; third finger, metacarpal 46, first phalanx 19, second phalanx 18; fifth finger, metacarpal 27, first phalanx 14, second phalanx 5; lower leg and foot (s.u.) 24.

Skull: greatest length 18.1; basal length in middle line 13.8; zygomatic breadth 11.2; anteorbital breadth 6.5; constriction 3.7; mastoid breadth 10.3; front of canine to back of m^3 6.8; front of lower canine to back of m_3 7.1.

Hab. Mangala, on the east bank of the Nile, 25 miles N. of Gondokoro.

Type. Adult male. B.M. no. 2.7.4.4. Original number 2805. Collected and presented by W. L. S. Loat, Esq.

p. 504

This bat differs from all known members of the genus by its possession of the unique caudal gland above described. In other respects it is a true *Nyctinomus*, belonging to the typical group with imperfect premaxillæ.

Nyctinomus Condylurus A. Smith, 1833

p. 54

Nyctinomus Condylurus, (Knob-tailed Nyctinome). Fur very short and silky; above the surface colour is brown beneath dull tawny white, verging upon dull brown on the sides; ears black and rounded at tips, each with a narrow stripe of fur on its outer surface, extending from the base almost to the circumference; lips with four or five deep furrows; wing membranes blackish brown; interfemoral membrane enveloping more than half of the tail, above it is thinly covered with short fur towards its base and below till near its posterior marging tail enlarged and wrinkled at the point. Length from nose to base of tail about three inches, the latter an inch and a half. - When the fur is reversed the hairs of the back and sides are found to be tawny towards their bases; those of the middle of the body beneath dull brown.

Inhabits South Africa, - about Port Natal.

Nyctinomus demonstrator Thomas, 1903

p. 504

A medium-sized thick-set species with united premaxillæ, conjoined ears, and small scent-glands on each side of the penis.

Ears rather small, rounded, united at their inner bases for a height of about 2.5 millim., but without any folded lobe: keel slightly thickened in lower third; antitragus higher than long, rounded above, with a broad base; tragus minute, broader above than below, with an incurved upper angle and concave anterior margin. Lips wrinkled. No gular sac. Pad at base of thumb rather small. Wings to the distal third of the tibia. Tail involved in membrane for about half its length. Penis unusually short, or at leas appearing short, as it projects by its tip only from the swollen mass of a pair of scent-glands surrounding its bas, their two openings separated by a narrow septum situation halfway along the penis on its lower surface.

Fur very short and close, that on the forehead behind the junction of the ears appearing to be suffused with some oily secretion.

Colour dark brown above, more blackish on head; below also brown, the median area more greyish brown. Wing-membranes brown above and below; interfemoral membrane brown above, whitish below.

Skull low, stout and strong; brain-case small; muzzle narrow. Median crest not developed except in the interorbital region; premaxillæ united round the small palatine foramina. Upper incisors long, straight, almost parallel, not far apart; lower incisors four, bilobate, the outer pair rather smaller than the inner; anterior upper premolar present, but exceedingly minute, placed in the outer angle between the canine and large premolar, which touch one another.

Dimensions of the type (measured in spirit): -

Forearm 44 millim.

Head and body 64; tail 32; ear 17; tragus 2.0; height of antitragus 3; third finger, metacarpus 43, first phalanx 18, second phalanx 18; fifth finger, metacarpus 27, first phalanx 12.4, second phalanx 5; lower leg and foot (s. u.) 22.

Skull: greatest length 19.7; basal length in middle line 15.8; zygomatic breadth 12.7; anteorbital breadth 7; con-

p. 505

striction 3.8; mastoid breadth 11.6; front of canine to back of m^3 7.5; front of lower canine to back of m_3 8.5.

Hab. Mangala, N. of Gondokoro.

Type. Adult male. B.M. no. 2.7.4.3. Collected and presented by W. L. S. Loat, Esq.

I cannot find any known species to which this *Nyctinomus* can be assigned. None of Heuglin's show any relation to it, even apart from the peculiar gland above described, which he might have overlooked. It is curious that the two Mangala species should each be distinguished by a glandular structure unique of its kind.

Nyctinomus dubius A. Smith, 1833

p. 54

Nyctinomus dubius. (Caffer Nictinome.) Fur rather long; above the surface colour is a dull deep brown, beneath a light tawny brown inclined on the sides to blackish brown. Ears brownish black and pointed; wing membranes dull black with a faint brownish tint; interfemoral membrane enveloping nearly two-thirds of the tail, the last third very slender and pointed; hairs on the feet dull white; furrows of upper lip very indistinct. Length from nose to base of tail about two inches, of tail an inch and a half. - On the back, each of the hairs is tawny white towards its base; beneath towards the middle of the body, tawny white throughout; on sides tawny white towards the base.

Inhabits South Africa, - between the Cape Colony and Natal.

Nyctinomus Emini de Winton, 1901

p. 40

Ears united by a broad band, probably as in *N. pumilus*.

Size rather larger than *N. pumilus* and *N. limbatus*. General colour dark sooty brown, the centre line of the belly grey or pure white; a tuft of snow-white hair is also found at the base of the humerus, and these white hairs continue

p. 41

down the side to the groin. The ears, face, and entire wing-membranes are black.

Forearm 43 millim.

Type B.M. No. 90.6.8.15, M. Mosambiro. Collected by Dr. Emin.

It is impossible to give a detailed satisfactory description of bats from dried skins.

Skull broader than that of *N. limbatus*, but not so broad as that of *N. major*, and distinguished from both by its prominent preorbital processes. The premaxillæ are joined, but are less perfectly ossified than in the allied species. The upper incisors are close together and parallel; the upper premolar is not in any way crowded, directly in the toothrow. Lower incisors not markedly bifurcate.

Nyctinomus fulminans Thomas, 1903

p. 501

General characters of *N. africanus*, Dobs., but with whitish belly and conspicuously smaller skull.

Size large, though rather smaller than in *africanus*. Ears

p. 502

large, evenly rounded, rising from the same spot on the muzzle; their anterior edge with four or five minute and inconspicous warts; their keel moderatly developed, not broadened or folded externally; antitragus as in *africanus*; tragus large, quadrangular, with rounded corners; a small angular projection present halfway down its outer margin. Wings to the ankles. Callosity at base of thumb unusually large. No gular sac.

Colour of body above dark chestnut-brown; below brown laterally, the median area of throat, chest, and belly white, becoming rather browner distally.

Skull smaller and conspicuously narrower than in *N. africanus*. A median crest developed along parietal suture, more developed than in *africanus*, but disappearing on interparietal, where the bone is smooth and transparant. Anteorbital and mastoid projections comparatively little developed. Premaxillæ incomplete mesially. Incisors $^{2}/_{4}$. Anterior upper premolar small, in general line of the tooth-row.

Dimensions of the type (measured in spirit): -

Forearm 60 millim.

Head and body 80; tail 53; ear 22; tragus on outer edge 7, breadth 4; height of antitragus behind 4; diameter of pollical callosity 3.2; third finger, metacarpal 57, first phalanx 25, second phalanx 7; lower leg and foot (s.u.) 28.

Skull: greatest length 22.5; basal length in middle line 17.7; zygomatic breadth 14; anteorbital bfreadth 8.5; interorbital constiction 4.7; mastoid breadth 13.2; front of canine to back of m^3 8.; front of lower canine to back of m_3 10.

Hab. Fianarantsoa, E. Betsileo, Madagascar.

Type. Male. B.M. no. 82.3.1.34. Collected by the Rev. W. Deans Cowan.

This is the "rather smaller, white-bellied, and light-winged form" of *N. africanus* referred to in Mr. de Winton's paper on the group. It is, I think, fully distinct enough to be separated specifically, as the skull-differences are very strongly marked, in additional to those of colour and locality.

Nyctinomus gambianus de Winton, 1901

p. 39

Much resembling *N. limbatu* in size and general appearance, but differing in having the lower parts uniform brown. The skull also closely resembles that of the East African species; but in this new bat the first upper premolar is only vestigial, so small, indeed that it is not possible to see it without the aid of a strong lens. This minute tooth is placed close against the canine, in the outer angle formed by the .... meeting of the canine and second premolar. The first lower premolar is also smaller in this species.

Forearm 37 - 38 millim. (type).

The males are not furnished with the crest of long hair on the back of the membrane connecting the ears, which is such a characteristic feature in *N. limbatus* from E. Africa.

Gambia, Lagos, Nigeria.

Type, M, B.M. No. 89.10.7.3. Gambia. Collected by Dr. Percy Rendall.

A specimen referable to this species formed the basis of Dobson's description of *N. pumilus*.

Nyctinomus hindei Thomas, 1904

p. 210

A whitish-winged member of the *N. pumilus* group.

Essential characters of ears, tragus, skull, &c., apparently as in *N. limbatus*, Peters. A marked tuft of brown, hairs behind the joining membrane of the ears.

Colour of upper surface chocolate-brown, finely flecked with white; the bases of the hairs (which attain about 4 - 4.5 mm. in length) rather lighter. Under surface brown, more or less washed superficially with whitish, especially along the middle line of the belly; a creamy white line edging the junction of the wings with the flanks. Ears, forearms, hind limbs, and interfemoral membrane dark brown. Wing-membranes near the body whitish brown, paling to white on the middle part of the wing, and darkening again at the tips to brown.

Skull about as in *N. Emini*, though with less marked preorbital processes. Small upper premolar outside the middle line of tooth-row, less crushed than in *limbatus*, more so than in *Emini*. Middle lower incisors deeply bifid.

Dimensions of the type (measured in skin): -

Forearm 40 mm.

Head and body (c.) 61; tail 35; thumb close to membrane 6; third finger, metacarpal 39, 1st phalanx 15.5; fifth finger 39.

Skull: greatest length 17.6; basal length 14.6; zygomatic breadth 11.4; front of canine to back of m^3 6.7.

Hab. Fort Hall, Mt. Kenya district, British East Africa. Alt. 4000 feet.

Type. Adult male. B.M. no. 3.3.2.4. Original number 134. Collected 1st Jan., 1903, and presented by Mrs. Hinde. Two specimens.

This *Nyctinomus* is most closely related to *N. Emini*, de Wint., of Usambiro*, German E. Africa, but differs by its whitish wings and more closely crushed upper premolars.

* Not Mosambiro, as accidentally printed in the original description, Ann. & Mag. Nat. Hist. (7) vii. p. 41 (1901).

Nyctinomus leonis Thomas, 1908

p. 373

Nyctinomus leonis, sp. n.

Nyctinomus brachypterus, Peters, Dobson, P. Z. S. 1878, p. 722; Cat. Chir. B.M. p. 426 (1878) (*nec* Peters, Reis. Mossamb., Säug. p. 59, pl. xv. fig. 1, 1852).

External characters as described by Dobson.

Skull of the high, not flattened *Nyctinomus* type, with well-marked median crest; emargination between premaxillæ very narrow, about 0.75 mm. in greatest breadth. Four lower incisors.

Measurements of type: -

Forearm 37.5 mm. (For other external measures, see Dobson.)

Skull: greatest length 19.4: basal length 15.5; zygomatic breadth 12.1; intertemporal breadth 4; mastoid breadth 11.3; palatal length 8; front of canine to back of m^3 7.

Hab. West Africa. Type from Sierra Leone. Other specimens from Fernando Po (*Capt. Downes*), Cameroons (*C. Bovallius*), and French Congo (*G. L. Bates*).

Type. Adult male skin. B.M. no. 62.12.23.3. Specimen *c* of Dobson's catalogue. Presented by J. Brown, Esq.

p. 374

This species, referred to *N. brachypterus* by Dobson, is evidently not that described by Peters, for the skull of the latter is no less than 21.5 mm. in length, while the typical skull of *N. leonis*, 19.4 mm. long, is the largest of the five skulls of the western form examined by me.

On the other hand, Dr. Jentink's *N. bemmeleni* from Liberia has, as he has been so good as to inform me, a skull onty 16.5 mm. in total length, with a tooth-row length of just 6.0 mm.

Nyctinomus leucogaster A. Grandidier, 1869

p. 337

Nyctinomus leucogaster

Parties supérieures d'un brun foncé, ainsi que la gorge et la poitrine. Abdomen blanc. Ailes médiocres à membrane blanchâtre. Les deux incisives supérieures sont fortes et pointues; les quatre inférieures sont très-petites. Lèvres très-fendues et ridées; la supérieure est fort développée. Oreilles larges, réunies par leur base et penchées en avant; elles naissent à l'angle des lèvres; l'oreillon est court et extérieur. Les deux doigts externes des pieds sont plus forts que les autres et garnis de poils longs. Queue longue et enveloppée dans la membrane interfémorale dans sa première moitié seulement.

Envergure, 21^c 1/2. Long. du nez à l'extrémité de la queue, 8^c 1/2. Long, des oreilles, 14^{mm}; et larg., 13^{mm}. Long, de la queue, 3^c.

Hab. Mahab, au Ménabé.

p. 337

Nyctinomus leucogaster

Upperparts of a dark brown, as well as the throat and chest. Abdomen white. Wings mediocre with whitish membrane. The two upper incisors are strong and pointed; the four inferiors are very small. Lips Very split and wrinkled; the superior is highly developed. Ears wide, united by their base and bent forward; they are born at the angle of the lips; the tragus is short and outward. The two outer fingers of the feet are stronger than the others and have long hairs. Tail long and wrapped in the interfemoral membrane for its first half only.

Wingspan, 21[c] 1/2. Length from the nose to the end of the tail, 8[c] 1/2. Length ears, 14[mm]; and width, 13[mm]. Length tail, 3[c].

Hab. Mahab, at the Menabe

Nyctinomus lobatus Thomas, 1891

p. 303

Nyctinomus lobatus, sp. N.

Allied to and of the same size as *N. tæniotis*, Raf. (*N. Cestoni*, Savi), but distinguished by its much larger ears, tragus, and antitragus, by the thinness of the ear-membranes and keel, and by its belly being pure white. Forearm 63 millim.

Hab. Turquel, Sük, inland British East Africa. Coll. F. J. Jackson, Esq.

A more extensive description was made in Thomas (1891b): 1. On a collection of small mammals made by Mr. F. J. Jackson in Eastern Africa -
Proc. Zool. Soc. Lond., 1891, II: 181 - 187 (which according to Duncan (1937: 74) was published in August 1891):

Nyctinomus lobatus, sp. N. [1]
a. ?. Turquel, Sük. 1/90. *Type*.

Allied to *N. cestoni*, Savi, or rather *N. tæniotis*, Raf., as it ought to be called, and to *N. africanus*, Dobs.; but distinguished from both by its larger ears, larger tragus, higher antitragas (fig. p. 183), and coloration, while in other respects it agrees sometimes with one and sometimes with the other, and forms in some respects a connecting-link between them.

Ears very large, rounded, laid forward they extend quite a quarter of an inch beyond the tip of the muzzle; their inner bases united on the muzzle; their substance comparatively thin and transparent; keel of the conch scarcely thickened below ; antitragus very high

p. 183

posteriorly, the notch behind it more than 5 millim. Deep, as compared to about 3 millim. In the two allied species. Tragus large and broad, quadrangular, its tip sharply angular, and its outer upper border long and straight. Lips apparently not deeply wrinkled. Gular sac apparently present. Pads at base of thumb distinct. Lower incisors 4. Colour everywhere above, and on the chin, shoulders, and sides of thorax below dark brown ; chest, belly, base of tail, and thighs to below knees pure white.

Dimensions: - Head and body 77 millim., tail 56; tail free from membrane 30 ; ears, length from base of post-antitragal notch to tip 30; forearm 63 (=2-47 in.).

This fine new Bat is distinguished at once from all the other species of the genus, except *N. miarensis*, Grand., and the two above-mentioned, by its much greater size, none of them having a forearm exceeding two inches in length. *N. miarensis* is at once separated by its structural characters and is not really allied to *N. lobatus*. Of the two species to which it is allied, *N. africanus* is a native of the Transvaal, and *N. tæniotis* of Abyssinia, extending northwards over a great part of the Palæarctic region: the new form is therefore intermediate between them in habitat as in many of its characters; but there can be no question as to the specific distinctness of all three.

[1] Preliminary descriptions of the new species were published in Ann. & Mag.
N. H. (6) Tii. P. 303 (1891)

Nyctinomus martiensseni Matschie, 1897

p. 84

In der Grösse übertrifft diese Fledermaus noch *N. africanus* Dobs und *cestoni* Savi, ebenso wie *lobatus* Thos. Sie unterscheidet sich von allen übrigen afrikanischen Arten durch die ungeheuer grossen Ohren, bei denen Tragus und Antitragus vollständig verkümmert sind. Praemolaren $^{2-2}/_{2-2}$; Ohren ziemlich durchscheinend; der Kiel der Ohrmuschel sehr schmal; Tragus verkümmert; Antitragus nicht angedeutet; die Ohren sind über der Nasenmitte verwachsen; Lippen sehr fein gefurcht, dünn, überhängend; Gularsack vorhanden.

Färbung: rauchbraun; eine Binde über Hals und Oberrücken weisslich.

Körper: von der Schwanzspitze zum oberen Ohrrand: 135 mm; Schwanz vom After: 43; freie Schwanzspitze: 28; Länge des Ohres vom vorderen unteren Rande der Oeffnung bis zur Spitze: 37; Unterarm: 66 mm.

Eine genauere Beschreibung dieser sonderbaren Fledermaus werde ich demnächst gelegentlich der Herausgabe der Peters'schen Fledermaustafeln geben.

Herr Martienssen, dem das Kgl. Museum für Naturkunde schon eine grosse Reihe sehr seltener Arten aus Usambara verdankt, hat ein M dieser Art bei der Plantage Magrotto unweit Tanga im Handei-Gebiet im August d. J. gefunden

Nyctinomus mastersoni Roberts, 1946

p. 306

A member of the *N. africanus, fulminans* and *lobatus* group, in which the upper lips are not wrinkled, the skull not so flattened as in the *N. aegyptiacus* and *bocagei* group, size rather large, hair on the integument broadly present between the humerus and base of the forearm and extending thinly in a line parallel with, but a little distance from, the forearm; in the dentition, with the upper anterior premolar small, its cusps about level with the cingulum of the large premolar, and lying rather on the outer side but within the tooth row. In size it is practically the same as in *N. fulminans* Thomas (*Ann. Mag. Nat. Hist.* (7), XII, 501; 1903) of Madagascar, and therefore smaller than *N. africanus* Dobson (*Ann. Mag. Nat. Hist.* (4), XVII, 348; 1876), known only by the type from Transvaal, and *N. lobatus* Thomas (*Ann. Mag. Nat. Hist.* (6), VII, 303; 1891) of the Suk country, Kenya Colony. It differs from *N. fulminans* in having the white median line below not extending to the throat, where the hairs are for the greater part white, but with dark brown tips, the pure white hairs only distributed from the pubic region to the chest. The reddish brown or chestnut colour characteristic of both *N. africanus* and *N. fulminans* may prove to be inconstant, for although the type and two other specimens are dark chocolate brown above and below, in one other specimen the upper parts are more reddish brown, while still another is decidedly erythristic, the upper parts being reddish brown and the under parts of body suffused with a brighter reddish colour, which extends to the white hairs of the integument

p. 307

between the femur and humerus, toning outwards to light buffy on the edges; but this erythrism is not uniform, as there is a broad normal coloured brown line on the right-hand side of the body both above and below. Normal coloured specimens agree best with the description of *N. lobatus*, chocolate brown above and below, except for the white median line and white on the integument adjacent to the sides. *N. fulminans* is said to have minute warts on the anterior edge of the ears (a character seen in *N. aegyptiacus* and *bocagei*), but these are lacking in the specimens examined of this new species. The callosity on the thumb is large, as in *N. fulminans*, and the skull is similar in having a sagittal crest from the interorbital region to the occiput, and also in having preorbital processes very slightly developed; the interparietals are swollen and raised slightly above the level of the parietals; the dentition is apparently the same, the anterior upper premolar small, in the tooth row, but rather pushed outwards; the cingulum of the lower canine is very much developed so that the pair of canines are not far apart and push the lower incisors (of which there are two pairs) forward; the anterior lower premolar is only about half the height of the adjacent large premolar, the latter with the usual high outer anterior and pointed cusp. There are apparently no glands present, either on the chin, or near the root of the tail on the border of the integument as described of *N. cisturus*.

Type: T.M. No. 9976, adult M, Chikupo Caves, Masembura Native Reserve, Bindura district, Southern Rhodesia, collected and donated by Mr H. B. Masterson; also four more specimens.

Nyctinomus Miarensis A. Grandidier, 1869

p. 337

Nyctinomus Miarensis

Semblable au *N. leucogaster*, mais de plus grande taille. Parties supérieures brunes; parties inférieures grises. Queue enveloppée dans la

p. 338

membrane interfémorale dans son premier tiers seulement.

Envergure, 39^{c} 1/2. Long, du nez à l'extrémité de la queue, 12^{c} 1/2. Long. de la queue, 4^{c} (la partie libre mesure plus de 2^{c} 1/2). Long. des oreilles, 2^{c}. 3^{mm}; et larg., 2^{c}, 2^{mm}.

Hab. Miari, pays situé entre Soua-haze et Soua-hané.

p. 337

Nyctinomus Miarensis

Similar to *N. leucogaster*, but larger. Upperparts brown; underparts gray. Tail wrapped in the

p. 338

interfemoral membrane for its first third only.

Wingspan, 39^{c} 1/2. Length from the nose to the end of the tail, 12^{c} 1/2. Length of the tail, 4^{c} (the free part is more than 2^{c} 1/2). Length ears, 2^{c}. 3^{mm}; and width, 2^{c}, 2^{mm}.

Hab. Miari, a country situated between Soua-haze and Soua-hané.

Nyctinomus ochraceus J.A. Allen, 1917

p. 455

Type, No. 48821, F ad. (skin and,skull), Medje, March 16, 1910; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig, No. 745.

Ears thick, united at base in front. Coloration unusual for a molossid.

Above, superficially, dark chestnut-brown, the hairs ochraceous-buff basally, showing, more or less at the surface, especially on the shoulders and sides of the neck where it often gives the prevailing tone to the coloration; below orange, varying in tone in different specimens from pale to deep orange. A tuft of lengthened dark chestnut-colorod hairs on the front part of the crown behind the connecting membrane of the ears. Ears blackish brown. Membranes naked; wing membranes from upper part of tibia; face naked, browhish. Interfemoral membrane narrow, much more than half the tail free. Tragus small, narrow and pointed, a little higher than wide. Antitragus low, evenly rounded above, broader at base than high, about 5.5 X 4.5 mm.

Collectors' measurements of type: Total length, 105 mm.; head and body, 72; tail, 33; foot, 11; ear, 18. Forearm (in skin), 37.7.

Collectors' measurements of type and 10 topotypes; Total length, 103 (100-106); head and body,71.6 (68-73); tail, 31 (29-34); foot, 11 (all 11); ear, 17.5 (17-19).

Forearm, same specimens, 38 (37.3-39.3).

Skull (type), total length, 18.6; condylobasal length, 16.6; zygomatic breadth, 117.; mastoid breadth, 10.8; breadth of braincase, 9; maxillar breadth, 8.3; inter-

p. 456

orbital breadth, 4; breadth at base of canines, 5.6; length of upper toothrow (with canine), 6;7; length of mandible, 12.2; angle to condyle, 3.6; depth at coronoid, 3.1; length of lower toothrow, 7.4.

Skulls of type and 10 topotypes, total length, 18.8 (18.2-19.4); zygomatic breadth, 12 (11.4-12.5).

Braincase low and flat, sagittal and lambdoid crests slightly developed, the latter indicated only in old adults; preorbital process absent or barely indicated. Premaxillæ emarginate behind base of incisors. Upper incisors small; slightly convergent apically, widely separated from each other and the canines. First upper premolar very small, in midline of toothrow and not crowded between the adjoining teeth. Lower incisors 2-2, small, crowded in a convex row between canines. First lower premolar about half the size of the second. Coronoid process small and low, barely reaching the level of the condyles, and directed outward.

This striking species is represented by 22 specimens, 18 skins with skulls and 4 in alcohol, all taken the same day at Medje, and all adult. Only 4 are males, and of the 14 female skins, 11 are labeled as "carrying an embryo in right uterus." One of the alcoholic specimens is in poor condition, the ears and membranes being abraded and light colored, and the orange of the underparts is faded to pale yellow. This specimen was taken at first to represent a different but (owing to its condition) an unidentifiable species, and was so listed in this paper, but Mr. Lang assures me that this is one of the 22 specimens of *N. ochraceus* taken at Medje, all on the same day, and that its present abraded and bleached condition is due to bad preservation due to an accident in transportation.

Nyctinomus ochraceus appears to be related to *N. thersites* Thomas but it is smaller (forearm 38, in *thersites* 41; skull 18.8 X 12; in *thersites* 20 X 12.5), and the lower premolars are not subequal as in *thersites*. *N. thersites* is described as "colour dark brownish chestnut, the glandular hairs behind the junction of the ears black." This applies fairly well to the upperparts of *N. ochraceus*, except that the lengthened hairs behind the ears in males are not black but dark chestnut. It is hardly possible, however, that this brief description could apply if the lower parts had been ochraceous-orange, as in the species here described.

Nyctinomus pusillus Miller, 1902

p. 245

Nyctinomus pusillus sp. nov.

Type. - Adult female (in alcohol), No. 37852/20997(°) United States National Museum. Collected on Aldabra Island, Indian Ocean, by Dr. W. L. Abbott.

Characters. - Externally similar to *Nyctinomus pumilus*. Skull and teeth noticeably smaller than in the related species.

External features. - In size as well as in details of external form *Nyctinomus pusillus* agrees so closely with *N. pumilus*, as to need no description.

Skull and teeth. - The skull is similar to that of *N. pumilus*, except that it is smaller and more lightly built, the interorbital profile is more concave, the basisphenoid pits are better defined, and the interpterygoid space is relatively wider. Teeth much smaller than in *N. pumilus* and inner segment of upper molars relatively broader, so that the protocone and hypocone of the first and second are actually further apart than in the larger species.

Measurements. - External measurements of type: total length, 84; head and body, 53; tail, 31; tibia, 11; foot, 7.8 (7); forearm, 46.6; first digit, 6.4; second digit, 35; third digit, 70; fourth digit, 58: fifth digit, 34; ear from meatus, 15.4; ear from crown, 10; width of ear, 14.

p. 246

Cranial measurements of type: greatest length, 15 (16.6);* basal length, 13.4 (14.8); basilar length, 12.8 (13.4); zygomatic breadth, 9.2 (10); interorbital constriction. 3 (3.6); greatest breadth of braincase above roots of zygomata, 8 (8.4); lachrymal breadth, 5 (6); mandible, 10 (11); maxillary toothrow (exclusive of incisors), 5.6 (6.6); mandibular toothrow (exclusive of incisors), 6 (6.8).

Specimens examined. - Two, both from Aldabra. Island.

* Measurements in parenthesis are those of an adult male *Nyctinomus pumilus* from Massowa, Red Sea (No. 38933/15546).

(°) Poole and Schantz (1942: 120) mention "Type designated by No. 37852/20997, an error for 20991/37852".

Nyctinomus rhodesiae Roberts, 1946

p. 307

Seemingly related to *N. ansorgei* Thomas (*Ann. Mag. Nat. Hist.* (8), XI, 318; 1913) from Malange, Angola, in general characters of size, colour, skull and dentition, but lacking the 'partly naked patch on the crown behind the junction of the ears', which is thinly haired in this new form, and the naked patch 'across the nape just in front of the shoulders', of which there is no sign in the present form. There are no glands on the border of the interfemoral membrane at the base of the tail, but a small gular gland, surrounded by a few short hairs, is present in the middle of the naked area of the chin. Ears in contact at the base. The skull has the cranium slightly raised above the dorsal level, the premaxillae not in contact, a slight sagittal crest from the interorbital constriction to the occiput, and a well-developed process interorbitally, near the anterior corner of the orbits; the upper incisors lie parallel but not in contact, the upper anterior premolar in the tooth row and small, its height about equal to the level of the cingulum of the large premolar; the lower canine has a much developed cingulum, so much so that the canines are either very close together or actually (as in the type) in contact; the two pairs of lower incisors are therefore rather crushed and pushed forward; the anterior lower premolar is as large as the posterior premolar, or even, as in the type, rather larger, and its cusp nearly as high as that of the large premolar. The upper lips are wrinkled with a few short bristles on the ridges, the ears without nodules on the anterior upper edges and the tail protrudes for at least two-thirds of its length (tail length 36 mm., free portion 24 mm.).

In colour this species is like *N. ansorgei* in being dark brown above, the throat broadly blackish and the underparts of body paler than the upper, the tips of the hairs tending to be lighter coloured and even whitish in some specimens, and the integument at the femurs tending to be white. The chin is very sparsely haired, almost naked.

Type: T.M. No. 9977, adult M, Chikupo Caves, Masembura Native Reserve, Bindura district, Southern Rhodesia, collected and donated by Mr H. B. Masterson; also five more specimens from the same source.

p. 308

Measurements of the above two new species are as follows:

(4) *N. mastersoni*; (4) *N. rhodesiae*
Head and body: 80 - 85; 65 - 67
Tail: 55 - 57; 36 - 36
Free portion of tail: 26 - 28; 24 - 25
Ear: 20 - 23; 19 - 21
Tibia and feet, c,u,: 31 - 33; 23 - 24
Skull: greatest length: 22 - 23; 19 (1)
median dorsal length: 18.3 - 19; 16.5 (1)
basilar length: 17.2 (1); 15.2 (1)
zygomatic width: 13.2, 14 (2); 11.5 - 12 (3)
mastoid width: 12.7, 13 (2); 10.5 - 11 (3)
width of brain case: 11.5 (3); 10 (3)
anterior interorbital width: 7.1 - 8.5; 6.3 - 7.1
interorbital constriction: 4.5 - 5.2; 4.2 (3)
posterior median height: 7.8, 8 (2); 6.5 (1)
height at m^3: 8 - 8.5; 7 - 7.5
c-m^3 length: 8.5 - 9.2; 7 - 7.5
mandible length: 16 - 16.5; 13 - 13.4
c-m_3 length: 9.5 - 10.1; 8.1 - 8.5

Nyctinomus thersites Thomas, 1903

p. 634

A medium-sized species, with proportionally short limbs, united ears, separated premaxillæ, and very small lower cheek-teeth.

p. 635

Body large as compared with the short forearms and legs. Muzzle short, upper lip distinctly furrowed. Ears short, opaque, their tips broadly rounded; inner margins united at base; anterior margin without minute horny points; antitragus as high as long, with a deep notch behind it; keel thickened below, but not flattened externally. Tragus minute, almost linear; a separate, very distinct, external basal projection developed halfway between its outer base and the inner side of the antitragus. Fur short, close, and velvety; hairs of back barely $2^1/_2$ mm. long, tufts* of long hairs (about $^1/_2$ inch in length) placed on each side of the rump; fur contined to body throughout, except a narrow rim along each side below. Colour dark brownish chestnut, the glandular hairs behind the junction of the ears black. Penis projecting but little from the surrounding flesh, without special scent-glands. Premaxillæ separated, but the opening between them small; anteorbital crests scarcely developed; sagittal crest low; lambdoid crest strong, forming a prominent projection on each side of the middle line. Lower jaw unusually thick and heavy.

Upper incisors thick, vertical, parallel, well separated. Anterior premolar small, but standing in the tooth-row, and separating the canine from the large premolar. Lower incisors four, bifid, overlapping. Lower premolars very abnormal in being subequal, the anterior scarcely shorter than the posterior. Molars unusually low-crowned, their vertical height considerably less than that of the thick mandibular ramus.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 41 mm.

Head and body 75; tail 32; ear 17; tragus on inner edge 1.2; third finger, metacarpus 40, first phalanx 17, second phalanx 16; fifth finger, metacarpus 26, first phalanx 9, second phalanx 4; lower leg 15, lower leg and foot (s. u.) 23.

Skull: greatest length 20; zygomatic breadth 12.5; front of canine to back of m^3 7.3.

Hab. Efulen, Cameroons.

Type. Old male. Collected by Mr. Gr. L. Bates. Three specimens.

By Dobson's synopsis this bat comes near *N. pumilus*, but may be readily distinguished from that species by its larger size and the many peculiarities, external and cranial, described above.

* These tufts appear to occur in many species, though seldom so well developed as in the present animal.

Nyctinomus unicolor A. Grandidier, 1870

p. 49

Nyctinomus unicolor

d'un brun assez foncé, qui est a peine plus clair sous l'abdomen. Queue libre dans plus de la moitié de son étendue. Oreilles fort grandes, qui sont réunies sur le front par une petite membrane. Lèvres épaisses et larges.

Longueur totale, 13 cent.; de la queue, 42 cent.; de la partie de la queue enveloppée dans la membrane interfémorale, 15 mill.; envergure, 41 cent. 1/2.

p. 49

Nyctinomus unicolor

a rather dark brown, which is scarcely clearer under the abdomen. Tail free for more than half of its extent. Ears very large, which are united on the forehead by a small membrane. Lips thick and wide.

Total length, 13 cent.; tail, 42 cent.; part of the tail wrapped in the interfemoral membrane, 15 mill.; wingspan, 41 cent. 1/2.

Otomops icarus Chubb, 1917

p. 433

Otomops icarus, sp. nov.

Like *O. wroughtoni* and *martiensseni* in the essential characters of skull and ear structure, including the practically complete suppression of both tragus and antitragus.

Colour very much as in *O. martiensseni*, the fur of the top of the crown, above the bases of the united ears, similarly pale brown and the back of the head dark brown, both with whitish bases to the hairs, in contrast to the deep uniform blackish-brown of the same parts in *O. wroughtoni*. But as compared with *O. martiensseni* the prominent whitish mantle so conspicuous in that animal is almost obsolete and there is but little whitish on the front of the neck. Lower part of body both above and below, deep blackish-brown, very much as in *O. wroughtoni*.

Skull more elongate than in *wroughtoni* or in the Congo specimen of *martiensseni*. Prof. Matschie does not give any cranial dimensions in his original description of the latter species.

p. 434

Dimensions of Type.

Forearm 66 mm.

Head and body 88 mm.; tail 45 mm.; ear 38 mm.; fifth finger, metacarpal 34 mm., first phalanx 20 mm., second phalanx 8 mm.; lower leg and foot (s.u.) 30 mm.

Skull: greatest length 27 5 mm.; basal length in middle line 24 mm.; zygomatic breadth 14 mm.; anteorbital breadth 10 mm.; interorbital constriction 5.7 mm.; mastoid breadth 14 mm.; front of canine to back of m_3 11 mm.

Hab. Durban, found helpless in gutter, apparently as a result of collision with street electric light.

Type. Male.

Otonycteris Peters, 1859

p. 223

Zwei Exemplare dieser neuen Gattung befinden sich im zoologischen Museum, welche aus der Sammlung der Hrn. Hemprich und Ehrenberg stammen sollen. Sie hat durch den Bau der Ohren und des Ohrdeckels die gröfse Ähnlichkeit mit der Gattung *Plecotus* und war unter diesem Namen auch aufgestellt; jedoch sind die Nasenlöcher nicht nach hinten erweitert, noch auf der oberen Seite gelegen, sondern sie sind einfach sichelförmig und nach vorn gerichtet wie bei der Gattung *Vespertilio*. In der Gestalt des Schädels nähert sich diese Gattung am meisten den *Nycticejus* und ebenso stimmt sie auch hinsichtlich der Gestalt und Zahl der Zähne ganz mit *Nycticejus* (*planirostris* Pet.) überein: $^{3\,1}/_{3\,2}{}^{1}/_{1}/^{1\,1}/_{6}{}^{1}/_{1}{}^{1\,3}/_{2\,3} = 30$.

Otonycteris Hemprichii Peters, 1859

p. 223

supra albescenti-brunneus, subtus albus, alis dilute brunneis.

Long. tot 0.110; cap. 0.025; aur. 0.030; tragi 0.015; caudae 0.045; antibr. 0.058; exp. alar. 0.320.

Ist diese Art übereinstimmend mit Gray's *Plecotus Christii*?

Pachyotus Gray, 1831

p. 38

The Bats, the Vespertiliones of Geoffroy, might for convenience be divided into three genera, the true Bats, *Vespertilio*, with thin ears and membranes and a hairy face, the *Pachyotus* with thick ears and membranes and bald swollen cheeks, including the genera *Nycticejus* and *Scotophilus* and the hairy-tailed species of America, (*Lasiurus*.)

Petalia (Nycteris) thebaica aurantiaca de Beaux, 1923

p. 91

(N. 1432) Tipo 1 F, in alcool, cranio estratto. Archers Post, I.1920, L. FRANCHETTI e L. TONKER.

Stato di conservazione buono, astrazion fatta per un processo arrestato di dissolvimento dell'integumento in corrispondenza del carpo e di alcuni diti.

Rivestimento peloso abbondante e soffice; singoli peli lunghi 12 mm. tra le spalle. Colorazione generale arancio-ocracea (ocrhaceous orange, Ridgw. XV) con brillantezza aranciona (orange, III); i singoli peli lievemente più chiari alla base. Parti ventrali soltanto impercettibilmente più chiare delle dorsali. alla base dorsale di ciascun orecchio una indistinta mac-

p. 92

chia chiara color cuoio aranciato (orange buff, III). Tale colore hanno anche i peli sulla superficie ventrale della membrana alare in corrispondenza del $^1/_4$ prossimale dell'avambraccio. Patagio bruno fosco (fuscous, XLVI); orecchio lievemente più chiaro.

Unghia del pollice uniformemente grigia chiara. Unghie del piede color crema diafano nella metà basale, intensamente bruno-aranciato nella metà distale.

L'*orechhio* ed il *trago* in nulla differiscono dalle Petalia thebaica, Geoff., d'Egitto.

Il *cranio* corrisponde per forma e dimensioni alle P. th. suddetta.

I *denti* invece offrono alcune particolarità degne di nota.

Premetto che gli II sono in parte anormali. $\underline{I_2}$ des. è spezzato alla base "ex vita". $\underline{I_1}$ des. è largo et *trifido*. $\underline{I_1}$ sin. è stretto e bifido, ma ha il lobo laterale troppo corto. $\underline{I_2}$ sin. è bifido e di forma identica a quella del P. th., Geoffr.

E peraltro indubitabile trattarsi di una Petalia con incisivi superiori bifidi!

P_4 è molto piccolo; resta nella linea dentale meglio che nella P. th.; è visibile dall'esterno, ed ancor meglio dall'interno, ma è appena visibile *dal disopra*, perchè P_3 et M_1 sono molto ravvicinati tra di loro e lo celano coi rispettivi cingoli, che si trovano a contatto o quasi l'uno dell'altro.

C è più grande e più decisamente uncinato che nella P. th. $\underline{C}$ è più alto, con profilo interno più rettilineo e punta mediale del cingolo più svilippata. P_3 è più alto e mostra una piccola cuspide anteriore particolarmente distinta. I MM sono tutti particolarmente alti e strettamente serrati l'uno contro l'altro. M_1 ha la cuspide anteriore particolarmente alta. M_3 è particolarmente lungo. I $\underline{MM}$ hanno il lobo basale interno (mesostile) assai più largo e grosso, ed esteso all'indietro con una punta tondeggiante.

Uguali resultati ottengo dal confontro con Petalie d'uguale statura di Keren, Setit, Agordat, Lugh, Aden.

Misure del Tipo. Testa più tronco mm. 50. Coda 05. Altezza dell'orecchio, margine mediale 26, laterale 30. Larghezza massima dell'orecchio appiattito 20.5. Altezza del trago 7. Braccio 21. Avambraccio 44. Pollice con unghia 10.5. Dito terzo, me-

p. 93

tacarpo 36, falange prima 23, fal. seconda 23. Coscia 20. Gamba 19. Piede con unghia 10.5. Sprone 14.5.

Cranio. Lunghezza massima con mandibola 20. Lungh. mass. C. -Occipite 10. Lungh. mass. della mandibola con II 12.4. Larghezza sull'arcata zigomatica 10.6. Larghezza della cassa cranica sulla squama temporale 8.4. File dentale $\underline{C}$-M_3 6.5. C-M_3 7. Altezza massima $\underline{C}$ 2.3. C 2.1. M_1 2.6.

Reputo indispensabile far sequire una tavola sinottica in cui alcune delle precedenti misure sono messa a confronte con quelle di altre forme componenti il "gruppo P. thebaica".

[table removed - eds.]

p. 95

Dalla presente tavola risulta chiaramente che vis sono entro il "gruppo thebaica" due distinte forme, una piccola settentrionale ed una grande meridionale. Ambedue si estendono pressochè in ugual misura al di là dell'Equatore, la piccola scendendo fino a Zanzibar ed oltre, la grande salendo fino nell'Eritrea. Attribuendo a queste due forme valore specifico, la piccola dovrà chiamarsi *P. thebaica*, Geoff., la seconda *P. capensis*, Sm.

Risulta inoltre che le dimensioni dell'orecchio, la proporzione tra lunghezza dal braccio e dell'avambraccio, e la proporzione tra lunghezza e larghezza della testa sono tutt'latro che costanti entro una stessa forma della stessa località.

Di ciò resta infirmata la validità specifica della *P. revoili*, Rob. (Bull. Soc. philom. Paris, 1881, V, p. 90; e Ann. Sc. Nat. Zool. XIII, 1882, art. 2, p. 3, Tav. 12 Fig 5-6-7); molto più che nemmeno il carattere che dovrebbe "immediatamente distinguere la P. revoili dalle due specie P. thebaica, Geoffr. e P. angolensis, Pet." (= capensis, Sm.), e cioè la situazione di P_4 nella fila dentale, ove è visibile dall'esterno (l.c. fig. 5), ha valore specifico, giacchè riscontro un P_4 ben visibile dall'esterno *e dal disopra*, e ben piantato nella fila dentale perchè P_3 e M_1 sono sufficientemente distanziati tra di loro, in esempl. di P. del Caior, Egitto, Lungh., Zanzibar, Aden, Keren, ed inoltre di *Saganeiti*, Harrar, Angola, Capo; mentre P_4 è scarsamente visibile dall'esterno, *poco o punto visibile dall disopra*, perchè P_3 et M_1 sono molto ravvicinanti tra di loro, e talvolta anche abbastanza energicamente spinto verso l'interno, in esemplari di Korosco, Setit, Agordat, *Saganeiti, Harrar, Angola*.

Gl. M. Allen (Bull. Mus. Comp. Zool. Harv. Coll. LIV, 9, 1911, p. 323) attribuì daltronde "only after much deliberation" 3 Petalie del Guaso Nyiro settentr. alla P. revoili, unicamente per le misore somatiche, che viceversa riscontro rientrare in quelle ottenute anche su Petalie egiziane soltanto.

Ed il Lönnberg (Arkiv Zool. Stockh. 10, 1916, art. 12 p. 5) attribuì 1 P. del gruppo thebaico alla P. revoili, pure unicamente per le dimensioni somatiche, appoggiandosi ad Allen (l.c.). Ma come nel caso precedente riscontrol tali dimensioni presso P. thebaica egiziane, eccezion fatta per l'orecchio lievemente (3 mm.) più lungo.

p. 96

L'attribuzione della P. del gruppo thebaica dell'Eritrea, Africa orient. inglese ed Uganda alla P. revoili (K. Andersen, Ann. M. Nat. Hist. London 1912, X, p. 550) deve quindi sembrare alquanto arbitraria, tanto alle caratteristische dentali precedentemente discusse.

Ma se, come credo, la P. thebaica dell'Eritrea non va distinta sottospecificamente da quella dell'Egitto (v. Senna, Arch. zool. Napoli, II, 3, 1905, p. 284) anche la sottospecie *adana*, K. A. (l.c.) resterà difficilmente distinguibile dalla thebaica tipica.

Credo infine, in base alla descrizione-tipo (Peters, Monatsb. Ak. Wiss. Berlin, 1870, p. 905, fig. 7), che la *P. damarensis* possa essere considerata tutt'al più come una sottospecie, di P. capensis Sm. e la stessa sorte seguirebbero quindi la *P. d. brockmani*, K. A. e la *P. d. media* K. A. (l.c.) non sempre distiuguibili tra di loro (confr. tavola delle misurazioni).

Tornando ora alla *P. di Archers Post*, penso ch'essa *rappresenti in sostanza una varietà di colorazione della P. thebacia* (confr. Senna, l.c. p. 281 per l'Asellia tridens, Geoff), ma mi trattengono dal considerarla fin d'ora come tale le caratteristiche dentali rilevante, la quasi uniformità di colorazione tra parti super. ed infer., la singolare distribuzione di colore nelle unghie del piede.

Il quatro sinottico del gruppo "P. thebaica" (v. K. Andersen, l.c. 1912) andrebbe pertanto a mio avviso così modificato:

P. thebaica, Geoffr. Egitto, Sinai, Africa orient. inglese e tedesca, Zanzibar;

[P. th. adana, K. A.]. Aden.

[P. th. revoili, Rob,]. Somalia settentr.

P. th. aurantiaca, de B. Africa orient. Brit.: Archers Post.

P. th. gambiensis, K. A. Gambia

P. capensis, Sm. Africa merid. fino alla Zambesia ed Angola.

[P. c. damarensis, Pet. Damaraland, Namaqualand, Lago Ngami, Tette]

[P. c. brockmani, K. A. Eritrea, Somalia.

[P. c. media K. A.]. Abissinia (Harrar).

Petalia aurita K. Andersen, 1912

p. 547

Dentition (incisors and p_4), tragus, and external dimensions as in *P. hispida*, but ears much longer, skull larger, toothrows longer. Forearm of type 43 mm..(in forty-seven adult *P. hispida* 37.2-43), ear from base of inner margin 21.5 (16.5-18.7); skull, total length 18.7 (in thirty-two adult *hispida* 16.5-17.8), condyle to front of canine 16.1 (14-15.3), c-m^3 (crowns) 6.5 (5.5-6.1).

Type, F ad. (alc.), Kilifi, British East Africa, collected and presented by G. D. Trevor-Roper, Esq., B.M. 89.1.11.1.

Other specimens from Maungu, B.E.A., and Burao, Somaliland.

Petalia damarensis brockmani K. Andersen, 1912

p. 548

Probably the north-eastern representative of *P. d. damarensis*, from which it is distinguishable only by the larger average size of the skull. Total length of skull (fourteen specimens) 21-21.5 mm. (20-21.2 in six *d. damarensis*), total length of lower jaw 13.7-14.2 (12.7-13.7), maxillary tooth-row (crowns) 7.2-7.7 (7-7.5). Forearm 47-51, ear from base of inner margin 29-31.5 mm.

Type, F ad. (skin), Upper Sheikh, British Somaliland, 4300', 11 Jan., 1910, collected and presented by Dr. R. E. Drake-Brockman, B.M. 10.3.27.4. The range of this form is known to extend to Erythrea. *P. d. damarensis* occurs in Damaraland and Namaqualand, through the Lake Ngami region, eastward to Tette.

Note. - *P. d. brockmani* should not be confused with the smaller, shorter-eared *P. revoili*, winch belongs to the same section of the genus and occurs in the same region (forearm 41-45, ear 26-26.5, maxillary tooth-row 6.5-6.8 mm.). '

Petalia damarensis media K. Andersen, 1912

p. 548

Probably the Abyssinian representative of the foregoing form, from which it differs by its conspicuously smaller size: total length of skull of type 20.6 mm., of lower jaw 13, maxillary tooth-row 6.8, forearm 45.5, ear from base of inner margin 29.

Type, ad. (skin), Harar, Abyssinia, 19 Jan., 1912, collected by Hr. G. Kristensen, presented by the Hon. N. C. Rothschild, B.M. 12.2.28.1.

Petalia gambiensis K. Andersen, 1912

p. 548

Tragus of the *P. thebaica* type, but species differing from any other form of the *thebaica* section by its remarkably small size. Forearm (type and topotype) 39-40.8 mm.,

p. 549

third metacarpal 29, ear from base of inner margin 23-23.5, skull (total length) 18.5, maxillary tooth-row (crowns) 6.1-6.2.

Type, ad. (akin), Dialocote, French Gambia, 7 March, 1910, presented by G. Fenwick Owen, Esq., B.M. 11.6.10.10.

Note. - Gambia is inhabited by two other species of *Petalia, P. hispida* and *P. macrotis*.

Petalia major K. Andersen, 1912

p. 547

Similar to *P. arge* (p_4 large, tragus lingulate), but easily distinguished by its conspicuously larger size, being about equal in dimensions to *P. æthiopica luteola*. Forearm of type 49 mm. (39.5-45 in ten adult *arge*); skull, total length 22.2 (19.5-20.2), condyle to front of canine 19.7 (16.8-17.7), maxillary tooth-row 7.8 (6.8-7.3).

Type, F ad. (alc.), Ja R., Cameroons, 23 Jan., 1906, collected by Mr. G. L. Bates, B.M. 9.10.2.49.

Petalia nana K. Andersen, 1912

p. 547

Allied to *P. arge* (p_4 large), but considerably smaller, and with proportionately much smaller ears (tragus not differing in shape, being lingulate as in *arge*). Forearm of type 34 mm. (39.5-45 in ten adult *arge*), third metacarpal 25.7 (30.5-34.2), tibia 14.5 (20-23.7), ear from base of inner margin 15.5 (23-26.5), maxillary tooth-row (c-m^3, crowns) 5.7 (6.8-7.3).

Type, M ad. (alc.), Benito R., French Congo, collected by Mr. G. L. Bates, B.M. 0.2.5.46.

This is the smallest known form of the genus.

Petalia parisii de Beaux, 1924

p. 254

(N. 1449) Tipo. F, Balli, Somalia it. merid., 6 IV 1922. In alcool. Cranio estratto.

Stato di conservazione. In generale buono. Manca il pelo nella porzione mediana delle parti inferiori e sul dorso eccettuate la spalle.

Appartiene al gruppo *P. aethiopica* (Kn. Andersen, Ann. Mag. Nat. Hist. X, 1912, 549). Si distingue nettamente dalla *P. aethiopica*, Dobs. e *P. aeth. luteola*, Thos. per le dimensioni molto minori; dalla *P. macrotis*, Dobs. e *P. oriana*, Kershaw (Ann. Mag. Nat. H. X, 1922, 179) per le dimensioni molto minori e la forma del Tragus; dalla *P. woodi*, K. A. (Ann. Mag. Nat. H. XIII, 1914, 513) per le dimensioni del padiglione molto minori (mm. 21 contro 29) e per il colore delle parti inferiori, che è uguale alle superiori, anzichè bianco.

Tragus. Come quello rappresentato dal Dobson (Catal. 1878, Pl. XI, fig. 3) per la P. aethiopica, ma munito alla base del margine posteriore di un grosso lobulo orientato lateralmente.

p. 255

Dimensioni somaliche. Testa e tronco min. 47; coda 46; orecchio, margine interno 21; avambraccio 43; pollice (senza metacarpo, con unghia) 9; 3° dito: metacarpo 31.5, prima falange 22, seconda falange 22.2; 4° dito: metacarpo 33, prima fal. 11.8, seconda fal. 9 ; 5" dito: metacarpo 34, prima fal. 11.5 seconda fal. 10.8; tibia 19 ; piede senza unghia 8; unghie in media 2.

Cranio. Lunghezza massima colla mandibola in situ, II-occipite, mm. 19. Lunghezza massima C-occipite 18. Larghezza zigomatica 10.7. Larghezza massima sullo scudo frontale 7. Lungh. massima della mandibola, denti esclusi, 11.8. Lungh. massima della fila dentale superiore 6. Fila dentale inf. 6,9.

MM assai logori. CC relativamente grandi e robusti. P_3 assai piccolo, *nella*, fila dentale, prevalentemente mediale, ma pur riconoscibile anche nella veduta laterale.

Rivestimento peloso. Soffice e lungo (10 mm. sulle spalle) Tutto il braccio ed il terzo prossimale dell'avambraccio sono riccamente rivestiti. Il patagio è rivestito dorsalmente: nella metà prossimale della zona tra braccio ed avambraccio; su di una striscia larga 10 mm. lungo il tronco; nella zona tra la coscia e le prime due vertebre caudali. Ventralmente nella metà prossimale della zona tra braccio ed avambraccio, e, più scarsamente, nella zona tra gomito e ginocchio.

La colorazione d'insieme è buffy brown (Ridgw. XL) sulle spalle, più scura sul braccio; drab (XLVI) sulla testa e le parti inferiori. Patagio ed orecchio sono cinnamon drab (XLVI). I singoli peli sono lievemente più scuri e più grigi nel terzo o quarto basale. La zona nuda nasale è lateralmente orlata da una striscia di peli bianchi.

Unghie grige brune basalmente; chiare e diafane apicalmente.

Dedico questa nuova specie al Dottor Bruno Parisi, Direttore della Sezione Zoologica nel Museo Civico di Storia Naturale di Milano.

Petaliidæ Miller, 1910

p. 90

The generic name *Nycteris* as used for a group of Old World bats is currently assumed to date from Geoffroy and Cuvier, 1795. In reality it was not published in this sense until 1803, the name as it occurs in the earlier work being strictly a *nomen nudum*. But during this interval of eight years *Nycteris* had been applied by Borkhausen and Bechstein to a very different animal, the New York Bat of Pennant, now currently known as *Lasiurus borealis*. It is therefore necessary to substitute *Nycteris* Borkhausen 1797 for *Lasiurus* Gray 1831, *Petalia* Gray 1838 for *Nycteris* Geoffroy 1803, and the new family name *Petaliidia* for *Nycteridæ* Dobson 1875

Phyllorhina commersoni var. thomensis Bocage, 1891

p. 88

Deux individus, M et F adultes.

Ces individus ressemblent à *Ph. Commersoni* par leur conformation générale, par la forme de leur fer-à-cheval et par leurs caractères de dentition; mais ils différent de nos individus d'Angola et d'autres localités d'Afrique occidentale: 1° par leur taille, sensiblement plus petite; 2° par le nombre des plis cutanés latéraux du fer-à-cheval, trois au lieu de quatre; 3° par leurs couleurs, d'un brun-noirâtre foncé et uniforme en dessus, plus pâles en dessous, avec une tache blanchâtre sur le tiers supérieur de la face interne du bras. Les membranes des ailes et la peau nue des membres sont noires.

Chez la femelle de cette variété, comme chez la femelle du *Ph. Commersoni*, l'orifice du sac frontal est bien distinct, et ses appendices pubiens sont assez developpés ainsi que les mamelles, les uns et les autres noirs.

Dimensions:

	M; F
Longueur total (tête et tronc):	106 mm; 102 mm.
" de la tête:	34; 32
" de l'oreille:	25; 35
" de l'avant-bras:	82; 81
" du 3^{e} doigt:	126; 124
" du pollex:	18; 17
" de la queue:	29;30

Habitat: la femelle a été recueillie à Roça Saudade, le mâle à Ribeira peixe.

L'espèce est connue à St. Thomé sous le nom de Guimbu.

Comme je l'ai déjà remarque ailleurs, M. Greeff cite à peine deux chauves-souris de St. Thomé, *Cynonycteris straminea* et *Phyllorhina caffra*, l'une et l'autre non encore rencontrées dans cette île par M. Newton (V. Jorn. Ac. Sc. de Lisboa, 2.^{a} série, I, p. 197).

Phyllorhina commersonii var. marungensis Noack, 1887

p. 272

(Vergl. Taf. X, Fig.31 - 33.)

5 Exempl., darunter 1 F, Juli und August, Qua Mpala, Marungu. "Fliegt in der Dämmerung."

PETERS in: M. B. d. Berl. Acad. 1871, S. 318, DOBSON Cat. of the Chiropt. of Brit. Mus., S. 133; DOBSON Report of Brit Association, 1880, S. 11, Proc. L. Z. S. 1872, S. 364; 1878, S. 8798; 1870, S. 769.

Der Grund, weshalb die vorliegenden Ex. als *var. marungensis* bezeichnet werden müssen, liegt hauptsächlich in dem Nasenblatt, welches bei *commersonii* unten gerade, bei allen 5 Ex. von *var. marungensis* unten genau wie bei *Phill. cyclops* rundlich lanzettförmig ausgebogen ist, während das Blatt oben bei *cyclops* viel schmaler ist als unten. Das Blatt von *marungensis* sieht also so aus, wie wenn die untere Hälfte von *cyclops* mit der oberen Hälfte von *commersonii* zusammengesetzt wäre.

Diagnose von *commersonii* nach DOBSON:

Das Querblatt sO breit wie das horizontale, starke Stirndrïse. Unterarm so lang wie Kopf und Körper, Schwanzende frei, oben Kopf und Nacken hellbraun, Extremitäten grau, ein mehr oder weniger breites Band von derselben Farbe fliesst von der Schulter auf dem Rücken zusammen, Körperseiten grau, fast weiss bei manchen Exemplaren, unten weiss, ausgenommen ein brauner Fleck an jeder Schulter, am Bauch hat das Haar eine dunklere Färbung, manche Exemplare mit röthlicbem Schimmer. Kopf und Körper 4 Zoll 1 L. Kopf 1 Zoll 6 L. Unterarm über 4 Zoll; doch schwankt die Länge, die bei einigen nur $3^1/_2$ Zoll beträgt. Gebiss wie bei *Ph. cyclops*.

Körperlänge des grössten M 95 mm, Schwanz 25, der 3 anderen M 80 - 85, des F 75, Schwanz 15 mm.

Kopf kurz, dick, Schnauze breit, Ohren weit von einander entfernt, 0hr = $^2/_3$ Kopflänge, Unterarm erheblich länger als der Körper, Schwanz mit der Spitze aus der Schenkelhaut hervorragend.

Das fein und dünn behaarte Nasenblatt ist vorn an den Seiten wie bei *commersonii* und *cyclops* von 3 übereinander liegenden Blättern eingefasst, der vordere Theil spitz hufeisenförmig, vom Rande der Oberlippe 3 mm entfernt. Der vordere Rand auf 1 mm frei über-

p. 273

hängend, in der Mitte ein Grat, der nach der mittleren Oeffnung als ein 1 mm langer Zacken hineinragt, vom oberen Rande ragen auf beiden Seiten des Grats zwei spitzige gewundene Hautlappen in die Vertiefung hinein, das obere Stirnblatt in der Mitte mit einem Grat, am oberen Rande etwas herzförmig ausgeschnitten und auf 2 mm beutelförmig an den Seiten überhängend, unter jedem überhängenden Zapfen eine Vertiefung. Der vordere wulstige Rand derselben, welcher die obere Begrenzung der Nasenöffnung bildet, in der Mitte mit einem in die Tiefe ragenden Grat, in den beiden seitwärts desselben liegenden rundlichen Lappen ebenfalls je zwei feine Oeffnungen. Die beiden mittleren gewundenen Hautlappen bilden mit diesem Grat eine herzförmige Vertiefung, die Nasengruben liegen unter dem hinteren Blatt und sind durch die hertförmige Klappe geschieden. Die Oeffnung der Glandulardrüse ein feiner, an den Rändern behaarter Spalt über dem hinteren Blatt der bei weitem nicht so deutlich sichtbar ist wie in der Abbildung von *Ph. comm.* bei DOBSON und fast ganz in den Stirnhaaren versteckt ist. Breite des Stirnlappen 9 mm , Länge 4, Länge des ganzen Hufeisens 10, Breite 8.5, Länge der mittleren Oeffnung 3 mm. Ich verweise übrigens auf die Zeichnung, welche die komplicirte Bildung des Hufeisens deutlicher macht als viele Worte. Ohr an der Basis behaart, schlank Zugespitzt, 13 Querfalten nach dem äusseren Rande zu; dieser wenig ausgebuchtet, der innere Rand rundlich , unten legt sich der innere und äussere behaarte Rand am, so dass unten an der Ohrbasis die Ohröffnung nur einen schmalen Spalt bildet. Tragus fehlt. 2 mm vom inneren Rande geht eine starke Sehne der Lânge nach durch das Ohr bis auf 6 mm von der Spitze, von welcher der innere Ohrrand nach hinten umklappt. Ohrlänge 22 mm, grösste Breite unten 11, Länge des äusseren BAsallappens 5 mm, Entfernung der Ohren 16 mm.

Alle Maasse dem grössten Exemplar entnommen. Oberlippe und Rand der Unterlippe mit warzigem Rande, in der Mitte der Oberlippe ein nackter Grat, Mundspalte 11.5 mm lang, AUge klein, 2 mm lang, rund, 2 mm seitlich von dem die Nasenlöcher oben begrenzender Wulst. Unterarm sehr lang und stark, muskuloös, wie auch der Schenkel, Radius kräftig, 95 mm lang, Humerus 52.5. Vom Daumen a in der Flughaut eingehüllt, a = 8.5, b = 9, der stark gekrümmte braune Nagel 4.5. Finger I einer starke, oben 2 mm dicke, 75 mm lange Knochenleiste, b verkümmert, IIa = 72, b = 32.5, c = 52; IIIa = 69, b = 26, c = 16; IVa = 68, b = 26, c = 17. Die Enden der Phalangen nagelartig scharf. Tibia 39, Femur 32. Die zweiglidrige Fuss mit

p. 274

quergefalteten Ballen lang, mit starken, braunen Krallen. Sporn 8 mm. Die Flughout reicht bis zu $^2/_3$ der Tibia. Metatarsus 6, Phalangen a= 6, b = 10, Nägel 6 mm. Penis behaart, 6 mm lang, Schwanzwirbel sehr dunn, 7 mm frei, an der Spitze 5 - 6 weisse lang Haare. Beim F misst der Radius 95, Humerus 43, die ersten Phalangen von II, II, IV 63, 62, 61.5; tibia 34, Femur 25. Humerus und Vorderarm innen und aussen schwach behaart, Flughaut weiss als schmaler Saum bis über das Tarsalgelenk, zwischen Humerus und Tibia schwach weisslich bebaart, aussen nur am Rande der Tibia einige gelbe Haare. Flughaut zwischen Arm un Schenkel mit feinen Querfalten, die unter der Lupe aus sehr feinen warzigen Papillen bestehen, Behaarung zwischen den Schenkeln dünn gelblich graubraun mit hell Weissgrau melirt, da die Haare theils eine graubraune, theils eine weissliche Spitze haben. Bauch mehr gelblich weiss, in der Mitte mehr bräunlich. Der Oberkörper is in der vorderen Hälfte ähnlich wie unten mit mehr oder weniger Braun, hinter variirt die Färbung. Bie dem kleinsten M ist sie ähnlich wie vorn, nur in der Mitte des Rückens und auf dem Oberarm mehr lichtbraun, Rand des Hinterkörpers an der Flughaut und hinterer Rand des Oberarms mehr weiss. Bei einem älteren M is das Braun intensiver, gegen die Schulterns hell streifig abgesetzt, ohne eigentliche Streifen zu bilden. Beim dem grössten M ist die hintere Partie oben mehr rothbraun, nach vorn heller quertstreifig abgesetzt, die Mitte des Nackens dunkler, bei einem M die vordere Partie hell graubraun, wieter nach hinten reichend, das Braun viel dunkler un

nach vorn halbmondförmig abgesetzt. Allen gemeinsam aber ist die hellbelbiche Färbung des Bauches, die unter den Achseln lebhaft hellgelb wird und vorn duch einen nach hinten zugespitzten dreieckigen, dunkelumbrabraunen streifigen Fleck begrenzt wird. Das Weissgelb der Achselgegend schneidet gegen das Braun der Oberseite scharf ab. Der weisse Fleck unten an der Schulter ist bei dem grössten M matt weissgelb, sonst besonders lebhaft an der Innerseite des Humerus. Bei dem F ist die Färbung oben vorn dunkler, das mit weisslicher Sprenkelung abgesetzte Braun zieht zich weiter nach vorn und ist vorn dunkel sepiabraun, hinten der Rand mehr gelbbraun. Die Färbung bei *var. marungensis* variirt ebenso wie bei *commersonii*. Die Längenstreifen von *vittata* PETERS fehlen. Vergl. die Abbildungen von *vittata* PETERS, Säugethiere Taf. 6, Schädel Taf. 13, 7 - 13, *commersonii* bei DOBSON Taf. 9, Fig. 2, *cyclops* Fig. 1. Ueber *gracilis* PETERS S. 35.

p. 275

Die Schädel dem von *vittata* (auch bei BRONN Taf. 53, Fig. 4) sehr ähnlich/

Zähne: I $^{2}/_{4}$ C $^{1+1}/_{1+1}$ P $^{2+2}/_{2+2}$ M $^{3+3}/_{3+3}$

Die jüngeren M hahen von der Basis des Eckzahns gemessen die gleiche Sagittallänge von 32 mm, beim grössten M 33, beim F 31. Bei dem alten M fehlt der kleine Schneidezahn jederseits im Oberkiefer, den die übrigen besitzen. Beim F For. infraorb. länger, Jochbogen vorn und die bintere Schuppe schwächer, ebenso der ganze Oberkiefer und die Auftreibung der Nasenbeine, Massetergrube flacher, Eckzähne zarter und schwächer, der kleine Lückzahn niedriger.

Grösste Breite zwischen den Jochbogen bei F 17.5 mm, bei M adult 19.5, bei letzterem die grösste Breite am Hinterhaupt 15, die schmalste Stelle vorn an der Einschnürung 4.5, Breite des Oberkiefers 10, Schädelhöhe 14.5. Bullae aud, bestehen aus 2 Kapseln, die vordere bis dicht an den Condylus des Unterkiefers vorgezogen, je 3 mm breit , Hinterhauptloch 5.5 breit, 4.5 hoch, Zahnreihe von der Hinterseite des Eckzahns 10, Entfernung der C 8, Länge von C 7 mm, F 5. Der Unterkiefer besonders an der Sutura mentalis kräftig, Massetergrube tief; Eckfortsatz lang und schmal, nach hinten und aussen gerichtet, 2.5 lang; hinterer Ast schräg aufsteigend, Condylus 3 mm breit, Coracoidfortsatz dreieckig rundlich, hinten ausgebogen. Länge des Unterkiefers bis ZUm Condylus 24, Höhe des horizontalen Astes in der Mitte 3 mm. Zahnreibe 12,5. Entfernung hinten oben 8, unten 6 mm.

Zähne. C oben vorn und innen gerillt mit starker, übergreifender Basis, vorn und hinten an der Innenseite ein Zacken, P I ein kleiner, ganz nach oben gerückter, 0.3 hoher Stift, P II dreieckig, $^{1}/_{3}$ so hoch wie C, mit hinterem und innerem Nebenzacken, M I u. II mit den bekannten V-förmigen Höckern und niedrigem Seitenhöcker, M III V-förmig mit viel schwächeren Zacken. Im geschlossenen Zustands der Kiefer greifen die W-Höcker über die unteren M über. Die im knorpeligen ZWischenkiefer stehenden I, mit den Spitzen nach innen, sehr klein und rudimentär. Unten I klein, dreilappig mit langer Wurzel, C an der Basis mit wulstigem Rande, vorn nicht gerillt, hinten ausgekehlt, bei M ad. 6, bei F 4 mm hoch, P I = $^{1}/_{3}$ C, oben dreieckig zugespitzt, P II = $^{2}/_{3}$ C, vorn und hinten innen kleine Basalzacken, M W-förmig ohne innere Seitenzacken, M III verkleinert, Schon halb in dem aufsteigenden Aste sitzend. Sämmtliche Zähne oben und unten mit BasalwUlst.

Phyllorrhina bicornis Heuglin, 1861

p. 7

Grisescente-albida, cervice, collo. dorsoque obscurioribus, pilis omnibus apice fuscescentibus; facie pallide murina; regione inguinale pure alba; auriculis griseis, intus helicem versus violascentibus; prosthemate simplice replicato et cristam transversalem implicante; auriculis latis approximatis, margine interiore semilunare, exteriore falciforme, hic basi lobato.

Die Ohren sind um $^{1}/_{3}$ - $^{1}/_{4}$ kürzer als der Kopf, 6‴ lang, innen grossentheils ziemlich dicht und fein behaart, der Aussenrand Sförmig, an der Basis

p. 8

der Wurzel des Innenrandes sehr nahe gerückt und dort mit einem zugespitzten Ausschnitte versehen, innen mit 8 - 10 undeutlichen Querfalten. Die Nase mit drei halbkreisförmigen, aufeinander liegenden Blättern (Hufeisen) umgeben, deren zwei untere in der Oberlippengegend absetzen.

Zwischen den Nasenlöchern und dem nach vorne zu gerichteten Theile des obern Hufeisenblattes eine kleine fleischige Leiste, daneben jederseits ein kleiner hornförmiger Lappen, der auf- und rückwärts gebogen ist und wohl zum Verschliessen der Nasenlöcher dienen kann. Auf dem Nasenrücken steht ein niedriger, oben mit zwei flachen Kerben versehener Querkamm, auf dessen nach vorne gerichteter Seite vier in einer Linie liegende violette Wärzchen; dieser Querkamm ist umschlossen von einem an seiner hinteren Basis entspringenden, wenig erhabeneren ganzrandigen und oben und seitwärts umgefalteten, oben und hinten etwas behaarten *Prosthema*; und hinter letzterem endlich befindet sich ein ringförmiges, vorne mit etwas erhöhtem Rande versehenes, in der Mitte aber durchbohrtes Organ, das in eine Stirnrinne zu münden scheint.

Im Oberkiefer am beweglichen, etwas prolongirten Zwischenkiefer jederseits einen oben abgerundeten Schneidezahn. Im Gaumen 8 Querfalten. - Daumen vom ersten Gliede an frei. Der Zeigfinger besteht nur aus einer Phalange. Schenkelflughaut bis zur Zehenwurzel reichend. Schwanz mittellang mit wenig freier Spitze, das *Patagium anale* in sehr spitzem Winkel in ihn verlaufend. Zehen wie beim ganzen Genus zweigliederig.

Die Lippen sind mit kleinen violett-röthlichen Drüsen besetzt und fein behaart, der Pelz im allgemeinen graulich-weiss, alle Haare mit röthlich- bis rauch-grauen Spitzen, welche auf dem Rücken, Scheitel und Halse an Intensität der Färbung zunehmen. Gesicht hell mausgrau, Gegend um die Geschlechtstheile weiss. Ohrmuschel hell rauchgrau, im Innern ins Violette spielend. Flughäute schwärzlich. Körper 2" lang, Schwanz 11‴. Flugweite fast $10^{1}/_{2}$".

Phyllorrhina cyclops Temminck, 1853

p. 75

PHYLLORRHINA CYCLOPS.
PHYLLORRHINE CYCLOPE.

Cette espèce paraît habiter de préférence les rives

p. 76
boissées des eaux; elle vole, pendant le crépuscule, à la lisière des forêts voisines des rivières. Elle est facile à distinguer de ses congénères, par son pelage cotonneux, frisé et comme ébourifé partout. Le mâle, un peu en arrière de la feuille compliquée du nez, est muni d'un large syphon, qui s'ouvre sur le front; la femelle porte simplement le stigmate d'une ouverture, sans qu'il conduise à une bourse. La membrane interfémorale est découpée en demi cercle, et la courte queue qui s'y trouve engagée, n'a que sa pointe libre. Les oreilles sont longues, pointues et sans oreillon mobile.

Tout le pelage supérieur et inférieur est d'une même nuance, et il n'existe sous ce rapport aucune différence, qui puisse servir de moyen pour distinguer les sexes.

Le pelage supérieur est brun-noirâtre, mais le bout frisé de tous les poils est jaunâtre; en dessous il est brun-bistre, à bout des poils également jaunâtre. La feuille transversale qui prend naissance entre le pelage touffu du front, s'élève en deux lobes, séparés par une échancrure, de laquelle sort une petite feuille très-étroite; sur le bourrelet s'élève une autre petite feuille, à laquelle vient aboutir le large derme du fer-à-cheval, accompagné en dessous d'une seconde membrane. L'ouverture au front du mâle est entourée par le pelage laineux et enbourifé; la poche est également tapissée de poils onctueux. La moitié de l'antibrachium est couvert par le pelage.

Longueur du bout du museau à la pointe de la queue 3 pouces 6 lignes; hauteur des oreilles 1 pouce; queue 6 lignes; envergure 12 pouces 6 a 9 lignes; antibrachium 1 pouce 6 lignes.

p. 77
Patrie. L'on trouve cette espèce sur la rivière Boutry, côte de Guiné.

Phyllorrhina fuliginosa Temminck, 1853

p. 77

PHYLLORRHINA FULIGINOSA.
PHYLLORRHINE FULIGINEUX.

L'espèce nouvelle décrite ici sur un *sujet unique*, de sexe *féminin*, de toutes celles qui me sont connues est la moins affublée de membranes ou de feuilles nasales; les oreilles sont grandes et larges, et leur bord antérieur interne est garni de poils. La membrane interfémorale est ample et longue; la queue s'y trouve engagée totalement. Tout le système cutané est nu.

Parties supérieures du pelage d'un roux de rouille vif, mais la base de tous les poils est peinte de roux-doré; la tête, le devant du cou, toutes les parties inférieures ainsi que le ruban latéral, le long des flancs, sont d'un roux-doré vif. Pour toute membrane l'on voit seulement une feuille transversale, peu apparente, d'où se détache le petit fer-à-cheval en liséré, qui est un peu plus large vers le muffle, et qu'accompagnent deux petits plis, à peine visibles. La base postérieure, ainsi que le bord antérieur interne des grandes oreilles, sont couverts de poils. Les membranes sont nues et noires.

Longueur 3 pouces 4 lignes; dont la queue prend 1 pouce 3 lignes; envergure 11 pouces 6 lignes; antibrachium 2 pouces.

p. 78

Sur la vue d'un seul individu *femelle*; ce qui fait qu'on ne peut indiquer, s'il y a ou non différence de coloration du pelage dans les sexes, ni s'il est certain que le *mâle* soit pourvu d'un syphon.

Patrie. La côte de Guiné.

Phyllorrhina gracilis Peters, 1852

p. 36

Tafel VII. Tafel XIII. Fig. 14. 15.

Ph. rufocorticina, subtus ex albo rufescens, patagiis umbrinis; auriculis capite quarta parte brevioribus, lobulo distincto; prosthemate simplice, concaco, margine reflexo, apertura frontali transversali; plicis accessoriis ad utrumque ferri equini latus binis; digito quarto et quinto apice bifidis; metacarpo digiti quarti breviore quam digiti tertii; alis supra tarsum terminatis; crure capite longiore.

Longitudo tota 0,090; caudae 0,032; antibrachii 0,046; volatus 0,270.

Habitatio: Africa orientalis, Tette, 17° Lat. Austr.

Körper und Gliedmafsen schlank und zart. Die Ohren sind grofs, um ein Viertel kürzer als der Kopf, entwickelt etwas breiter als lang, an ihrer äufsern Oberfläche bis auf das letzte Viertel behaart; sie ragen mit ihrem vordem Rande bis nahe an die kleinen Augen, und sind auch an ihrer innern Fläche bis zum Längskiel. welcher durch das zweite Fünftel des Ohr verläuft, mit Haaren besetzt; an ihrem hintern Rande sind sie schwach ausgerandet, mit kurzer seitlich vorspringender Spitze; man kann 13 Querfalten zählen, deren mittlere sich bis zum Längskiel erstrecken; der Ohrlappen ist abgerundet und deutlich abgesetzt. Das Aug liegt der Ohrenbasis ein wenig näher als dem Schnauzenende. Das Hufeisen ist schmal, an den Seiten ein wenig ausgeschnitten, zu jeder Seite VOn zwei feinen Nebenfalten umgeben

p. 37

nach innen von den Nasengruben durch kleine am Ende zweizipflige Läppchen getrennt; die mittlere Abtheilung des Nasenbesatzes ist etwas breiter als lang, abgerundet dreieckig, am obern Rande behaart; das Prosthema ist einfach, am Rande nackt und nach oben umgeschlagen, durch keine Längsfalte mit der mittleren Abtheiling verbunden, so dafs nur eine einfache breite Grube zwischen denselben erscheint. Zu beiden Seiten, gleich hinter dem Prosthema, liegt eine drüsige Hervorragung, und nach der Mitte zu mehr zurück eine quere Oeffnun, aus der vorn ein kleines zungenförmiges Hautlappchen vorspringt, hinten ein paar längere Haarbüschel hervorkommen. Das Gesicht ist bis auf den nackten vordern Theil der Lippen kurz aber dicht behaart. Von der Mitte der Operlippe gehteine schmale nackte Leiste bis zum Nasenbesatz hinauf. Am Gaumen bemerkt man zehn quere Schleimhautfalten, von denen die sechs letzten gedrängter stehenden den Raum zwischen den beiden vorletzten Backzahnpaaren einnehmen. Der schlanke Körper ist doppelt so lang wie der Kopf. Die Mittelhandglieder nehmen vom zweiten bis fünften Finger progressiv an Länge ab. Die Phalangen des dritten Fingers zusammen sind kürzer als die Mittelhand desselben. Die kleinen Endglieder des dritten und vierten Fingers theilen sich in zwei Äste, auf dieselbe Weise, wie man es beim letzten Schwanzgliede der *Nycteris* beobachtet. Die Flughaut endigt am Unterschenkel, etwas oberhalb der Fufswurzel. Der Fufs ist nicht so lang wie der Unterschenkel; der Bau der Zehen und Krallen, wie bei der vorhergehenden Art. Die Schenkelflughaut ist zu jeder Seite zwischen dem Schwanz und dem Sporn flach ausgeschnitten. Der Schwanz ist mehr ab ein halb Mal langer als der Unterschenkel, und ragt mit einem kurzen Ende frei aus der Schenkelflughaut hervor: sein vorletztes Glied is das langste von allen.

Die Behaaring ist fein und land, läfst den gröfsten Theil des Oberarms und Schenkel frei, und geht an der Bauchseite nur ein wenig weiter als and der Rückseite auf die FlUghäute Uber. Die Längslaufen der Flughäute sind sowohl oben wie unten mit ganz kurzen Härchen versehen.

Die Farbe an der Rückenseite ist hell röthlich nelkenbraun, an der Bauchseite röthlich weifs, an der Brust mit stärkerem röthlichbraunen Aufluge. Im Gesicht ist die braune Farbe gestättigter. Die Haare des Rückens, des Oberkopfes und der Seiten des Halses sind an der Basis und Spitze röthlich braun, am übrigen gröfsten mittleren Theile weifs. Die Bauchhaare sind am Grundtheile braun, an der Spitze weifs. An der Brust finden sich Haare mit weilser und mit bräunlicher Spitze. Die Farbe der Flughäute ist hell umbrabraun. Die Nägel sind schmutzig weifs. Beim ausgestopften Thiere erscheint die Rückseite durch Auseinanderweichen der Haare gefleckt.

Der Bau der Eingeweide stimmt mit dem der vorigen Art ganz überein. Auch das Skelet weicht nur wenig ab. Man kann nur sechs getrennte Halswirbel unterscheiden; darauf folgt ein Knochenstück, das aus der Verwachsuug des siebenten Halswirbels und der zwei obersten Rückenwirbel mit den beiden ersten Rippen und dem Manubrium sterni hervorgegangen ist, an dem man aber keine Spur der ehemaligen Trennung findet; dann kommen

p. 38

noch zehn rippentragende Wirbel, fünf verwachsene erste und zwei getrennte letzte Lendenwirbel; das Kreuzbein besteht aus drei, und der Schwanz aus zehn Wirbeln, von welchen der letzte nur $^1/_2$ Mm. lang ist, der vierte und fünfte Endwirbel dagegen am meisten gestreckt erscheinen. Die beiden ersten Rippenpaare sind, wie oben bemerkt, verwachsen. Die drei folgenden verbinden sich durch besondere Knorpel mit dem Brustbein. Die 6te, 7te und 8te Rippe stehen mit demselben durch ein gemeinschaftliches breites Knochenstück in Verbindung, und die vier letzten sind frei. Der Schädel (Taf. XIII. Fig. 14, 15) zeigt keine so grofsen Knochenkämmen und die Gehöröffnung ist mehr nach der Mitte gerückt; die Zähne zeigen im allgemeinen dieselbe Form und Anordnung, doch ist die Schmelzleiste des letzten ohern und untern Backzahns etwas mehr entwickelt, und die oberen Schneidezähne sind undeutlich zweilappig.

Diese zierliche Art stammt aus dem Innern des Landes, aus Tette. Das einzige Exemplar, welches ich erlangte, ein Männchen, verlor sich, durch das Licht verlockt, in meine Wohnung. Die Nahrung besteht, wie aus dem Inhalte des Magens, Überbleibseln von Hymenopteren, hervorgeht, aus Insecten.

Von den hisher beschriebenen Arten ist mir keine bekannt, welche mit dieser südostafrikanischen zu verwechseln wäre.

Phyllorrhina megalotis Heuglin, 1861

p. 8

Minima; auriculis rotundatis, maximis fronte connatis; membrana semi-

p. 9

orbiculare (ferrum equinum) simplice; vellere sericato, facie nitide et delicatissime flavo-ferruginea; stria parva nigricante, per oculos ducta; notaeo pilis apice lata chocolalina, dimidio basali cinerascante albido; gastraeo albo, pallide isabellino-induto.

Diese sehr aberrante Art gehört wegen ihrer zweigliederigen Zehen und in Folge der vollständig gleichen Bildung der Finger und Schneidezähne und theilweise auch des Nasenbesatzes zu *Phyllorrhina*, weicht jedoch hievon in einigen Stücken ebenso sehr ab, als von *Rhinolophus*: die Ohren sind nämlich sehr lang, breit und gerundet, auf der Stirn sich sehr genähert, dort durch eine niedrige Hautfalte verbunden, nach vorn stehend und ihr Aussenrand an der Basis über die des Innenrandes dem Maule zu vorgerückt; der breite Lappen des ersteren (Aussenrandes) kaum durch eine leichte Kerbe vom Rande geschieden, nach vorn tief und fast rechtwinkelig zum Grunde des Ohres eingesenkt Ohrmuschel mit ungefähr 20 feinen, aber sehr deutlich ausgesprochenen Querfalten, der Innenrand und ein ihm naheliegender und mit demselben parallel laufender Faltenrückeh innen behaart. Das Hufeisen selbst besteht nur aus einer einzigen Falte, in der beckenartig vertieften Nasengrube seitwärts je ein und in der Mitte ein drittes, wohl theils zum Verschluss der Nasenlöcher dienendes Fleischläppchen, die zusammen einer Ankerform - - zu vergleichen sind; dahinter der mit vier nach vorne gerichteten Wärzchen oder Drüsen versehene ungekerbte Querkamm, der nach hinten strahlenförmig mit einem rundlichen, auf- und vorgerichteten niedrigen Hautblatt geziert ist. Die Flughautspitze erreicht kaum den Vorderfuss; die Fusswurzel ist ganz frei; das erste Daumenglied dagegen beiderseits von ihr umschlossen. Der Schwanz ganz vom *Patagium interfemorale* eingeschlossen; von der Calcaneusspitze zieht sich eine feine hornige, an den Schwanzspitzen zusammenlaufende Vorstreckung herab. An seiner Spitze einige feine Härchen; ebenso die Zehenglieder mit einzelnen kleineren borstenartigen Haaren bekleidet.

Die Zähne genauer zu analysiren, ist mir auf der Reise unmöglich, da ich das einzige Exemplar (M) nicht seciren möchte. Bezüglich der Stellung der Schneidezähne im oberen beweglichen Zwischenkiefer und was die Zahl der

p. 10

Schneide- und Eckzähne ($^1/_2$ - $^1/_1$ anbelangt, weicht diese neue Art gar nicht von *Phyllorrhina* ab. Die oberen Eckzähne nach innen und vorne und nach aussen und hinten mit einer Zahnkrone versehen, die etwas am Hauptzahne heraufläuft und oben eine ausgezackte Spitze hat. Gaumen mit 6 Falten, deren 2 erste fleischig, dick und breit und mit vielen Papillen oder Widerhäkchen besetzt sind.

Die Behaarung der Schnauze ist verhältnissmässig kräftig und dicht, an den übrigen Theilen des Körpers sehr fein und sammtartig. Gesicht fuchsroth ins Gelbe, welche Farbe nach hinten zu allmählich verläuft und am Kinn fast nicht ausgesprochen ist; durch die kleinen Augen ein schwärzlicher Streifen. Oberseite weisslich-grau, alle Haare mit breiter chokolade-brauner Spitze; Unterseite weisslich, namentlich seitlich fein rothgelblich überflogen; die Ohren sehr hell -, Flughaut wenig dunkler graulich. Im Innern der Ohren zwischen den Falten ja eine Reihe weisslicher, drüsenartiger Punkte.

Diese Art fliegt, wie es scheint, bei Nacht; in der Dämmerung habe ich sie nie gesehen. Sie ist äusserst behende und flink in ihrer Bewegung.

Phyllorrhina vittata Peters, 1852

p. 32

Tafel VI. Tafel XIII. Fig. 7 - 13.

Ph. cervina, vittis quatuor dorsalibus albitlis, cervice albide irrorata, gastraeo canescente, lateribus albis, alis fuscis; auriculis ovatis, acuminatis; apertura frontali magna longitudinali; prosthemate lato, foveis quatuor insigni; plicis accessoriis ad utrumque ferri equini latus quaternis; cauda crure breviori.

Longitudo a rostro ad caudae apicem 0,150, capitis 0,040, antibrachii 0,105.

Habitatio: Africa orientalis, Insula Ibo, 12° 20 ' Lat. .Austr.

Phyllorrhina vittata. W. PETERS, Mittheilung in der Gesellschaft naturforschender Freunde zu Berlin, am 21. August 1849.

Der Kopf dieser grofsen Hufeisennase ist doppelt so lang wie breit und hoch; die Schnauze vorn stumpf und breit. Das Auge liegt in der Mitte zwischen Ohr und Schnauze; die Augenlidränder sind ringsum mit abstehenden Haaren besetzt. Die Ohren sind um ein Drittel kürzer als der Kopf, lang zugespitzt, am hintern Rande bogenförmig ausgeschnitten, und haben dreizehn Querfalten, von denen nur acht bis neun sehr hervorspringen; am vorderen Rande, am Längskiel, und am untern Drittel ihrer Aufsenfläche sind sie lang behaart; die Ohrecke ist klein und undeutlich abgegrenzt. Der Nasenbesatz ist ähnlich wie bei *Phyllorrhina (Rh.) insignis*, Horsfield; die vordere Abtheilung, das Hufeisen, ist einfach, viel breiter als lang, jederseits nach innen durch eine dreieckige Klappe von den Nasengruben getrennt, und in der Mitte vor ihnen mit einem abgerundeten Längswulst versehen: neben jeder Seite des Hufeisens erheben sich vier progressiv an Gröfse abnehmende Hautfalten; die mittlere Abtheilung, deren Gestalt man mit einer Hübe vergleichen kann, welche ihr spitzes Wurzelende zwischen die aufgewulsteten inneren Nasenränder absendet, ist sehr kurz, drei Mal so breit wie lang; die hinterste Ahtheilung, das Prosthema, ist so lang und breit wie die vorhergehende, hinten mit der Stirnhaut durch zwei, vorn mit der rühenförmigen Abtheilllng durch fünf Falten, zwisehen denen vier tiefe Gruben liegen, verbunden. Hinter dem Nasenblatt, sowohl bei dem Männchen wie bei dem Weibchen, liegt eine $3^1/_2$ Millimeter lange wulstig gerandete Spalte welche in eine geschlossene behaarte Höhle führt, und zu beiden Seiten derselben eine warzenförmige, durch Borsten ausgezeichnete Hervorragung mit zwei sehr feinen Oeffnungen, den Ausmündungen kleiner Drüsen. Die Lippen sind breit, an ihrer Aufsenfläche sparsam behaart und durch zahlreiche Drüsenhervorragungen ausgezeichnet. Die Schleimhaut der Unterlippe springt in der Mitte in Form einer dreieckigen glatten Fläche hervor, welcher eine kleinere körnige nackte Stelle der Oberlippe entspricht. Die Maulöffnung ist halbkreisförmig und reicht eben so weit nach hinten wie das Hufeisen. Die Schleimhaut des Gaumens bildet neun wulstige Querfalten. Der Körper ist stark und doppelt so lang wie der Kopf. Die Flughäute setzen sich ganz seitlich und entfernt von einander an. Der Oberarm ist um eine Hälfte länger

p. 33

als der Kopf; der Vorderarm und die Finger sind ebenfalls sehr lang, so dafs die Flugweite nahe an zwei Fufs beträgt. Der Daumen ist kurz, und die Halsflughaut setzt sich nicht über sein Mittelhandglied hinaus an. Die Mittelhandglieder der folgenden Finger nehmen progressiv vom zweiten bis fünften ein wenig an Länge ab. Die Phalangen des dritten Fingers zusammen sind länger als der Mittelhandknochen desselben. Die beiden Phalangen des fünften Fingers sind um ein Geringes länger als die entsprechenden Glieder des vierten Fingers. Alle vier Finger sind mit einem kleinen knorpeligen Endgliede versehen, welches eine einfache Verlängerung derselben darstellt. Der Oberschenkel ist nur wenig kürzer als der Unterschenkel, welcher ebenso lang ist wie der Kopf. Die Flughäute gehen his auf die Fufswurzel herab. Die Zehen sind kräftig; die erste und fünfte um ein Geringes kürzer als die mittleren; ihre Krallen sind merklich gröfser als die Daumenkrallen. Der kurze Schwanz ragt mit seinen letzten beiden Gliedern aus der spitzwinklig ausgeschnittenen Schenkelflughaut hervor.

Die Behaarung ist reich, an der Bauchseite, zumal am Halse und an der Brust viel länger als am Rücken; auf den Oberarm dehnt sich die Behaarung vorn und hinten gleich weit aus; am Oberschenkel dagegen geht sie an der Rückenseite weiter herab als an der Bauchseite. Die Schenkelflughaut ist bis zur Mitte sparsam und lang behaart, die Seitenflügel zeigen dagegen nur zerstreute kurze Härchen auf den Querfalten.

Die Farhe des Rückens ist rehbraun, bei dem Weibchen ins Kästenbraune spielend, mit vier gelblichweifsen Längsbinden, von denen zwei längs des Ansatzes der Seitenflügel, und zwei etwas verwischte vom Nacken herabsteigend neben der Wirbelsäule verlaufen. Oberkopf und Nacken sind mit Weifs besprengt. Die Bauchseite ist graulich weifs, an den Seiten mit einem gelblicnweifsen Saum, der sich über den Ansatz der Halsflughaut nach dem Rücken herumschlägt. Das Gesicht ist schmutzig weifs. Die nackten Theile der Lippen, der Nasenbesatz und die Ohren sind von brauner Hautfarbe. Die Flügel sind dunkelbraun, die Nägel braunschwarz. Die braunen Rückenhaare sind zum Theil einfarbig, zum Theil weifs beringt, die des Oberkopfes und Nackens zum Theil mit weifsen Spitzen versehen; die Haare des Bauches sind an ihrem Enddrittheile schmutzig weifs, im übrigen braun; die weifsen Haare zur Seite der Brust und über dem Ansatz der Halsflughaut sind einfarbig.

Das Skelet zeichnet sich, wie das der Hufeisennasen überhaupt, durch die Stärke und Breite der Rippen aus. Der siebente Halswirbel, die beiden ersten Rückenwirbel, das Manubrium sterni und die beiden ersten Rippen sind zu einem Stücke mit einander verschmolzen, eben so sind die fünf ersten Lendenwirbel zusammengewachsen, wodurch der Brustkasten eine vogelähnliche Festigkeit erhält. Es sind 11 Rippenpaare vorhanden, von denen sich 7 mit dem Brusthein verbinden. An dem Brustbein kann man aufser dem mit den ersten Rippen verwachsenen breiten Manubrium noch zwei Knochenstücke und den knorpligen Fortsatz des Processus xiphoideus unterscheiden. Die Wirbelsäule besteht aus 42 Wirbelkörpern. Diese zerfallen in 7 Halswirbel, 11 Brustwirbel, 7 Lendenwirbel, von denen der erste einen ganz kleinen zwei Millimeter langen Rippenfortsatz trägt, 4 verwachsene Kreuzbeinwirhel, und

p. 34

13 Schwanzwirbel. Die ersten Schwanzwirbel nähern sich in ihrer Gestalt noch sehr den Kreuzbeinwirbeln, wodurch es hier eben so wie bei andern Flederthieren schwierig wird, eine genaue Grenze zwischen Schwanz- und Kreuzbeinwirbeln zu ziehen. Die Länge des Schädels (Taf. XIII.) beträgt etwas weniger als ein Drittel der Wirbelsäule; die Längsgrähte desselben ist aufserordentlich stark und die Nähte sind so verwachsen, dafs sich die Grenze der einzelnen Knochen nicht mehr bestimmen läfst. Gebifs: $^{3\,2}/_{3\,2}{}^{1}/_{1}{}^{1\,1}/_{4}{}^{1}/_{1}{}^{2\,3}/_{2\,3} = 30$. Die beiden oberen kleinen Schneidezähne stehen getrennt, jeder in dem vordem Ende des Zwischenkiefers seiner Seite, nach vorn gerichtet; ihre Gestalt ist abgerundet, von aufsen nach innen und unten schräg abgestutzt. Die vier unteren Vorderzähne stehen senkrecht und der Quere Dach in zwei Reihen zwischen den Eckzähnen zusammengedrängt; ihre Krone ist dreilappig und zwar so, dafs der äufsere Lappen immer der kleinere ist. Die oberen Eckzähne sind sehr grofs, an ihrer Aufsenseite doppelt gefurcht, vorn und hinten mit einem starken Absatz versehen. Die unteren Eckzahne sind kleiner, ohne Furchung und nur am hintern Rande des stark entwickelten Cingulums durch einen kleinen hakigen Absatz ausgezeichnet. Von den obern Backzähnen ist der erste ein ganz kleiner rundlicher, nach aufsen gedrängter Lückenzahn; der zweite ist eckzahnförmig und hat drei Nebenzacken, einen vorderen sehr kleinen, einen hintern gröfseren, und einen inneren ganz oben an seiner Basis; der dritte und vierte sind an Gröfse und Form einander ähnlich, aufser den fünf Höckern auf ihrer w förmigen Schmelzleiste noch mit einem sechsten oben an ihrer innern Seite versehen: die Schmelzleiste des fünften und letzten, welche kaum halb so grofs ist wie die vorhergehenden, ist unvollständig, V förmig. Der erste untere Lückenzahn ist einwurzelig, an der Spitze zusammengedrückt, breit lanzettförmig schneidend; der folgende Lückenzahn ist

zweiwurzelig, dreiseitig, langspitzig und in seiner Gestalt der ersten Hälfte der darauf folgenden Backzähne entsprechend; diese, der dritte und vierte haben eine nach innen offene W förmige Schmelzfalte mit drei inneren und zwei äufseren Höckern, von denen der vordere äufsero der gröfste ist; der fünfte untere Backzahn ist wie die vorhergehenden gestaltet, aber es mangelt ihm das letzte Viertel, so dafs er nur vierhöckerig erscheint.

Das Oberarmbein trägt neben seinem äufsern Condylus ein kleines besonders eingelenktes Knochenstück, an welchem die langen Streckmuskeln der Hand entspringen und welches allen Fledermäusen zuzukommen scheint. Die Ulna ist rudimentär und das Olecranon getrennt. Die Handwurzel besteht aus sieben Knochen, welche in zwei Reihen, drei in der ersten, vier in der zweiten, liegen. Die Fibula ist sehr fein aber vollständig (Taf XIII. Fig. 13), wie auch bei allen übrigen Hufeisennasen, vorhanden. An dem Unterschenkel schliefst sieh die Fufswurzel an, welche eben so wie bei dem Menschen aus sieben Knochen in zwei Reihen, drei in der ersten und vier in der zweiten Reihe besteht. Darauf folgt die Reihe der fünf fast gleich langen Mittelfufsknochen, und dann die Zehen, von denen jede aus einem sehr langen Basalgliede und aus dem krallentragenden gekrümmten Endgliede besteht.

Die Zunge ist mit platten hornartigen Papillen hedeckt, welche auf der Mitte ihre vordem Hälfte gröfser und zwei- bis dreispitzig sind. Der Oesophagus geht sogleich unter

p. 35

dem Zwerchfell in einen bohnenförmigen, 35 Millimeter langen Magen über, welcher links in einen gröfsern, rechts in einen kleinem Blindsack erweitert ist; der durch eine kreisförmige Schleimhautfalte abgegrenzte Pförtner liegt ganz nahe neben der Cardia. Der ganze Darm hat eine Länge von 38 Centimetern. Die Leber liegt mehr nach rechts, und besteht aus drei Hauptlappen, einem linken gröfsern, und zwei rechten kleineren; die Gallenblase, welche grofs und von eiförmiger Gestalt ist, liegt in dem tiefen mittlern Einschnitte, wodurch der linke Lappen von dem rechten getrennt wird. Die Milz legt sich schief an den linken Blindsack des Magen, ist sehr schmal, an dem untern Ende zugespitzt und 25 Millimeter lang. Das Pancreas ist vielfach gelappt, sehr ausgedehnt und dünn. Die Nieren sind bohnenförmig, ungelappt, 9 Millimeter lang, und bestehen im Innern aus drei in sehr lange Papillen endigenden Pyramiden. Die Nebennieren sind platt, abgerundet dreieckig, ihr gröfster Durchmesser nur $^1/_2$ Millimeter lang. Die Luftröhre ist unter dem Kehlkopf zu beiden Seiten blasig erweitert. Die Lunge bildet jederseits nur einen einzigen Lappen. Das Herz hat eine Länge von 14, an der Basis eine Breite von 10 Millimetern. Der Uterus des Weibchens ist zweihörnig. Die Hoden des Männchens liegen in der Bauchhöhle; die Ruthe desselben ist 12 Millimeter lang, die Oeffnung der Harnröhre sehr weit, und die Eichel an ihrer untern Hälfte mit einem breiten Knorpel versehen. Sehr merkwürdig ist der Bau der Höhle vor der Stirn, in welche die Längsspalte hinter der Nase hineinführt; ihre Wandung besteht nämlich aus einer halbkugeligen Knorpelkapsel, die heim Durchschnitt vorn dicker als hinten erscheint; an ihrer concaven nach aufsen gekehrten Wandung münden zahlreiche Drüsehen aus, welche besonders in der vordem Hälfte starker angehäuft und entwickelt sind; aus dem hintern Theile dagegen ragen lange vorwärts gerichtete Haare hervor, welche durch das bräunliche Drüsensecret angefeuchtet sind.

Der Inhalt des Magens bestand aus Sand und Überbleibseln von Insecten.

Die beiden einzigen Exemplare, welche ich von dieser grofsen Hufeisennase erhalten habe, wurden auf Ibo, einer der Querimba-Inseln, gefangen, und zwar wurde eins derselhen auf einer Cocospalme erhascht, wo es sich durch Palmwein berauscht hatte.

Die einzige Art, welche durch ihre Gröfsenverhältnisse mit der unsrigen übereinkommt ist A. Wagners *Ph. (Rh.) gigas* aus Benguella. Sie unterscheidet sich aber leicht durch die rufsbraune Farbe, durch nur drei falten zu jeder Seite des Hufeisens, durch den Mangel (oder die Kleinheit?) der Stirnöffnung, und durch die nicht bis zur Ferse herabreichenden Flughäute.

Pipistrellus (Pipistrellus) permixtus Aellen, 1957

p. 200

Type. - F adulte, Dar es Salam, Tanganyika, 1905 (Hürstel). Musée zoologique de Strasbourg, n° 12c. Spécimen en alcool; crâne extrait, incomplet.

p. 201

Description. - C'est une espèce très semblable à *P. nathusii* (Keys. Et Blas.), mais à oreilles plus petites, n'arrivant pas à l'extrémité du museau lorsqu'elles sont repliées en avant; le sommet de l'oreille est arrondi, son bord externe légèrement concave. Le tragus est falciforme; sa plus grande largeur est atteinte un petit peu au-dessus du niveau de la moitié de la hauteur de son bord interne. Le pouce est allongé. Le patagium, attaché à la base du 5^{e} orteil, englobe complètement la queue. Le pied est plutôt petit. Le lobe postcalcanéen, large, bien marqué, est du type *nathusii*. Les plis palataux présentent la disposition suivante: 1er entier, droit, situé au milieu de C; 2^{e} entier, biarqué, au milieu de P^{4}; les quatre suivants interrompus au milieu, incurvés en arrière et partant respectivement du milieu de M^{1}, du bord antérieur de M^{2}, du bord postérieur de M^{2} et du milieu de M^{3}; 7 ^{e} entier, biarqué, partant du bord postérieur de M^{3}; cette disposition rappelle beaucoup celle figurée par KUZYAKIN pour *nathusii*.

A la face dorsale, les poils s'étendent à peine sur le cinquième proximal de l'uropatagium. La couleur primitive ne peut être indiquée, car après un séjour de plus de 50 ans dans de l'alcool, l'animal est fortement décoloré. Tout au plus, peut-on dire que les poils sont bicolores, foncés à la base, clairs au sommet.

La forme générale du crâne est assez semblable à celle de *nathusii*. Le rostre est toutefois moins déprimé et la boîte crânienne plus petite. Les processus préorbitaires sont moins développés. Comme chez *nathusii*, il n'y a pas de processus postorbitaires. La crête sagittale est bien marquée postérieurement, de même que les crêtes lambdoïdes. Les arcades zygomatiques sont fines. Le crâne est relativement plus large que chez les espèces du groupe *pipistrellus* (voir ci-dessous).

La dentition est du type *pipistrellus-nathusii*: I^{1} est bicuspide, la pointe postérieure arrive aux deux tiers de la hauteur de la pointe antérieure. I^{2} atteint la hauteur de la pointe postérieure de I^{1}; une première pointe secondaire latéro-externe se voit parfaitement par-devant et arrive au tiers de la hauteur de la couronne; une deuxième pointe postéro-interne est plus basse. C a une pointe postérieure atteignant le sixième de la hauteur de la couronne.

p. 202

P^{2} est situé sur le côté interne de la rangée dentaire et est bien développé, environ comme I^{2}; sa pointe, qui arrive au niveau de la pointe postérieure de C, est bien visible en vue latérale. P$_{4}$ est séparé de C et atteint environ les deux tiers de la hauteur de la couronne de C. Les molaires sont normales. Les incisives inférieures sont tricuspides et légèrement imbriquées. C est plus large que chez *nathusii*; sa longueur le long du cingulum est subégale à la hauteur de la couronne à son bord antérieur. P$_{2}$, don't la couronne est dirigée vers l'extérieur, mesure la moitié de la hauteur de C et les trois quarts à quatre cinquièmes de P$_{4}$.

[Table removed - eds.]

Remarques. - Si cette nouvelle Pipistrelle ne présente aucun caractère singulier, elle ne s'en trouve pas moins différenciée par un ensemble de particularités qui ne se rencontrent chez aucune autre forme africaine.

Parmi les espèces à I^{1} bicuspide, à I^{2} bien développé et à P^{2} bien visible extérieurement, elle trouve sa place dans la clef suivante:

1. Taille relativement grande. Avant-bras de 32 mm et davantage. Long, du crâne de plus de 12.5 mm. Rangée dentaire supérieure (C-M^{3}) de 4.6 à 5 mm. -> 2.

- Taille plus petite. Avant-bras de 32 mm environ ou moins. Long, du crâne de moins de 12.5 mm généralement.

p. 203

Rang. Dent. Sup. (C-M^{3}) de 3.6 à 4.2 mm: *nanus, pipistrellus, helios, nanulus, stampfli*.

2. Lobe calcanéen présent. -> 3.

- Lobe calcanéen absent: *fuscipes*

3. Canine inférieure longue et étroite; son plus grand diamètre le long du cingulum dépasse à peine la moitié de la hauteur de la couronne à son bord antérieur. Rostre déprimé. Crâne allongé, rapport larg. Zygomatique X 100 / long, totale = 600 à 610: *nathusii*.

- Canine inférieure plus forte; son plus grand diamètre le long du cingulum est subégal à la hauteur de la couronne à son bord antérieur. Rostre moins déprimé. Crâne moins allongé, rapport larg. Zygomatique X 100 / long, totale = 666: *permixtus* sp. nov.

Il faut rechercher dans la faune paléartique et orientale des affinités plus précises avec cette nouvelle espèce.

Le synopsis de DOBSON (1878: 211) conduit à *abramus*, espèce à laquelle cet auteur rattache *nathusii* et *coromandra* comme synonymes. DOBSON signale "*abramus*" à Zanzibar (spécimen e", p. 228). *P. abramus* (Temm.) est considéré aujourd'hui comme une espèce uniquement extrême-orientale (à l'ouest, jusqu'en Birmanie, selon ELLERMAN et MORRISON-SCOTT, 1951); il est probable que l'exemplaire de Zanzibar, de DOBSON, appartient à la même espèce que le mien, de Dar es Salam.

TATE (1942) a fait une revision des formes paléarctiques et orientales du genre *Pipistrellus*. Parmi les subdivisions adop-

p. 204

tées (p. 235), la nouvelle espèce peut entrer dans les groupes *abramus, coromandra* et *ceylonicus*:

Rapport : ((larg. Zygomat. X 100) / long. Totale), selon les mesures de TATE:

groupe *pipistrellus*
(qui comprend *nathusii*). . . De 601 à 610, moyenne 606
groupe *coromandra* . . . . . "603" 666" 633"
groupe *ceylonicus* . . . . . "664" 734" 688"
groupe *abramus* . . . . . "639" 734" 693
P. permixtus 666

Si l'on ne prend en considération que les groupes *coromandra* et *ceylonicus*, don't les représentants habitent les côtes de l'océan Indien, il semble, pour autant qu'un seul spécimen permette d'en juger, que c'est de *coromandra* (*sensu lato*) que *P. permixtus* est le plus proche. Parmi les formes ou espèces de ce groupe *coromandra*, on ne peut guère retenir que *aladdin* Thom. (Perse) et *coromandra* Cray (Indes) pour comparaison. Selon les mesures de TATE (1942: 291), ces formes sont toutes deux de taille inférieure à *permixtus*.

Il est certain que *P. permixtus* n'est pas un élément autochtone de la faune africaine. Ses affinités le rapprochent nettement des formes paléarctiques et orientales.

Pipistrellus abaensis J.A. Allen, 1917

p. 442

Type, No. 48979, F ad. (skin and skull), Aba, Belgian Congo, Dec. 18, 1910; Herbert Lang and James P, Chapin. American Museum Congo Expedition. Orig. No. 1825.

Size of *P. nanus*, but much lighter in coloration, and with the sides of lower back broadly naked.

Upperparts light brown or pale isabella-color, the hairs nearly unicolor from base to tip; underparts pale buffy gray, the basal portion of the hairs nearly black, the tips light grayish, with a slight buffy tone. Wing membranes attached to the entire length of the basal joint of the outer toe. Ear small, pointed, about equally convex on both borders.

Type, total length (collectors'; measurements), 77 mm.; head and body, 44; tail, 33; foot 7; ear, 10. Additional measurements from skin: Forearm, 31.4; third metacarpal, 29.7; tibia, 12.4; foot, 6; ear 7.2. An adult female topotype is larger: Total length (collectors' measurements), 84; head and body, 53; tail, 31; foot, 8; ear, 12. Forearm (in skin), 32.1; third metacarpal, 30; tibia, 12.8; foot, 6.8; ear, 9. (The skull of this specimen, No. 48980, is lost.)

Skull (type), total length, 11.7; breadth of braincase, 6.2; interorbital breadth, 3.1; maxillar breadth, 4.6; upper toothrow, 4; length of mandible, 8.1; lower toothrow, 4.2. Incisors subequal in size, the inner one slightly bifid, P^2 exceedingly minute, inserted on extreme inner edge of toothrow.

Represented, by 3 specimens, the type and two topotypes; both of the latter lack skulls. Only two of the specimens, both females, are adult, one slightly larger than the other, but both indistinguishable in coloration.
The third specimen is an immature male with the epiphyses not ankylosed but nearly adult in respect to size. It differs from the others in the pelage being nearly black above but somewhat lighter and more brownish below. All three of the specimens agree in having the sides of the lower back naked, the bare space being 5 to 6 mm. wide and 17 to 20 mm. long, extending from the base of the tail membrane anteriorly for more than half the length of the body. This feature, combined with small size, pale coloration and

p. 443

subequal upper incisors should render the present form easily recognizable. As said above, it is about the size of *P. nanus*, from which it differs strikingly in coloration, in the shape of the ears, and in the character of the upper incisors and upper premolars. It does not appear closely related to any described species.

Pipistrellus aero Heller, 1912

p. 3

Uaragess Pipistrelle

Type from summit of Mount Garguez, Mathews Range, altitude 7,000 ft., British East Africa, adult male; No. 181812, U.S. Nat. Mus.; collected by Edmund Heller, August 26, 1911; original number, 4110.

Characters. - Similar to *fuscatus* in color and in the position of the first upper premolar which is placed well inside of the tooth-row, but size of body much less, equal to that of *nanus*, which differs from it in the position of the minute first upper premolar which is in the tooth-row and can be seen from the outside. Skull larger than in *nanus*.

Coloration. - Dorsal coloration uniform vandyke-brown; underparts lighter wood-brown, the hair everywhere slate-black at base; membranes, feet, ears,, and tail black.

Measurements. - Head and body, 42 mm.; tail, 32; foot, 6; ear, 10.5; forearm, 31.5.

Skull: Condylo-incisive length, 12; zygomatic breadth, 8.5; mastoid breadth, 7; length upper tooth series to outer edge of canine, 4.8; condylo-incisive length of mandible, 9.

Two additional specimens, from the summit of Mt. Garguez are in the collection. They agree with the type in color, size, and dental characters. This species was seen only in the heavy forest on the summit of the mountain. Numbers of them were seen at dusk every evening but no other species was noted at so high an altitude.

Pipistrellus ariel Thomas, 1904

p. 157

Pipistrellus ariel, sp. n.

A pigmy species of a very pale colour.

Size very small, not exceeding that of *P. nanus*; form slender, limb-bones unusually light and delicate. Fur long, but not dense; hairs of back rather over 7 mm. in length. General colour above pale bufFy, the slaty bases of the hairs showing through; below similar, but slightly paler. Membranes pale brown, without lighter edging; naked throughout, except quite close to the body. Ears rather short; inner margin strongly convex below, with very small basal lobule, slightly convex above; tip rounded off; outer margin convex, slightly above, strongly below, with a long, low, rounded antitragal lobe. Tragus rather short, broadest rather above its inner base, inner margin straight, tip rounded, outer margin evenly convex; basal lobule distinct, rounded.
p. 158

Wings to the base of the toes. Post-calcareal lobule very narrow. Tip of tail little projecting.

Skull, as compared with that of *P. nanus*, similar in size, but with a broader, flatter muzzle and smaller brain-case. Median palatal spine less developed. Base o£ skull between bullæ conspicuously narrower.

Incisors slender, conical, unicuspid terminally, though each has a minute basal cusplet on its cingulum behind; the outer two thirds the height of the inner. Small upper premolar unusually minute, hidden in the inner angle between the closely adpressed canine and large premolar, and lower than their cingula, so as to be quite invisible from without. Lower incisors trifid, overlapping, subequal in horizontal length, but the outer pair slightly thicker than the others. Anterior lower premolar two thirds the height of the second, small in section, the canine and large premolar almost touching each other on its inner side.

Dimensions of the type (the measurements in inverted commas taken by the collector in the flesh): -

Forearm 30 mm.

"Head and body 34"; "tail 34"; "hind foot 5"; "ear 10"; tragus on inner edge 3.1; third finger, metacarpus 27, first phalanx 9.3, second phalanx 10; fifth finger 36; tibia 12.5.

Skull: greatest length 11.3; basal length in middle line 8.4; breadth of brain-case 5.5; front of canine to back of m^3 3.7; least breadth of basioccipital between bullæ 0.6.

Hab. Eastern Egyptian desert, lat. 22° N., long. 35° E. Alt. 2000 feet.

Type. Adult female. Original number 28. Collected 12th August, 1903. Two specimens.

This most interesting little bat is widely different from any species yet described, the proportions of its upper incisors distinguishing it at once from most members of the genus. Its anterior upper premolars are so minute that they would probably be overlooked by any worker only examining spirit-specimens; but there is no recorded "*Vespertilio*" of so small a size in Egypt.

Pipistrellus crassulus Thomas, 1904

p. 206

Pipistrellus crassulus, sp. n.

A medium-sized species with disproportionally short forearms.

General build thick and heavy. Muzzle broad, swollen. Ears short, laid forward they do not nearly reach to the tip of the muzzle; inner margin straight below, convex above; tip evenly and broadly rounded; outer margin straight above, slightly convex below; basal lobe small, rounded. Tragus of medium length, its greatest breadth opposite its

p. 207

inner base; inner margin straight, tip rounded, outer margin gently convex, ending below in a small basal lobule. Thumbs short, with thickened but not enlarged basal pad. Wings from the base of the toes. Calcars about equal in length to the free border of the uropatagium; postcalcareal lobules distinct but narrow. Tail involved in membrane almost to the tip. Penis very long, slender.

Fur 3.5 - 4.0 mm. long on back. Uniformly dusky brown above, scarcely paler below. Membranes blackish brown throughout, without any trace of white margins.

Skull broad, stout and flattened, conspicuously broader and heavier, especially anteriorly, than in *P. pipistrellus*, which has a much longer forearm. Upper profile straight, the frontal region not inflated.

Inner upper incisors very thick, bifid; the postero-external cusp nearly as long as the main one; outer incisor slender, unicuspid, reaching about halfway from the cingulum to the tip of the inner tooth. Small upper premolar in the inner angle between the canine and large premolar, which touch one another outside it; not visible from without. Lower incisors broad, bifid. First lower premolar about three fourths the height of the second.

Dimensions of the type (measured in spirit): -

Forearm 28 mm.

Head and body 47; tail 27; ear 10; tragus on inner edge 3.5; thumb, free of membrane (c. u.) 4; third finger, metacarpus 26, 1st phalanx 9, 2nd phalanx 8.8; fifth finger 37; lower leg 12; hind foot, from back of calcar (c. u.) 7; penis 11.

Skull: greatest length 12.7; mastoid breadth 7.7.

Hab. Efulen, Cameroons.

Type. Adult male. Collected by G. L. Bates. One specimen.

This bat, with the short forearm of such pigmy species as *Pipistrellus Stampflii* and *minusculus*, has a very much larger body and head. The breadth and flatness of the skull are particularly noticeable.

Pipistrellus culex Thomas, 1911

p. 458

Pipistrellus culex, sp. n.

F. 100. Kabir. 2700'. B.M. no. 11.3.24.4. Collected 15th May, 1910. *Type*.

A very small pale species. Inner upper incisors practically unicuspidate.

Size rather greater than in *P. stampflii* and *minusculus*. Fur about 4.5 mm. in length on the back. General colour above near "wood-brown," below rather paler, the hairs both above and below blackish slaty basally. Ears with a well-marked squarish lobe at the base of their outer margin; tragus without basal lobule, broadest opposite the middle of its straight inner margin. Wings from the base of the outer toe. Calcar with a narrow calcareal lobule.

Skull very delicate, low and narrow; the brain-case narrower than in *P. stampflii*.

Upper incisors slender, unicuspid, the outer nearly as long as the inner. (If a secondary cusp has been present on the inner tooth it must have been very small and close to the tip of the tooth.) Small premolar half internal, visible from without. Lower incisors tricuspid, not overlapping.

p. 459

Dimensions of the type (the starred measurements taken in the flesh): -

Forearm 28.5 mm.

Head and body *39; tail *27; ear *9; tragus on inner edge 2.6; third finger, metacarpus 27, first phalanx 9; lower leg and hind foot (c. u.) 14.5.

Skull: greatest length 11.1; basi-sinual length 8.6; interoibital breadth 3.3; breadth of brain-case 5.9; palatosinual length 4.2; front of canine to back of m^3 3.6; front of p^4 to back of m^2 2.2; three lower molars 2.5.

Hab. and *Type* as above.

This little bat would seem to be readily distinguishable from the other small species of the genus by its pale colour and unicuspid upper incisors.

Pipistrellus deserti Thomas, 1902

p. 4

71. M. Mursuk. 30/5/1.

A small buff-coloured desert ally of *P. kuhli*, with a particularly small skull.

Size smaller than *P. kuhli*, but the forearm-length not so much less than in that form as to be in proportion with the much smaller skull. General structure, of ears, wings, and dentition, as in *P. kuhli*. Ears and tragus pale transparent buffy, little darker than the general colour. Wings dark brown, the usual white edging very conspicuous. Interfemoral paler brown, white posteriorly.

Colour of fur pale buffy, between cream and pinkish buff of Ridgway, strikingly different from the colour in ordinary *kuhli*. The hidden bases of the hairs dull slaty. Belly-hairs blackish slaty basally, whitish buff terminally. Skull very small and delicate; the total length, the breadth across brain-case, and the length of the tooth-series, all conspicuously, less than in *P. kuhli*, whether from Europe, Morocco, Tunis, or Egypt.

Dimensions of the type: -

Forearm 29.5 mm.

Head and body (measured in flesh) 43; tail (do.) 33; ear (do.) 10; third finger, metacarpal 29, first phalanx 10, second phalanx 8.5; lower leg and hind foot (c.u.) 22.

Skull - greatest length 11.6, median length above 10, median length below 9; interorbital breadth 4.1; intertemporal breadth 3.1; breadth of brain-case 62; front of canine to back of m^1 4.3.

Type. Adult male. Original number 71.

Although with the general characters of *P. kuhli*, I do not feel justified in calling this Bat only a subspecies of that animal, for other North-African bats of this group, while tending towards *P. deserti* in colour, show no approach to its conspicuous reduction in size of skull. Examples of *P. kuhli* from Morocco (*Dodson*), Tunis (*Anderson*), and Egypt (*Anderson*), all have skulls of the full normal size.

Two names might have been thought to refer to it. Cretzschmar's *V. marginatus* from Nubia is paler in colour than usual, but Dr. Andersen's specimens show that the form from there is of the usual size.

Pipistrella minuta Loche, on the other hand, is so far smaller as either to be a totally different form, or, more probably, the young of some indeterminable species. Its locality is in the Algerian range of *P. kuhli*.

Pipistrellus eisentrauti Hill, 1968

p. 45

Holotype: M. Eisentraut No. 498 (skin and skull, the right bulla and right first and second lower molars missing). Adult M. Camp V, Dikume-Balue, Rumpi Highlands. 18th. February 1967. Collected by Professor Martin Eisentraut and now in the collection of the Museum Alexander Koenig, Bonn, No. 68.5.

Other material: M . Eisentraut No. 198 (skin and skull). Adult F. Camp II, Mount Kupe, c. 1,100 metres. 30th. November 1966. B.M. 67.2129 (originally M. Eisentraut 643) (skin and skull). Old F. Buea, Mount Cameroon. 15th. March 1967. Both collected by Professor Martin Eisentraut: the first in the collection of the Museum Alexander Koenig, Bonn, the second presented to the British Museum (Natural History).

Diagnosis: A large pipistrelle (forearm length c. 33.5 - 35mm.) characterised by high braincase with elevated frontal region which is almost as high as the occiput; expanded supraorbital region with slight but clearly defined supraorbital ridges terminating in an angular junction with the orbital margin, the upper surface of the rostrum thus more or less pentagonal; high, massive rostrum; absence of basioccipital pits and by long, narrow upper incisors which are bicuspid and blade-like.

Description: Dorsal pelage dark brown, the hairs unicolorous: ventral pelage slightly paler, the hairs bicolored, basally blackish brown, tipped with dark brown. The specimen from Buea is slightly paler above and below than the other two and ventrally is a little tinged with buff. Ears of moderate size, rounded at

p. 46

the tip, margin smoothly convex anteriorly with a small basal lobe, posteriorly nearly straight in distal part, proximal part convex with small antitragal lobe. Tragus a little more than one third the length of the ear, its tip rounded, its greatest width at about one half its height; margin nearly straight anteriorly with slight basal concavity, posteriorly slightly convex for most of its length but nearly straight at the base. Wing inserted at base of first digit: a small post-calcaneal lobe or epiblema.

Braincase broad, inflated, frontal region elevated almost to the occipital height; slight sagittal and lambdoid crests. Interorbital region wide; rostrum short, deep and massive, its upper surface nearly pentagonal in outline; supraorbital region inflated and swollen with a shallow median depression, the supraorbital ridges slight but clearly defined, terminating in an obtusely angular junction with the orbital margin which is nearly vertical anteriorly. Narial emargination short, narrow, rounded posteriorly, extending for approximately one half of the distance from the tip of the rostrum to the anterior orbital margin. Palate short, wide, with a narrow, U-shaped anterior emargination extending posteriorly almost to a line joining the posterior faces of the canines; broad, ligulate post-palatal spicule. Basioccipital pits lacking: width of bullae equal approximately to one and one half times their distance apart.

Inner upper incisor (i^2) long; narrow, blade-like, its longitudinal diameter approximately twice its transverse diameter, so orientated that posteriorly it is directed slightly inwards from the toothrow. It is strongly bicuspid, with a large anterior cusp and an equally massive but slightly lower posterior cusp: there is a low, undeveloped posterior cingulum cusp. Outer upper incisor (i^3) short, wide, its longitudinal diameter little more than one half its transverse diameter, lying laterally and slightly posteriorly to i^2 with its longer axis nearly transverse to the toothrow. Its principal cusp extends almost to the tip of the posterior cusp of i^2: it is hollowed posteriorly and flanked by low lateral cingulum cusps. Canines
slender and delicate but relatively massive at the base, with a low posterior cingulum cusp: the upper canine almost in contact with the posterior upper premolar (pm^4). Anterior upper premolar (pm^2) small, with well-developed cingulum and conical cusp, just visible externally, recessed into the angle between the posterior face of the canine and the anterior face of pm^4. Lower incisors tricuspid and slightly imbricated: anterior lower premolar (pm_2) reduced, its height and basal area little more than one half that of the posterior lower premolar (pm_4).

Remarks: Apart from any other features, the large size and especially the large skull of *P. eisentrauti* readily distinguish it from many of the African species of *Pipistrellus* with bicuspid i^2 such as *nanus, nanulus, musciculus* and *pipistrellus*. Its narrow tragus, high braincase and inflated supraorbital region disassociate it from *savii*: no specimens of *permixtus* Aellen, 1957 or *inexspectatus* Aellen, 1959 are available, but Dr. H.-J. Kuhn of Frankfurt/M. has kindly loaned photographs of the skulls of the type specimens so that comparison could be made. *Pipistrellus eisentrauti* is larger than either of these and has a higher braincase which is more elevated frontally while neither *permixtus* nor *inexspectatus* has the supraorbital region so expanded that the upper surface of the rostrum assumes a pentagonal outline. *Pipistrellus crassulus* approaches *eisentrauti* in size and also displays some lateral expansion of the supraorbital region: however, in *crassulus* the braincase is low and the frontal not elevated, the rostrum lower and less massive than in *eisentrauti* and shallow basioccipital pits are present.

Pipistrellus eisentrauti bellieri De Vree, 1972

p. 412

TYPE - KMMA (Tervuren) RG 35686, skin and skull, adult F. Adiopodoumé (5° 19-21' N - 4° 7-8' W), alt. 0 - 30 m, 19th November 1969. Collected by the author, but prepared and labelled in the Laboratoire d'Ecologie (L. BELLIER) of the ORSTROM, original number AX 0104.

DIAGNOSIS - Differing from *Pipistrellus eisentrauti* in its generally smaller size; hairs of the pelage unicolorous throughout their length land shorter; skull with less inflated frontal region, but with characteristic rostrum, with upper surface nearly pentagonal in outline.

DESCRIPTION - The colour of the dorsal pelage is dark brown; the ventral pelage is paler. The hairs, both above and below, are unicolorous throughout their length. The wing membranes are blackish-brown and there is no white hind-margin. The wing is attached to

p. 413

the base of the first toe. The interfemoral membrane is dark brown; a small postcalcaneal lobe is present. The ears are blackish-brown; the tip is rounded off, its external border straight in the upper part and convex in the lower part. There is a small semicircular antitragal lobe. The tragus has its greatest width at about one half the height of its internal border. The tip is rounded; the inner margin is straight, the outer convex in the upper part, nearly straight at the base and provided with a small basal lobule.

The skull 1s proportionately large. The frontal region is inflated and elevated, but not to the same extent as in *P. eisentrauti* from Cameroun. There is a slight sagittal crest and the lamboidal crests are clearly developed. The rostrum is short and wide; its upper surface is more or less pentagonal in outline. The supraorbital region is swollen, but there are no pronounced median or lateral depressions in the rostrum. The supraorbital ridges are very slight. The palate is longer than it is wide. There is a relatively broad and U-shaped anterior palatal emargination and a broad post-palatale spicule. The width of the bullae is equal to 1.4 times their distance apart.

The right upper incisors are broken and the whole dentition is unfortunately very warn. The left inner upper incisor is long, narrow and bicuspid, but it is impossible to determine the relative height of the cusps; there is a low posterior cingulum cusp. The outer upper incisor is short and wide, extending well beyond the cingulum of the inner upper incisor; its principal cusp is completely worn; there is a well developed posterior cingulum cusp. The upper canine is not in contact with the posterior upper premolar. The anterior upper premolar is small, lying in the toothrow and visible from the outside; it has a well developed cingulum and a conical cusp. The lower incisors are tricuspid. The anterior lower premolar is a little more than half the height of the posterior lower premolar. The lower canine has a low antero-lingual cingulum cusp.

REMARKS - This single specimen from Ivory Coast was carefully compared with the types or other specimens of all previously described African species of *Pipistrellus*, present in the British Museum (London), the Museum Alexander Koenig (Bonn), the

Museum d'Histoire Naturelle (Genève) and the Koninklijke Museum voor Midden-Afrika (Tervuren). It is obviously a distinct west African representative of *P. eisentrauti* of Cameroun. Its distinguishing features are well marked, but in view of the poor knowledge of the variability

p. 415

of the characters on which the species are founded, such as size, colour, form of tragus and tooth proportions, it is thought best to give the Ivory Coast form subspecific status at present. It may be stressed that a critical revision of the species of *Pipistrellus* is highly desirable.

P .e. bellieri resembles *P .e. eisentrauti* HILL, but is smaller, has unicoloured and not bicoloured ventral pelage, a less inflated frontal region and a slightly smaller braincase. The hairs of *eisentrauti* are about 2 mm longer than in *bellieri*. It is of interest to remember in this connection that *eisentrauti* is a montane form, the collecting localities lying over 1000 m, while *bellieri* is a lowland form, the type locality lying at sealevel. The difference in size and in the length of the hairs is in all likelihood due to this difference in altitude.

Some points of comparison may be noted with other species possessing a bicuspid inner upper incisor, with which this new pipistrelle might be confused. *P. crassulus*, which is of about the same size and has also an unicoloured ventral pelage, is distinguishable by its lower braincase, less inflated frontal region and its dorsal profile being nearly straight. *P. crassulus* has the supraorbital region also somewhat expanded, but the rostrum is clearly smaller and lower than in *P. eisentrauti bellieri* (see table 1).

P. inexspectatus is of about the same external size, but has a bicoloured pelage; its skull is relatively smaller, the rostrum lower and the supraorbital region much narrower than in *P. e. bellieri* (see table 1). Moreover in *inexspectatus* there is a pronounced depression on each side of the rostrum, a character which it shares with *P. anchietae*.

P.e. bellieri is equal to or slightly larger than *P. nanus, P. nanulus* and *P. musciculus*, but its much larger skull, massive rostrum and expanded supraorbital region immediately distinguishes it from either of these species.

Pipistrellus fouriei Thomas, 1926

p. 288

F. 1390 (very old). Ukualukasi, N.W. Ovamboland. 3900'. 7 October, 1924. B.M. No. 25.12.4.20. *Type*.

A very minute species, pale with bicolor fur.

Size very small, the skull as small as in *P. ariel* and *culex*, although the forearm is not so short as in *nanulus*, *pusillulus*, and some others with larger skulls. Build light and delicate, not as in some of the minute Congo species. General appearance very like that of the East African *P. helios* Heller, the hairs of the upper surface similarly drab, the hairs dark slaty at base, then drabby whitish, darker drab terminally. Under surface paler drab, the hairs blackish slaty for their basal three-fouths, those along sides and on the base of the interfemoral drabby whitish to their roots. Ears rather narrow, inner margin slightly convex, upper half of outer margin straight or even concave. Tragus of medium size, rather broader terminally, but by no-means as in the Noctule, as Peters says is the case in his *pusillulus*. Wing membranes greyish brown, with white edges; interfemoral with whitish transverse lines.

Skull low, light and delicately built, the brain-case flatter than in *ariel* and *helios*, more as in *culex*. Upper incisors apparently about as in *nanus*, but being much worn in the single specimen, their exact shape cannot be described, the outer incisor about three-fourths, the height of the inner. Small premolar well developed, visible from outside, the canine and large premolar not touching each other outside it.

Dimensions of the type:-
Forearm 29 mm.
Head and body 38 mm.; tail 30. Third finger, metacarpal 27, first phalanx 9; lower leg and hind foot 16.

Skull: greatest length 11 mm.; condylo-basal length 10.1; breadth of brain-case 5.8; palato-sinual length 4; breadth across molars 4; combined length of large premolar and first two molars 2.3; front of canine to back of m^3 3.5.

Hab. And Type as above.

The pale colour and small skull of this tiny Bat will readily distinguish it from any described species. It has, indeed, a smaller skull than any known species except *P. ariel* and *culex*. Bocage's *P. bicolor* from Angola is a dark-coloured form, while the skull of Peter's *pusillulus*, as figured in his plates of Chiroptera, is decidedly larger, almost equalling that of *P. nanus*.

Tome's *P. rusticus*, obtained by Andersson in this same region, also has a very much larger skull. The two co-types of it are in the British Museum, received in the Tomes collection, and of these No. 7.1.1.419, an old female, may be now selected as its lectotype.

Named in honour of Dr. Fourie, of Windhuk, who has rendered assistance to Capt. Shortridge in various ways, an assistance which has been the more effective because of his own very considerable knowledge of the Mammalogy of South-West Africa.

Pipistrellus fuscipes Thomas, 1913

p. 315

Near *P. rueppelli* and *pulcher*, but outer incisors larger.

General characters, including the striking contrast between the white or buffy underside and the greyish upperside, as in *P. rueppelli* and *pulcher*, but the membranes rather paler, while the forearms, hind legs, feet, and tail are darker, apparently black, so as to form a marked contrast with the pale

p. 316

membranes. Feet large in proportion. Calcar long, without post-calcareal lobule. Wings to the base of the fifth toe.

Skull rounder and more swollen than in *P. rueppelli*, the frontal region broader and more convex, and the brain-case more inflated. Supra-orbital edges more rounded, less ridged. Bony palate slightly shorter posteriorly.

Inner upper incisors not so long as in *P. rueppelli*, bicuspid, the secondary cusp well developed. Outer incisor much larger than in *rueppelli*, its longer cusp falling not far short of the outer cusp of the inner incisor, its base with two small secondary cusps, postero-internal and postero-external. Small upper premolar well developed, nearly half the height of the large premolar, quite visible from without, in the centre of the fairly large space between the canine and large premolar.

Dimensions of the type (the italicised measurements taken in the flesh): -

Forearm 36 mm.

Head and body 49; tail 41; ear 12; third finger, metacarpal 34.5, first phalanx 12.6, second phalanx 11; tibia 14; hind foot (c. u.) 10.

Skull: greatest length 13.5; basi-sinual length 9.8; front of canine to back of m^3 4.8.

Hab. Uganda. Type from 60 miles W. of Entebbe. Alt. 3700'.

Type. Adult male. B.M. no. 6.7.1.5. Original number 1. Collected during the Ruwenzori Expedition by R. E. Dent. Several specimens.

In both *P. rueppelli* and *P. pulcher* the outer incisor is minute, and in the type of the latter species, which in other respects seems nearest to *P. fuscipes*, there is no indication of the characteristic contrasted coloration of the limbs and membranes.

Pipistrellus helios Heller, 1912

p. 3

Samburr Pipistrelle

Type from Merelle Water, 30 miles south of Mt. Marsabit, British East Arica; adult male; No. 181813, U.S. Nat. Mus.; collected by Edmund Heller, July 22, 1911; original number, 3065.

Characters. - Related most closely to *nanus* but size much less and coloration much paler; size of *culex*, but inner upper incisors broad

p. 4

and bifid at tip; from *ariel* it differs in bifid inner upper incisor and large size of first upper premolar

Coloration. - Dorsal haired area ochraceous-buff; the hair at extreme base deep black; underparts lighter, buff in color, the hair deep black on the basal two-thirds of its length; ears naked, clay color; membranes blackish, narrowly edged by white.

Measurements. - Head and body, 45 mm.; tail, 31; hind foot, 5; ear, 9; forearm, 27.5.

Skull: Greatest length, 11; condylo-incisive length, 10.6; basilar length, 8.3; zygomatic breadth, 7; interorbital constriction, 3.2; palatilar length (nasal notch), 4.1 ; upper cheek teeth, 2.9; condyio-incisive length of mandible, 7.7; coronoid-angular depth of mandible, 2.8.

Three specimens of this diminutive Pipistrelle are in the collection. All were collected in the Northern Guaso Nyiro watershed.

Pipistrellus inexspectatus Aellen, 1959

p. 226

Type. - M adulte, en alcool. Ngaouyanga, vallée de la haute Bénoué, Cameroun, 11.7.1947; coll. A. Monard et V. Aellen, n° orig. 954. Musée d'Histoire naturelle de La Chaux-de-Fonds.

Cette espèce a été confondue jusqu'à présent avec *Pipistrellus marginatus* (Cretzschmar). La description originale de *Vespertilio marginatus* Cretzschmar (1826) est insuffisante pour une identification sûre; aucun caractère et aucune mesure du crâne ne sont donnés; la dentition, en particulier, n'est pas décrite. TEMMINCK (1837), qui donne une nouvelle description de *V. marginatus*, rapporte à celui-ci des spécimens de Tripoli et de Sardaigne; il précise que la première incisive est "longue et droite" et la seconde "accolée à la canine, très petite".

V. marginatus a été couramment mis en synonymie de *Pipistrellus kuhli*, avec des raisons plus ou moins valables. L'assertion la plus probante est fournie par MERTENS (1925), qui a revu le type de CRETZSCHMAR déposé au Senckenberg-Museum et qui le rapporte à *P. k. kuhli*.

Cependant, G. M. ALLEN (1914) avait réhabilité l'espèce de CRETZSCHMAR en lui identifiant un spécimen F obtenu à El Garef,

p. 227

près de Roseires (Soudan). L'auteur précise que sa Pipistrelle possède une première incisive supérieure (I^1) fortement bicuspide et mesurant environ deux fois la hauteur de la seconde incisive. Comme chez *P. kuhli*, I^1 est unicuspide et I^2 plus petit que la moitié de I^1, il ne pouvait s'agir de cette espèce.

Lors de la Mission scientifique suisse au Cameroun, j'ai récolté un spécimen que je rapportais à *P. marginatus*, en acceptant la réhabilitation de ALLEN (cf. AELLEN, 1952). Grâce à l'amabilité du Dr H. Felten, j'ai obtenu les précisions désirables concernant le type de *Vespertilio marginatus*: le crâne étant resté dans la peau et vu l'état vétusté de celle-ci, il serait risqué de l'extraire. Par contre, le Senckenberg-Museum (Frankfurt) possède un autre spécimen, récolté par RÜPPELL au même endroit, la même année, donc un topotype: I^1 est unicuspide et I^2 est plus petit que la moitié de I^1. Il ne fait alors plus de doute pour moi que *Vespertilio marginatus* Cretzschmar (1826) = *Pipistrellus kuhli* (Kuhl, 1819).

La Pipistrelle trouvée dans le N du Cameroun ne peut être assimilée à aucune espèce africaine; il convenait donc de lui donner un nouveau nom.

Diagnose. - *Pipistrellus* de taille moyenne (avant-bras 31 mm, long, du crâne 13 mm). I^1 bicuspide. I^2 environ de la moitié de la hauteur de I^1. P^2 très petit, non visible du côté externe ; C et P^4 sont en contact. I_{1-3} tricuspides. Tragus ayant sa plus grande largeur au niveau du tiers inférieur de son bord interne; lobule de la base du bord externe présent. Oreilles de longueur moyenne (11,5 mm) à sommet largement arrondi. Un liseré blanc très net au patagium, de la pointe de la queue à celle du troisième doigt.

Description. - Je renvoie à la description détaillée que j'ai donnée, sous le nom de *Pipistrellus marginatus* (Cretzschm.) (AELLEN, 1952: 80-81).

Remarques. - Cette nouvelle espèce ne semble avoir comme plus proche parent que *Pipistrellus anchietae* (Seabra), d'Angola. Toutefois, cette dernière s'en distingue par la couleur,
par des oreilles plus petites et pointues, par les longueurs relatives des quatrième et cinquième métacarpes (cf. HILL et

p. 228

CARTER, 1941). Ces différences sont peut-être seulement d'ordre subspécifique; mais il faudra attendre une revision générale des Pipistrelles africaines pour tenter de tels regroupements de formes.

Le spécimen du Soudan, attribué par G. M. ALLEN à *Pipistrellus marginatus*, semble bien devoir être assimilé à *P. inexspectatus*: le patagium possède le liseré blanc, la dentition correspond parfaitement; seul le crâne est plus petit (voir mesures ci-dessous).

Parmi les espèces africaines à I^1 bicuspide, à I^2 bien développé et à P^2 non visible extérieurement, la nouvelle espèce trouve sa place dans la clé suivante:

1. Taille très petite: avant-bras de 30 mm ou moins, long, du crâne inférieure à 11,5 mm
musciculus Thom., *? pagenstecheri* (Noack)

- Taille plus grande: avant-bras généralement de plus de 30 mm, long, du crâne 11,5 mm ou plus. --> 2

2. I_{1-3} bicuspides. *crassulus* Thom.

- 1^$_{1-3}$ tricuspides. --> 3

3. Tragus ayant sa plus grande largeur au niveau du milieu de son bord interne. *savii* (Bonap.)

- Tragus ayant sa plus grande largeur au niveau du tiers inférieur de son bord interne. --> 4

4. Oreilles petites et pointues. Pas de liseré blanc au patagium. *anchietae* (Seabra), *rusticus* (Tomes)

- Oreilles plus grandes et largement arrondies. Un liseré blanc très net au patagium. *inexspectatus* sp. nov.

Je n'indique ci-dessous que les principales mesures. Pour plus de détails, je renvoie à ma description de 1952.

Pipistrellus Kuhlii fuscatus Thomas, 1901

p. 34

Similar in all essential respects, in size, proportions, shape of ears and tragus, and in dentition, to the true *P. Kuhlii*, but distinguished by its uniform dark colour. The body is dark smoky brown above and scarcely lighter below, and the ears and volar membranes are uniformly dark slaty grey, without trace of the white edging so characteristic of *P. Kuhlii*.

Dimensions of the type (an adult male in spirit): -

Forearm 35 millim.

Head and body 45; tail 34; ear 12.5; tragus on inner edge 4; third finger, metacarpal 32, first phalanx 12, second phalanx 10; lower leg 14.5.

Type. Male. Collected 19th October, 1900, and presented by Sir H. H. Johnston

---

Pipistrellus marrensis Thomas and Hinton, 1923

p. 249

M. 633, 653, 656. Foot-hills of S. Jebel Marra. 4000'.

Essentially as in *P. deserti* Thos., but of smaller size and darker colour.

Colour comparatively dark and rich, much like that of Egyptian specimens of *P. kuhli*, the general hue of the upper parts being near "Dresden brown. " of Ridgway. Ears noticeably darker than back. Wings dark brown, with usual whitish edgings; interfemoral paler. Tragus shorter and broader than in *deserti*, with

p. 250

broadly rounded tip and parallel borders; the inner border the longer. Forearm not exceeding 28 mm. (29.8 in *deserti*).

Apart from its slightly smaller size, the skull agrees with that of *P. deserti*. The outer upper incisor and the small upper premolar p^2 appear to be a little more reduced than in *deserti*, but the available material shows a rather wide range of variation in these respects. In the type-skull i^2 is both absolutely and relatively much smaller than in the only known skull of *deserti*; and the point of the tooth does not rise above the cingulumi of i^1. The small premolar is also greatly reduced, and so crowded between the canine and p^4 that it is not easy to detect. But in the fragments, all that is left of the two other skulls from Jebel Marra, the teeth in question, though rather smaller than in *deserti* are considerably larger than in the type.

Dimensions of the type: -

Head and body 37 mm.; tail 21; hind foot 5.5; ear 12. Forearm 26.5; third finger 46 (m.c. 24.5; phalanges 8.7 - 7.5 - 5.5); lower leg and hind foot (c.u.) 14.5.

Skull: greatest length 11.2; median length above 9.6; median length below 8.1; interorbital breadth 4.3; intertemporal breadth 3.4; breadth of brain-case 6.7; canine to m^3 3.8.

Hab. Foot-hills, S. Jebel Marra; altitude 4000'.

Type. Adult male. B.M, No. 23.1.1.15. Original No. 633. Collected April 3, 1921.

This interesting little bat is, no doubt, closely related to *P. deserti*, described from Tripoli. Its smaller size, darker colour, shorter tragus, and possibly more reduced dentition seem to warrant its receiving distinct specific rather than subspecific rank. The individual variation noticed in the dentition is of some interest in a group in which, normally, even minute dental characters are surprisingly constant.

Both *marrensis* and *deserti* are apparently closely allied to *P. kuhli*; and we can see no good reason for placing them in the genus *Scotozous* (cf. Miller, Fam. & Gen. Bats, p. 206, 1907).

Pipistrellus minusculus Miller, 1900

p. 647

Type. - Adult female (in alcohol no. 84500 U. S. National Museum. Mount Coffee, Liberia, May, 1894. O. F. Cook. collector

Characters. - Similar to *Pipistrellus stampflii* (Jentink), but smaller, the tail relatively longer and color "more reddish brown."

Ears. - The ears are rather short; laid forward they extend to extremity of muzzle. Anterior margin of conch abruptly convex at base, then slightly convex to narrowly rounded tip. Posterior border concave to middle, then somewhat more strongly convex to deep notch separating antitragus from rest of ear. Antitragus small but sharply defined, subquadrate in outline, its height to its width. Inner surface of conch with five or six ill-defined cross ridges.

Tragus blunt, slightly curved forward, broader above than at base.

Membranes. - The membranes are very thin and delicate. Wings from base of toes. Free border of uropatagium longer than calcar.

Feet. - The feet are short, scarcely one-half as long as tibiæ. Calcar nearly double as long as foot, terminating in a distinct lobe, and noticeably keeled posteriorly.

Fur. - Fur short, that on middle of back about 5 mm. in length. It is closely confined to body, barely extending on membranes except as a thin sprinkling of scattered hairs.

Color. - Dorsal surface raw umber, slightly more yellowish posteriorly than anteriorly. Ventral surface yellowish wood-brown, in pubic region tinged with gray. The hairs are everywhere slaty black through basal half or more. Ears and membranes blackish brown,

p. 648

the wings and uropatagium with a very narrow pale border along free edge.

Skull. - The skull of *Pipistrellus minusculus* (figs. 43b), which I am unable to compare with that of *P. stampfli*, is considerably smaller than that of the European *P. pipistrellus* (fig. 43a). The reduction in size if chiefly due to shortening of the rostrum and flattening of the braincase, but, aside from the general difference in size and form, there are no very striking characters to distinguish the skull of the African animal. The premaxillaries in *P. minusculus* are more abruptly bent downward than in *P. pipistrellus*, the anterior nares thus appearing to open more distinctly forward and less upward. Interpterygoid space *slightly broader than long*. Audital bullæ relatively smaller than in *P. pipistrellus* and space between them actually as well as relatively greater.

Teeth. - The teeth are essentially as in *P. pipistrellus*, though much smaller. Crown of middle upper molar narrower and with more narrowly conical protocone. Hypocone of first and second molars minute but distinct. The mandibular teeth present no peculiarities.

Measurements. - External measurements of type: total length 70; tail vertebræ 31; tibia 9.4; foot 5.4; calcar 9; forearm 26.6; thumb 4.8; second digit 23; third digit 45; fourth digit 40; fifth digit 35; ear from meatus 8; ear from crown 7; width of ear 7; tragus 4.4.

Cranial measurements of type: greatest length 11; basal length 10; basilar length 8; median palatal length 4.6; lachrymal breadth 4.8; least interorbital breadth 3.2; zygomatic breadth 7; mastoid breadth 6.2; occipital depth 3.6; upper toothrow (exclusive of incisors) 4; mandible 7.4; mandibular toothrow (exclusive of incisors) 4•

Specimens examined. - Three, all from the type locality.

Remarks. - I should hesitate to separate this species from *Pipistrellus stampflii* had not Dr. Jentink made comparison of one of the Mount Coffee specimens with the type of the latter. After pointing out an

p. 649

error in the original description of *P. stampflii* in which the length of forearm is recorded as 32 mm. instead of 27 mm.. he continues (in letter under date of April 22, 1900) : "your Liberian bat is still smaller [than *P. stampflii*], but its tail is longer. I think it is a new species, particularly as it is much browner-red colored than *stampflii*. As far as I can see the dentition is the same, though all the teeth appear to be smaller." The more important measurements of the type of *Pipistrellus stampflii* are: total length 62; tail vertebræ 24; forearm 27

Pipistrellus musciculus Thomas, 1913

p. 316

A very minute species with unicolor fur.

Size excessively small, smaller than in any known bat. General colour perfectly uniform umber-brown, slightly darker than Ridgway's "burnt umber," the hairs ot the same colour from base to tip; under surface similar, though appearing slightly lighter owing to the glossy tips to the

p. 317

hairs. Ears and membranes very dark, practically black. Inner margin of ears strongly convex at base, straight above; outer margin concave above, convex below. Tragus of medium size, its inner margin slightly concave, its outer convex, with an unusually large angular basal lobe. Wings to the base of the toes. Post-calcareal lobule well developed.

Skull very small, rounded, with short broad muzzle and proportionally high brain-case, not so flattened as in *P. minusculus* and other pigmy species. Palate extended posteriorly further than in any of the allied forms.

Upper inner incisor bicuspid, outer incisor probably also bicuspid, but too worn down in the type for exact description, its tip about equalling the posterior cusp of the inner incisor. Anterior premolar small, not visible externally and not exceeding in height the cingular cusps of the canine and large premolar. Lower incisors small, tricuspid, not crowded or overlapping.

Dimensions of the type (the italicised measurements taken in the flesh): -

Forearm 24.4 mm.

Head and body 40; tail 24; ear 9.5; third finger, metacarpus 23.5, first phalanx 10.6; lower leg and hind foot (c.u) 15.2.

Skull: greatest length: 10.7; condylo-basal length 10.4; basi-sinual length 8; zygomatic breadth 7.5; intertemporal brain-case 5.5; palato-sinual length 4.4; front of canine to back of m^3 3.5; p^4-m^2, length on cuter edge 2.5.

Hab. Bitye, Ja River, S.E. Cameroons. Alt. 2000'.

Type. Old male. B.M. no. 13.2.8.1. Original number 622. Collected 3rd September, 1912, by Mr. G. L. Bates.

"Caught in hollow palm leaf stalk - another got away." - *G. L. B.*

This minute species appears to be the very smallest bat as yet descibed, its forearm being less than an inch in lenth. It is readily distinguishable from the other small African species by its short stumpy skull, elongated palate, and unicolor fur, the allied species having the fur dark basally and pale terminally. In *P. pusillulus*, Peters, which was described as having a forearm only 25 mm. in length, the skull is as large as in *P. nanus*, to which Dobson was probably right in referring it; its fur, as in the oter small species, was bicolor.

Pipistrellus nanulus Thomas, 1904

p. 198

A pigmy species with very short forearm. A bone in the penis.

Size very small. Form fairly stout, the body large in proportion to the short forearms, which are shorter than any hitherto recorded in this genus. Fur of medium length; hairs of back about 4 mm. long. Muzzle thick and broadly rounded, the glandular prominences well developed. Ears rather short, their inner margin straight basally, gradually curving round to form ihe broadly rounded end to which there is no defined tip; outer margin slightly concave mesially, slightly convex below; basal lobe low, well defined posteriorly. Tragus of medium length, fairly broad, its broadest part opposite the middle of its inner margin; the latter straight or faintly concave, tip blunt, outer margin convex; basal lobe sharply angular. Limbs and feet short; wings to the base of the toes; postcalcareal lobule narrow, distinct; extreme tip of tail projecting; penis with a bone, its prepuce hairy to the tip.

Colour (in spirit) blackish brown above and below. All the membranes also very dark, without lighter edging.

Skull broad and rounded, with large low brain-case and short muzzle; upper profile line practically straight. Base of skull between bullæ broad, its bony edges running outwards quite to the bullæ.

Upper incisors prominently bicuspid; the inner one with its large postero-external secondary cusp falling but little short of the main cusp, and exceeding by about the same distance the top of the outer incisor; secondary cusp of the latter posterior, about halfway up its main cusp. Anterior upper premolar comparatively large, filling up the triangle between the canine and second premolar, which are separated from each other external to it; its tip visible externally just behind the hinder edge of the canine. Lower incisors tricuspid, overlapping.

Dimensions of the type (measured in spirit): -

Forearm 25.5 mm.

Head and body 41; tail 25; ear 8; tragus on inner edge 2.7; third finger, metacarpus 23, first phalanx 9, second phalanx 12; fifth finger 33; lower leg 10; hind foot 5.6.

Skull: greatest length 11.1; occiput to bottom of nasal

p. 199

notch 9.5; breadth of brain-case 6.1; front of canine to back of m^3 3.9.

Hab. Efulen, Cameroons.

Type. Male. B.M. no. 4.2.8.8. Collected by Mr. G. L. Bates.

This bat shares with the larger *P. crassulus* of the same region, also discovered by Mr. Bates, a disproportionately short forearm, the length of this member being less than has been hitherto recorded in any Pipistrelle, and nearly the least of any known bat. From *P. minusculus*, Miller, apparently its nearest ally, *P. nanulus* may be readily distinguished by its rounded ears and other differences in detail.

Pipistrellus Rüppelli senegalensis Dorst, 1960

p. 473

Type: 1 F, ad, Richard-Toll, Sénégal; septembre 1958; capturé dans un filet tendu près d'un point d'eau.

Cette forme se distingue des *Rüppelli* typiques par une taille supérieure, perceptible entre autres dans la longueur de l'avant-bras. Le crâne comporte un rostre plus fort, plus renflé à son extrémité. Les dents présentent un aspect semblable à celles de *Rüppelli*, mais sont de dimensions nettement plus fortes; la rangée dentaire est légèrement plus longue surtout en ce qui concerne les molaires dont chacune prise individuellement est plus grande, surtout plus large que son homologue chez *Rüppelli*. La première prémolaire supérieure est très petite, pour ainsi dire invisible chez *Rüppelli*. Elle est exclue de la rangée dentaire, le diastème relativement grand chez *Rüppelli* n'existant pas chez la forme du Sénégal; la 2^{e} prémolaire et la canine se trouvant en contact, la 1re prémolaire est en effet comprimée dans l'angle intérieur de ces deux dents. Ceci peut dans une certaine mesure être interprété comme une conséquence du plus grand développement des dents qui ont repoussé la première prémolaire vers l'intérieur. Les dents de la mandibule inférieure sont elles aussi plus fortes que chez *Rüppelli*.

Notons par ailleurs que les bulles tympaniques sont plus longues et plus volumineuses chez la forme du Sénégal. Voici à titre d'in-

p. 474

dications les principales mensurations de notre spécimen par comparaison avec celles de spécimens provenant du Soudan (région du Haut-Nil).

Sénégal; Soudan

Avant-bras: 34.4; 32, -, -

Longueur maximale du crâne: 13.9, 13.6, 13.6, 13.2

Longueur de la rangée dentaire supérieure (C-M^3): 5; 4.5, 4.6, -

Le pelage des parties supérieures paraît plus foncé chez *senegalensis*, principalement du fait de la couleur de la base des poils qui est brun noirâtre très foncé chez *senegalensis*, chez qui seule l'extrémité du poil est claire comme la totalité du poil chez *Rüppelli*. Le dos est en fort contraste avec le dessous du corps, recouvert d'un pelage blanc pur. Les oreilles et les membranes sont foncées.

La forme du Sénégal est dans l'ensemble étroitement apparentée à celle de l'Est Africain. Mais plusieurs de ses caractères sont suffisamment distincts de ceux de *Rüppelli* pour justifier la séparation. Cela est particulièrement vrai pour la morphologie et la dimension des dents. *Senegalensis* est manifestement le représentant "occidental" de *Rùppelli*, répandu depuis le Soudan (ex Soudan anglo-égyptien) jusqu'à l'Uganda. Le type de Pipistrelle possède donc une aire de répartition qui s'étend largement vers l'Ouest. Sa présence dans toute la bande sahélienne allant du Sénégal à la mer Rouge est probable.

Pipistrellus vernayi Roberts, 1932

p. 16
Pipistrellus vernayi sp. nov.

A large species having the raised, but rather swollen, brain case of typical forms of the genus, the outer upper incisor about half the height of the inner, the small anterior upper premolar wedged between and separating the canine from the large premolar.

The skull shows grooves on the frontal median line, the cranium swelling up and outwards in the anterior portion, descending behind to the normal height, but with two slight swellings near the occipital and above the mastoid, and swellings again in the occipital region; bullae about equal in diameter to the length of the three upper molars; the larger upper premolar with a canine-like anterior cusp, raised high above the level of the posterior cusps; the tips of the upper canine, large premolar and foremost cusp of the first molar in about the same plane. The small outer upper incisor shows traces of cusps about midway on the inner and outer edges; inner incisors decidedly bifurcate, the two points diverging and under low magnification resembling two teeth, but the outer cusp lower than the inner. The tips of the lower canine, large premolar and two highest points of the m_1 are on the same plane and at an obtuse angle to the line of the tooth-row, but the anterior lower premolar is at the same level as the posterior outer cusps of the large premolar and molars; the lower three pairs of incisors are normally placed, at right angles, and are trifid.

Colour of the upper pale mouse grey and under parts pure white; base of hair above for two-thirds dark grey, but below the hairs are white to the base. Ears naked and dark brown, the muzzle covered with fine bristles, also darker than the back.

p. 17
Type: T.M. No. 6546, adult ♂, Maun, Ngamiland, 29th May, 1930, No. 648, Vernay-Lang Kalahari Expedition. Length of head and body 56, tail 41, hind foot (c.u.) 9. ear 12, span of wings 278, tragus 4, penis 12 mm. Forearm 35.3, 1st phalanx of 3rd digit 35.5. 2nd 12.5, 3rd 9.5. Skull: length of canine to occiput 14.6, zygomatic width 9, width of brain case 7.6, width of palate across outside of m^2 6, width across upper canines 4, length of upper tooth-row (c-m^3) 5, height at bullae 6.7 mm.

Platymops Thomas, 1906

p. 499

Ears widely separated, as in *Mormopterus*. Lips without Wrinkles, covered with short stout bristles. Forearms shagreened. Wings short. Metacarpal of third finger only one third longer than that of fifth; first phalanx of fifth finger much shortened, one third the length of the metacarpal and not longer than the second phalanx. A small untufted gular sac present in both sexes.

Skull of the general outline in upper view of that of *Mormopterus*, but extraordinarily flattened vertically. Crests much reduced, the sagittal absent and the lambdoid not

p. 500

meeting in the middle line. Premaxillary notch narrow, not expanded behind. Mesopterygoid fossa without median bony ridgte. Ramus of lower jaw very low vertically.

Incisors $^{1-1}/_{4}$; ther upper pair long, nearly parallel, bicuspid, the lower ones subequal, all bicuspid. No trace of a small upper premolar, thouth the large p^4 does not touch the canine.

Type *Platymops Macmillani*.

This most remarkable bat is readily distinguishable from any member of the *Nyctinomus* group by its extraordinarily flattened head, unusual digital proportions, shortened wings, and dental formula. In this group it has a curious analogy with the Vespertilionine genus *Mimetillus*, being modified in its proportions and the shape of its head almost exactly in the same way, and having a strong superficial resemblance to it.

Platymops barbatogularis Harrison, 1956

p. 549

Amongst a number of bats received from Mr. John G. Williams of Nairobi, which he obtained in the extreme south-eastern part of Sudan during 1953, were two small Flat-headed Bats belonging to the genus *Platymops* Thomas.

Platymops barbatogularis, sp. nov.

As type specimen I nominate an adult male (No. 2.1897) in my collection obtained on June 10th, 1953.

Type Locality. - Lokomarinyang Marsh, Ilemi Triangle, S.E. Sudan, 5° 02' N., 35° 33' E.

Paratype : an adult female (No. 1.1867) in my collection obtained on June 10th, 1953 at the same locality.

Description of the Type.

This specimen is similar to *P. macmillani* in size and in general characteristics. Whereas in *P. macmillani* a small untufted gular sac is present in the lower throat region of both sexes, in this animal the sac contains a prominent tuft of brownish hairs. These hairs can be seen protruding from the semicircular orifice of the sac and when this is everted they are seen to average about 2 mm. in length (see fig. 1). Such a tufted gular sac is not known in Molossid bats.

A further striking character is provided by the distinctive pattern on the chest and abdomen of this animal (see fig. 1). The central part of the chest and abdomen is creamy white in colour extending up to the throat to surround the gular sac. The lateral areas

of the chest and abdomen from the axillse backwards are also creamy white, in contrast to *P. macmillani* in which this area is blackish (vide Thomas, 1906). In *P. barbatogularis* the central and lateral whitish areas are sharply divided by a broad brown stripe on each side commencing anteriorly behind the antitragal lobe of the ear and extending backwards, at first curving outwards to the antebrachial membrane and then inwards to extend straight down the belly as a stripe about 3 mm. in width as far as the lower abdomen, which is practically naked. The exact shade of colour of the type is a little doubtful as the specimen has been immersed in alcohol for a time, but it is remarkable that the thoraco-abdominal stripes are clearly a darker shade of brown than the dorsal surface of the body.

p. 550

Direct comparison with the colour of *P. macmillani* is not possible as the only available specimen of that species, the type, has been in alcohol fifty years and as a result it is greatly faded. Thomas's description was based on eight examples and from it *P. barbatogularis* clearly differs greatly in colour as well as in pattern. Thomas stated that *P. macmillani* is smoky blackish on the back, dull whitish below in the middle and blackish along the sides. The type of *P. barbatogularis* is a uniform light brown colour above approximating to Drab of Ridgway (plate 3, No. 18) while the darker brown thoraco-abdominal stripes approximate to Sepia of Ridgway (plate 3, No. 3). These colours may have been affected somewhat by immersion but clearly differ greatly from *P. macmillani*.

(Furthermore it may be noted here that a third specimen of this bat in the Coryndon Museum, Nairobi, was prepared very shortly after it was collected and Mr. Williams tells me that this one also was pale light brown in the flesh.* Therefore little doubt remains that the colour of this species is as described above in the type).

* Since going to press this specimen has been sent to the author for examination and its colour is almost identical with that of the type. This specimen also shows a narrow whitish margin to the wing membrane between the foot and the 5th digit, a feature present in the Type but less well marked.

p. 551

The skull of the type is slightly shorter than that of the type of *P. macmillani*, with a more squat relatively shortened rostrum. Until more material of both species becomes available however, the significance of this must be considered doubtful. No differences in dentition have been detected. It may be noted here that no trace of a small upper premolar can be found in the type but a minute one is present on the left side in the paratype. A minute upper premolar is present on one side in the type of P. macmillani so that its presence must be regarded as a variable feature in the genus.

The paratype (No. 1.1867) closely resembles the type in all the above-mentioned features but the thoraco-abdominal stripes are partially interrupted by a small whitish patch just below the nipples.

Flesh measurements of the type and paratype (in mm.).
Total Length; Forearm; Hind; Foot; Ear
Type No. 2.1897: 80 (fresh); 31.8; 7; 11
Paratype No. 1.1867: 87 (fresh); 31.1; 7; 12.2

(Measurements from spirit, relaxed, except for the overall length, which was measured by the collector in the fresh specimens.)

Skull measurements of the type and paratype (in mm.).

Condylobasal length; Lacrymal breadth; Breadth of Braincase; Depth of Braincase; Mandibular toothrow (c-m_3; Maxillary toothrow (c-m^3; Mandible
Type No. 2.1897: 14.9; 7.3; 9.8; 3.7; 5.8; 5.6; 11.3
Paratype No. 1.1867: 14.2; 7.2; 9.7; 3.9; 5.6; 5.1; 10.5

This remarkable little Flat-headed Bat is at present only known from the type locality. Mr. Williams has kindly forwarded some field notes. The species was found over a small permanent waterhole and marsh immediately N.N.E. of Lokomarinyang, which is the north-eastern extension of a block of mountainous country overlooking a vast plain to the north. Immediately above the marsh were cliffs in which there were long, narrow, horizontal fissures but these were so inaccessible that he was unable to confirm whether they were the bats' day-time retreat, but this seems more than likely from the recorded habits of other members of the genus. Although short winged they had a rapid erratic flight when hunting over the marsh about thirty feet up or lower. They appeared when it was nearly dark and they were feeding upon small beetles.

This species is immediately recognizable amongst the known members of the genus by its tufted gular sac and brownish thoraco-abdominal stripes. It is approximately the same size as *P. macmillani*, but considerably smaller than the two species known in S. Africa which are *P. petrophilus* Roberts (Forearm given by Roberts 1951 as 38 - 42 mm.) and *Platymops haagneri* Roberts (Forearm 36 - 37 mm.). Further material of this rare and interesting genus is clearly needed for a more detailed comparison of their coloration and size.

Platymops barbatogularis parkeri Harrison and Fleetwood, 1960

p. 270

Type: Adult female, No. 2. Lualeni Borehole, Maktau, southern Kenya Colony (03° 25' S., 38° 10' E.). 12 February, 1958. Collected by Ian Parker. In the collection of the British Museum (Nat. Hist.), South Kensington, London.

Description: Similar in all essential features to *barbatogularis* but larger both in external and cranial dimensions and differing significantly in colouring.

Gular sac present and tufted as in the typical race, its orifice lying transversely in the lower throat region and measuring 3.6 mm. across in the spirit specimen. The tuft of coarse brownish glandular hairs which it contains measures about 1.6 mm. long and becomes obvious when the sac is everted.

The thoraco-abdominal stripes are present as in the typical race and are darker than the dorsal surface of the body, there being a small bare area just distal to the nipples, interrupting the stripe centrally, as in the typical form. The thoraco-abdominal stripe in this animal, however, is broader distally than in *P. b. barbatogularis*, extending further laterally and leaving only a narrow band of pale creamy hairs lateral to it, which extends along the medial edge of the wing-membrane from the axilla to the knee (vide Plate 4). The internal borders of the stripes have just the same disposition as in the typical form, leaving a creamy white central area, commencing at the chin, surrounding the gular sac and widening on the upper thorax and narrowing again gradually towards the lower abdomen, which is naked of hairs at its extremity, as in the typical form.

Although the colour of this specimen may have been modified by immersion in alcohol, it is clear that both the dorsal surface and the thoraco-abdominal stripes are darker than in the typical race. The colour of the back approximates nearly to Grey 31 (Plate 15 C.6, Maerz and Paul, 1950) while the thoraco-abdominal stripes approximate nearly to Castor (Plate 16 A.8, Maerz and Paul).

Measurements of the Type: Total length 91, forearm 34.5, hind-foot 7, tail 29, ear 17 mm.

Cranial Measurements of the Type: Condylobasal length 16, zygomatic breadth 12, breadth of braincase 10.1, depth of braincase 4.2, mandible 12 mm.

p. 271

Apart from the marked difference in cranial size from the typical form no essential difference in cranial or dental characters is to be noted.

In view of the great rarity of these bats the paratypical series of *P. b. parkeri* has been studied in great detail in comparison with *P. b. barbatogularis*.

Colour: The colour of the dorsal surface is in all instances much darker than the typical form and varies only a little in the series. The three immature specimens tend to be a slightly greyer brown on the back, and the adult male a shade browner than the three adult females. The pale central area of the throat and abdomen is whiter in the immature animals, more creamy in the adults. The thoraco-abdominal stripes do not differ significantly in shape or colour in the series, save that the bare nipple spots are absent in the adult male and three immature animals. In the adult male the narrow band lateral to the stripe from axilla to knee is brownish instead of creamy or white, although not so dark as the stripe itself. In all the specimens in our series the stripes are darker than the dorsal surface of the body.

Size: In both external and cranial dimensions all the adults exceed the typical form, while one immature female with the upper milk incisor still in situ has dimensions equal to those of the adult Type of *P. b. barbatogularis*. The Tables below bring together the measurements of all known specimens of the species.

[table removed - eds.]

p. 272

Gular Sac: The sac is present in all specimens of this series and it is macroscopically as already described in *P. b. barbatogularis*. No difference can be detected between its condition in the adults of both sexes. The transverse opening in the lower throat region measures from 3.6 to 5.5 mm. across, the largest dimension being that of the adult male. The pocket itself is about 3.5 mm. deep and in all the specimens contains the tuft of coarse brownish glandular hairs as described in the typical race. This tuft can be seen in the sac and protrudes from it when the sac is everted. The hairs are from 1.2 to 3 mm. long in the four adults. The tuft is present in the three immature animals, but it is scantier, the hairs measuring 1.2 to 1.6 mm. in length. When the skin of the lower throat region is examined from its internal aspect it is seen that there is a fan-shaped glandular body, creamy white in colour in the fixed specimen, which is flattened dorso-ventrally and which extends to a depth of about 3.5 mm. from the sides and floor of the pocket. In the adult male specimen the greatest width of the sac with its associated glandular body is 13.2 mm., while its greatest length from the orifice of the sac to the caudal extremity of the gland is 6.8 mm., its greatest thickness anteriorly being 3.5 mm. The anterior (i.e. ventral) and surfaces of the pocket appear devoid of glandular tissue macroscopically. While there is no apparent difference in the appearance of this glandular body in the adult male and females, it is noticeably

p. 273

less well developed, although present in the three immature specimens. The opportunity has been taken to study the histological structure of the gular sac and its associated gland.

The entire sac of the adult male specimen, with its orifice and the attached glandular body described above, was excised and sections cut across its long axis obliquely and stained with haematoxylin and eosin. Unfortunately fixation of the tissue was imperfect and the haematoxylin staining is consequently rather poor, but the basic structure of the sac is, nevertheless, quite clear.

The actual cavity of the sac is lined with stratified squamous epithelium with a thin layer of desquamating keratin. Hair follicles are seen growing into the sac from all sides. Three types of glandular structure are seen to be associated with the sac (vide Fig. 1). Along that aspect of the pocket which is macroscopically not covered by the fan-shaped glandular body it is seen that the hair follicles are associated with simple flask-shaped glands penetrating deeply below the hair follicle roots. These glands closely

resemble those described elsewhere in the gular sac of *Otomops martiensseni icarus* (vide Harrison, 1957) and are regarded as a primitive type of sebaceous gland. In the part of the sac which is covered by the fan-shaped body, however, these glands are seen to be entirely replaced by large complex lobulated glands of sebaceous type. The two types of gland have quite different structure and staining reactions. The primitive glands stain deeply with eosin, they contain no lobules and, as in *Otomops*, their cells-appear to proliferate inwards and break down to form a grandular eosinophilic debris which discharges into the hair follicles. The complex sebaceous glands are much larger and there are twenty-three separate ones visible in these sections grouped along the central part of the fan-shaped body. They tend to be triangular in shape with their bases distal to the pocket, the largest glands being about 100 µ by about 50 µ in size. Each gland consists of numerous lobules of typical foamy sebaceous cells which discharge their contents into a large intraglandular reservoir. This is situated in the centre of each gland and it has tributaries extending into the larger lobules. The reservoir leads to a wide and nearly straight duct, which is itself lined by sebaceous cells and which is about as long as or a little longer than the gland itself, that is about 100 µ in length and about 10 µ in width. Both the reservoirs and the ducts of these glands contain an oily secretion produced by the breakdown of the sebaceous cells. Each duct discharges into a hair follicle.

p. 274

The third type of gland associated with the pocket lies on each side laterally, forming the corners of the fan-shaped glandular mass. In this situation there are six to nine large lobules, irregularly shaped, which are seen to consist of a mass of coiled tubules and which are clearly apocrine glands. Their tubules are lined by a cubical or cubo-columnar epithelium. In an adult female in which the whole sac was similarly excised and examined the histological structure is similar to that of the male, and part of the glandular body removed from the Type is also histologically similar.

It is clear, therefore, that the gular sac of *P. barbatogularis* is a highly elaborated glandular structure; that it contains three distinct types of gland and that it differs materially both in macroscopical anatomy and in microscopical structure from the gular sac as described in other species of *Molossidae*: *Cheiromeles* (Harrison and Davies, 1949), *Otomops martiensseni* (Harrison, 1957), *Molossus* (Schaffer, *vide* Grassé, 1955, p. 1732). It is interesting to note that the gular sac of *Molossus* differs in many respects from that of *P. barbatogularis*. Thus it occurs only in the males, in which the pocket itself is small without any tuft of glandular hairs. A large mass of gland tissue surrounds the whole pocket, consisting of a deep apocrine layer and a superficial one of sebaceous glands. It is interesting to note that the sebaceous glands of *Molossus* have intra-glandular reservoirs as in *P. barbatogularis* but they open by pores into the pocket, unassociated with any hairs. It is clear that the detailed structure of the gular sac, which occurs in several genera of *Molossidae*, provides important characteristics of the various genera and species, exhibiting a marked diversity of structure in the various species possessing it.

Wing membranes, Ears and Facial Bristles: The narrow pale border of the wing membrane between the tarsus and the tip of the fifth digit is present in all these specimens just as described in the typical race, but it is not well marked in the immature specimens. There is no apparent difference from *P. barbatogularis* in the distribution of the warty excrescences on the forearms, thumbs and metacarpals, and these are present in the adults and immature animals (*vide* Plate 2); nor can any other differences in the wing membranes be detected, nor in the ears, tragi or facial bristles.

Feet: All the toes of adult and immature animals alike are adorned with long hairs as in the typiral race, while the outer aspect of the first and fourth toe is similarly densely covered with short recurved hairs. The long hairs reach about 10 mm. in length, the short ones about .1 mm.

p. 275

Body Form: One of the most striking features of the bats of the Genus *Platymops* is the marked flattening, not merely of the head, as indicated by their popular name, but also of the body (*vide* Plate 5). A section through the thorax of an adult female is shown in Fig. 2, made at the level of the mid-point of the sternum, with the skin removed, to illustrate the marked flattening of the thorax. This is without doubt an adaptation to the creature's habitat and represents an extreme degree of the body form towards which all the crevice-dwelling *Molossidae* tend and also some other bats, notably *Tylonycteris*.

Skull and Dentition: As already noted in the description of the Type there is no essential difference in the cranial or dental characters of this race as compared with the typical one, apart from the greater size of the skull in *P. b. parkeri*, and the main features of the skull shown in Fig. 3 are those of the Genus, already described in detail elsewhere (Miller, 1907, p. 255). It may be noted, however, that there is marked individual variation in the development of the lambdoid crest, this being strongly developed in the adult male, less so in the adult females and absent in the immature skulls. Even in the adult male, however, there is no trace of a sagittal crest, the surface of the cranial vault being actually slightly hollowed out in the mid-line.

The dentition also shows no constant difference. It is of interest to record that in this series, as in the typical race, the small upper premolar is inconstant. It is absent on both sides in the adult male and all three adult females, while it is bilaterally present in two of the immature animals and lost on one side in one of them. This confirms the impression that this minute functionless tooth is deciduous and in process of complete loss in *Platymops* and is of no systematic importance; the Sub-Genus *Sauromys* Roberts being untenable on this account. It appears, however, that the southern African representatives of the Genus possess no gular sac, a fact which has received little emphasis hitherto, and it seems that the Sub-Genus might be maintained on the basis of that character rather than on the inconstant dental feature on account of which Roberts first erected it.

It is of interest that one of the immature specimens retains the upper milk incisors *in situ*. The milk tooth lies to the outer side of the permanent incisor and slightly behind it (*vide* Fig 4.), and its tip just reaches the secondary cusp of the permanent tooth. The milk incisor is a tall spicule in form, strongly recurved caudally

p. 276

towards its conical tip, and it possesses on its lateral side a faint indication of a secondary cusp corresponding to that of the permanent tooth.

External Genitalia: The opportunity is taken to describe and figure the external genitalia of this species, which have not hitherto received attention.

The penis of the adult male is situated pre-anally and no scrota swelling is visible externally. The penis measures 6.8 from the base of the shaft dorsally and the shaft is 2.1 mm. in width. A prepuce is present, and when this is retracted the glans penis is revealed as a sub-rectangular body when viewed from above (*vide* Fig. 5). The glans measures in length 1.8, by maximum width 1.6, by .6 mm. in depth. It is flattened dorso-ventrally and bluntly expanded distally with a slight ridge-like elevation in the mid-line dorsally. The urethral meatus is situated in the centre of an oval smooth area on the distal part of its ventral surface, which is hollowed out when seen from the lateral aspect. The remainder of the glans is covered by minute horny excrescences. A few long hairs project over the glans from the prepuce dorsally and the shaft is covered with short hairs.

The vulva of the female (*vide* Fig. 6) is slightly elevated above the surrounding skin and the skin around the vaginal and anal orifices is pigmented blackish. The vaginal orifice is transverse, measuring 2.8 mm. in width, and the mucosa at the orifice is smooth. The glans clitoridis, which is oval and rather flattened, projects from an opening between the vaginal orifice and an elevated clitorideal pad anterior to it. This pad is surmounted by two blunt elevations laterally, between which arise a few long hairs projecting over the glans clitoridis. The anal orifice is puckered by mucosal rugae and it is separated from the vaginal orifice by a small perineal space.

Breeding Biology: The nipples were prominent in all three of the adult females, lying below and slightly anterior to the axilla and measuring from 2.2 to 3.8 mm. long and from .9 to 1.2 mm. in width; their long axis lying parallel to that of the thoraco-abdominal stripe. The mammary glands of all three were hypertrophied measuring from 11-15.8 in greatest length and from 6-7.1 in width and about 3.8 mm. in maximum thickness. The mammae were situated over the lateral aspect of the thorax and upper abdomen, only just extending on to the ventral and dorsal surfaces of the trunk, differing in this respect from the condition noted in the lactating *Tadarida (Chaerephon) pumila websteri* (Harrison, 1958). Histological sections were prepared of one mammary gland from each of the adults, and these were stained with haematoxylin and eosin.

p. 277

These fully confirm the condition of lactation, the glandular acini being distended with globular secretion and the epithelium actively secreting, while many of the ducts are distended with milk. This is consistent with the presence of immature animals in the series, one with upper milk incisors *in situ*. The uteri of these adult females were also examined, but although there was a slight swelling of the right cornu in the Type, measuring 2 in width by 3 mm. in length, no evidence of a new pregnancy was found in the sections prepared. It is clear, therefore, that in this series a season of parturition had occurred a little before the time of capture in mid-February.

Habits: These remarkable creatures were found beneath a stone, where they shared their retreat with scorpions. It is of interest to note that in South Africa *Platymops* have occasionally been found by zoologists who were in fact searching for scorpions beneath flat slabs of rock (Roberts, 1951, p. 103). It is clear that the whole body form of these bats is remarkably well adapted for such narrow recesses, and it may be concluded that the glandular secretion of the gular sac in *P. barbatogularis* becomes smeared on the floor of the retreat as the bat crawls about within it, and perhaps thus marks the home of the colony with a characteristic odour. It may also be that the tuft of glandular hairs in the sac may act as a kind of scent paint brush. Whether there is any special significance in the association with scorpions is a point that might well claim the further attention of zoologists.

SYSTEMATIC REMARKS

The occurrence of this form in southern Kenya led to a careful consideration of the description of *Mormopterus setiger* Peters, 1878, amended in 1881 (type-locality: Ndi, Teita, Kenya Colony). It is clear from certain points in the description that this form is a *Platymops*. Thus the upper incisors are bicuspidate, the skull very flattened (unfortunately no cranial measurements were given), the upper surface of the forearms is covered with warts and a gular sac is present, which is apparently untufted. In all these features it resembles *P. macmillani*, from which, however, it differs in being larger and also different in colour. It is larger than typical *P. barbatogularis* and approximately the same size as *P. b. parkeri*, and differs from both these forms in colour and in lacking the thoraco-abdominal stripes, which are darker than the dorsal surface of the body in *P. barbatogularis*. It also differs by lacking the glandular tuft in the gular sac. It is unfortunate that the Type of *P. setiger* has probably been lost, according to Prof. Dr. K. Zimmermann, (*in litt.*), so that the further elucidation of the status of this form must await the collection of further material.

Platymops haagneri Roberts, 1917

p. 5

Platymops haagneri spec. nov.

A small species having an affinity to *P. petrophilus* in the dental formula, flattened skull, absence of a definite antitragus, shortness and number of the bristles on the toes, and in the horny points on the upper part of the ears being situated near the horizon of the ear; but differing therefrom in its smaller size, the horny points on the ears only two in number; the lower P2 much smaller than the P4, which is higher, the tips of M_1, P_4 and C forming an almost straight line at a slight angle rising forward; the upper incisors are also comparatively shorter than in *petrophilus*, and·a cingulum can be seen in P2 with the aid of a lens. The lower incisors are bifid. The bony palate extends well behind the molars.

Dimensions of the type in spirits: Length of the head and body 50 mm.; of the tail 32, of the free portion of the tail 13.5; ear, height 10, breadth 13.5; height of the tragus 2.3; length of forearm 37; pollex (c.u.) 5; third digit, metacarpal 37, 1st phalanx 14, 2nd without cartilage 12; fourth digit, metacarpal 36, 1st phalanx 12.5, 2nd phalanx without cartilage 6; fifth digit, metacarpal 25, 1st phalanx 10, 2nd 4.7; tibia 10; hind foot, length (c. u.) 6.5. Skull: Greatest basal length 16.2; zygomatic width 10; width at

mastoid 9.8; width of brain case 9; interorbital constriction 3.7; basilar length 13.1; palate length 5.5; length of dental series, from front of C to back of M3, 6; width of palate taken outside the molars 7; greatest length of mandible 12.

Type: Adult male from Keetmanshoop, Damaraland, presented to the Museum by Mr. Sigmund Haagner.

These two species apparently belong to the genus *Platymops* Thos., but differing as they do in the dental formula, the P^2 being present, I propose to place them in a new subgenus bearing the name of SAUROMYS, of which *P. haagneri* maybe taken as the genotype. The following figures will indicate the difference in the height of the skull of *N. aegyptiacus* and the present new species, the measurements having been taken from the tips of the P^4 vertically parallel to the top of the premaxilla:

N. aegyptiacus 6.5 mm., *P. petrophilus* 4.2, *P. haagneri* 4.

Platymops haagneri umbratus Shortridge and Carter, 1938

p. 282

Platymops (Sauromys) haagneri umbratus subsp. n.

One specimen from Kliphuis, northern spur of the Cedarberg.

A Cape subspecies of *P. haagneri*, distinguished by its dark coloration.

Colour above smoky seal-brown, a shade paler than in *Nyctinomous bocagei*; under surface smoky-brown, several shades lighter than the

p. 283
upper surface; ears and flying membranes almost black - as opposed to comparatively pale horn-brown in typical *haagneri*.

In typical *haagneri* (series from Goodhouse, lower Orange River, examined, and a single specimen from Berseba, Great Namaqualand) the colour above is drabby brown, paler and less cinereous than the under surface of umbratus, and pale burly, approaching whitish, below.

Type (in the Kaffrarian Museum). - Adult male, original number 2827, collected 7th December 1937 at Kliphuis, Pakhuis Pass, 11 miles N.E. of Clanwilliam, N.W. Cape Province.

Dimensions of Type. - H. and b., 61; tl., 31; hf., 8.5; ear, 15; forearm, 37 mm.

Skull. - Basal length, 16.2; zygomatic width, 10; width of brain case, 9; interorbital constriction, 3.7; length of palate, 5.5; upper dental series (from front of canine), 6; mandible, 12.5 mm.

Genus new to the Cape Province.

Platymops Macmillani Thomas, 1906

p. 500

Size about as in *Mormopterus acetabulosus*, the abnormally short forearms giving a deceptive idea of the general bulk. Fur short; hairs of back about 3 mm. in length. General colour above smoky blackish, below dull whitish along the middle area, blackish along the sides. Limbs dark above, whitish below; membranes dark throughout, except that the surface near the body below is lighter, as is the extreme edge of the plagiopatagium. Ears widely separated, triangular, their anterior edge evenly convex, their tip rounded; antitragal notch scarcely perceptible. Tragus fairly large, quadrate, its inner edge about equal to its breadth at tip. Upper side of forearm, wrist, and basal half of third metacarpal thickly and coarsely shagreened with small round warts, very much as is the case in *Vespertilio Floweri*, de Wint. Wing-membrane attached to the distal third of the tibia. Upper side of the short lower leg flattened, finely granulated. Proximal plantar pad very prominent. Penis short, without special modifications.

Skull and teeth as described above.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 32 mm.

Head and body 51; tail 27; tail free from membrane 15; ear 15; tragus on inner edge 2; third finger, metacarpus 31, first phalanx 12.5, second phalanx 11; fifth finger, metacarpus 23, first phalanx 6.5, second phalanx 6.7; lover leg 11; calcar 16.

Skull: condylo-basal length 16; basal length in middle

p. 501

line 13; zygomatic breadth 11.2; breadth between preorbital processes 7.4; interorbital constriction 3.8; greatest mastoid breadth 10.2; height from basion to top of brain-case 4; palatal length in middle line 5.9; front of canine to back of m^3 6; front of lower canine to back of m_3 6.6.

Hab. N.E. Africa, between Adis Ababa and Lake Rudolf.

Type. Adult male. Presented by W. N. M^{c}Millan, Esq. Collected by Ph. C. Zaphiro. Seven specimens examined.

The peculiar flattening of the head of this bat - even to the abolition of the sagittal crest and the reduction in the vertical thickness of the lower jaw - probably indicates that it either lives in small cracks in trees or rocks, into which it may creep beyond reach of enemies, or else that it frequents some large-leaved plant (such as banana or cactus), between whose leaves the other bat with a similarly shagreened forearm (*Vespertilio Floweri*) was found by Mr. N. C. Rothschild.

I have named this most interesting bat in honour of Mr. W. N. M^{c}Millan, to whose liberality science is indebted for the exploration of which it is part of the outcome.

Platymops petrophilus Roberts, 1917

p. 4

This bat has a superficial resemblance to *Nyctinomus aegyptiacus* (S. African specimens), but upon close examination is found to differ in having the ears more widely separated at the inner base; the antitragus represented by a mere thickening of the lobe; horny points on the upper part of the ear commencing near the rim of the ear and not far down as in aegyptiacus; the thumb very thick ;the first and fifth toes also very thick-equal to double that of either of the other three-and thickly covered above and on the outer surface with fine whitebristly hairs, but with hardly any of the very long vristles found in *aegyptiacus*; the ears are haired as in *aegyptiacus*, but the area around the fibulae is more sparsely covered with white hairs. The ears arise about 4mm. apart to a height of a little more than 1 mm. and the upper margin thence for about 13 mm. is practically horizontal, thence curving downwards little way, increasing the breadth of the ear to 15 mm., then downwards and very slightly inwards for about 9.5 mm. to a point whence an increasing tendency inwards for 4 mm. carries the lower margin in an almost straight line to the outer base; the antitragus is represented by a broadening and thickening of the lobe, flattened or slightly folded on the upper surface, with only a slight emargination beyond its outer edge; the tragus is like that of *aegyptiacus*, quadrate, rather narrower at the base than the tip,with a slight nitch in the outer edge. The horny points on the upper margin of the ear are five in number just below the horizon, the rest on the edge of the ear, producing a saw-like horizon. The lips are wrinkled, the nostrils sub-lateral and no glands appear to be present. The wings arise on the tibia at about one-third of the length of the tibia from the feet.

The skull of the type is, unfortunately, fragmentary, having been crushed when the rock was overturned under which it had taken up its abode. Nevertheless, from what there is of it, the dentition is clearly seen to be numerically identical ,with that of *N. aegyptiacus*, but the skull is flattened as in *Platymops* Thos. (Ann. & Mag. N.H., ser. 7, vol. 17, p. 499, 1906) ;the premaxillae do not meet anteriorly, and the incisors are large and convergent ; the foremost premolar (P 2) is small but easily seen without the aid of a lens, and is situated between the C and P4, well within the tooth row; the lower anterior premolar is slightly smaller than the posterior premolar.

Dimensions (taken from a spirit specimen) : Length of the head and body 53 mm., of the tail 38, of the free portion of the tail 15; diametre of the ear, vertically 14, horizontally 15; height of tragus 2.5; length of snout to the inner base of the ear 7; forearm 42; thumb 7; third digit, metacarpal 43, 1st phalanx 16, 2nd without the cartilage 15, with the

p. 5

cartilage 22 ; fourth digit, metacarpal 41, lst phalanx 15, 2nd phalanx without cartilage 8.5, with cartilage 11.5; fifth digit, metacarpal 27, lst phalanx 11, 2nd with the cartilage 7.5; tibia 9; hind foot length (c.u.) 8, breadth 4 ; breadth of ankle pad 2. Skull: Length of dental series, from front of C to back of M3, 7.4 ; greatest length of mandible 13.5.

Type: Adult male, in spirits, taken by G. van Dam at Bleskop, near Rustenburg, 2nd February, 1917.

Platymops petrophilus erongensis Roberts, 1946

p. 308

Of about the same size as *P. p. petrophilus* Roberts (*Ann. Transv. Mus.* VI, 4; 1917: Bleskop, Rustenburg district), but in colour pale brownish grey above (instead of tawny olive), below greyish white (instead of pale tawny olive), and ears light brownish instead of dark brown.

Measurements of eighteen adults (including the type) from Eronga Mountain, and, in brackets for comparison, of two specimens, including the type, of which the skull is broken, of *P. p. petrophilus*: Head and body 55 - 62 (53, 53); tail 33 - 40 (38, 35); hind foot (c.u.) 7 - 8.5 (8); ear 13 - 17 (14, 13.5). Wing span in ten measured in the flesh 275 - 302. Forearm 38 - 41.5 (42, 39.5); 3rd digit, metacarpal 39.5 - 43 (43, 42); 1st phalanx 15 - 16 (16, 17.5), 2nd phal. 16.5 - 19.5 (22, 20); 4th digit, metacarpal 38.5 - 42.5 (41, 42); 1st phal. 12.5 - 14.5 (15, 14.5), 2nd phal. 8.5 - 10.5 (11.5, 11.2): 5th digit, metacarpal 26 - 29 (27, 27.5). Tibia and foot (c.u.) 18 - 19.5 (19, 19). Skull, greatest length 17 - 18 (17.5); nasal cavity to occiput 15 - 16.5 (15.6); basilar length 13.2 - 14.8 (15); zygomatic width 10.5 - 11.6 (11.5); mastoid width 9.8 - 10.8 (11.3); width of brain case 8.2 - 8.9 (9); posterior median height 4.6 - 5 (4, 6); interorbital, anterior, width 6.3 - 7.1 (7.2); interorbital-constriction 3.5 - 4 (3.7); c-m^3 series 6.1 - 6.5 (6.4,

6.4); width across m^3 7.2 - 7.7 (7.3); width across upper canines 4.3 - 4.7 (4.7); mandible length 11.8 - 12.5 (12.8, 12.8); c-m_3 series 6.7 - 7.3 (7.1, 6.8).

Type: T,M, No, 9494, adult M, Ombu Farm, Eronga Mountain, Omaruru district, South-west Africa; also nineteen more skins and skulls and others in alcohol.

Platymops petrophilus fitzsimonsi Roberts, 1946

p. 308

In size about the same as *P. p. petrophilus* Roberts, but in colour paler and more greyish, especially about the head and neck, which are lighter than the back, and below paler and more whitish; the ears are blackish, contrasting with the hair of the head.

Measurements of the type and another F captured at the same time: Head and body 60, 57; tail 40, 35; hind foot (c.u.) 9, 9; ear 15, 14; wingspan 292, 272. Forearm 40, 38; 3rd digit, metacarpal 41, 40; 1st phal. 15.5, 14.5 and phal. 19, 18; 4th digit, metacarpal 41.5, 41.5; 1st phal. 13.5, 13; 2nd phal 10.5, 9.5; 5th digit, metacarpal 10.5, 9, Tibia and foot (c.u.) 19, 19. Skull, greatest length 17.8, 17.2; nasal cavity to occiput 16.2, 15.5; basilar length 15, 14; zygomatic width 11, 10.5; mastoid width 11, 10; width of brain case 9, 8.5; posterior median

p. 309

height 4.7, 4,6; interorbital, anterior, width 6.7, 6,8; interorbital constriction 3,6, 3.7; c-m^3 series 6.1, 6.1; width across m^3 7.5, 7; width across upper canines 4.5, 4.4; mandible length 12.3, 11.8; c-m_3 series: 6.5, 6.3.

Type: T.M, No, 8968, adult F, Mitchell's Pass, near Ceres, Cape Province; also another F from the same place; captured by Dr V. FitzSimons under a cleft rock.

Plecotus æthiopicus Heuglin and Fitzinger, 1866

p. 546

Von dieser bis jetzt noch unbeschriebenen Art überbrachten Heuglin's Leute ein Exemplar vom Bahr-el-abiad.

Plecotus teneriffae Barrett-Hamilton, 1907

p. 520

Plecotus teneriffæ sp. n.

This bat resembles *P. auritus* of Britain, but has much larger wings. The *colour* is apparently darker, but cannot be taken as reliable from the old dried skin upon which this description is based: it is, above, near Ridgway's "hairbrown," the hair-tips lighter; below, dirty yellowish white, the dark basal portions of the hairs not evident.

The type has no skull.

The *dimensions* (in millimetres) of the type are as follows: -

Head and body 52; tail 45; ear from the notch 35; tragus 14; thumb without claw 6; longest digit 73; basal joint of fifth digit 35; basal joint of second digit 37; forearm 44; tibia 18.5; hind foot (without claw) 8.

Hab. Teneriffe.

p. 521

The *type*, a dried skin, is No. 87.4.18.1 of the British Museum collection, and was taken at Orotava, Teneriffe, by Señ. R. Gomez on the 3rd of April, 1887.

The large wings of this bat mark it as distinct from any other known *Plecotus*.

Propottininae Butler, 1984

p. 175

Subfamily PROPOTTININAE nov.

Diagnosis: Lower molars with low relief and poorly differentiated cusps, but posterior trigonid crest retained, and talonid not shortened; M/3 less reduced than in other Pteropodidae, and M3/ probably present; mandible fairly robust.

Propotto Simpson, 1967

p. 50

Type-species: *Propotto leakeyi* new species.

Known distribution: Miocene of Kenya; Songhor and probably Rusinga.

Diagnosis: Lorisids with variable lower cheek teeth closely resembling those of *Perodicticus*. P3-M3 rounded, ovate in outline with low, blunt, poorly defined cusps. P4 not oblique, excavated anterointemally and with vague metaconid; talonid with shallow basin, papillated. Ml-2 with low, blunt, almost median protoconid and smaller metaconid posterointernal to it. Talonids basined, with blunt hypoconid; entoconid region papillated without clear definition of cusps. Ms reduced, essentially a flattish crown with a central basin surrounded by a vaguely cuspidate rim.

Discussion: The apparently degenerate characters of the highly peculiar cheek teeth of this genus are like those in the Recent *Perodicticus* but may be even more extreme in the fossils. The details are so extremely variable in both that it is conceivable that almost any apparently diagnostic feature of the fossils might recur in the living forms, but in fact I cannot match all the characters listed above in a fair series of *Perodicticus* jaws and generic distinction seems warranted. Another possible distinction is that all three of the fossil jaws seem to deepen forward in a peculiar way that I have not seen in Perodicticus but that is approached in some specimens of its Asiatic vicar *Nycticebus*.

The three specimens on which this genus is based were not known to Clark and Thomas, and they have not heretofore been mentioned in print.

Propotto leakeyi Simpson, 1967

p. 50

Holotype: Specimen R of consolidated list.

Hypodigm: Specimens R, S, and T.

Known distribution: Miocene, Songhor , and probably Rusinga.

Diagnosis: Only known species of the genus. Measurements of lower teeth as in Table 4.

Discussion: The generic diagnosis calls attention to the most striking features of these specimens, and the accompanying figures obviate need for further verbal description. These peculiar dentitions are unlike any previously described in fossils and resemble those of the living pottos but are perhaps even more extreme in modification of the more primitive, more insectivore-like cheek teeth of other lorisids. The three specimens vary markedly in size, proportions, and structure of the teeth and at first sight seem hardly compatible with reference to a single species. However, *Perodicticus potto* is almost if not quite as variable in the same ways, and valid separation of species among the fossils will require larger samples, if it is called for at all.

SKULLS AND UPPER DENTITIONS

No associated upper and lower dentitions are known. The one Uganda specimen, the facial part of a skull, is the only nomenclatural type including upper teeth. As it cannot be compared with the Kenya types, it is a special case.

The Kenya specimens of skulls and upper teeth are from the same localities or areas as the lower jaws, including the five nomenclatural types, and it is presumable that they may for the most part if not altogether represent the same species. As is almost always true of fossil mammals, more lower than upper teeth and jaws are known.

Lower teeth of *Progalago dorae*, *P. songhorensis*, *Komba robustus*, and *K. minor* fall into four corresponding size groups without overlap among the known samples. *Propotto leakeyi* is of about the same size as *Progalago dorae*, but it is so distinctive morphologically that its upper teeth could almost surely be recognized if found. (They are not known.) The smallest species known from lower dentitions, *Komba minor*, should be recognizable by its size, or, at least, upper teeth too large to occlude can be excluded from consideration. In fact none of the upper teeth here available could belong to this species.

There remain three species of different sizes based on lower jaws and teeth: *Progalago dorae*, *P. songhorensis*, and *Komba robustus*, in sequence of decreasing size. Of the eight specimens with upper teeth, one (AI of consolidated list) is so poorly preserved as not to warrant any attempt at identification. The other seven do fall into three groups as regards size. They are here taken as possibly corresponding with the three named species based on lower jaws. These references are, however, quite uncertain. The skull and upper tooth specimens are not included in specific hypodigms (except *Mioeuoticus bishopi*) or definitely referred to species. They are here described as cf. *Progalago dorae*, etc.

Pteropus comorensis Nicoll, 1908

p. 87

Pteropus comorensis.

On one occasion we visited a small island situated in the middle of the harbour. This island, which is marked on the charts as "Buzi," was thickly covered with vegetation, and in some places it was impossible to force a way through the prickly clumps of acacia trees. The heat was intense, and I have never felt the sun so much as I did on Buzi.

…

This little island was tenanted by a large colony of fruit bats.‡ They were, however, in the thick trees on the inaccessible side of the island, where it rises straight up from the sea. Every evening numbers of them flew across to the main island,

‡ *Pteropus comorensis*

p. 88

and one evening, on our way back to the ship after a day's collecting in the mangrove swamps, we shot one as it flew over the steam launch. Its fur was of a reddish colour, thick and soft. A most unpleasant skunk-like smell clings to one's hands after touching one of these bats, and this is especially noticeable when the animal has just been shot. On several occasions I saw these fruit bats splash into the salt-water of the harbour, but whether they were drinking or washing I do not know.

[The first paragraph mentioned above doesn't actually belong to the description, but was separated from it by a paragraph on swifts (*Cypselus mayottensis*). However, I did include it since it refers to "this little island" in the first sentence of the description, which might indicate that the type locality can be restricted to "Mayotte: Buzi Island".
Furthermore, the name *Pteropus comorensis* was mentioned as a footnote, hence the use of the "‡" symbol.]

Pteropus Gambianus Ogilby, 1835

p. 100

Two undescribed *Pteropi*, brought over by Mr. Rendall, present some modifications of dentition which have not been observed in other species, and which appear to indicate a subgenus, probably representing the common Asiatic forms on this coast of Africa. These animals have the incisors and canines of the same form and number as the rest of the genus, but there are only three molarcs in the upper and five in the lower jaw. The incisors are small and regular, the canines of intermediate size; the first false molar in the lower jaw is small and of the normal form, but the second in this jaw and the first in the upper are of the same form as the canines, and very little inferior to them in size, so that when the mouth is opened there appear to be four canines in each jaw; next follows in either jaw a tooth with a large fang upon the outer edge and a smaller one within, which is of intermediate form between the true and false molars; after which come two normal molars in the lower and one in the upper jaw. All the molars are separated from one another by a vacant space on each side; this gap is particularly large between the real and spurious canines or first false molars in the upper jaw, the corresponding space in the lower having, in its centre, the small false molar already mentioned.

Expanse of the wings: 1 f 8 in.

p. 101

The fur is of a very soft woolly texture, and of a uniform reddish mouse colour over every part, only rather lighter on the sides of the neck and belly than on the superior surface of the body. The wings are ample, naked except upon the thighs and arms, and of a light brown colour; there is no real interfemoral membrane; but the whole posterior face of the thighs and body is margined with a narrow band of integument about half an inch broad, and covered above with the same description of hair as the back. The ears are small, naked, erect and elliptical, and the eyes placed much nearer to them, and consequently at a greater comparative distance from the muzzle, than in the ordinary *Pteropi*

Pteropus Haldemani Hallowell, 1846

p. 52

Description. - General expression ferocious; head resembling that of a dog; ears of moderate size, smooth for the most part, obtuse at the tip, hairy at base externally; there is no tragus; body dark brown above; neck, occiput and vertex same colour, but lighter than upon the back; wings and interfemoral membrane of a sienna brown colour above and below; thorax and upper part of abdomen and sides brown; the rest of the abdomen is white; there are two long and thin hairs upon the muzzle; lips full, nostrils prominent, their margins being surrounded by a fold of the skin; eyes rather large, irides - ; wings long; that portion of the membrane included between the phalanges naked, the remainder more or less hairy above and below; upper surface of the interfemoral membrane hairy, with the exception of a small part at its posterior extremity which is naked; under surface also hairy, but much less so than upper; no tail; tibia and fibula included within the membranes; four slender toes, compressed, of nearly equal length, the outer one being a little shorter than the others; they are sparsely furnished with thin hairs, varying in length; the terminal phalanx of each is provided with a robust, sharp and incurvated nail. The index finger like the thumb is also furnished with a short and incurvated nail.

Measurements. Inches.
Total length: $3^{1}/_{2}$

Length of head: $1^{3}/_{4}$
Distance between anterior margin of nostril and anterior canthus of eye: $^{5}/_{8}{}^{1}/_{10}$
Distance between angle of mouth and anterior canthus of eye: $^{3}/_{8}$
Length of neck, body and tail: 3
Length of forearm; 3
Lengtfr of tibia: $1^{1}/_{4}$
Spread: $14^{1}/_{4}$
Length of thumb: $^{3}/_{4}$

p. 53

Incisors. $^{2-2}/_{2-2}$ Canines. $^{1-1}/_{1-1}$ False Molars. $^{1-1}/_{2-2}$ Molars. $^{2-2}/_{3-3}$

This species I have named after my esteemed friend, S. S. Haldeman, Esq., author of the N. American Limniades, who obtained it with other African animals from Dr. Goheen, Physician to the American Colonization Society.

Pteropus labiatus Temminck, 1837

p. 83

PTEROPUS LABIATUS.
ROUSSETTE LABIAIRE.

Portrait du mâle Pl. 39 fig. 1, 2 la femelle 3.

Cette belle roussette, dont le mâle est remarquable par la longueur extrême des pinceaux onctueux et par le prolongement labial au deux mâchoires, est de la taille de notre *vespertilion murin* d'Europe. Son museau est long; ses dents incisives sont fines et entassées; un appendice membraneux de peu de largeur sert d'interfémorale, et quoique entourant le coccyx par un rudiment elle n'est point visible sur cette partie, étant cachée et totalement couverte en dessus comme en dessous par les poils qui revêtent une grande portion de cette membrane adhérante au tibia: membranes des ailes naissant immédiatement des flancs. Oreilles longues et pointues.

Pelage cotonneux sur toutes les parties du corps, particulièrement sur le dos, moins, ou plus lisse aux parties inférieures.

Le mâle, porte tout le long du bord des deux mâchoires un prolongement de la partie labiaire qui tombe de plusieurs lignes au-delà du bord inférieur et cache totalement l'ouverture ou la fente latérale de la bouche, à-peu-près de la même manière comme dans le chien dogue de forte race; ce singulier appareil, propre aux deux machoires, donne à la tête du mâle de cette espèce une physionomie toute particulière. Le pelage cotonneux des parties supérieures revêt aussi toute la région humérale et le bord de la membrane alaire adhérante aux flancs; ce pelage ainsi que celui de la tête qui est court et ras, porte une teinte isabelle roussâtre, mais d'un ton plus roux vers le dos et surtout à la croupe; insertion des oreilles et bord postérieur de celles-ci couvertes de poils blancs; de chaque côté du cou qui est d'un brun roussâtre, nait une ample touffe de longs poils d'un blanc pur; ces larges pinceaux qui recouvrent probablement un appareil onctueux forment deux panaches dont les poils sont divergent d'un centre commun. La poitrine, la région humérale, les flancs et la région du coccyx sont

p. 84

roux clair; le milieu du ventre où les poils sont assez courts et lisses est d'un blanc terne. Toutes les membranes ont une teinte couleur feuille-morte.

La femelle dont nous donnons la tête vue de profil, pl. 39 fig. 3, ne diffère point remarquablement par la coloration du pelage, mais elle manque de tout vestige d'appendice labial; et n'a point de pinceaux ou de poils divergens aux côtés du cou.

Longueur totale 4 pouces 1 ou 2 lignes; envergure 15 pouces; antibrachium 2 pouces 4 lignes.

Patrie: M. Botta a déposé au Musée de Paris deux individus de cette belle et nouvelle espèce, découverte dans son voyage en Abyssinie. Les sujets du musée des Pays-Bas ont été acquis, l'un à Londres sans indication de patrie, l'autre à Paris, provenant des collections de Mr. Botta.

Pteropus Leachii A. Smith, 1829

p. 433

Pteropus Leachii, mihi.

P. suprà fusco-cinereus, infrà sordido-cinereus, caudâ liberâ.

Colour above a sort of brownish gray, beneath a dirty pale smoke gray; incisors short, strong, regular, and rounded at tips; head long; ears of moderate length and rounded at the apices; membranes blackish, interfemoral one only edging the inner side of each hinder extremity; tail free. Length from forehead to root of tail, four inches; length of tail, three-quarters of an inch; expanse of wings, thirteen inches. Found abundantly in the gardens about Cape Town during the fruit season, and often proves very

destructive to vineyards in the night. A larger species of the same genus inhabits the interior, but I have not yet been able to obtain a perfect specimen. Named after the celebrated naturalist Dr. Leach, F.R.S.

Pteropus macrocephalus Ogilby, 1835

p. 101

The whole length of this species is barely 6 inches, the length of the head 2 inches, and the expanse of the wings about 1 foot 3 inches. The colour, form and appearance are much the same as in the last species, but the *Pter. macrocephalus* is at once distinguished by the great size of the head, as well as by the colour of the flying memhranes which are very dark brown, nearly approaching to black. The canine teeth also, as well as the head, are of much larger size, and the interfemoral margin is narrower. Dr. Horsfield, from the great length of the head, thinks that this species may approximate to the *Macroglossus* of M. F. Cuvier, the *Pter. rostratus* of his own 'Zoological Recsearches in Java.' It is to be observed, however, that it differs in denrition from that animal, as well as from all other *Pteropi* hitherto described; and, with the *Pter. Gambianus*, may furnish the type of a new geuns to those who regard such modifications as amounting to generic characters. Mr. Rendall's collection contains numerous specimens of both the species here described

---

Pteropus mascarinus Mason, 1907

p. 221

Pteropus mascarinus, sp. n.

Skull. - With moderately long but heavy muzzle, flattened and scarcely concave frontal region. Sagittal crest weakly developed, almost obsolete.

Measurements. - A few of the measurements can only be given approximately owing to the damaged condition of the specimen: -
Upper length (approximate) 49 mm.; condylo-basal length (approximate) 46; basilar length (approximate) 44; median palate length 28; breadth between outer sides of canines 9.8, inside canines 4.3 ; outside p.4 13.8, inside p. 4.8; outside

p. 222

m.2 13, inside m.2 9.2; zygomatic breadth (approximate) 27; least interorbital breadth 7.8; the dimensions of the structure behind postorbital process cannot be taken; greatest breadth of brain-case 15; occipital depth 11; mandible 40.6; maxillary tooth-row exclusive of incisors (alveoli) 20.1; mandibular tooth-row exclusive of incisors (alveoli) 22.3.

Teeth. - With the longitudinal grooving characteristic of the genus *Pteropus*, very strongly developed, somewhat large and heavy for the size of the animal; canines long and sharp, both above and below, with unusually acute and prominent postero-internal basal ledges, those of the maxillary in particular; first upper premolars very minute, but would have been still persistent in the type and standing in the tooth-row.

Measurements. - The sizes of the upper incisors and second upper molars are omitted, as these teeth are wanting in the specimen. Vertical length of upper canine 7.5 mm.; horizontal length of upper canine 3.5; horizontal length of p.3 3.8, width 2.3; horizontal length of p.4 3.8, width 3; horizontal length of m.1 4.1, width 2.1. Lower teeth - combined breadth of incisors - ?; height of canine (from basal ledge behind) 5 ; horizontal length of anterior premolar 2; of p.3 3.8, width 2.1; horizontal length of p.4 3.5 ; of m.1 4.3, width 2; horizontal length of penultimate molar 3, width 1.8; horizontal length of m.3 1.5, width 1.4.

Locality. - Round Island, North-east Mauritius.

As compared with the now existing *Pteropi* of the Mascarenes, this species occupies a place intermediate between *Pteropus vampyrus* and *Pt. rodricensis*, in size only, the dentition being typical of *Pteropus*, whereas the two above species fall into the subgenus *Spectrum*. The only other fruit-bat occurring in the Mascarenes is *Pt. rubricollis*, and this has been placed by Matschie in his subgenus *Sericonycteris*. A great analogy, in fact, exists between the dentition of *Pt. mascarinus* and those species of *Pteropus* (*tonganus, Gouldii*, and *conspicillatus*) inhabiting Australia and the islands of the Pacific Ocean.

The limb-bones call tor no special description, the most perfect specimen being the right femur, which measures 40 mm.

Since the above was written a few additional bones referable to this new species, and representing two younger individuals, have been received. Their fragmentary condition has, however, failed to add any additional particulars to the above description of this interesting and lost species.

Pteropus mollipilosus H. Allen, 1862

p. 159

Head small; ears large. Envergure great. Interfemoral membrane scanty. Tail very small, free. General hue olive brown: brighter upon the back of the neck, where a faint dusky-brown line is seen traversing the thick fur of this region. Antero-posteriorly a patch of the same hue lies upon each shoulder; that upon the back is thinner and darker. The interfemoral membrane is well

furnished with soft olive brown hair, which becomes more scanty and shorter as it runs down the legs and the back of the feet to the claws. Back of the humerus and ulna thinly covered with the hair of the prevailing hue; anterior part of neck russet; belly of the same prevailing color as the back, with an inclination to dusky red upon the thighs.

* This disposition of the superior incisors is peculiar. We know that these teeth frequently vary; as, for instance, in the genus Hypoderma, where the young animal has i $^{4}/_{4}$ and later in life $^{2}/_{2}$; the elderly animal possessing but $^{2}/_{0}$. Thus, the difference in the number of the incisors is not of the importance which might at first sight be supposed. It is interesting, however, to know that this is the only instance of incisorial variation as yet seen among the species of Epomophorus.

p. 160

Fine straggling hairs clothe the inferior surface of the ulna and humerus, and stretch out upon the membrane down along the sides of the body and upwards upon the interbrachial membrane. Everywhere the hair is very soft.

The skull is of medium size, not crested. The postorbital processes are long and incline outward and downward to within two lines of the zygomas. The intermaxillary bone is not thrown forward and downward as in other Pteropi, but is on the same level as the roof of the mouth. The first premolar above is larger than the incisors. The same tooth on the lower jaw is also of good size, but less tubercular than in other species.

The dimensions are as follows:

Length from nose to base of tail: 8.0
" " " commencement of membrane: 3.0
" of head: 2.3
" from nose to eye: 1.0
" " eye to ears: 0.6
Between eyes: 0.9
" ears: 1.3
Height of ears: 0.10
Length of tail: 0.3
" superior extremity: 6.6
" thumb: $1.7^{1}/_{2}$
" first joint: $0.4^{1}/_{2}$
" second joint: 1.3
" index finger: 3.0
" third " : 8.0
" fourth " : 6.5
" fifth " : 5.0
Envergure: 26.0

It will be observed that the length of the inferior extremity and the expanse of wing membrane are greater than usual, when the other proportions are taken into consideration.

Hab. Western Africa; discovered by M. Duchaillu.

Pteropus rodricensis Dobson, 1878

p. 36

Ears slightly longer than the muzzle, but projecting by their upper third only from the long fur surrounding them; ear-conch moderately broad in lower three fourths, very abruptly narrowed above by flattening of the upper fourth of the inner margin and a deep concavity of the corresponding part of the outer margin, terminating in a narrow acute tip; more than two thirds of the concave surface of the conch is well clothed with moderately long hairs, the uppper fourth and the back of the ear naked or with a few short hairs only (Plate III. Fig. 1).

Fur long and dense, in quality intermediate between that of *Pt. Edwardsii* and *Pt. Vulgaris*; that covering the back of the head, neck, and shoulders very long, on the back shorter but not appressed, the hairs directed backwards, extending thickly upon the wings almost as far outwards as a line drawn from the proximal third of the

p. 37

humerus to the knee, upon the femur, knee, and adjoining wing-membrane along the proximal third of the tibiæ, about two thirds of which are thickly covered with straight hairs directed backwards, their distal thirds being nearly naked as well as the feet; and, although the fur of the back extends upon the interfemoral membrane, it does not conceal its posterior margin, and its lower third, supported by the calcanea, is naked. Beneath, the antebrachial
membrane is covered with long thinly-spread hairs, and similar hairs clothe the wing-membrane between the humerus and femur, and extend outwards in a broad band behind the forearm. Face reddish brown, with a few greyish or shining hairs: chin and throat darker brown; top of the head and nape reddish or yellowish brown, passing into a band of bright yellow, which extends across the back of the neck from shoulder to shoulder, and downwards on the sides of the neck and thorax, limited by a longitudinal band of dark fur passing backwards from the chin along the thorax to the abdomen, which is clothed with dark brown fur, of which some hairs have greyish or shining extremities; fur of the back behind the shoulders dark brown, the extremities of the hairs more or less yellowish. In the male the extremities of the hairs on the head and back are much brighter-coloured than in the female.

First upper premolar deciduous; the second upper premolar and the second and third lower, also the first and second upper molars and the first lower, have each a small but distinct posterior basal cusp; even the small first lower premolar has an indication of a posterior basal cusp; last upper molar very small and circular, not as large as the first lower premolar; last lower molar slightly larger than the first lower premolar.

Length (of an adult M preserved in alcohol), head and body 7", head 2".2, ear 0".9, ear from tip of nostril 2", eye from tip of nostril 0".8, forearm 4".9; thumb-metacarp. 0".35, ph. And claw 1".6; third finger-metacarp. 3".3, 1st ph. 2".4, 2nd ph. 3".55; fourth finger-metacarp. 3".25, 1st ph. 2", 2nd ph. 1".85; fifth finger-metacarp. 3".35, 1st ph. 1'.5, 2nd ph. 1".45; tibia 2".25, calcaneum 0".6, foot 1".15.

Pteropus rufus E. Geoffroy Saint-Hilaire, 1803

p. 47

2. Esp. La roussette marron. *Pteropus rufus*. (Geoff.)

Caract. Pelage roux, le dos, depuis les épaules, de couleur marron-foncée.

The great bat from Madagascar. Edwards, Aves, t. 4, pl. 180.

Descript. T. 0,^{m}29 (10 p. 7 l.). Envergure 0,^{m}86 (2 pi. 6 p.), incisives supérieures intermédiaires plus grandes et plus rapprochées entr'elles que les latérales, point de queue; dessus du corps roux, beaucoup plus clair sur la tête; les épaules et le cou bruns en dessous; museau noir.

Patrie. Madagascar.

N°. XC. Individu envoyé par le citoyen Macé, naturaliste.

Pteropus rufus princeps K. Andersen, 1908

p. 367

Pteropus rufus princeps, subsp. n.

Similar to *Pt. rufus rufus*) (*Pt. edwardsi* auct.), but skull and external dimensions conspicuously larger. Total length of skull 77 mm. (69 - 73.8 in the typical form of the species); mandible 62 (54.5 - 58.2); forearm 170.5 (158.5 - 165.5).

Type. M ad. Alc. And skull, Fort Dauphin, S.E. Madagascar; collected by M. Cloisel ; B.M. 91.11.30.10.

Remarks. - The typical smaller form of the species is apparently confined to the northern and central part of Madagascar.

Pteropus Schoënsis Rüppell, 1842

p. 131

Pteropus schoënsis (Rüppell).

Diagn. Pteropus ecaudatus, auriculis brevibus, halluce elongato, corporis colore cervino, regione epigastrica canescente; macula albicante ante et post auriculas, ad latera faciei a naribus per oculos fascia umbrina; unguibus nigris.

Ich hatte Zweifel, ob dieses Thier nicht etwa das Jugendalter von *Pteropus Whitei* Bennet, (*Pt. labiatus* Botta) sey. Die wenig abgenutzten Doppelspitzen der Schneidezähne des einzigen von mir untersuchten Thieres deuten auf ein junges Individuum hin. Aber bei genauer Vergleichung ergab es sich, dass bei der hier zu beschreibenden Art das Daumenglied bei weitem länger, und die Ohren vergleichlich viel kürzer sind als bei dem Bennet'schen *Pteropus*. Ich bedauere, dass die Untersuchung der Schädel beider Thiere nicht thunlich ist, um jegliche Ungewissheit über die Artenverschiedenheit zu lösen. Die Körperausmessung gab folgendes Resultat:

Zoll. Lin.
Ganze Körperlänge von der Nasenspitze bis zum Mittelrand der sehr kurzen Interfemural-Membran: 8 9
Flugweite: 18 -

p. 132

Vorderarmknochen: 1 11
Daumenglied, ohne Nagel: - 6 $^{1}/_{2}$
Verticalhöhe des Ohrs: - 4 $^{1}/_{2}$

Die Grundfarbe der ganzen Behaarung ist rehfarbig, welches auf dem Bauch und der Kopfmitte ins Hellgraue, und auf dem Rücken mehr ins Röthliche ober geht; von den Nasenlöchern aus verläuft durch die Augen nach dem Ohre zu ein kaffeebrauner Streifen; oberhalb und unter der Basis des Ohrs ist ein Büschel grauwelsser Haare. Auf der innern Seite der Flughaut ist die Behaarung längs des Körpers und an dem Vorderarm hellgrau, und auf der Rückenseite der Flughaut rothbraun. Die robusten, etwas comprimirten Nägel sämmtlicher Zehen sind schwarzbraun.

Das hier beschriebene Exemplar scheint weiblichen Geschlechts zu seyn; es ward mir aus dem Reiche Schoa, südlich von Abyssinien, zugeschickt.

Pteropus stramineus E. Geoffroy Saint-Hilaire, 1803

p. 48

4. Esp. La roussette jaune. *Pteropus stramineus.* (Geoffr.)

Hab. in regione Gambiensi, *D. Rendall*.

Obs. Scopa humeralis forsan maribus propria.

In naming this remarkable *Bat* in commemoration of an individual who had no share in its discovery and by whom it was never seen, I may seem, strictly speaking, to have erred; but it is time that technical zoology should record the name of one who was by

p. 38

no means unversed in its mysteries, and who has long maintained the highest rank as a popular zoologist. Gilbert White, of Selborne, was the first Englishman who ascertained the existence of indigenous *Bats* other than the two known as European to Linnaeus: to that good man and excellent observer be this singular species dedicated, - a species belonging to one of the few groups of *Bats* that are of direct utility to the human race, and which, preying not on other animals, rest contented with the simple fruits of their native woods.

Pterygistes azoreum Thomas, 1901

p. 33

Very similar to the other species, which scarcely differ among themselves except in size, but smaller than any of them.

General characters, so far as can be made out on the single specimen, as in *P. Leisleri*, to which this form was assigned by Drouet and Peters. But the size is markedly less, the general build is lighter, the ears appear to be rather broader and more rounded, while the tragus is slightly narrower and more pointed.

Colour, in a spirit-specimen, apparently of the usual dark brown characteristic of *Pterygistes*. Hairs of back about 6 millim. in length.

Skull, as compared with that of *P. Leisleri*, smaller and more delicate throughout, smooth, unridged, no sagittal and scarcely any lambdoid crests perceptible in an old male. Teeth practically identical throughout with those of *P. Leisleri*.

Dimensions of the type (an old male, in spirit): -

Forearm 37 millim.

Head and body 54; tail 42; ear 12; tragus, length on inner edge 3, breadth 2; third finger, metacarpus 36.5, first phalanx 15, second phalanx 10.5; fift finger, metacarpal 31,

p. 34

first phalanx 8, second phalanx 4.7; lower leg 17; hind foot (s. u.) 7.7.

Skull: greatest length 14.2; basipalatal length 11; zygomatic breadth 9.4; posterior breadth 9; breadth between orbits 6.4; constriction 4.4; length of palate 5; breadth between outer borders of m^2 6.2; front of canine to back of $m.^3$ 5.1.

Hab. St. Michael's, Azores.

Type. Male. B.M. no. 65.10.2.1. Collected and presented by F. DuCane Godman, Esq. One specimen only.

The single specimen has all its claws, both of feet and thumb, worn down quite blunt. Whether this is accidental or due to the nature of its habitat remains to be seen.

From the gigantic *P. maximus* and *lasiopterus*, through *P. noctula, stenopterus*, and *Leisleri*, there is a regular gradation in size down to this small Azorean representative of the group, all of them differing from each other in little else but size and the correlated development of the cranial ridges.

I accept with some hesitation the generic separation of the *noctula* group from *Pipistrellus*, advocated by Gray, Jerdon, H. Allen, Miller, and Mehely, on the ground that not only is the general build of the body different, but that the wings even are different in shape, owing to the reduction in length of the fifth digit. At the same time it must be admitted that some of the Indian species of *Pipistrellus*, such as *P. ceylonicus, chrysothrix, mordax*, &c., approximate to a certain extent to *Pterygistes*, and render the distinction less marked than it appears to naturalists who have only compared with each other such extreme forms as *Pterygistes noctula* and *Pipistrellus pipistrellus*.

Pterygistes madeiræ Barrett-Hamilton, 1906

p. 98

Pterygistes madeiræ, sp. n.

This bat is similar to *P. Leisleri*, Kuhl, of Britain, but perhaps smaller and with quite different skull. The colour is

p. 99

unascertainable in the old spirit-specimens, which alone are available for examination.

The *skull*, as compared with that of *P. Leisleri*, is slightly smaller, less massive, and relatively longer and narrower, characters which, although quite apparent to the eye, do not stand out so clearly when expressed in words. It is not at all like the much smaller *P. azoreum* Thomas, with its somewhat inflated cranium and depressed nasal region.

The *dimensions* in millimetres of a female (in spirit) are as follows: -

Head and body 55; ear 12; tragus 4; greatest expanse of wing 240; thumb and claw 6; longest digit 74; basal joint of fifth digit 32; basal joint of second digit 40; forearm 43; tibia 16; hind foot (without claws) 7.5.

Skull (of the type): greatest length 15; basipalatal length 11.5 ; zygomatic breadth 9.5; posterior breadth 9; breadth between orbits 8, at constriction 4.5 ; length of palate 6.5; breadth between outer borders of m^2 6.75 ; length from anterior border of canine to posterior border of m^3 5.25.

Hab. Madeira.

This species is evidently the representative of *P. Leisleri* in Madeira, and it is remarkable how different it is from its neighbour *P. azoreum* of the Azores. It is described from specimens in the R. F. Tomes collection procured by Mason. According to the custom of his day, Tomes identified his specimens with *P. Leisleri* from which species, however, it is clearly differentiated by its characteristic skull.

The*type* is no. 1 of the Tomes collection in the British Museum (a female).

R[hinopoma] cystops macinnesi Hayman, 1937

p. 530

A dwarfed form of the well-known species of Egypt and the Sudan, having a shorter forearm and a much lighter and smaller skull.

Type. - Brit. Mus. no. 36.11.4.45. Adult male in alcohol, collected on Bat Island, near Central Island, Lake Rudolf, April 24th, 1934. Another male and a female examined taken at the same time and place.

Description of Type. - Externally similar to true *cystops*, but having a forearm measurement of only 46 mm. (47 mm. in the other two specimens). In adult *cystops* the forearm averages 52, sometimes reaching 55. The colour of the fur is similar to that of the typical form, a pale plumbeous-fawn, paler at the base.

The skull is notably smaller and weaker than that of *cystops*; the sagittal crest is very weak, being barely indicated, while in *cystops* it is strongly developed in both sexes. The rostrum is narrower, the bullæ smaller, and the reduction in the size of the teeth is illustrated by the breadth of m^2 in *macinnesi* being 1.8, while in the type and another specimen of adult *cystops* the figures are 2.2 and 2.3 respectively. Compared with the skulls of
Rhinopoma pusillum Thos., from Persia, and *muscatellum* Thos., from Muscat, two species of approximately similar external dimensions, the skull of this new form is quite distinct, being smaller and narrower, with smaller teeth. In the following table the measurements of three specimens of *macinnesi* are compared with those of the types of *cystops, pusillum*, and *muscatellum*: -

p. 531

[table removed - eds.]

This discovery extends the known range of the genus into Uganda, and I have pleasure in associating with it the name of Mr. D.G. MacInnes, to whom much of the success of the mammal-collecting was due.

Rhinolophus abæ J.A. Allen, 1917

p. 428

Type, No. 49113, F ad. (skin and skull), Aba, Uele district, Belgian Congo, Dec. 15, 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig, No. 1756.

General coloration drab-brown, a little darker above than below, the middle of the back slightly darker (blackish brown) than the rest of the upperparts, sides of the shoulders a little lighter. Fur almost uniformly colored from base to tip, the median zone being only slightly lighter than the base and tips.

Ears long and pointed, the anterior border slightly convex (increasingly so apically), the posterior nearly straight (slightly concave toward the apex), the antitragus large and high (vertical depth anteriorly 5-6 mm.). Breadth of horseshoe in skins (when not unduly shrunken), 8.5-9.5 mm. Nose-leaf broad at base (about 6.5 mm.), acutely pointed, and about 6 mm. in length. Sella about 3 mm. broad at base and 4 in height (as nearly as can be judged in softened skins), slightly concave on anterior face, with a posterior extension of about 3 mm., highest in front with a slight median axial depression.

Type, collectors' measurements: Total length, 85; head and body, 63; tail, 24; foot, 12; ear, 24. Forearm (from skin), 52.3; tibia, 20; foot, 11.

Skull (type), total length, 22.9; zygomatic breadth, 11.9; breadth at canines, 5.8; maxillary breadth, 8.1; upper toothrow (front of c-m^3), 7.8; lower jaw (incisors to condyle), 15.1; lower toothrow (c-m_3), 8.8.

Represented by ten specimens, skins and skulls (2 males, 8 females) all collected at Aba, December 15-17, 1911. Collectors' measurements (1 male, 7 females, all adult):

p. 429

Total length: 85 (80 - 89); Head and body: 61 (57 - 64); Tail: 24 (22 - 27); Foot: 12 (11 - 13); Ear: 22.9 (22 - 24)

Forearm, same specimens, 53 (50-54). Skull (6 specimens), total length, 23 (21.9-23.6); zygomatic breadth, 11.7 (11.3-12.2); breadth at base of canines (9 specimens), 5.9 (5.6-0.2); maxillar breadth (across front corner of m^3), 8.3 (7.8-8.6).

P^2 is present on both sides in 3 skulls, on one side in 2 skulls, and absent on both sides in 4 skulls.

The series is very uniform in coloration; an immature male differs from the others in being lighter and grayer, and is somewhat smaller.

This form, appears to be a northern representative of the *Rhinolophus auger* group, of which several forms have been described from the Zambesi region and southward by K. Andersen.

Rhinolophus acrotis Heuglin, 1861

p. 10

Rh. medius, digitis valde elongatis, alis ad apicem caudae usque porrectis; auriculis mediis, acutis, margine externo S-forme, lobulo lato accessario obtuse marginato instructis: - ferro equino duplice margine superioris libero, medio antico-inciso, margine (ferri equini) inferioris labiis connato; glandulis violaceis circumdato; latere sellae anteriore medium versus angustato, basi concava, plicis duabus ad nares usque ductis; apice vix rectangulare; prosthemate latiore, lanceolato, acuminato, parte anteriore plicis duabus transversalibus erectis ornato; phalangis exterioribus quarti et quinti digiti apice paullo bifurcatis, digito secundo phalangis duabus, tertio, quarto et quinto phalangis tribus instructis. Vollere pallide murino, subtus pallidiore. Long. a naso ad basin caudae 2" - extensio alarum 13" - caud. 1" 3"' - auriculis $9^1/_4$"' - antibrach. 1" 9"'.

Gleicht in Rücksicht auf Construction des Nasenbesatzes, Form der Ohren

p. 11

u. s. w. sehr der *Rh. minimus*, Heugl., ist aber viel grösser, die Ohren verhältnissmässig kleiner und spitziger, Nasenblatt doppelt, jedoch nur der Rand des oberen frei, die *Sella* mit breiter Vorderhand, die Endglieder des vierten und fünften Fingers an der Spitze gegabelt. Zeigfinger zweigliederig. Im Ohr 6 deutlichere und 1 - 2 minder hervortretende Querfalten. Zahnsystem - so weit dies ohne Dissection beobachtet werden kann - regelmässig; untere Schneidezähne je 2 auf jeder Kieferseite, nicht sehr klein, am schaufelförmigen Rande der Schneide dreizackig.

Nasenblalt, wie gesagt, doppelt, das untere mit einer regelmässigen Reihe von violetten Drüsen umgeben. Der Körper der Sella seitlich zusammengedrückt, die höchste Spitze ziemlich erhaben über die Spitze der vorderen Wand. *Prosthema* kurz, lanzettförmig mit 2 nach vorne aufgeschlagenen Querfalten, an der Basis jederseits mittelst eines kleinen Läppchens mit dem Hufeisen verbunden. Im Gaumen drei grosse und dahinter drei schmälere Querfalten, welch letztere ihrer Länge nach nochmals getheilt sind. Flughaut und Finger sehr lang, das erste Daumenglied beiderseits vom *Patagium* eingeschlossen; ebenso der Schwanz, in dessen Spitze das *Patagium interfemorale* spitz verläuft. Das letztere, sowie die Partie zwischen Armen und Füssen innen fein behaart.

Die Farbe des Pelzes hell-mausgrau, Unterseite noch etwas lichter als der Rücken, Flughäute, Ohren und Nasenbesatz fleischfarb-grau. Nägel hellfleischfarb mit weisslicher Spitze und rostbraunem Fleck in der Mitte. Zehenrücken mit weisslichen feinen borstenartigen Haaren besetzt.

Rhinolophus acrotis brachygnatus K. Andersen, 1905

p. 73

Diagnosis. - Like *Rh. acrotis Andersoni*, but upper and lower tooth-rows, as well as mandible, distinctly shorter.

Skull and dentition (two skulls examined). - Although being apparently, on an average, larger than *Rh. a. Andersoni*, the present form has a smaller skull, smaller teeth, shorter tooth-rows and mandible (conf. measurements).

Colour. - The general colour of the single skin at my disposal (F imm.) is much darker than in the type of *Rh. a. Andersoni* (M imm.): greyish "drab" on the upperside, tinged with "mouse-grey" on the hinder back; "ecru-drab" on the underside; base of hairs on the back of the same colour as the underside.

Type. - M ad. (in alcohol). Ghizeh, Lower Egypt, Dec. 16th, 1891; collected and presented by Dr. J. Anderson. B. M. no. 92.9.9.7. There is a second specimen (F imm., skin) in the Museum from the same locality.

Distribution. - Known only from Ghizeh.

Remarks. - The absence, even in immature individuals, of the lower p_3 and upper p^2 distinguishes this form sufficiently from the only species with which it could possibly be confounded, viz. *Rh. euryale* and *Rh. clivosus*. Up to the present time three forms of *Rh. acrotis* have been described: *Rh. acrotis* (typicus) from Keren, Erytrea; *Rh. a. Andersoni* from the Eastern Egyptian Desert, about 22° N., 35° E.; and *Rh. a. brachygnathus* from the environs of Cairo.

Measurements of *Rh. acrotis brachygnathus* and *Andersoni*.

[table removed - eds.]

Rhinolophus acrotis schwarzi Heim de Balsac, 1934

p. 483

Un spécimen F de Tamanrasset, n° 114, 5-11-27.

L'histoire de ce spécimen est singulière: il a été déjà mentionné par MONOD sous le nom erroné de *Rhinolophus fumigatus* RÜPPEL (= *Rh. antinorii* DOBSON). La fausse détermination n'est pas imputable à MONOD, mais bien à l'illustre O. THOMAS, à qui le spécimen avait été soumis. L'erreur est explicable par le fait que O. THOMAS avait négligé d'examiner le crâne et n'avait pas dépouillé l'animal. Toutefois, la petite taille du spécimen a elle seule aurait pu le frapper.

Rh. acrotis était connu jusqu'ici de l'Erythrée et de l'Égypte (remonte jusqu'au Caire). Sa présence à Tamanrasset ainsi qu'à Djanet d'où nous avons reçu trois autres spécimens grâce à l'obligeance du Dr FOLEY montre que ce Chiroptère est bien établi dans les massifs centraux du Sahara et qu'il ne s'agit pas d'individus erratiques ou migrateurs. Son aire de répartition se trouve ainsi étendue considérablement vers l'Ouest (d'une distance de l'ordre d'au moins 2.500 kilomètres). Le fait a une importance biogéographique certaine et il se reproduit d'ailleurs pour d'autres Mammifères sahariens.

Au surplus les spécimens des massifs centraux constituent une race géographique particulière qui mérite d'être nommée.

La race nominale, *Rh. acrotis acrotis* V. HEUGLIN, a été décrite de l'Erythrée (Keren). Postérieurement THOMAS décrivit une race

p. 484

plus petite, *Rh. acrotis andersoni*, d'après un spécimen immature, provenant de l'Est de l'Égypte (22° N - 35° E). Cette race ne fut pas admise par ANDERSEN, l'infériorité de taille d'un spécimen immature ne pouvant être prise en considération. Ultérieurement le même ANDERSEN décrivit une race de petite taille, *Rh. acrotis brachygnathus* en provenance de la Basse-Égypte (Caire, Giseh). Mais nos spécimens du centre du Sahara sont encore plus petit que *brachygnathus*. E. SCHWARZ a bien voulu comparer le crâne de Tamanrasset à ceux d'*acrotis* (= *andersoni*) et de *brachygnathus* du Br. Muséum. Il nous a confirmé par écrit que ce spécimen était de façon marquée, plus petit que les animaux du Musée britannique, et qu'il méritait d'être décrit. D'autant plus qu'il s'agit ici d'une forme géographiquement très éloignée des autres, probablement isolée dans les massifs sahariens centraux, et en tout cas représentant un extrême.

Nous proposons de la dédier au Dr E. SCHWARZ sous le nom: *Rhinolophus acrotis schwarzi* nov. subsp.

Type: F adulte en alcool, Djanet, Tassili des Azdjers (nous préférons ne pas prendre pour type le spécimen de Tamanrasset dont les avant-bras sont brisés et qui ne peuvent être exactement mesurés).

Diagnose: Forme plus petite que *Rhinolophus acrotis brachygnathus* (avant-bras 45-46 mm., long, condylo-incisive 17 mm;), de teinte gris cendré clair (4 spécimens examinés).

[table removed - eds.]

Rhinolophus adami Aellen and Brosset, 1968

p. 443

TYPE. - F adulte, en alcool. Grotte de Kimanika, Kouilou, République du Congo, 9.1.1967; coll. J.-P. Adam, no orig. 12/8G. Muséum de Paris 1968-408.

PARATYPES. - M adulte. Grotte de Meya-Nzouari, Kouilou, République du Congo, 26.7.1963; coll. J.-P. Adam, Muséum de Genève 1129.84.

2 FF subadultes. Mêmes lieu, date et collecteur que le type, no orig. 3/8G et 8/8G. Muséum de Paris 1968-409 et 1968-410.

DIAGNOSE. - *Rhinolophus* de taille moyenne (avant-bras 47 à 49 mm; long crâne 20,3 à 20,6 mm). Feuille nasale grande (long. 15 à 16 mm, larg. 8,5 à 9 mm) à connectif arrondi dépassant quelque peu le sommet de la selle; lancette non acuminée, à bords droits ou un peu convexes; selle à dossier (procès vertical) large et à bords concaves. Troisième métacarpe non réduit, supérieur à 90 % du cinquième métacarpe. P^2 dans la rangée dentaire, séparant nettement C de P^4. P_3 implanté au bord externe, mais bien développé et séparant P_2 de P_4. Crâne étroit: largeur zygomatique (qui est inférieure à la largeur mastoïde) mesurant moins de la moitié de la longueur totale (au bord antérieur de C). Pont palatal long; son bord médian antérieur arrive au niveau du bord antérieur de M^1.

DESCRIPTION. - Les dimensions externes (sauf la feuille nasale) entrent pour la plupart dans les limites de variation de *R. capensis*. Les oreilles sont très grandes, elles mesurent plus de la moitié de la longueur de l'avant-bras. Le bord interne est assez régulièrement convexe de la base au sommet; celui-ci est bien marqué et forme un angle droit, ou même un peu aigu, toutefois fortement arrondi à la pointe; le bord externe est nettement concave vers le sommet, puis très légèrement convexe jusqu'à l'antitragus. Celui-ci est régulièrement convexe et séparé du pavillon par une encoche à angle très obtus; il mesure environ 13 mm de l'insertion de base à l'encoche.

La feuille nasale est très caractéristique de cette espèce; elle est grande, surtout longue. Le fer à cheval recouvre presque tout le museau et présente une large échancrure au milieu de son bord antérieur. La selle est très large (3.2 mm) et son procès vertical (dossier) est environ aussi large que haut; ce procès est un peu plus large à la base qu'au sommet et ses bords latéraux sont légèrement concaves; il en résulte un étranglement au milieu de la hauteur (voir tableau de mensurations). Le connectif a une pointe régulièrement arrondie qui dépasse quelque peu le sommet du dossier de la selle. La lancette, triangulaire, possède des bords latéraux légèrement convexes et une pointe peu aiguë, donc absolument pas acuminée comme c'est le cas chez les espèces comparables, *simulator, bembanicus* et *capensis*.

La lèvre inférieure présente trois sillons délimitant deux lobes bien développés, comme chez *simulator* et *capensis*.

p. 444

Le patagium s'insère à la partie distale du tibia ou à la cheville.

Le troisième métacarpe n'est pas réduit; il mesure toujours plus des 90 % du cinquième. La queue est plus longue que la moitié de l'avant-bras.

La coloration de cette nouvelle espèce ne présente rien de particulier. Le type (F) est brun assez clair sur le dos; la face ventrale est gris-brunâtre. Les paratypes sont plus foncés dessus, mais le ventre est aussi gris-brunâtre; l'un (8/8G) est même blanchâtre au bas-ventre. La feuille nasale est très claire, couleur chair. Les oreilles sont brunes, un peu plus foncées au sommet. Le patagium est brun foncé.

Le crâne présente des proportions semblables à celles de *simulator-bembanicus*. Il est très étroit: sa plus grande largeur n'atteint pas la moitié de la longueur totale (mesurée au bord antérieur de C). Le renflement nasal est fortement marqué; le profil général du crâne rappelle beaucoup celui de *bembanicus* figuré par SENNA (1914, p. 2). La largeur zygomatique est égale ou inférieure à la largeur mastoïde. Le rapport largeur zygomatique sur longueur C-M^3 est nettement inférieur (1.26) à celui mesuré sur *capensis* (1.38 à 1.41), et *simulator-bembanicus*

p. 445

[table removed - eds.]

p. 446

(1.30 à 1.40); ce rapport illustre particulièrement bien cette étroitesse du crâne, le pont palatal, mesuré au milieu, est remarquablement long et comparable à celui de *simulator-bembanicus*: il constitue les 38 à 39.5 % de la longueur C-M^3, alors que chez *capensis* il ne représente que les 34 à 3 5% (*simulator*: 38.5 %; *bembanicus* 42.5 %). Le milieu du bord antérieur du pont palatal arrive au niveau du bord antérieur de M^1; le point médian du bord postérieur se situe entre M^2 et M^3. Un long pont palatal est un caractère archaïque chez les *Rhinolophus*. Dans notre nouvelle espèce, cette ancienneté se manifeste aussi dans la denture.

Au maxillaire supérieur, P^2 est situé dans la rangée dentaire et sépare nettement C de P^4; les pointes de C et P^4 sont séparées de 2 mm. La hauteur de P^2 atteint ou dépasse légèrement le cingulum de C.

Au maxillaire inférieur, P_3 est inséré sur le bord externe de la rangée dentaire et sépare P_2 de P_4. P_2 est remarquablement petit; cette dent n'atteint pas la moitié de la hauteur de P_4 et rappelle, par ce caractère, *R. alticolus*.

REMARQUES. - Il est curieux de constater la découverte dans une région géographique restreinte - l'ancienne AEF - de deux espèces nouvelles de *Rhinolophus* en l'espace d'une dizaine d'années. *R. silvestris*, décrit en 1959, est une espèce bien individualisée ayant son plus proche parent dans une espèce orientale, *deckeni*. La nouvelle espèce *R. adami* est proche, elle, de deux formes d'Afrique du Sud-Est, deux formes que plusieurs auteurs pensent devoir être synonymes: *simulator* et *bembanicus*. *R. bembanicus* n'est connu que par le type, provenant de Zambie. *R. simulator* a été signalé en Tanzanie, au Malawi, en Zambie, au Katanga (?), en Rhodésie, au Mozambique, au Botswana et en République d'Afrique du Sud (Transvaal et Natal).

Afin de pouvoir comparer facilement notre nouvelle espèce à ses plus proches parents, nous avons divisé les espèces africaines du groupe ferrumequinum en deux sous-groupes ainsi définis:

Groupe *ferrumequinum*: connectif à sommet arrondi et bas, ne dépassant pas ou seulement de peu le procès vertical de la selle. Largeur du fer à cheval inférieure à 9 mm (atteignant exceptionnellement 9 mm).

Sous-groupe *ferrumequinum*: P^2 externe ou absent. C et P^4 en contact ou presque: espèces: *ferrumequinum, augur, darlingi, clivosus*.

Sous-groupe *capensis*: P^2 dans la rangée dentaire, séparant nettement C de P^4: espèces: *capensis, alticolus, denti, swinnyi, simulator, bembanicus, adami*.

Rhinolophus aethiops diversus Sanborn, 1939

p. 42

Type from Bakel, Senegal, French West Africa. No. 19.7.7.2774 British Museum (Natural History). Adult female in alcohol. Collected September 27, 1887. From the Lataste collection.

Characters. - Averages smaller than either *a. aethiops* or *a. eloquens*, with a narrower horseshoe and sella and a shorter lancet. The type, when dried, is darker than *aethiops*, being in general a faded brown. The hairs above are of uniform color to the base; below they are slightly darker at the base. The type, however, has been in alcohol for many years and the only skin is more than one hundred years old.

The type skull is like that of *aethiops* but much smaller. Upper premolar two is present on one side only and is so minute that it is hard to see even with a lens. Lower premolar three is present on both sides and is also very minute.

Measurements. - Type (maximum and minimum of topotypes in parentheses): Forearm 53.2 (52.8 - 55.6); third finger, metacarpal 40.6 (39 - 40.7), first phalanx 16 (16 - 17.7), second phalanx 30.3 (30 - 31.5); fourth finger, metacarpal 41.9 (41 - 42.7), first phalanx 9.6 (9.8 - 10.3), second phalanx 18.7 (17.9 - 18.7); first finger, metacarpal 41.9 (42 - 44), first phalanx 12.6 (12.5 - 13.2), second phalanx 13.9 (14.1 - 14.6). Ear 27 (27 - 28); tail 28.6 (28.8 - 32.7); tibia 22.6 (22.8 - 23.5). Skull of type: greatest length 23.1; condyle-basal

p. 43

length 19.6; palatal length 2.9; width across nasal swellings 6.1; interorbital width 2.6; zygomatic width 11.9; mastoid width 10.5; width of braincase 9.5; upper toothrow 8.8; width across canines 6.6; maxillary width 8.7; supraorbital length 6.4.

Specimens examined. - Total 7. Bakel, Senegal, 2 males (alc.), 2 females (alc.); "River Gambia," 1, no sex. Nerokoro, near Tambikunda, Sierra Leone, 1 male (alc.), 1 female (alc.). All in British Museum.

Remarks. - All the forms of *R. aethiops* are very much alike except *a. hildebrandti*, which is the largest. *R. diversus* does not agree very well either with typical *aethiops* from Angola or with *a. eloquens* from the Sudan, being smaller and darker. The two specimens from Sierra Leone are not included in the measurements as they are both subadult and are only referred to *R. diversus*.

Rhinolophus alcyone Temminck, 1853

p. 80

RHINOLOPHUS ALCYONE.
RHINOLOPHE ALCYONE.

C'est la seule espèce de cette section qui ne soit parvenue de la partie littorale de l'Afrique, dont nous nous occupons. Elle est munie d'une folicule en fer-de-lance, large à sa base, mais peu haute et munie de deux rangées de petites caritées: un socle repose sur le bourrelet et est entouré du large fer-à-cheval bordé d'un petit plis du derme. Les oreilles sont grandes et hautes, terminées par un oreillon mobile.

Nous n'avons pu observer qu'une femelle; il est dès-lors incertain s'il faut attribuer l'existence d'un syphon, dans le mâle.

Le pelage de la femelle est pour toutes les parties su-

p. 81

périeures; d'un rouge-vif couleur de briques cuites; en dessous d'une teinte plus claire, couleur de rouille. Les oreilles n'ont que la base poilue; leur pointe est recourbée en déhors; celles-ci; de même que toutes les autres parties du derme sont noires.

Longueur jusqu'au bout de la queue 3 pouces; la queue seule 9 lignes; envergure 11 pouces; antibrachium 1 pouce 9 lignes.

Patrie. La rivière Boutry à la Guiné.

Rhinolophus alcyone alticolus Sanborn, 1936

p. 108

Type from cave at 5,800 feet on Mount Cameroon, Cameroon Mandate. No. 42596 Field Museum of Natural History. Adult female. Collected July 2, 1934, by R. and L. Boulton.

Diagnosis. - A member of the *landeri* group with reduced second phalanx of fourth finger. Like *alcyone* but much smaller. With the exception of the ears, which are larger, about the size of *lobatus*. Skull with characters of *alcyone*; size of *lobatus*, but narrower.

Color. - General color of upper parts dark brown, between Raw Umber and Mummy Brown (Ridgway, 1912). Base of hairs much lighter. Below brownish gray.

Skull. - As in *alcyone* in that p_3 is partly in tooth-row and separates p_2 and p_4, but much smaller. Length as in *lobatus*, but with shorter tooth-rows and narrower throughout.

Measurements. - Type and three topotypes: forearm 46.2 (46.2 - 47.1); third digit metacarpal 31.8, first phalanx 14.3, second phalanx 25.5; fourth digit metacarpal 34.6, first phalanx 7.7, second phalanx 15.7; fifth finger metacarpal 35, first phalanx 10.1, second phalanx 17.7. Ear, from meatus 22, from crown (dry) 15, width (dry) 14.1. Tibia 17.3; foot 9; calcar 11.9. Skull: total length 19.2 (19.2 - 19.6); total length to canine 18.5 (18.4 - 18.9); basilar length to canine 14.9 (14.7 - 15); interorbital width 2.4 (2.4 - 2.5); zygomatic width 9 (9 - 9.1); mastoid width 9.1 (9 - 9.1); width of brain case 8 (7.9 - 8); width across canines 4.4 (4.3 - 4.5); width across m^3-m^3, 6.4 (6.3 - 6.4); width of nasal swelling 4.8 (4.8 - 4.9); upper tooth-row c-m^3, 6.6 (6.6 - 6.7); lower tooth-row c-m_3, 6.9 (6.7 - 6.9); mandible 11.9 (11.8 - 12.1).

Specimens examined. - Type and three topotypes.

Rernarks. - This race appears to be a highland form most closely related to *alcyone* and a western representative of *lobatus* from East Africa. Thomas (Ann. Mag. Nat. Hist., (8), 7, p. 458, 1911) listed a *Rhinolophus* from Panyon (4,000 feet), Nigeria, as "near *R. alcyone*" which may be the same. Andersen (Ann. Mus. Civ. Stor. Nat., Genova, (3), 2, p. 190, 1905-06) has published an excellent series of measurements of this group.

Rhinolophus Andersoni Thomas, 1904

p. 156

Rhinolophus Antinorii, Anderson and de Winton, Mamm. Egypt, p. 96, pl. xvi. fig, 2 (1902) (nec Dobs.).

Allied to *R. clivosus*, Rüpp., but with no small anterior premolars and different colour.

General characters as in *R. clivosus*, the nose-leaf and ears being apparently very much as in that species; perhaps the front face of the median vertical process is slightly more narrowed upwards, but the difference is very slight; horseshoe small, not covering the muzzle laterally. Wings from the ankles.

Colour drab-grey, the hairs above slightly darkened terminally, those of the belly drab-grey throughout. In *R. clivosus* the belly is white. Membranes transparent greyish, rather darker along the centres of the digital interspaces.

Skull with a broader heavier muzzle and nasal region than in *R. Dobsoni* (the bat considered by Dobson as *R. clivosus*) or than in *R. euryale*.

Small premolars, both upper and lower; absent in every specimen, the large upper premolar pressed close against, even overlapping, the canine. In *R. clivosus* the small premolars are present both above and below.

p. 157

Dimensions of the type (measured in the flesh): -

Forearm 46 mm.

Head and body 53; tail 28; ear 22.

Skull: front of canine to occiput 19; length in middle line 16; front of bony palate to basion 12.5; breadth of palate across m^2 7.5; tip of upper canine to tip of large premolar 1.6; front of lower canine to back of m_3 8.3.

Type. Male. Original number 26. Captured 3rd August, 1903. Four specimens.

"Arabic name 'Wat-wat'; Bisharin name 'Humush-Kilite.'" - *A. M. M.*

In the British Museum collection there is already a spirit-specimen of this bat, obtained by Dr. J. Anderson at Gizeh. This is the *R. Antinorii* of that naturalist's 'Mammals of Egypt,' a note being appended by Mr. de Winton drawing attention to its possible identity with *R. clivosus*. It is certainly not *R. Antinorii*, which is larger in all ways and has especially a much larger nose-leaf, the horseshoe of which nearly covers the muzzle.

With *R. clivosus* it has no doubt a nearer affinity, but seems to differ sufficiently by its different colour and the constant absence of the minute premolars to be recognized as a distinct species. I have also ventured to distinguish the Kordofan bat described by Dobson under the name of *R. clivosus*, as it has the small premolars quite separating the canines from the large premolars.

Whether the queer greenish colour of the two specimens of *R. Dobsoni* ("sulphur-brown above, beneath canary-colour," Dobson) is natural or the result of defective preservation can only be determined when further examples are obtained.

Rhinolophus augur K. Andersen, 1904

p. 380

Short diagnosis. - Apparently allied to *Rh. ferrum-equinum*, but readily distinguished by its much smaller ears and shorter tail. Forearm 54-57 mm.

Nose-leaves. - Horseshoe not covering muzzle laterally. Sella pandurate, as in *Rh. ferrum-equinum*, but decidedly narrower. Posterior connecting-process triangular, obtusely pointed, its upper margin straight, shorter than the vertical height of sella. Lateral margins of lancet deeply emarginate.

Ears. - Not reaching tip of the muzzle, when laid forward. Tip attenuated and acutely pointed. Outer margin strongly concave below the tip of the ear. Greatest width of ear equal to its length from notch on outer margin to tip.

Wings. - General characters as in *Rh. ferrum-equinum*, but forearm on the average shorter, its maximum length (57.2 mm. in a series of 15 specimens) being almost exactly like mean measurements in *Rh. ferrum-equinum* (57 mm., 31 specimens from Europe). 5th metacurpal slightly longer than 4th. 2nd joint of 3rd finger almost twice the length of 2nd joint of 5th finger. In the folded wing, tip of 1st joint of 3rd and 5th fingers opposite posterior point of elbow. Plagiopatagium inserted at the tarsal joint.

p. 381

Tail. - Much shorter than in *Rh. ferrum-equinum*, its length (31.3 mm, on average) being almost exactly the same as the 2nd joint of 3rd finger (30.7 mm.) ; in *Rh. ferrum-equinum* much longer (36.7 against 29.5 mm.). Hinder border of interfemoral, between tip of calcars, slightly triangular.

Colour (16 skins). - General colour above "drab," with a tinge of fawn. Individual hairs "ecru-drab" at base, drab at tip. On the middle of the back an ill-defined (in some individuals scarcely perceptible) horseshoe-shaped patch, approaching "wood-brown"; branches of this patch on the shoulder-region, convexity backwards. Length of hairs on middle of back about 7.5 mm. Underside bright ecru-drab, more or less tinged with vinaceous buff on the breast and sides of the body. Ears (dried) transparent brown, membranes dark brown. Adult individuals vary but very slightly in colour, some being more greyish, others more fawn in hue. Young specimens (5 skins) are much duller coloured; fur above greyish brown; horseshoe-patch on back indicated, but rather indistinct; below bright grey, with a slight rosy tinge.

Dentition. - Essentially as in *Rh. ferrum-eguinum*. Upper *c* and p^4 closely approximated, their cingula actually touching each other or separated only by an almost hair-fine interspace. Upper p^2 minute, blunt, placed in the outer angle formed by *c* and p^4, hardly rising to the level of the cingulum of the canine; this small tooth is present in all of the fourteen skulls examined, but will no doubt be found wanting in very old individuals with much-worn teeth (cf. *Rh. augur zambesiensis*). Upper p^4 as high as two thirds of the canine. Lower p_2 one third of p_4. Lower p_3, when present, extremely small, placed on the external side of the tooth-row, blunt, as high as the cingulum of p_4; in nine out of fourteen skulls examined this tooth is wanting, and every trace of the alveole has disappeared; in a tenth specimen (adult) the tooth is wanting on both sides, but the left alveolus is still to be traced: in the remaining four skulls p_3 is present on both sides; three of these latter are skulls of young bats, the fourth of an apparently adult individual, though still with almost unworn teeth. As proved by these facts, the presence or absence of p_3 in this species varies individually, without any bearing on differences in geographical distribution: of six specimens from the same cave, taken by the same collector and in the same season of the year, two have lost both the tooth and every trace of the alveolus, while in four specimens it is present on both sides; evidently it is most often to be found

p. 382

in *young* individuals, more rarely in full-grown, perhaps never in very old. Lower p_4 a little higher than antero-exterior cusp of m_1.

Measurements. - Below under *Rh. augur zambesiensis*.

Type. - M ad. (skin). Kuruman, Bechuanaland, 4000 feet, collected by Mr. R. B. Woosnam, April 19th, 1904. B.M. no. 4.10.1.1. Original no. 26. "Caught in an old mine; of fifteen taken there was only one female."

Distribution. - Specimens have been examined from the following localities: - Zuurbron, Wakkerstrom, S. Transvaal (1 specimen in alcohol); De Kaap, S. Transvaal (2, alcohol); near Krügersdorp, S. Transvaal, 4900 feet (6 skins); "Transvaal" (1, alcohol); Vredefort Road, N. Orange River Colony (1, alcohol; 2 skins); Kuruman, Bechuanaland, 4000 feet (8 skins). It will probably be found generally distributed over the whole of that part of South Africa which is irrigated by the Orange River and its confluents ("Orange River Area," in the zoogeographical sense of that term).

Remarks. - The present species has been confused with *Rh. ferrum-equinum* and *Rh. capensis* to such extent that it will be difficult to disentangle its synonymy without examination of the specimens recorded in literature. *Rh. capensis* differs mainly in the following points: - It is much smaller: forearm 49.5 mm. (average of eleven specimens), against 56 in *Rh. augur*; the ears much longer (20.5 mm. from base of inner border) and broader (16.7 mm.); tip of the ear obtusely pointed; sella only very slightly narrowed in the middle, its lateral margins subparallel in their upper half; posterior connecting-process shorter, its upper margin concave; all metacarpals and finger-joints much shorter, therefore the wing very much narrower in antero-posterior direction; even a badly prepared skin of *Rh. capensis*, in which the shape of the ears and nose-leaves is unrecognizable and the length of the tail not to be relied upon, can always be at once distinguished from *Rh. augur* by taking the measurement of the 2nd joint of the 3rd finger (22-26 mm., against 28.7-32 in *Rh. augur*); the tail remarkably short (20.8 mm.), only about the same length as the tibia, far shorter than the 2nd joint of 3rd finger, &c. The skull of *Rh. capensis* is slightly smaller; the nasals more swollen; the auditory bullae larger; the basioccipital therefore still narrower; the tympanic ring larger. As far as the available material goes, *Rh. capensis* seems to be restricted to the *western part of the Cape Colony*, as far north as the mountains on which the coast-rivers spring, eastwards to Winter-Bergen.

p. 383

Rh. augur bears, in fact, much more resemblance to *Rh. ferrum-equinum*. The differences between the two species have already been pointed out above. Whether, however, this resemblance is indicative of true relationship, or rather of convergence owing to similar habits and similar effects of natural surroundings, is open to question. It is in this connexion worth while mentioning that no doubt all the previous records of the occurrence of *Rh. ferrum-equinum* in Africa south of the Mediterranean subregion rest on confusion with other species; that, consequently, the two species, at the present time at least, are separated from each other by almost the whole of the tropical region of Africa.

Rhinolophus augur zambesiensis K. Andersen, 1904

p. 383

Short diagnosis. - Very dark-coloured. In size somewhat intermediate between *Rh. augur* and *Rh. a. zuluensis*. Forearm 53.3-54.8 mm.

p. 384

Colour (1 skin). - In the two forms just described the more or less distinct dark zone on the back takes the form of a horseshoe-patch. In the present race this patch extends over the whole of the back, giving the upperside of the animal an almost uniform brown colour, approaching "mummy-brown." Underside light "drab," somewhat darker in shade than in *Rh. a. zuluensis*. Ears and membranes (dried) black; in spirit-specimens the ears are "raw umber," the wings blackish brown.

Dentition. - The only skull examined is of a very old individual with much-worn teeth; both upper p^2 and lower p_3 are wanting, and no trace of their alveoli is to be seen. In younger individuals the dentition will no doubt be found to agree with that of the other races.

Type. - M ad. (skin). Fort Hill, N. Nyasa, about 9° 40' S., 33° 20' E., collected by Mr. A. Whyte, July 1896, presented by Sir Harry Johnston. B.M. no. 97.10.1.18. Original no. 136.

Distribution. - Specimens examined: - Mazoe, Mashonaland, 17° 30' S., 23° 30' E. (3, in alcohol); Zomba, Nyasa, 15° 30' S., 35° 30' E. (1, alcohol); and the type. - From these localities it may be supposed that the present form is generally distributed over the whole of the area which is irrigated by the Zambesi and its confluents.

Remarks. - As will be seen from the above, the three forms of *Rh. augur* just described are characteristic of three distinct zoogeographical districts of S. Africa: - *Rh. augur* of the Orange River District (in wider sense); *Rh. a. zuluensis* and *zambesiensis* of the areas from which I have derived their names*.

Rhinolophus augur zuluensis K. Andersen, 1904

p. 383

Short diagnosis. - A small and darker-coloured race of *Rh. augur*. Forearm 51.2-54.5 mm.

Colour (8 skins). - Fur above approaching "wood-brown." Horseshoe-patch on back nearest to "russet." Beneath light "drab," tinged with pinkish buff on the sides of the body.

Measurements. - See table under *Rh. augur zambesiensis*.

Type. - F ad. (skin). Jususic Valley, 20 miles N.W. of Eshowe, Zululand, 1000 feet, collected by Mr. C. H. B. Grant, Nov. 17th, 1903, presented by 0. D. Rudd, Esq. B.M. no. 4.5.1.8. Original no. 602. "Caught in old gold-driving."

Distribution. - Specimens examined: - King William's Town (1, in alcohol); Port Natal (1, alcohol); typical locality (8 skins). This race will probably be found generally distributed over the whole of the Natalese Province, southwards to Winter-Bergen, northwards to about the latitude of Delagoa Bay, westwards to the mountain-range in which the coast-rivers rise.

Remarks. - The obvious difference in size and colour, combined with the distinct geographical distribution, entitle this form to subspecific rank. It cannot be confounded with young individuals of the typical form: young *Rh. augur* are greyish brown above, bright grey with a slight rosy tinge beneath; *Rh. a. zuluensis*, owing to a stronger development of the darker-coloured tips of the hairs, next to wood-brown above, light drab beneath.

Rhinolophus axillaris Allen, 1917

p. 429

Plate LI, Fig. 2.

Type, No. 49175, M ad. (skin and skull), Aba, Uele district, Belgian Congo, Dec. 17, 1911; Herbert Lang and James P. Chapin. American Museum Congo Expedition. Orig. No: 1807.

Apparently a member of the *R. landeri* group. Has two phases, a dark brown and a rufous phase.

Dark phase. - Type, above dark hair-brown with a faint rufescent tone in strong light, the fur dull gray-brown basally, with long hair-brown tips (in some specimens forming a dark broad V-shaped area on the lower back); below much lighter, the fur pale brownish plumbeous basally, the tips darker, giving a pale brownish wash. At the base of each arm is an axillar patch of short, stiff, dark rust-colored hairs, about 4 by 6.5 mm. in area, in strong contrast with the surrounding fur, both in color and texture. Ears and feet pale brown, membranes darker.

Total length (collectors' measurements), 77 mm.; head and body, 52; tail, 23; foot, 11; ear, 18 1.

Rufous phase. - Above rich cinnamon-brown, the fur basally pale gray, with long dark cinnamon-brown tips; below pale buffy white, with a grayish tone.

The red phase is represented by a single specimen, in which the glandular axillary area is pale yellow. The dark phase is represented by 4 specimens, in one of which an axillar glandular area is not evident, and in a second is less strongly marked than in the other two. All were taken at the same locality and practically on the same date (three on Dec. 17, the other two respectively on Dec. 13 and 15).

Collectors' measurements (3 males, 2 females): Total length, 79 (75-84); head and body, 54 (52-58); tail, 26 (23-29); foot, 11 (10-12); ear, 19 (18-22).

The skull of the type is badly crushed. The measurable skulls give the following: Total length, 3 skulls, 20 (all 20); zygomatic breadth, 2 skulls, 10.2 and 9.6; breadth at base of canines, 4 skulls, 5.4; breadth at m^3, 6.9 (6.7-7.2).

p. 430

P^2 is greatly reduced but stands in the toothrow, closely crowded between the canine and p^3.

A peculiar and strongly marked feature of this species is the axillar gland, rendered conspicuous by a short tuft of stiff rust-colored hairs.

Rhinolophus brockmani Thomas, 1910

p. 192

Rhinolophus brockmani, sp. n.

A very pale-coloured species, allied to *R. lobatus* and *dobsoni*.

General characters as in *R. dobsoni*, the nose-leaf apparently quite as in that species. Colour remarkably pale, the hairs of the upper surface white with a brown tip about a millimetre in length, and of the under surface wholly white from base to tip.

Skull as compared with that of *R. dobsoni* rather longer and narrower, with a more elongate brain-case. Opening of posterior nares rather broader.

Cheek-teeth markedly smaller, the molars (particularly m^3) narrower, and the inner lobe of m^1 and m^2 smaller, so as to have a larger space between each tooth. Small upper premolar large, in the centre of the unusually extended space between the canine and p^4, a space double as broad as in *R. dobsoni*. P^4 with its antero-external corner projecting forward in front of the anterior

edge of the narrow inner lobe, the latter being in *R. dobsoni* practically the most anterior part of the tooth, no angular external projection being present; inner lobe of the same tooth much narrower than in *R. dobsoni*.

Dimensions of the type (the starred measurements taken in the flesh): -

Forearm 44 mm.

Head and body* 45; tail* 26; ear* 18. Third finger, metacarpus 29; 1st phalanx 14, 2nd phalanx 25; lower leg and foot (c. u.) 27.

p. 193

Skull: greatest length 18; front of canine to back of m^3 6.6.

Hab. Upper Sheikh, Somaliland. Alt. 4500'.

Type. Adult female. B.M. no. 9.12.17.4. Original number 237. Collected 13th November, 1909, and presented by Dr. R. E. Drake-Brockman. Two specimens.

The most striking character of this bat is its peculiar whitish colour, other members of the group being generally some shade of grey. Unfortunately the colour of the original specimens of its nearest ally *R. dobsoni*, from Kordofan, cannot be determined, but the difference in the skulls and teeth is quite sufficient to separate the two.

A number of *R. acrotis*, Heugl., were obtained at the same time and place.

Beschreibung

Die Farbe der zarten wolligten Haare der hügeligten Hufeisennase ist ein lichtes graubraun, das auf dem Rücken dunkler, auf dem Unterleibe heller scheint. Die äusseren Riechwerkzeuge sind von sehr zusammengesetzter Art. Die hufeisenförmige wulstige Membran hat in ihrem Mittelpunkt eine Vertiefung, in welcher der Nasenknorpel sich zu einem

p. 48

kleinen Trichter gestaltet; hinter demselben erhebt sich ein quer aufgerechgestellter Knorpel, der ziemlich stark an seiner Spitze, flach zugerundet in seiner Mitte, länglich ausgehöhlt und über den Trichter etwas herübergebogen ist. Von diesem läuft eine gerade nacht hinten gerichtete dünne und gezackte Membran zu der hintersten quer stehenden lanzettförmigen, welche sie mit der vorderen verbindet. Die hinterste Membran ist dünn, schliesst sich nach vorne an die hufeisenförmige Membran an, nach hinten geht sie in die allgemeine Haut über, und is desswegen an ihrer hinteren Fläche mehr behaart, als an der vorderen. Rings

um diese Riechwerkzeuge stehen einige Borstenhaare. Von vorne gesehen nehmen sich diese sämmtlichen Membranen aus wie übereinander aufgeschichtete Hügel, von denen die hinterste die Spitze bildet. Die Ohren sind am äusseren Rand etwas ausgeschnitten, und wie die Flügel und Schwanzhäute, braun.

Vaterland. Die hügelichte Hufeisennase wurde bie Mohila gefunden.

Aufenthalt. Mauern und Felsen.

Rhinolophus clivosus hillorum Koopman, 1989

p. 4

HOLOTYPE: AMNH 257044, a female obtained by Andrew S. Voros (5924) in early October at the John Hegbe Farm near Zozoma, ca. 2 mi SW Voinjama in Lofa County, extreme northwestern Liberia at ca. 500 m elevation. This would place it at ca. 8°25'N, 9°35'W. The holotype consists of an entire

p. 5

specimen preserved in alcohol with the skull extracted and cleaned.

DIAGNOSIS: Larger than other subspecies of *R. clivosus*. Much larger than any of the northern subspecies (*bocharicus*, which many regard as a separate species, *clivosus, brachygnathus, schwarzi, acrotis*) and somewhat larger than the eastern and southern *keniensis, zuluensis*, and *augur*. Selected measurements are as follows (range of *hillorum* followed by combined range of *keniensis, zuluensis*, and *augur*): forearm length (52 - 57, 50 - 56); condylocanine length (20.5 - 21.7, 18.7 - 20.5); zygomatic breadth (12.7 - 13.3, 11.1 - 12.2); mastoid width (10.8 - 11.5, 9.7 - 11.1); width across last upper molars (9.0 - 9.4, 7.6 - 8.6); maxillary toothrow length (8.9 - 9.4, 7.6 - 8.8). The size difference is particularly evident in the breadth of the palatal area and the volume available for the temporalis musculature as shown by the width across the molars and the zygomatic breadth. Going along with this are the larger teeth of *hillorum* and the absence in all three known specimens of the anterior upper premolar. This tooth is almost always present, albeit greatly reduced in *keniensis zuluensis*, and *augur* (only 1 out of 40 skulls examined for this character). It seems evident that even if the very similar *keniensis, zuluensis*, and *augur* were combined into one subspecies, *hillorum* would still remain distinct.

ETYMOLOGY: I name this subspecies after the two (often confused) eminent mammalogists named John E. Hill: J. Eric (1907 - 1947), and J. Edwards (1928 -). I have known both of them and feel that each, in different ways, has been important in my understanding of African bats, to which both made outstanding contributions.

LOCALITY RECORDS: LIBERIA: Voinjama: AMNH 257044; Tokadeh, Nimba, 600 m: BM 79.459. CAMEROON: Lake Manenguba, Manenguba Mountains, 1800 m: ZFMK 69.485. All three specimens are preserved in alcohol with the skulls extracted and cleaned.

Rhinolophus Commersonii E. Geoffroy Saint-Hilaire, 1813

p. 263

J'ai trouvé cette espèce parmi les dessins, et manuscrits de Commerson, avec la désignation et les caractères suivans:

Chauve-souris du fort Dauphin, île de Madagascar. *Vespertilio, obscure caudatus, auribus simplicibus, amplis, acuminatis, erecties, patulis; naso duabus valvis transversis, late secedentibus hiulco.*

On ne pourroit confondre cette chauve-souris qu'avec le

p. 264

diadème: mais outre qu'elle est un peu plus petite que celui-ci, sa feuille est d'un tiers moins large, de même que sa queue est aussi du tiers plus courte. De plus, la membrane interfémorale qui se termine dans le diadème par un bord à angle saillant, est à angle rentrant dans cette espèce.

Il n'y auroit que l'éloignement des lieux, *Madagascar* et *Timor*, où se trouvent ces deux rhinolophes, pour autoriser la conjecture qu'ils forment deux espèces très-différentes.

J'ai annoncé plus haut que les rhinolophes se ressemblent par les couleurs et la disposition des poils: dans tous, en effet, la toison est épaisse, bien fournie et moelleuse: le poil est fauve en dessus, et blanc jaunâtre en dessous.

J'ai trouvé le trident dans les plus profondes excavations des montagnes, en Egypte et notamment dans les parties les plus reculées des tombeaux des rois et du temple de Denderah.

Ainsi dans, les pays chauds comme dans les pays froids, les rhinolophes recherchent également les lieux écartés; l'état de la température ne leur en fait donc pas une nécessité: en aurois-je trouvé la vraie raison en l'attribuant au défaut d'oreille interne?

Les rhinolophes de France ne rentrent pas tous les soirs en été dans les cavernes qu'ils habitent l'hiver. Songeroient-ils à s'épargner des allées et venues, et les fatigues du trajet dans leurs demeures souterraines? On ignore où ils se retirent pour passer le jour.

Rhinolophus Darlingi K. Andersen, 1905

p. 70

Diagnosis. - Differs from all other South-African *Rhinolophi* by the combination of these two characters: cingula of the upper canine and p^4 in immediate contact with each other; forearm 46.7-47.7 mm.

Nose-leaves. - Extreme length 14-14.5 mm. Horseshoe covering almost the whole of the muzzle; no tooth-like projection on either side of the median notch; greatest width 8.1-8.5 mm. Sella naked, slightly constricted below the middle, broadly rounded off at summit; vertical height 4 mm.; breadth at base, at constriction, and at summit

p. 71

2.1, 1.5, and 1.7 mm. Posterior connecting-process very short, rounded, in side view very nearly semicircular, scarcely projecting beyond the summit of the sella (this kept in vertical position). Lancet very long, scarcely constricted, its lateral margins evenly converging towards the tip; distance from the posterior transverse bridge to the tip of the lancet 4.2 mm.

Ears. - Reaching tip of muzzle, when laid forward: not attenuated below the tip; this latter blunt. Width of ear about equal to its length from notch on outer margin to tip.

Wings. - 5th metacarpal equal to (or only a mere trifle longer than) 4th. 1st phalanx of 4th finger about $^2/_3$ the length of 2nd phalanx. Plagiopatagium inserted on tarsus.

Tail. - Much longer than the tibia, about the same length as the 3rd metacarpal. Hinder margin of interfemoral triangular.

Colour. - General colour of adult individuals (2 skins) rather dark brownish drab above, "drab-grey" beneath. Base of hairs on back of the same colour as the underside. Length of fur on middle of back about 10 mm. - Immature specimens (2 skins) have a more greyish tinge on the back, but the difference from adult examples is very slight (but may perhaps be more pronounced in still younger individuals).

Skull. - Hinder border of palatal bridge opposite (or very slightly behind) the middle of m^3.

Dentition. - Cingula of the upper canine and p^4 so closely approximated as to completely touch each other. Upper p^2 quite on the external side of the tooth-row; in one skull (F ad.) with unworn teeth it is as high as the cingula of the adjacent teeth; in two other skulls with slightly worn teeth it is hair-fine, hardly perceptible without a lens (therefore presumably lost in still older individuals). Lower p_3, when present, external to the tooth-row, not reaching the upper margin of the cingula of p_2 and p_4; in a little more advanced age p_3 is lost.

Type. - Ad. (skin). Mazoe, Mashonaland, 4000 ft., June 13th, 1895; collected by J. ff. Darling, Esq. B. M. no. 95.8.27.1. Original no. 35. "Taken in mining adit." Five paratypes (three skins, two in alcohol) are in the British Museum.

Distribution. - A young *Rhinolophus* from Angola (B. M. no. 64.8.16.3*) is indistinguishable from the species here

* *Rh. æthiops*, specimen "e" in Dobson's Cat. Chir. Brit. Mus. (1878) p. 122.

p. 72

described, in external characters as well as in skull and dentition. Its geographical distribution therefore, probably, is from Angola across South Africa, eastwards at least to Mazoe.

Remarks. - The short diagnosis given above will, in every case, prevent confusion of the present species with any other hitherto known South-African *Rhinolophus*. *Rh, Landeri, lobatus, simulator*, and *Denti* differ, altogether, in having the upper p^2 placed in the tooth-row, separating the canine and p^4 by a distinctly perceptible interspace. *Rh. Landeri* is much smaller (forearm about 43 mm.), with much shorter ears, much narrower sella, higher connecting-process, much shorter tail (18-21 mm.), and with the 1st phalanx of the 4th finger peculiarly shortened (less than, or equal to, half the length of the 2nd phalanx). *Rh. lobatus*, which is of about the same size as *Rh. Darlingi*, may at once be separated by having the posterior connecting-process long, pointed, projecting like a small "horn" far beyond the summit of the sella. *Rh. simulator* is smaller (forearm 43.5-45 mm.); the front face of the sella is "rough" owing to the presence of very short hairs (most easily to be observed under a lens). *Rh. Denti* is much smaller (forearm 41-43 mm.); front face of sella as in *Rh. simulator*.

The species is named in honour of Mr. J. ffolliott Darling, to whom the British Museum is indebted for so many valuable accessions to its collection of South-African mammals.

[table removed - eds.]

Rhinolophus darlingi barbertonensis Roberts, 1924

p. 5

Rhinolophus darlingi barbertonensis subsp. nov.

Similar in structural characters to *R. darlingi* Andersen (Ann. and Mag. N.H. (7), xv, p. 20), which occurs in the highveld from Nyasaland to Transvaal, but differing therefrom in its consistently smaller size, especially in the skull. The following dimensions will serve to show this difference, those in brackets being of the typical form (from a specimen taken at Pretoria) and the others from the type taken in the district of Barberton; altogether ten specimens of the smaller form, from Barberton, Louws Creek, Gravellot Mine (near Leydsdorp) and Mokeetsi, all below the Drakensberg Mountains, and twelve of the larger, from Pretoria, have been compared, and the figures given represent the normal, hardly any overlapping being perceptible in the external dimensions, and less in the cranial. Length of head and body 45 (55), tail 33 (32), hind foot with claws 8 (8), ears 20 (21), all taken in the flesh. Length of forearm 45 (49); third finger, metacarpal 34 (36), first joint 4.5 (16.8), second joint 24.5 (26); fourth finger, metacarpal 33.2 (34.5), first joint 8.4 (9.8), second joint 15.2 (18); fifth finger, metacarpal 34 (36), first joint 11.2

p. 60

(11.8), second joint 4 (16.5) ; tibia and foot with claws 26 (28), Skull: length from front of canines to occiput 18,8 (19.5); width of brain case 8,8 (9.2), width across canines 5 (5.5) ; length of upper tooth row, from front of canines to back of hindmost molar 6.8 (7.2).
Type: Adult female, T.M. No. 2476, taken at Louws Creek, Barberton, on March 4th, 1920.

Rhinolophus darlingi damarensis Roberts, 1946

p. 303

A paler form than those of the eastern parts of South Africa, paler drab grey above and whiter below, the wings also averaging longer, though the skull is only slightly larger on the average.

Measurements of type from Oserikari, and minima and maxima of seven with skulls from Kochina, Great Karas Mountains, of a skin without a skull from Neudamm, and for comparison, in brackets, six with skulls from Transvaal of *R. d. darlingi* K. Andersen: Head and body 60, 53 - 56 (56 - 60); tail 30, 28 - 31 (27 - 33); hind foot (c.u.) 11 - 13 (8 - 10); ear 20, 18 - 21 (19 - 21); wing span 344, 300 - 315 (2), (290 - 315 in six). Forearm 50, 48 - 50.5 (Neudamm 51), (47.5 - 49); 3rd finger metacarpal 33.5, 32.5 - 35 (Neudamm 36), (31.2 - 32); 1st phalanx 18.5, 14.5 - 17.5 (15.8 - 16.8); 2nd phalanx 26, 25 - 29 (25 - 27.5); 4th finger metacarpal 37.5, 34 - 38.5 (34 - 36); 5th finger metacarpal 37.5, 36 - 39.5 (35 - 37). Skull, greatest length from canines 20.5, 19.5 - 20.5 (19 - 20); dorsal median length 17.7, 16.5-17.7 (16.5 - 17.2); zygomatic width 10.7, 9.9 - 10.5 (9.8 - 10.5); width of brain

p. 304

case at mastoid 8.4, 8 - 9 (9.1 - 9.2); width across m^3 7.9, 7.4 - 7.5 (7.4 - 7.7); width across canines 5.7, 5.1 - 5.7 (5.2 - 5.5); c-m^3 series 7.7, 7.1 - 7.6 (7 - 7.4).

Type: T.M. No. 9474, adult F, Oserikari, Okahandja district, South-west Africa. Also seven with skulls from Kochina, Great Karas Mountains, Great Namaqualand, and one without skull from Neudamm, near Windhoek, Southwest Africa.

Rhinolophus Deckenii Peters, 1868

p. 705

Rh. fumigatus Ptrs., non Rüppell, Monatsber. 1866. p. 885).

Aufsenrand des Ohres mit einer stumpfwinkeligen Einbucht; die hintere Spitze des Sattels abgerundet, viel kürzer als seine vordere Oberfläche, welche nur sehr wenig in der Mitte verschmälert erscheint und an der Spitze abgerundet ist; Hufeisen jederseits am mittleren Einschnitt mit einem spitzen Zacken, am Rande flach wellenförmig. Der erste obere kleine Prämolarzahn niedrig und stumpf, nach aufsen gedrängt. Flughaut geht etwas über den Hacken herab. Die Behaarung ist lang und fein, oben dunkler, unten heller röthlichbraun.

Mafse eines ausgewachsenen Weibchens.

Das einzige Exemplar stammt aus der Sammlung des Baron C. von der Decken, von der Zanzibarküste. Erst neuerdings erhielt ich ein Exemplar von Rüppell's *Rhinolophus fumigatus* in Weingeist zur Untersuchung, woraus ich ersah, dafs es nicht, wie ich glaubte, mit dieser Art zu vereinigen sei.

Rhinolophus Denti Thomas, 1904

p. 386

Allied to the European *R. euryale*, but smaller.

Size very small, among the smallest species of the genus. Leading characters (in the order used in Dobson's synopsis): posterior upper premolar separated from the canine, though not very widely, the small anterior premolar in the tooth-row, towards its outer side; horizontal portion of the sella not widely expanded, though (allowing for shrinkage in the dried skin) it would appear to be more so than is usual in the allied species; upper margin of the posterior connecting process forming a marked projection, rounded terminally, rising considerably above the summit of the front of the sella; sides of the vertical process of the sella parallel, summit broadly rounded off; antitragal notch shallow.

Horseshoe large, covering most of the muzzle, circular, its anterior edge sharply notched in the centre; lancet short, conical, its sides evenly convergent upwards, thickly covered with fine fur, similar in colour and quality to that of the head. Ears of medium size, their inner margin evenly convex, tip sharply pointed, upper half of outer margin slightly concave; antitragal notch not deep and the lobe itself comparatively little convex. Hind limbs slender and delicate. Wings from the lower third of the tibiæ. Interfemoral membrane finely fringed posteriorly.

Fur close and fine, about 7 mm. long on the back. General colour above pale grey, the individual hairs dull whitish, with dark brown tips. Under surface nearly white. Membranes brown, the plagiopatagium and interfemoral inconspicuously edged with white.

Skull with the nasal convexity more developed than in *R. euryale*, less than is figured in Peters's *R. lobatus*. Palate ending opposite the posterior edge of the internal lobe of m^2.

Dimensions of the type (those in inverted commas taken by the collector in the flesh): -

Forearm 42 mm.

"Head and body 41"; "tail 21"; "ear 20"; nose-leaf (dry) 9.2 X 6.3; lower leg and foot (c.u.) 25.5.

p. 387

Skull: greatest length 17; basal length to front of canines 13.2; breadth of brain-case 7.6; palatal bridge 1.9; front of upper canine to back of m^3 5.9; front of lower canine to back of m_3 6.6.

Hab. Kuruman, Bechuanaland. Alt. 1300 m.

Type. Male. B.M. no. 4.4.8.2. Original number 7. Collected 24th January, 1904, by R. E. Dent. Two specimens.

"Caught in a house."

This species, the smallest of South-African *Rhinolophi*, seems to represent *R. euryale*, but may be readily distinguished from that, as from all others, by its proportions, its pale colour, the high attachment of its wing-membranes, and its unusually hairy lancet.

Rhinolophus denti knorri Eisentraut, 1960

p. 3

Material: 5 Exemplare, 1 M (Tgb. Nr. 90), 15.XI.1956, 1 M (Tgb. Nr. 165), 27.XI.1956, bei Nyembaro am Salung-Plateau, 12 km westlich Kolente. - 1 M, 2 FF (Tgb. Nr. 127-129), 19.XI.1956, bei Nerebili, 400 m Meereshöhe.

Die 5 vorliegenden Exemplare von *denti* sind der erste Nachweis der bisher nur in südlichen Gebieten Afrikas gefundenen Art für Westafrika. Während die Nominatform nach den bisherigen Funden nordwärts kaum weit über den 20. südlichen Breitengrad hinausreicht, liegen die Fundorte in Guinea etwa auf dem 10. nördlichen Breitengrad. In der Luftlinie gemessen sind die nächsten Fundorte in den beiden Verbreitungsgebieten über 4000 km voneinander getrennt. Bei dieser großen Entfernung könnte man recht erhebliche morphologische Unterschiede der beiden Formen erwarten. Dies ist jedoch keineswegs der Fall. Immerhin berechtigen die vorhandenen Abweichungen zu einer subspezifischen Abtrennung.

Die Rasse *knorri* ist etwas kleiner als die Nominatform. Besonders auffallend ist die geringe Länge der Ohren und Hinterfüße. Dagegen ist das Gebiß nicht nur relativ, sondern auch absolut kräftiger. Die Fellfärbung ist dunkler und zeigt einen stärkeren bräunlichen Ton gegenüber einem mehr blaßgrauen Ton bei der Nominatform.

Typus: M (Tgb. Nr. 165 A), 27.XI.1956, Höhle bei Nyembaro am Salung-Plateau, 12 km westlich Kolente, KNORR leg., Staatliches Museum für Naturkunde Stuttgart, Katalog-Nr. 6111. Kopf-Rumpf-Länge: 40 mm, Schwanz: 17 mm, Ohr: 17 mm, Hinterfuß: 6.5 mm, Unterarm: 37.5 mm, Tibia: 15.5 mm, gesamte Schädellänge: 17.0 mm, Jochbogen: 8.0 mm, maxillare Zahnreihe: 6.0 mm, Mandibellänge: 10.5 mm, mandibulare Zahnreihe: 6.0 mm.

Knorri ist in der Größe nur wenig von der typischen Form *denti* unterschieden. Sehr deutlich zeigt sich dies beim Vergleich der immer am korrektesten festzustellenden Schädelmaße (Tabelle 2). Die Durchschnittswerte für die gesamte Schädellänge und die Länge der Mandibeln sind bei *knorri* nur um ein geringes kleiner, und die Variationsbreiten greifen weit ineinander oder überdecken sich. Das gleiche gilt auch für andere Schädelmerkmale, und deren Durchschnittswerte ergeben meist nur geringe Differenzen.

p. 4 - 5

[table removed - eds.]

p. 6

[table removed - eds.]

Auffallend sind die durchweg etwas geringereren Körpermaße von *knorri*, wobei sich aber auch wieder in den meisten Fällen die Variationsbreiten überschneiden. Hervorzuheben sind die deutlich kleinere Ohrlänge und die geringere Länge der Hinterfüße. Sofern diese erheblichen Differenzen nicht auf verschiedener Meßmethode der verschiedenen Sammler beruhen, dürften die geringeren Maße für *knorri* typisch sein, zumal sich auch die Variationsbreiten nicht überschneiden.

Sehr charakteristisch für *knorri* erscheinen die Unterschiede in der Ausbildung des Gebisses. Zwar sind die Zahnproportionen selbst etwa die gleichen, ganz allgemein aber besitzt die Guinea-Form trotz ihrer geringeren Körper- und Schädeldimensionen ein kräftigeres Gebiß. Beim Vergleich (Abb. 2) fällt besonders die größere Breite der Molaren auf. Diese Unterschiede zeigt auch folgende Gegenüberstellung:

Durchschnittliche Breite der oberen Molaren (M^1; M^2; M^3)
knorri (5 Exemplare): 1.5; 1.52; 1.43
denti (2 Exemplare): 1.3; 1.4; 1.3

p. 7

Die Fellfärbung ist bei der neuen Form dunkler als bei der Nominatform. Die Tönung der Oberseite ist bei vier Exemplaren der vorliegenden kleinen Serie mittelgraubraun und als "Brownish Olive" zu bezeichnen. Bei F Nr. 127 ist sie etwas heller und geht mehr nach "Dresden Brown" über. Die Unterseite ist grauweißlich und bei dem letztgenannten Tier schwach cremefarben. Bei allen ist die Bauchmitte heller, die Seitenpartien etwas dunkler. In der Gesamtfärbung heben sich die 5 Stücke von *knorri* deutlich gegen die von mir durchgesehenen Exemplaren von *denti* ab. Letztere sind auf der Oberseite bedeutend heller (Buffy Brown) und mehr grau; nur einige zeigen einen etwas bräunlichen Ton. Ebenso ist bei allen die Unterseite heller, und zwar schmutzigweiß. Die Flughäute sind bei *denti* mehr bräunlich, bei *knorri* mehr grauschwärzlich.

Die vorliegenden Stücke wurden ebenso wie die der vorhergehenden Art, zum Teil mit diesen am gleichen Platz, in Höhlen gefangen, die bei Nyembaro und Nerebili im Hinterland von Guinea, etwa 150 km von Conakry entfernt, liegen.

Rhinolophus Dobsoni Thomas, 1904

p. 156 - footnote

Rhinolophus clivosus, Dobs. Cat. p. 120 (nec Rüppell).

Type. Specimen *b*. F. B.M. no. 47.5.7.49. (Forearm 44 mm.)

Hab. Kordofan.

As Peters has shown, the true *R. clivosus* of Rüppell, from Mohila, Arabia, is one of the group with the large upper premolar pressed close against the canine, the small premolar being in the outer angle. In Dobson's bat, on the other hand, although he puts it in the same group, the anterior premolar separates the second premolar from the canine. This difference cannot be due, as he supposed, to immaturity, one of the specimens at least being fully adult.

Rhinolophus empusa K. Andersen, 1904

p. 378

Short diagnosis. - Anterior upper and middle lower premolars placed in the tooth-row. Sella wedge-shaped (deltoid). Horseshoe as broad as muzzle. A conspicuous dark patch under each eye. Forearm 48 mm.

Nose-leaves. - Horseshoe covering the muzzle laterally; a small tooth-like projection on each side of median notch; underlying leaf easily visible all round. Sella wedge-shaped; breadth at base about three fourths of vertical height; lateral margins plainly converging (with a scarcely perceptible constriction in the middle) towards the summit, which is subacutely pointed. Posterior connecting - process long, pointed, slightly curved forwards, as an erect horn, about five sixths the vertical height of the sella, thus projecting far beyond the summit of the sella. Lateral margins of lancet concave in the middle, tip behind constriction about 2.3 mm.

Ears. - Rather short, scarcely reaching tip of muzzle, when pressed forwards along the sides of the head. Tip obtusely pointed. Outer margin concave below the tip. Notch on outer margin shallow, almost rectangular. Extreme breadth of ear somewhat greater than the distance from the notch to the tip.

Wings. - 5th metacarpal longer than 4th. 1st joint of 4th finger equal to three fifths the length of 1st joint of 3rd finger. On the folded wing the tip of the 1st joint of the 5th finger reaches as far back as the posterior point of the elbow; tip of 1st joint of the 3rd finger falling only a trifle short of the same point. Plagiopatagium inserted at base of metatarsus.

Tail. - Much longer than tibia, about the same length as the combined 1st and 2nd joints of the 4th finger. Tip of tail projecting 2 mm. beyond the membrane (a character

p. 379

which, however, no doubt will prove to be subject to a certain amount of individual variation). Hinder border of interfemoral, between tips of calcars, almost square.

Colour (of spirit-specimen). - Light brown above, greyish beneath. Sides of face yellowish white, with a strongly marked dark brown patch under each eye. Membranes dark brown; free margin of plagiopatagium very narrowly bordered with whitish. Forearm, metacarpals, and fingerjoints yellowish.

Skull. - Essential characters as in *Rh. Blasii*, but parietal region of skull still more globular; frontal region considerably less constricted. Extreme width of brain-case slightly greater than zygomatic width. Median anterior point of palatal bridge opposite front of m^1; median posterior point drawn out into a tooth-like projection. Upper margin of mandible from condyle to base of coronoid process almost straight. Coronoid process very small, projecting only a trifle beyond the highest cusp of m_1.

Dentition. - Small anterior upper premolar (p^2) placed in the tooth-row. Upper canine and posterior premolar (p^4) widely separated. Cusp of p^4 three fourths the height of the canine. Middle lower premolar (p_3) extremely small, but *placed entirely in the tooth-row*, separating p_2 and p_4 from each other; p_2 one third the height of the canine. Cusp of lower p_4 not quite as high as the antero-exterior cusp of m_1.

Type. - F ad. Zomba, Nyasa, collected by Mr. A, Whyte, Jan. 1893, presented by Sir Harry Johnston. B.M. no. 93.7.9.33.

Distribution. - Only one specimen, the type, examined.

Remarks. - This fine species stands quite alone among the African *Rhinolophi*, being the only hitherto known species with a wedge-formed sella. Its nearest ally is the South European *Rh. Blasii*. In dentition *Rh. empusa* occupies a slightly more primitive position than *Rh. Blasii*: in the former the lower p_3 is still entirely in the tooth-row, in the latter it is just on the point of being driven out on the exterior side of the tooth-row.

Measurements of the type.

Nose-leaves: mm.
Front of horseshoe to posterior point of lancet: 13.8
Extreme width of horseshoe: 9
Vertical height of sella: 3.1
Width of sella at base: 2.3
Ears:
Base of lower margin to tip: 15.2
Notch on outer margin to tip: 11.8
Extreme width: 13.2

p. 380

Wings: mm.
Forearm: 48
3rd finger, metacarpal: 30.8
" 1st joint: 15.7
" 2nd joint: 24
4th finger, metacarpal: 33.7
" 1st joint: 9

" 2nd joint: 15
5th finger, metacarpal: 35
" 1st joint: 11
" 2nd joint: 12
Tail, from anus: 25.3
Tibia: 20.2
Hind foot (c. u.): 9.8
Skull:
Extreme length: 19.8
Basal length: 15.2
Extreme width of brain-case: 9.3
Zygomatic width: 9
Maxillar width, across outer margin of m^3: 6.1
Orbital constriction: 2.8
Palatal bridge: 2.6
Med. post, point of palate to front of premaxilla: 6.2
" " " for. magnum: 9
Mandible; condyle to front of incisors: 13.1
Teeth:
Front of upper canine to back of m^3: 6.5
Front of lower canine to back of m_3: 6.8

Rhinolophus euryale tuneti Deleuil and Labbé, 1955

p. 50

Nous avons pris un certain nombre de Rhinolophes euryales (*Rhinolophus euryale* BLASIUS 1853) dans la grotte d'El Haouaria (Cap Bon), et un unique exemplaire dans une grotte très profonde située entre Testour et El Aroussa. En mai, puis en septembre ces Rhinolophes étaient fréquens; en novembre, ils devinrent rares; le 12 décembre, nous n'en trouvâmes qu'un seul, comme d'ailleurs à Tsstour le le 25 décembre. Migre-t-il en hiver?

p. 51

TROUESSART ne fait que supposer *Rhinolophus euryale* BLASIUS, en Tunisie. Au Maroc, on a trouvé la sous-espèce *Rhinolophus euryale barbarus* (K. ANDERSEN et MATSCHIC 1904) à Rabat (CABRERA 1932).

Le tableau 3 (p. 52) donne ses mensurations en millimètres.

DIAGNOSE. - Les côtés de la selle, vue en avant, sont parallèles. Le connectif, rétréci après le milieu et à bords très concaves, présente, vu de profil (cf pl. XXI) une pointe inférieure aiguë et très en avant, et une pointe supérieure obtuse qui tend à la surplomber sans toutefois la dépasser.

La lancette reste conique, vue de face, comme dans le Grand Rhinolophe et le Petit Rhinolophe.

Le patagium, extérieurement, s'insère au talon, tandis qu'intérieurement l'uropatagium ne se déploie qu'à 3 ou 4 mm du talon. La membrane interfémorale reste plus ou moins triangulaire. Les membranes alaires sont de couleur sombre

p. 52

bistre, comme l'oreille; celle-ci, de même couleur, présente une pointe aiguë tournée dehors et non échancrée et un antitragus arrondi dont la largeur est le double de la hauteur. La face dorsale est beige cendré sombre, tandis que la face ventrale est d'un blanc légèrement beige. La feuille nasale ne couvre pas tout le museau.

DISCUSSION. - *Rhinolophus euryale* nov. subsp. de Tunisie ne peut se comparer à *Rhinolophus hipposideros vespa Laurent* 1937, car il est beaucoup plus grand, et son connectif, de profil

p. 53

ne ressemble pas du tout au connectif obtus et très postérieur du *Rhinolophus hipposideros*.

On peut penser au Rhinolophe de Méhély, espèce orientale, mais le nôtre est nettement plus petit. Sa lancette est conique et non à bords très concaves, devenant presque parallèles et la pointe postérieure du connectif n'est jamais aiguë, mais obtuse et tend à surplomber la pointe aiguë inférieure (cf. fig. 2). Enfin, les dimensions dû crâne de *Rhinolophus mehelyi carpetanus* CABRERA sont supérieures a celles du crâne du Rhinolophe tunisien. Il se rapprocherait de *Rhinolophus blasii* PETERS, de la région méditerranéenne orientale, mais en diffère par son connectif, sa fourrure moins foncée, ses oreilles bistres, etc.

En comparant notre sous-espèce tunisienne à *Rhinolophus euryale barbarus* (ANDERSEN et MATSCHIC), type Tanger, elle en diffère par ses dimensions plus petites (avant-bras, doigts), par son antitragus deux fois au moins plus large que haut, par son connectif moins aigü, plus obtus, plus postérieur; ses ailes et oreilles sont plus foncées, presque comme celles de *Rhinolophus Mehelyi*.

Enfin, en comparant les dimensions de notre Rhinolophe a celles des Rhinolophes euryales de l'Institut Scientifique Chérifien, d'origine non précisée, données par M. PANOUSE, on constate que les premières sont, dans l'ensemble, supérieures aux

secondes. Nous pensons donc que le *Rhinolophe euryale type El Haouaria* (Cap Ron) pourrait être une sous-espèce originale tunisienne que nous nommerons *Rhinolophus euryale tuneti* DELEUIL et LABBÉ.

[The name *tuneti* first appears on p. 53 - eds.]

Rhinolophus foxi Thomas, 1913

p. 314

Closely allied to *R. deckeni*, Peters, of East Africa, but greyer in colour and with smaller teeth.

Size rather less than in *R. deckeni*. General colour above "drab-grey," below more whitish grey. Nose-leaf and ears apparently as in *deckeni*.

Skull as in *R. deckeni*, but rather smaller; the nasal

p. 315

swelling just about as in *deckeni*, larger than in *ferrumequinum* and *augur*. Bony palate extending slightly further forward, to the level of the junction between p^4 and m^1. Teethall slightly smaller than in *deckeni*, the combined length of p^4-m^2, on outer edge, being 5.3 mm. as against 5.8 in that species. Minute premolar still further reduced, absent on one side in each of the specimens, and on the other quite minute, smaller than an incisor, and placed in the narrow outer anble between the closely jammed canine and large premolar.

Dimensions of the type (the italicised measurements taken in the flesh): -

Forearm 50 mm. (F 51).

Head and body 57; tail 29; ear 25; third finger, metacarpal 36.5, first phalanx 16; lower leg and foot (c. u.) 30.

Skull: greatest length to front of canines 22.2; naso-occipital length 18.7; palatal length 3; front of canine to back of m^3 8.5

Hab. Kabwir, Bauchi Plateau, Northern Nigeria. Alt, 2500 feet.

Type. Adult male. B.M. no. 13.2.5.1. Original number 45. Collected 14th November, 1912, and presented by Mr. J.C. Fox, of the Cambridge University Mission. Two specimens, male and female.

This is evidently a western representative of *R. deckeni*, but the difference in the general size of the teeth and the reduction of the small premolar prevent my treating it as a subspecies of that bat, from which it is most readily distinguished by its much paler colour.

The British Museum possesses a good example of *R. deckeni* from Tanganiko, near Mombasa, collected and presented by Mr. A. Blayney Percival.

Rhinolophus fumigatus Rüppell, 1842

p. 132

Rhinolophus fumigatus (Rüppell).

Diagn. Rhinolophus alis octava parte majoribus Rhinolopho clivoso, (cui posthemate auriculisque persimilis) vellere villosissimo, colore cinerascente fusco.

Der fleischige Nasenaufwuchs ist bei dieser Art ganz wie bei *Rhinolophus clivosus*, nämlich zwei über einander gestellte, nach oben einfach zugespitzte Hautläppchen, unten durch einen hufeisenförmigen Fleischauswuchs begrenzt; der seitliche Rand der Ohren ist bei beiden gleich ausgeschweift, und der untere Rand derselben halbelliptisch aufwärts umgebogen; auch sind die Verhältnisse der einzelnen Körpertheile so ziemlich die nämlichen, nur ist bei der Schoënser Art der Schwanz kürzer, dagegen der Vorderarm und die ganze Flugweite merklich grösser, wie aus nachstehender Zusammenstellung ersichtlich ist;

	Rhinoloph. clivosus. / Rhinoloph. fumigatus.
	Zoll. Lin. / Zoll. lin
Ganze Körperlänge von der Nasenspitze bis zum Schwanzende:	3 3 / 3 4
Schwanz besonders gemessen:	1 - / - 10
Verticalhöhe des Ohres:	- 8 / - 9
Länge des Vorderarms:	1 8 / 1 11
Grösste Flugweite:	9 9 / 11 -
Daumenglied (ohne Nagel):	- 2 / - 2
Tibia:	- 8 / - 10

p. 133

Der ganze Körper ist dick mit einem ziemlich langen, dunkelrauchgrau gefärbten Pelz bedeckt, wodurch sich der Gesammthabitus dieses Thiers gleichfalls von *Rhinolophus clivosus* unterscheidet.

Vaterland: das Reich Schoa, südlich von Abyssinien.

Rhinolophus fumigatus exsul K. Andersen, 1905

p. 74

Diagnosis. - Apparently similar in all essential characters to *Rh. fumigatus* (=*Antinorii*); but decidedly smaller. Forearm 49.5 mm.

External characters. - To judge from a dried skin, the shape of the nose-leaves and ears is the same as in *Rh. fumigatus*. The lateral margins of the sella bear the dense clothing of long hairs characteristic of the *fumigatus*-group of species; the hairing on the front face of the sella seems to be sparser and shorter than in the typical form. General colour above dark greyish "drab" darkest on the hinder part of the back, brighter drab on the underside of the body; base of hairs, throughout, dark smoke-grey.

Measurements. - Under the next form.

Type. - Ad. (skin). Kitui, British East Africa, 3500 ft., Jan. 3rd, 1901; collected and presented by Mrs. H. Hinde. B. M. no. 1.5.6.3. Original no. 68. The type is the only specimen known to me.

Distribution. - Probably the whole of the Ukamba district.

Remarks. - This is evidently a southern offshoot of *Rh. fumigatus*, cut off from the (Abyssinian) main stem of the species, and developed into a distinct race. From *Rh. Deckeni*, an inhabitant of nearly the same regions, it is easily distinguished by the longer and differently shaped nose-leaves, by having the margins of the sella clothed with long straight hairs, by the much smaller size (forearm in *Rh. Deckeni* 54.7 mm.), by having the 4th metacarpal only about 2 mm. longer than the 3rd (in *Rh. Deckeni* 5 mm. longer), by the comparatively very short 2nd phalanx of the 5th finger, &c. I have not seen a skull of this form; it will, no doubt, be found to have lost both the lower p_3 and the upper p^2, agreeing in this respect with *Rh. fumigatus* and differing from *Rh. Deckeni*.

Rhinolophus Geoffroyii A. Smith, 1829

p. 433

Rhinolophus Geoffroyii, mihi.

R. suprà ligneo-fuscus ; subtùs sublignicolor, membranis nigris, interfemorali transversè venosâ; caudâ vix præter apicem porrectâ; superiore membranæ nasalis lobo suprà acuminato.

Colour above wood brown, beneath lighter; membranes black, interfemoral one veined longitudinally, and the tip of the tail just extending beyond its posterior margin; upper lobe of nasal membrane pointed above; eyes small and nearly in front of the inner edges of auricles; ears large and patulous, nearly as long as the head, pointed, and each with an inferior lobe towards the base of the outer margin, which is separated from the principal by a deep intervening notch: interfemoral membrane semicircular behind. Length from the tip of nose to com-

p. 434

mencement of interfemoral membrane, three inches; length of latter, one inch; expanse of wings, thirteen inches. Inhabits the whole of South Africa.

This species decidedly differs from both the *Rhinolophus affinis*, and *Rhinolophus minor*, of Horsfield, not only in size and colour, but also in the depth of the notch in the outer edge of the auricle, as well as in the form of the nasal appendages, &c.

Rhinolophus Hildebrandti eloquens K. Andersen, 1905

p. 74

Diagnosis. - A small race of *Rh. Hildebrandti*. Forearm 57.7-60.5 mm.

Wings. - *Rh. Hildebrandti* is among the largest species of

p. 75

its genus; *Rh. H. eloquens* barely surpasses *Rh. Ferrum-equinum*. The reduction in size affects mainly the forearm and metacarpals, far less the phalanges. In the length of the forearm the largest specimens of *Rh. H. eloquens* fall short of the smallest individuals of the typical form; this character, therefore, evidently affords a most reliable mark of distinction between the two races. As to the metacarpals, maximum measurements of *Rh. H. eloquens* approach, very closely, minimum measurements of *Rh. H. typicus*.

Colour. - *Rh. Hildebrandii* (4 skins) is dark greyish "drab" on the upperside, bright drab beneath. *Rh. H. eloquens* (3 skins) is tinged with "wood-brown" above, next to "broccoli-brown" beneath. Base of the hairs, on the upper and under sides, dark smoke-grey. Immature individuals (1 skin) are slightly duller in colour than adults.

Skull and dentition. - All the measurements markedly smaller than in typical *Rh. Hildebrandti*. The length of the upper and lower tooth-rows, as being almost quite independent of the individual variation, is the best character by which to distinguish between the skulls of the two forms (conf. measurements below). In *Rh. Hildebrandti* (6 skulls) the upper p^2 is nearly always present and easily perceptible; the lower p_3 very minute, but generally not completely wanting. In *Rh. H. eloquens* p^2 is exceedingly small, hair-fine, even under a strong lens; p_3 (as it appears from examination of four skulls) almost always wanting, even in immature specimens.

Type. - Ad. (sk.), unsexed. Entebbi, Uganda; collected and presented by F. J. Jackson, Esq. B. M. no. 99.8.4.4. Three other specimens, from the same locality, are preserved in the Museum.

Distribution. - Probably the whole of the district surrounding Albert, Albert Edward, and Victoria Nyanza.

Remarks. - The present form is of great interest from a phylogenetic no less than from a zoogeographical point of view. *Rh. Hildebrandti* and *Rh. Fumigatus* (=*Antinorii*)* form a well-defined group of species, agreeing in the general form of the ears, in the size and shape of the horseshoe, the sella, and the posterior connecting-process, in having the margins and front face of the sella clothed with long hairs, in the general form of the wings, the comparative shortness of the tail, and the more essential characters of the skull

* Together with *Rh. Æthiops*; but this species, although extremely interesting as the hitherto only known West-African representative of the group, has a more isolate position, differing much more from the two other species than these latter inter se.

P. 76

and dentition. Until now, however, the very large *Rh. Hildebrandti* and its small counterpart, *Rh. Fumigatus*, have been without any intermediate link, widely separated in size as well as in geographical distribution. *Rh. H. eloquens* greatly reduces the gap between the two species; in all the points in which *Rh. H. eloquens* differs from *Rh. Hildebrandti typicus*, it approaches *Rh. Fumigatus* - in size, in colour, in dentition. *Rh. Hildebrandti* is decidedly the most primitive form: the upper p^2 is distinctly perceptible, the lower p_3 only occasionally wanting; in the Uganda race p_2 is markedly reduced in size, p_3 almost always completely lost; in the northern *Rh. Fumigatus* p^2 is but very rarely present, p_3 never. Uganda, the typical locality of *Rh. H. eloquens*, is, so to speak, "on the way" between the areas of *Rh. Hildebrandti* (from Mazoe to Mombasa) and *Rh. Fumigatus* (S. Somali and Abyssinia). It is not improbable that, when the region between Uganda and Abyssinia is better explored, we shall have to regard *Rh. Hildebrandti* and *Rh. Fumigatus* no longer as distinct "species," but rather as *peripheral forms* of one species, bound together by races intermediate in characters and in geographical distribution.

The subjoined table of measurements gives the difference in size, from the smallest form of *Rh. Fumigatus* to the largest form of *Rh. Hildebrandti*. If I had been arranging the forms from a phylogenetic point of view, the order would have been just the reverse (the names of the races read from right to left).

Rhinolophus hildebrandti perauritus de Beaux, 1922

p. 22

Somalia mer., territ. dei Rahanuin, 10.XI.11. *Int. in alc.* C. E. 12238; 3 FF; *Cotipi*. Le dimensioni somatiche superano di poco i maxima segnati da Andersen (Ann. Mag. Nat. Hist. XV, 1905, p. 76) per il *Rh. fumigatus*. Le orecchie e le membrane fogliacee nasali sono però più grandi. Le dimens. dei denti sono quelle del *Rh. hildebrandti eloquens*, And. (l.c.). P_2 ben percettibile. Lungh. della testa in carne mm. 25; test + tronco 57; coda 31; avambraccio 54-55; 3° metacarpo 39; 4° mtc. 41-41.5; 5° mtc. 41-42. Padiglione: lungh. mssm. 20; largh. in posiz. natur. 18; lungh. membrana fogliacea nas. 20; lungh. del ferro di cavallo 9-10; sua largh. 11-12; lungh.

p. 23

C-M_3 8.5-9; C-M_3 9.5-10. - *Colore*: Parti super. grige chiare (light drab, Ridgw. XLVI); singoli peli grigi chiarissimi nei $^5/_6$ basali (pale drab gray, ibid.); drab nel $^1/_6$ apic.. Parti infer. grige biancastre (pale olive buff, Ridgw. XL). Membrana alare bruna fuliginosa.

Annotaz.. Fui lungamente in dubbio se attribuire questo Rh. alla forma *fumigatus fumigatus*, And.; ma dopo accurati contronti con fumig. tipici determ. dall'a. della spec., e con *hildebrandti*, Pet. dovetti decidermi a farne una nuova sottospec., la quale costituisce daltronde un ulteriore appoggio alla supposiz. già espressa dallo stesso And. nel 1905, *che hildebrandti e fumigatus consituiscano una specie unica*.

Rhinolophus Hildebrandtii Peters, 1878

p. 195

(Taf. 1. Fig. 1.)

Diese Art schliesst sich durch die Form des Nasenbesatzes am nächsten an *Rh. fumigatus* und *aethiops* an, ist aber grösser, die grösste unter den bisher aus Africa bekannt gewordenen Arten. Das Hufeisen ist a am Rande einfach abgerundet, ungekerbt, vorn eingeschnitten, neben dem Einschnitte wulstig, aber ohne zahnartigen Vorsprung. Jederseits neben dem Hufeisen befindet sich, wie bei *Rh. aethiops*, nur vorn eine rudimentäre Falte. Die vordere Seite des Sattels ist etwas biscuitförmig eingebuchtet und überragt etwas den vorderen Theil des oberen bogenförmigen Sattelrandes; der ganze Sattel ist höher und Länger als bei *Rh. aethiops*. Der ganze Nasenbesatz ist mehr oder weniger dicht behaart. Die Ohren sind gross und breit, am Ende zugespitzt, aussen mit 10 Querfalten. Die Behaarung ist weich und reichlich, einfarbig, oben dunkelblond, unten graubraun.

Rhinolophus hilli Aellen, 1973

p. 101

Type. - F adulte, en alcool. Uwinka, Préf. Cyangugu, Rwanda, alt. 2300 m, 25.8.1964; coll. U. Goepel. Zoologisches Muséum der Universitât Zürich, n° 481.

Derivatio nominis: en l'honneur de John Edwards Hill, du British Muséum, dont les remarquables travaux ont beaucoup contribué à la connaissance de la systématique des chiroptères.

Diagnose. - Appartient au groupe *philippinensis* et est voisin de *ruwenzorii* Hill. Diffère de ce dernier par: a) une taille générale plus petite, b) le connectif de la feuille nasale bien développé, c) le crâne à boîte crânienne et le rostre plus larges.

Description. - Les dimensions externes et crâniennes sont un peu plus faibles que celles de *ruwenzorii*: inférieures en moyenne de 5 à 10 %. L'avant-bras mesure 53 mm, alors que chez *ruwenzorii*, il est de 55.5 mm (56 et 57) pour la F, et un peu plus faible pour le M.

Les oreilles, remarquablement grandes, sont très semblables à celles de *ruwenzorii*. Comme chez ce dernier, le bord antérieur de l'antitragus n'est pas concave et ne porte pas de sec à sa base (caractères de *maclaudi*).

La feuille nasale, qui ressemble en général à celle de *ruwenzorii*, en diffère surtout par le connectif. Dans notre nouvelle espèce, la selle (partie basale) est en forme de coupe (calice), moins évasée que chez *maclaudi*. Chez

p. 102

ruwenzorii, les bords latéraux de la partie basale de la selle seraint plus étalés (cf. fig. 2, in Hayman, 1960); mais chez le spécimen de Butembo que j'ai examiné, la selle ressemble beaucoup à celle de *hilli*. Ce caractère semble donc variable; il est d'ailleurs fort possible que sur l'animal vivant on puisse observer les deux positions cup-like et wing-like, expansions en rapport avec les émissions d'ultrasons: étalées, les "ailes" recouvrent les orifices des narines, repliées en calice, elles les dégagent un peu. Le procès vertical de la selle est semblable chez les deux espèces, de même que le fer-à-cheval et la lancette. Par contre, le connectif est nettement différent. Obsolète chez *ruwenzorii*, il est parfaitement développé chez *hilli*, entre le procès vertical de la selle (dont il n'atteint pas le sommet) et la lancette. Ce caractère me parait important et justifie la séparation en deux

espèces. Sur les côtés du museau, en avant, il y a une foliole secondaire (secondary leaflet, cf. Rosevear, 1965, fig. 49) de chaque côté, aux 3/4 cachée par le fer-à-cheval, et non rattachée directement au reste de la feuille nasale. Cette foliole fait défaut chez *maclaudi*, mais est présente chez *ruwenzorii*, bien que non encore signalée.

La lèvre inférieure présente un sillon médian net et deux échancrures latérales.

Le patagium s'insère au milieu du tarse.

Les longueurs respectives des métacarpes et des phalanges des 3e, 4e et 5e doigts correspondent exactement au schéma donné par Andersen pour *philippinensis* (1905: 247), c'est-à-dire que l'aile est de structure très primitive. Le 3e métacarpe est très peu raccourci (environ 90 % du 5e), le 4e métacarpe est à peu près égal au 5e. Ces deux caractères correspondent à ceux de la section *philippinensis*. Par contre, un certain allongement des 2es phalanges, et surtout de celle du 3e doigt, est un caractère propre aux sections *trifoliatus* et *sedulus* (du groupe *philippinensis*). La structure de l'aile de *ruwenzorii* est tout à fait semblable à celle de *hilli*.

Les plis palataux sont du même type que celui décrit chez *ruwenzorii*, mais ils sont tous, sauf peut-être le 6e, séparés au milieu. La fourrure est douce et bien fournie, comme chez *ruwenzorii*. La coloration est quelconque et très uniforme: brun foncé dessus et dessous, les oreilles et le patagium un peu plus clair.

p. 103

Le crâne présente une forme et des proportions semblables à celles du *ruwenzorii*. Toutefois, il est relativement plus large au niveau du rostre: le rapport largeur M^3-M^3 sur longueur C-M^3 (alv.) est plus grand que 1 (1.05) chez *hilli*, alors qu'il est inférieur ou égal à 1 chez *ruwenzorii* (0.92 à 1.0), moyenne de 3 spécim. 0.95). La boîte crânienne est aussi plus large: le rapport largeur mastoïde sur longueur basale, utilisé par Hill (7), est de 0.6 chez *hilli* et seulement de 0.57 à 0.58 (2 spécim.) chez *ruwenzorii*. Enfin, la largeur zygomatique est pratiquement égale à la largeur mastoïde chez *hilli*, alors qu'elle est plus faible chez *ruwenzorii*.

mesures en mm: *R. hilli* type F; *R. ruwenzorii* type F, M Butembo
tête et corps: 60; 67, 66
avant-bras: 53; 57, 56
3e doigt, métacarpe: 37.5; 40, 40
- 1ère phalange: 17; 18.5, 17.5
- 2e phalange: 29.5; 32, 30
4e doigt, métacarpe: 41.5; 44, 43
- 1ère phalange: 11; 12, 11.5
- 2e phalange: 19; 20, 19.5
5e doigt, métacarpe: 42; 46.8, 43.5
- 1ère phalange: 12.5,; -, 13
- 2e phalange: 18; -, 18
queue: 30; 31, -
tibia: 23; 23.5, 23
pied, sans griffe: 12.5; 12, 12
oreille, longueur: 29; 32.5, 32
- largeur: 22; -, 26
feuille nasale, long; 22; -, (18)
fer-à-cheval, larg; 12; -, (13)
crâne:
longueur totale: 23.8; 25.9, -
long, condylobasale: 21.1; 23.3, -
longueur basaie (C): 18.0; 20.7, -
pont palatal: 3.4; 3.6, 3.4
largeur zygomatique: 10.6; 11.2, -
largeur mastoïde: 10.8; 12.0, -
larg. interorbitaire: 2.7; 2.6, 2.7
largeur M^3-M^3: 8.0; 8.2, 7.5
largeur C-C: 5.7; 5.9, 5.4
longueur C-M^3 (alv.): 7.6; 8.2, 7.9
longueur C-M^3 (cour.): 8.1; 8.9, 8.3
longueur P^4-M^3: 6.0; 6.3, 6.2
long, mandibule: 15.1; -, 15.9
longueur C-M_3: 8.3; -, 8.7

Le pont palatal comme chez *ruwenzorii* est remarquablement long; il représente environ 45 % de la longueur de la rangée dentaire C-M^3. C'est un caractère propre au groupe *philippinesis*.

p. 104

Au maxillaire supérieur I^1 a une couronne plate, usée; il est fort possible que cette dent était bifide à l'état jeune, comme chez *ruwenzorii*. P^2 est situé au bord externe de la rangée dentaire et sépare C de P^4. Très petite, cette dent n'arrive pas à la hauteur du cingulum de C. Chez le type de *ruwenzorii*, P^2 est plus développé, mais c'est un caractère quelque peu variable, car chez *ruwenzorii* de Butembo, la dent est moins développée. P^4, M^1, M^2, et M^3 sont semblables chez *hilli* et *ruwenzorii*.

Au maxillaire inférieur, I_1 est bicuspide, mais probablement tricuspide à l'origine (dispartion par usure de la cuspide centrale), plus petit que I_2. I_2 est bicupside à droite et tricuspide à gauche. P_3 est minuscule et déporté en dehors de la rangée dentaire, de sorte que P_2 est en contact avec P_4; chez *ruwenzorii*, P_3 sépare encore un peu P_2 de P_4. P_2 est plus petit que la 1/2 de P_4.

Il est évident que ces constatations, basées sur un très petit nombre de spécimens, ne seront peut-être pas confirmées lorsqu'on disposera de plus de matériel.

Remarques. - Dans sa revision des *Rhinolophus* du groupe *philippinensis*, Andersen n'avait connaissance pour l'Afrique que de l'espèce *maclaudi* Pousargues, qu'il incluait sans hésiter dans ce groupe d'espèces orientales. Laurent, lui, concluait que *maclaudi* constituait un type africain archaïque isolé, n'entrant pas dans l'un des groupes d'Andersen, n'ayant donc pas d'affinités avec des espèces d'Asie. On connaît maintenant 9 spécimens de *maclaudi*, provenant tous de la Guinée, aux environs de Conakry.

Il me semble que les conclusions d'Andersen restent valables, surtout depuis que l'on connaît l'existence d'une deuxième espèce de ce groupe en Afrique, soit *Rhinolophus ruwenzorii*, décrit par Hill en 1942 et retrouvé à plusieurs reprises dans la région du Mt Ruwenzori et de l'Ituri. Il y a actuellement huit spécimens de *ruwenzorii*: le type F de la Butahu Valley, 1 F de R. Mahoma, 3 MM du Mt Hoyo, 3 spécimens de Butembo, du Mt Hoyo et de la cave de Matata. Tous ces spécimens proviennent du Zaïre (ancienne Province du Kivu), sauf celui de la R. Mahoma qui est de l'W de l'Ouganda.

L'étude morphologique indique des affinités certaines avec les espèces orientales du groupe *philippinensis*. La nouvelle espèce décrite ci-dessus vient encore confirmer ces affinités. A mon avis, il s'agit de types archaïques reliques, maintenant isolés, mais ayant une origine commune avec les espèces orientales du groupe *philippinensis*. Andersen a subdivisé son groupe en trois sections: aucune des espèces africaines ne cadre exactement dans l'une de ces sections, mais elles répondent parfaitement à la définition même du groupe.

Rhinolophus hilli est nettement plus proche de *ruwenzorii* que de *maclaudi*. Il est possible, qu'à la lumière de nouvelles observations basées sur un matériel plus abondant, on doive considérer le *hilli* seulement comme une sous-espèce de *ruwenzorii*. Cela n'a d'ailleurs pas de grande importance. Par contre, il me semble impossible d'entrer dans les vues de Hayman et Hill, qui pensent que *maclaudi* et *ruwenzorii* pourraient être conspécifiques. La structure et la forme différentes des feuilles nasales et des oreilles, pour ne parler que de ces formations externes, ne peuvent pas être des caractères subspécifiques.

Biologie. - Les rares spécimens de *maclaudi* et de *ruwenzorii* dont on connaît l'origine précise, proviennent de grottes. Le type de *hilli* a été capturé au filet dans une forêt de montagnes. Il s'agit d'une F adulte portant un embryon de 15 mm.

Rhinolophus keniensis Hollister, 1916

p. 2

Type from west side of Mount Kenia, British East Africa, at 7,000 feet altitude. United States National Museum No. 166352, adult male in alcohol with skull removed. Collected August 27, 1909, by Edmund Heller. Orig. No. 1154.

Description. - A small member of the *Rhinolophus augur* group, differing from *R. a. zambesiensis* in the small size of the nose-leaf (greatest width of horse-shoe, 6.8; compared with 8.0-8.3 in *zambesiensis*), shorter forearm, and shorter tibia. Skull somewhat larger, with slightly more robust teeth, than in *zambesiensis*.

Measurements of type. - Forearm, 52 mm.; tibia, 21; greatest length of ear from anterior margin, 18.9; greatest width of ear, 12.2; third finger metacarpal, 34.8; first phalanx, 17.4; fourth metacarpal, 39.5; first phalanx, 11.3; fifth metacarpal, 40.3; first phalanx, 12.8. Skull: Greatest length, 22.8; condylobasal length, 20.4; zygomatic breadth, 12; postorbital constriction, 3; mastoid breadth, 10.7; mandible, 15. Teeth: Canine to m^3, 8.6; breadth across upper canines, 6.6; greatest breadth across upper last molars, 8.4; lower canine to m_3, 9.

Remarks. - This new bat is readily separable from all the other species of *Rhinolophus* known from British East Africa by the combination of narrow horse-shoe, hairless sella, and position of small upper premolar entirely without the tooth row. It is doubtless a northern representative of *R. augur*, and perhaps it intergrades directly into *R. a. zambesiensis*. Doctor Lönnberg and Mr. Oldfield Thomas have recorded *R. a. zambesiensis* from Kilimanjaro, but I am not aware that a member of the group has up to now been noted in British East Africa.

Specimen examined. - One, the type.

Rhinolophus landeri guineensis Eisentraut, 1960

p. 1

Material: 10 Exemplare, 1 M, 3 FF (Tgb. Nr. 27-30), 5.X.1956, nahe Tahiré, am Fuße des Kelesi-Plateaus. - 1 M, 1 F (Tgb. Nr. 121, 126), 19.XI.1956, nahe Nyembaro am Salung-Plateau, 12 km westlich Kolente. - 2 MM, 2 FF (Tgb. Nr. 133, 136-138), 23.XI.1956, bei Darsalam am Kankuja-Plateau, 8 km westlich Kolente.

Diese neue Form stimmt in den wesentlichen Merkmalen mit von mir am Kamerunberg gesammelten Stücken von *Rh. landeri landeri* Martin überein, zeichnet sich aber durch größere Körper- und Schädelmaße aus und zeigt darin gewisse Übereinstimmung mit der im Kongogebiet und in Ost- und Südostafrika lebenden Subspezies *lobatus* Peters. Ferner sind die bei den MM vorkommenden Drüsenhaarbüschel unter der Achsel nicht bräunlich getönt, sondern rein weiß. Es scheint daher berechtigt, diese westlichste Form als besondere Subspezies abzutrennen. Ich schlage für sie den Namen *guineensis* vor. Soweit ich die Literatur überblicke, sind die von KNORR gesammelten Stücke der Erstnachweis der Art für Guinea.

Typus: M ad. (Tgb. Nr. 28), 5.X.1956, Tahire am Fuße des Kelesi-Plateaus, etwa 500 m Meereshöhe, KNORR leg., Staatliches Museum für Naturkunde Stuttgart, Katalog-Nr. 6103. Kopf-Rumpf-Länge: 50 mm, Schwanz: 26 mm, Ohr: 17 mm, Hinterfuß: 8.5 mm, Unterarm: 44.3 mm, gesamte Schädellänge: 20.6 mm, Jochbogenbreite: 10 mm, maxillare Zahnreihe: 7.3 mm, Mandibellänge: 13.3 mm, mandibulare Zahnreihe: 8 mm.

In Tabelle l sind die Körper- und Schädelmaße für *guineensis* angegeben und den entsprechenden Maßen der Nominatrasse und der Rasse *lobatus* Peters (= *axillaris* J. A. Allen, vgl. HAYMAN in SANDERSON) gegenübergestellt. Fast sämtliche Durch-

p. 2

schnittswerte von *guineensis* liegen höher als die von landeri, dagegen berühren oder überschneiden sich die Maximum- und Minimumwerte sehr häufig. Besonders auffallend ist die größere Länge der Tibia und ferner die höheren Werte für die gesamte Schädellänge, die Mastoidbreite, die Mandibellänge und die Länge der oberen und unteren Zahnreihe. In Abb. 1 kommen die unterschiedlichen Schädelmaße zum Ausdruck. Bei der Gegenüberstellung der Guinea-Rasse mit der Rasse *lobatus*, für die in der Literatur nur verhältnismäßig wenige Angaben vorliegen, ist die weitgehende Übereinstimmung der Unterarm- und Tibialänge festzustellen.

In Übereinstimmung mit der bedeutenderen Körpergröße sind auch die an den frischtoten Tieren festgestellten Körpergewichte bei *guineensis* mit 9.1 (8 - 11) g wesentlich höher als bei *landeri* (von Kamerun) mit 6.2 (5 - 7) g.

Entsprechend der größeren Schädelmaße bei *guineensis* gegenüber *landeri* ist auch das Gebiß kräftiger entwickelt. Hervorzuheben ist die relative Kleinheit von P_1, der ähnlich wie bei *alcyone* höchstens die halbe Länge von P_3 erreicht, während er bei meinem Material von *landeri* aus Kamerun (EISENTRAUT 1956, vgl. auch die Angaben von AELLEN bis zu $^2/_3$ der Höhe von P_3 ansteigt. Im übrigen aber entsprechen die Zahnproportionen denen der Nominatrasse.

Weitgehende Übereinstimmung zwischen *guineensis* und *landeri* besteht hinsichtlich der Ausbildung des Nasenaufsatzes, lediglich übertreffen bei erstgenannter Form die absoluten Maße - entsprechend den allgemein größeren Körpermaßen - die von *landeri*. Während z. B. die Breite des Hufeisens bei einem Alkoholstück von *guineensis* 9 mm beträgt, erreicht sie bei *landeri* nur etwa 7 mm.

p. 3

Die Färbung der mir vorliegenden Guinea-Stücke läßt oberseits eine Variation von dunklerer zu hellerer graubräunlicher Tönung erkennen (nach RIDGWAY von Clove Brown über Olive Brown zu Tawny Olive). Ein Stück (Nr. 136) zeigt eine blaßrotbraune Fellfärbung, jedoch ist auf der hinteren Rückenmitte eine sich stark abhebende, dunkelgraue Haarpartie vorhanden (vielleicht Jugendmauser?), bei einem weiteren Stück (Nr. 126) ist diese Färbungstendenz in ganz schwach angedeuteter Form ebenfalls zu erkennen. Die Unterseite zeigt die übliche fahle Aufhellung.

Bei den bisher bekannten Formen der Art wurde eine charakteristische rotbraune Färbung der Achseldrüsenhaare (soweit vorhanden) bei den MM hervorgehoben. Im Gegensatz dazu zeigen drei MM von *guineensis* zwar ebenfalls die Ausbildung eines solchen Haarschopfes, dieser ist aber reinweiß und hebt sich von den umliegenden grauen Haarpartien scharf ab. Einem M (Nr. 39) fehlt dieses Merkmal ganz (vielleicht jugendliches Exemplar).

Das F Nr. 133 (Alkohol) besitzt deutlich ausgeprägte, gleichlange Afterzitzen; sein Uterus ist in völligem Ruhezustand, die Uterushörner jedoch sind gut entwickelt, und zwar das rechte etwas stärker als das linke.

Die von Herrn KNORR gesammelten Stücke wurden während der Tagesruhe in Felshöhlen erbeutet, wo sie zusammen mit anderen Fledermausarten (*Rhinolophus denti, maclaudi, foxi, Hipposideros caffer, jonesi, Nycteris aethiopica* und *gambiensis*) vorkommen. Die Fundplätze befinden sich nahe den Orten Tahiré, Nyembaro und Darsalam in einem etwa 150 km von der Küste (Conakry) entfernt liegenden Gebiet von Südkindia.

Rhinolophus lobatus Peters, 1852

p. 41

Tafel IX. Tafel XIII. Fig. 16, 17.

Rh. colore opace umbrino, subtus pallidiore; alis nigrofuscis; auriculis elongatis, ellipticis, acuminatis, parum excisis, lobulo alto; plica transversali prosthematis superiore distincte lobata; deutibus molaribus superioribus utrinque quinis, inferioribus senis; metacarpo digiti quarti longiore quam digiti quinti; alis usque ad tarsum porrectis.

Longitudo tota 0,085; caudae 0,026; antibrachii 0,045; volatus 0,290.

Habitatio: Africa orientalis, Sena, Tette, 17° Lat. Aust.

Die Ohren sind elliptisch, zugespitzt, um ein Fünftel kürzer als der Kopf; der Einschnitt zwischen der Ohrmuschel und dem Ohrlappen ist gering; der Ohrlappen selbst ist hoch, an beiden Ecken gleichmäfsig abgerundet, an seiner äufsern Fläche so wie die Ohrmuschel über zwei Drittel behaart. Das Hufeisen zeigt drei concentrische falten; die vordere Querfläche des Sattels ist etwas unter der Mitte zusammengedrückt, biscuitförmig; die vor der Lanzette sich erhebende Spitze ist dreieckig, so lang wie die Querfläche; die Lanzette ist länger als breit, nach unten gleichmäfsig, ohne vorspringende Seitenlappen, erweitert; die Scheidewand zwischen dem mittleren und oberen Zellenpaar ist zu beiden Seiten lappenartig abgesetzt. Auf den vorspringenden Falten des ganzen Nasenbesatzes finden sich zerstreute borstenförmige Haare. Das Maul ist abgerundet, bis unter den hintern Rand des Hufeisens gespalten; die Lippen haben in der Mille einen nackten wulstigen Rand; die innere Fläche

der Oberlippe ist jederseits durch einen grofsen warzigen Vorsprung ausgezeichnet. Die kleinen Augen stehen doppelt so weit von der Schnauzenspitze wie von den Ohren entfernt. Am Gaumen sieht man sieben quere Schleimhautfalten, drei vordere gröfsere, entfernter von einander stehende, und vier hintere, weniger hervorragende und näher an einander gedrängte; die letzte derselben ist grade und ungelheilt, die übrigen bilden doppelte in der Mitte zusammenstofsende Bögen. Die Behaarung des Körpers ist an der Rückenseite länger als an der Bauchseite. Die Pha-

p. 42

langen des Daumens sind ganz frei. Das Mittelhandglied des vierten Fingers ist das längste von allen, wie bei *Rh. hippocrepis*, Hermann, und das des dritten Fingers das kürzeste, wie bei allen bis jetzt bekannten Arten der Gattung *Rhinolophus* im engern Sinne. Die erste Phalanx des vierten Fingers ist sehr kurz, weniger als halb so lang wie die erste Phalanx des dritten Fingers. Die zweite Phalanx des fünften Fingers ist um die Hälfte länger als die erste desselben. Alle vier unbenagelten Finger tragen ein kurzes knorpeliges Endglied. Die Flughäute gehen bis zur Fufswurzel herab; sie sind oben nackt, an der Bauchseite dagegen zwischer Oberschenkel und Oberarm mit zerstreuten langen Härchen bewimpert. Der Schwanz ist um ein Viertel länger als der Unterschenkel, und ragt mit seinem kurzen knorpeligen Endgliede aus der Schenkelflughaut hervor; das vierte und fünfte Endglied sind die längsten und von gleicher Gröfse. Die Schenkelflughaut ist oben und unten bis zum vierten Endglied mit zerstreuten Haaren bewimpert. Die Spornen sind nur sehr schwach. Die Nägel der Zehen sind ein wenig länger und gekrümmter als die Daumenkralle.

Die Farbe des Rückens und der Halsseiten ist braun, wie die eines dunklen Umbers und die Bauchseite zeigt ganz denselben Farbenton, aber viel blasser und verwaschen. Die Haare sind sämmtlich einfarbig, nur werden die Rückenhaare nach dem Grunde zu alle mählig immer blasser. Die kleinen Haarbüschel auf der Unterseite der Flughäute, welche selbst von schwarzbrauner Farbe sind, erscheinen weifslich. Die Ohren sind von der Farbe der Flughäute. Das Gesicht ist um das Hufeisen herum dunkler. Die Nägel sind gelblich.

Der Schädel (Tafel XIII. Fig.16. 17), obgleich beträchtlich gröfser, nähert sich in seine Gestalt am meisten dem von *Rhinolophus hippocrepis* Herm.; auch der Fortsatz des Unterkieferwinkels hat dieselbe horizontale Lage und fast rechtwinkelig abgehende Richtung wie bei dieser kleinen europäischen Hufeisennase. Der kleine obere erste Lückenzahn ist aber nicht lang und spitzig, sondern ganz niedrig und ragt mit seiner stumpfen Spitze nicht über den Rand der benachbarten Zähne hervor, und im Unterkiefer findet sich zwischen den beiden falschen Backzähnen noch ein ganz kleiner nach aufsen gedrängter Zahn, so dafs die Zahl der untern Backzähne sich im Ganzen auf sechs beläuft. Die Formel des Gebisses ist daher bei diesem Thiere $^{3\,2}/_{3\,3}\,^{1}/_{2}\,^{1}/_{4}\,^{1}/_{1}\,^{2\,3}/_{2\,3} = 32$. Die Wirbelsäule besteht aus 7 Halswirbeln, 11 Rückenwirbeln , 7 Lendenwirbeln, 3 Kreuzbeinwirbeln und 11 Schwanzwirbeln. Die beiden ersten Rippen sind mit dem letzten Halswirbel und mit den beiden ersten Rückenwirbeln verwachsen, die vier folgenden verbinden sich durch normale Zwischenstücke mit dem Brustbein, und die siebente und letzte wahre Rippe steht durch ein sehr breites plattes Knochenstück mit demselben in Verbindung. Der Magen ist kugelförmig und geht zunächst in einen weiten Darm über, der sich gegen die Mitte seiner Länge plötzlich um die Hälfte verengert, und erst nahe vor seinem Ende sich wieder etwas erweitert. Die Länge des Darmcanals ist 145 Millim. Die Leber ist dreilappig, und trägt unter dem mittleren Lappen eine gestreckte hirnförmige Gallenblase. Die Milz ist $3^{1}/$ Mm. breit, und etwa dreimal so lang wie breit. Die Nieren sind ungelappt, bohnenförmig, an ihrem oberen Ende etwas dicker als um unteren. Die Ruthe des Männchens

p. 43

enthält einen 3 Mm, langen Knochen. Die Luftröhre bildet unter dem Kehlkopf eine kleeblattförmige blasige Erweiterung. Die Lungen bestehen jederseits nur aus einem einzigen unregelmäfsig quadratischen Lappen, dessen Ecken sehr spitz ausgezogen sind.

Von dieser Art besitze ich vier Exemplare, Männchen und Weibchen, von denen eins aus Tette, drei aus Sena herstammen. Die aus Sena wurden unter dem vorstehenden Dache eines alten Gebäudes gefunden. Nach dem Inhalte des Magens und Darmcanals zu urtheilen, besteht ihre Nahrung aus Insecten.

Die in der Diagnose angegebenen Kennzeichen characterisiren diese Art hinreichene, um sie von den verwandten africanischen Formen zu unterscheiden. *Rh. capensis*, Lichtenstein, hat nur vier obere Backzähne, die Flughäute lassen einen Theil des Schienbeins frei und das Mittelhandglied des fünften Fingers wird nicht vom vierten überragt. *Rh. clivosus*, Rüppell, hat zwar dieselbe Form der Backzähne, aber die Farbe ist röthlich, die Form des Nasenbesatzes und das Verhältnifs der Gliedmalsen

verschieden. *Rh. fumigatus*, Rüppell, welche in der Gröfse mit unserer Art übereinstimmt, weicht durch Färbung, durch die noch gröfsere Verlängerung des Vorderarms, und, da sie mit *Rh. cliovsus* sonst übereinstimmen soll, auch in dem Verhältnifs der Millelhandglieder und in dem Bau der Lanzette von derselben ab.

Rhinolophus Maclaudi Pousargues, 1898

p. 358

Parmi les Mammifères nombreux et intéressants recueillis par M. le Docteur Maclaud dans l'île de Conakry, sur les côtes de la Guinée française, se trouvait un Cheiroptère du genre *Rhinolophus* présentant un ensemble de caractères qui le distinguent nettement de toutes les autres formes congénériques.

Cette nouvelle espèce est de grande taille, plus grande que toutes celles signalées jusqu'à présent sur le continent africain, car elle dépasse en dimensions le *R. Hildebrandti* (Pet.) de l'Afrique orientale et ne le cède à cet égard qu'au géant du genre, le Rhinolophe deuil, *R. luctus* (Tem.), des hautes terres de l'Inde continentale et archipélagique. Sa taille n'est pas le seul caractère qui la rapproche des grandes espèces indiennes pour lesquelles Gray avait créé lés sous-genres *Aquias* et *Phyllotis*; elle leur ressemble

p. 359

aussi par le mode de conformation de la feuille nasale et en particulier de la selle ou partie centrale. Cette dernière peut être comparée, dans son ensemble, au pétale labellé de certaines fleurs: sa portion basilaire est cordiforme; chacune de ses deux ailes symétriques s'élève d'abord verticalement au-dessus de la cloison nasale, puis s'étale et s'épanouit latéralement et enfin s'incurve en haut vers son bord supérieur, de manière à ménager entre elles une cavité assez profonde en forme de coupe évasée, analogue à celle que l'on remarque chez les *R. mitratUs* (Blyth) et *R. philippinensis* (Wat). La partie supérieure de la selle, bien développée en longueur comme en largeur, dessine une sorte de languette dirigée en haut et en avant. Un autre caractère spécial à cette nouvelle espèce consiste dans le mode de structure de la partie antérieure de la feuille nasale ou fer à cheval, qui, sur son bord interne longeant extérieurement chacun des orifices nasaux, se redresse verticalement en une lame membraneuse assez élevée, qui vient doubler de chaque côté, comme un calice, l'espèce de corolle formée par la portion basilaire de la selle. Enfin je signalerai tout particulièrement la longueur démesurée des conques auditives, dont les dimensions relatives sont énormes et qui, au point de vue absolu, dépassent même en longueur, celles du *R. luctus*, le mieux pourvu sous ce rapport.

La diagnose de cette espèce remarquable peut être résumée de la façon suivante:

La partie terminale ou supérieure de la feuille nasale, bien développée,

p. 360

triangulaire, remonte presque verticalement jusqu'entre les oreilles et présente latéralement les trois replis et les vacuoles ordinaires. La partie antérieure horizontale de la feuille ou fer à cheval est large, légèrement échancrée au milieu de son bord antérieur et surplombe toute 1a lèvre supérieure; le long de son bord interne attenant aux narines elle se relève de chaque côté en une lame verticale très développée dont les amorces descendent en s'atténuant graduellement vers son bord antérieur.

La portion basilaire de la selle est cordiforme, creusée en coupe, beaucoup plus large que sa portion supérieure verticale (section b' *du Synopsis de Dobson*), chacune de ses ailes s'étalant latéralement et se relevant ensuite verticalement. La partie supérieure de la selle a la forme d'une languette dressée, assez longue, et conserve la même largeur jusqu'à son sommet, arrondi et recourbé en avant. La lame membraneuse verticale (*posterior connecting process*) qui rattache cette languette à la partie supérieure de la feuille est concave, peu élevée et n'atteint même pas son sommet. La lèvre inférieure ne présente qu'un seul sillon médian peu profond. Les oreilles sont énormes, d'un quart plus longues que la tête et hors de proportion avec la taille de l'animal; leur bord interne, garni près de la base d'un duvet rare et court, est régulièrement convexe jusqu'au sommet assez peu aigu, légèrement arrondi et dirigé en dehors; leur bord externe, un peu échancré et concave dans le quart supérieur, devient ensuite régulièrement convexe. A l'intérieur se voient douze replis parallèles très accentués. L'antitragùs, très élevé, est séparé du bord externe par une encoche profonde et anguleuse; sa surface bosselée présente en haut une partie bombée et convexe, plus bas une dépression circulaire profonde formant cuvette; son bord supérieur, arrondi et convexe, se replie en dehors en s'enroulant en ourlet; son bord antérieur, profondément concave, vient se terminer comme un soc au-dessous et au niveau de l'œil. La membrane alaire, très développée, de'un brun sombre, prend ses attaches aux malléoles. La queue est relativement courte, et sa pointe extrême dépasse un peu la membrane interfémorale. Celle-ci est de grandeur médiocre, triangulaire en arrière et relativement moins développée que chez le *R. luctus*.

Le pelage est doux, bien fourni, mais assez court, d'un blond châtain uniforme, un peu plus clair sur la face inférieure du corps.

La première prémolaire supérieure est petite, peu élevée, assez distante de la canine, au contraire très rapprochée de la deuxième prémolaire,

p. 361

contre laquelle elle est accolée. La deuxième prémolaire inférieure est très réduite, enchâssée dans l'angle qui sépare les premiére et troisième prémolaires et pincée par conséquent un peu en dehors de la rangée dentaire.

Le seul spécimen recueilli par M. le Docteur Maclaud est une femelle adulte, prise pendant la période d'allaitement, comme l'indiquent ses mamelles extrémement turgides. Sur la région pubienne se voient les deux appendices tétiniformes ordinaires.

Ses principales dimensions sont les suivantes:

Longueur de la tête et du corps: 96^{mm}0
- de la queue: 41 0
- de la tète: 33 0
Dimensions de la feuille nasale: 26 X 16 0
Longueur totale de la selle: 14 0
Largeur maximum de sa partie basale: 9 5
Largeur de la partie supérieure ou languette: 5 0
Longueur de l'oreille, de la base de son bord interne au sommet: 44 0
Longueur de l'antitragus, de la pointe de son bord externe au sommet: 17 0
Longueur de l'avant-bras: 68 0
- du métacarpien du 3^{e} doigt: 47 0
- de la 1re phalange du 3^{e} doigt: 23 0
- de la 2^{e} phalange du 3^{e} doigt: 36 0
- du métacarpien du 5^{e} doigt: 50 0
- de la 1re phalange du 5^{e} doigt: 17 0
- de la 2^{e} phalange du 5^{e} doigt: 22 0
- du tibia: 31 0

Cette espèce, que je dénommerai *Rhinolophus Maclaudi* en l'honneur de M. le Docteur Maclaud, a été prise sur l'île même de Conakry, mais elle doit se rencontrer également un peu plus au large, sur les îles de Los, et d'autre part, sur les côtes et dans l'hinterland de nos possessions de la Guinée française; elle vient grossir le nombre, assez restreint du reste, des espèces du même genre, dans cette partie de l'Afrique où l'on n'a encore signalé que le *R. alcyone* (Tem.), le *R. fumigatus* (Rüpp.) et le *R. clivosus* (Rüpp.).

Hab. Fernando Po.

This species of *Rhinolophus* is remarkable for having the complicated fleshy appendages of the muzzle divided in the longitudinal direction. Each half of this apparatus is composed of two leaflets, the margins of which are free, though but little elevated; the foremost of these is shaped somewhat like the human ear, and terminates in front in a small prominent lobe, which is situated over the opening of the nostril; the second or hindermost leaflet on each side approaches to a circular form. Upon separating these four leaflets a large pit is observable on the upper surface of the muzzle, and the hinder margin of this pit terminates in a nearly semicircular and slightly elevated fleshy ridge, which is densely clothed with fur. The ears are large, rounded at the extremity, but inclining to a pointed form, and separated from each other on the top of the head by a space of about two and a half lines in width; on the inner side, and towards the base, is a narrow oblique ridge: the tragus is about two and a half lines in length, narrow, rounded at the extremity, and somewhat dilated near the base on the outer margin. The wing and interfemoral membranes join the foot at the base; the latter extends to the extremity of the tail, which terminates in a bifurcated cartilage; numerous minute papillæ are observable on the margin of the interfemoral membrane. The general colour of the animal, in spirit, is gray-brown, but with an ashy tint on the under parts of the body, and is darker than that of the *Rhinolophus Hipposideros* of authors.

Rhinolophus micaceus de Winton, 1897

p. 524

Rhinolophus micaceus, sp. n.

Colour above and below dark soft rich purplish brown, flecked with silver-grey. The fur is so fine that it is difficult to see if the hairs are truly annulated ; but as the silvery speckling comes and goes as the animal is turned in the light, it appears to arise wholly from the glint of the light on the brown fur. It is not possible to give particulars of noseleaf, the specimen being dried. Length of fur on the back 11.5 millim.

Measurements taken in flesh by collector: -

Head and body 90 millim.; tail 23; hind foot 17; ear 26; forearm 69.

Skull : greatest length 28 millim.; greatest breadth 15.3; breadth of brain-case 11.5; intertemporal constriction 3.9; basal length 22.9; between tips of canines 6.5; length of entire tooth-row 10.5.

Type (F): Como River, 75 miles from Gaboon, 6th July, 1897.

Collected by Mr. G. L. Bates.

Rhinolophus ruwenzorii J. Eric Hill, 1942

p. 1

TYPE. - Amer. Mus. Nat. Hist. 82394, F adult, alcoholic with skull removed. Brought in by natives with a *Rousettus lanosus* from a cave, December 24, 1926, south side of Butahu Valley, western slope of Mount Ruwenzori, altitude 7,500 feet.

DIAGNOSIS. - Like *Rhinolophus maclaudi* Pousargues (1897, Bull. Mus. d'Hist. Nat., Paris, III, pp. 358 - 361, 2 figs.) from French Guinea, but smaller, with lateral margins of nostrils less developed and with less concavity in the anterior margin of the antitragus. Skull with relatively broader braincase, shorter palatal bridge, more abrupt nasal swellings and narrower zygomatic spread.

Rhinolophus ruwenzorii is larger in body than *R. aethiops* or *R. hildebrandti*, but the measurement of the forearm is approximately as in these species.

The noseleaf is quite unlike that of any African species except *R. maclaudi*, and it differs from the noseleaf of that form only in minor details: lateral margins of the nares form a low ridge, rather than "coming to double, as a chalice, the sort of corolla formed by the basal part of the sella" (Pousargues, describing *R. maclaudi*); horseshoe more widely divided anteriorly and without the shallow emarginations near the medial side of the anterior margin.

The ears are much like those of *R. maclaudi* but differ in details: notch separating the antitragus less acute; anterior concavity of the antitragus less marked; terminal plowshare-like process ("soc," described and figured by Pousargues) obsolete in the new form.

Pelage abundant and soft, about 13 mm. long on the shoulders. Coloration (possibly faded after 15 years in alcohol): upperparts darker than Bister; underparts near Benzo Brown; wings and ears near Fuscous-Black. (Names of colors in capitals from Ridgway, 1912, "Color Standards and Color Nomenclature.") *R. maclaudi* was described as light chestnut ("blond chatain"); it appeared darker than this in 1937, more like our specimen.

SKULL. - Similar to that of *R. maclaudi* (examined and photographed in 1937, while studying material in European museums under a grant from the Carnegie Corporation of New York), but smaller (13 to 20 per cent in most measure-

Crowns P^4-M^3: 6.3, 8.1

ments) with relatively broader brainease (mastoid-basal index 58 rather than 54.5) and less spreading zygomatic arches (their spread less than, rather than greater than, mastoid breadth). Nasal swelling more pronounced and abrupt; intertemporal "neck" shorter; maxillary root of

p. 2

zygoma weaker than in *R. maclaudi*; palatal bridge shorter. A well-developed pit between the posterior roots of the pterygoid plates in both species.

DENTITION. - Cheek teeth smaller; upper incisor bifid; P^2 in toothrow, but minute, about as high as cingulum of C^1; M^1 with poorly developed hypocone, this is little more than a cingulum in M^2 (the molars are similar in *R. maclaudi*); lower incisors tricuspate, the medial pair smaller, overlapping lateral ones; P_3 minute, "squeezed" laterally between P_2 and P_4; the former large, squarish in outline from above, about threefourths as high as P_4.

The palatal ridges are most like Seabra's schema for *R. hipposideros* (Jorn. Sci. Math. Phys. Nat., Lisbon, [21 V, pp. 248-252), but the second ridge runs between the minute first premolars, and the last four ridges are incomplete medially.

Type. - M adulte, en alcool. Grotte de N'Dumbu, Lastoursville, Gabon, 4.8.1957; coll. P. Strinati et V. Aellen. Muséum d'Histoire naturelle de Genève, n° 965.40.

p. 229

Cette nouvelle espèce a été signalée par SANBORN (1953) sous le nom de *Rhinolophus f. fumigatus* Rüppell. L'auteur américain a examiné un spécimen M provenant de la grotte de Bongolo, près de Lébamba, Gabon; il l'a comparé à neuf *R. fumigatus* typiques du British Muséum et l'a trouvé identique, à part une rangée dentaire plus longue et une largeur maxillaire plus grande. Il est curieux que le biotope de forêt équatoriale, opposé à celui de savane ou de steppe de *R. fumigatus*, n'ait pas attiré l'attention de SANBORN. Les mensurations publiées par ce dernier montrent à l'évidence que son spécimen appartient à ma nouvelle espèce. En fait, les différences existant entre le Rhinolophe du Gabon et *R. fumigatus* ne permettent même pas d'attribuer le premier, en qualité de sous-espèce, au second.

Il est probable que *R. silvestris* a été confondu parfois sous le nom de *Rhinolophus ferrumequinum* (Schreber). Ainsi, un nouvel examen du spécimen "u" provenant du Gabon, que DOBSON (1878) classe sous ce nom, montrera très probablement qu'il s'agit de la nouvelle espèce.

Diagnose. - *Rhinolophus* de taille plutôt grande (avant-bras 50 mm, long, du crâne 23,4 mm). Feuille nasale à connectif à sommet arrondi et très bas, ne dépassant pas le processus vertical (dossier) de la selle; fer à cheval large (10 mm) recouvrant tout le museau. Troisième métacarpe réduit, inférieur à

p. 230

90% du cinquième métacarpe. P^2 très réduit et externe, de sorte que C et P^4 sont presque en contact. P_3 tout à fait rudimentaire, non fonctionnel; P_2 et P_4 se touchent.

Description. - Les oreilles atteignent le bout du museau, lorsqu'elles sont rabattues en avant; elles sont peu acuminées; l'antitragus est séparé du pavillon par une encoche à angle droit ou un peu obtus; le bord externe est sinueux, un peu concave avant le sommet; le bord interne est convexe dans la partie basale, droit au sommet. La feuille nasale est large et recouvre tout le museau; le fer à cheval est fortement échancré au milieu et un peu festonné sur les bords; l'échancrure n'est pas accompagnée, de chaque côté, d'une petite dent, comme PETERS (1867) l'indique pour *R. deckeni*. La selle est large (3,2 mm) et son processus vertical (dossier) étranglé au milieu, il mesure 1,9 mm de large au sommet. La pointe du connectif est très basse et largement arrondie. La lancette est en forme de triangle équilatéral; ses côtés sont droits, à peine concaves vers le sommet. Il y a un seul sillon au milieu de la lèvre inférieure. Le patagium s'insère à la cheville. Le troisième métacarpe est réduit, c'est-à-dire qu'il mesure moins des 90 % du cinquième métacarpe, exactement dans les mêmes proportions que chez *R. deckeni*. Les deuxième phalanges du troisième et du quatrième doigt sont relativement courtes: elles mesurent respectivement moins du double des premières phalanges. La queue est assez longue et mesure plus de la moitié de la longueur de l'avant-bras.

La coloration est tout à fait semblable à celle de *R. ferrumequinum* (Schreber).

Le crâne présente un renflement nasal bien prononcé. Les palatins s'arrêtent, en avant, au niveau de la moitié antérieure de M^1. La première prémolaire supérieure (P^2) est très réduite et externe; la canine et la seconde prémolaire (P^4) sont presque en contact. La réduction de P^2 est toutefois moins accentuée que chez *R. fumigatus* et semble du même ordre que chez *R. deckeni*. A la mandibule, la première prémolaire (P_2) est très basse, bien que de section appréciable; elle n'atteint pas la

moitié de la hauteur de la troisième prémolaire (P_4). La seconde

p. 231

prémolaire (P_3) est tout à fait rudimentaire, non fonctionnelle et externe; P_2 et P_4 sont en contact.

Remarques. - Il n'est pas étonnant que cette espèce ait été confondue par SANBORN avec *R. fumigatus*. Elle lui ressemble beaucoup, du moins superficiellement: la feuille nasale et les caractères dentaires sont très semblables. Cependant, on peut relever les différences essentielles suivantes:

	R. silvestris	*R. fumigatus*
Longueur de l'avant-bras:	environ 50 mm,	51 à 56 mm
Longueur du 3e doigt:	76,5 à 80 mm,	82,2 à 96 mm
Longueur du 3e métacarpe par rapport au 5e:	inférieur à 90 %,	supérieur à 90 %
Longueur de la queue:	super, à la moitié de l'avant-bras,	infér. À la moitié de l'avant-bras
3e doigt, 1re phalange:	super, à la moitié de la 2e phal.,	infér. À la moitié de la 2e phal.
4e doigt, 1re phalange:	super, à la moitié de la 2e phal.,	infér. À la moitié de la 2e phal.

D'autre part, les proportions du crâne ne sont pas les mêmes. Le crâne de *R. silvestris*, qui est plus court que celui de *R. fumigatus*, présente une série dentaire C-M^3 plus longue et une largeur maxillaire M^3-M^3 plus large. P^2 est moins rudimentaire, semble-t-il, chez *silvestris* que chez *fumigatus*.

La répartition géographique actuellement connue de *Rhinolophus f. fumigatus* Rüppell comprend l'Erythrée, l'Ethiopie, le Soudan[1], les Somalies anglaise et italienne, le Kenya, le Tanganyika[2], la Rhodésie du Nord. D iverses formes ont été rapportées à *R. fumigatus*, en tant que sous-espèces ou synonymes:

aethiops Peters, 1869. Loc. Typ.: SW Africain.
= *R. f. aethiops*, sec. ELLERMAN, MORRISON-SCOTT et HAYMAN (1953).

macrocephalus Heuglin, 1877. Loc. Typ.: Ethiopie.
= *R. f. fumigatus*, sec. ANDERSEN (*Ann. Mag. Nat. Hist.* (7) 14: 453, 1904).

p. 232

antinorii Dobson, 1885. Loc. Typ.: Ethiopie.
= *R. f. fumigatus*, sec. ANDERSEN (*Ann. Mag. Nat. Hist.* (7) 14: 453, 1904).

exsul Andersen, 1905. Loc. Typ.: Kenya.
= *R. f. exsul*, sec. ANDERSEN (Ann. Mag. Nat. Hist. (7) 15: 74, 1905).

eloquens Andersen, 1905. Loc. Typ.: Ouganda.
= *R. aethiops eloquens*, sec. SANBORN (*Zool. Ser. Field Mus. Chicago* 24: 42, 1939).
= *R. f. eloquens*, sec. ELLERMAN, MORRISON-SCOTT et HAYMAN (1953).

Il y aura lieu, certainement, d'assimiler encore les formes suivantes à *Rhinolophus fumigatus*:

foxi Thomas, 1913. Loc. Typ.: N Nigeria.
abae J. A. Allen, 1917. Loc. Typ.: Uelé, Congo belge.
perauritus de Beaux, 1922. Loc. Typ.: Somalie.
diversus Sanborn, 1939. Loc. Typ.: Sénégal.

Rhinolophus silvestris a, comme plus proche parent, non pas *R. fumigatus*, mais *R. deckeni* Peters (1867). Ce dernier n'est malheureusement pas bien connu. La localité typique est la côte NE du Tanganyika, face à l'île de Zanzibar; la description de PETERS est assez sommaire et seules les mensurations externes sont données. DOBSON (1878) rapporte *R. deckeni* à *R. ferrumequinum* (Schreber). THOMAS, en 1910, cite *R. deckeni* à Rombo (Tanganyika), mais quelques années plus tard, il précise que la détermination est erronée et qu'il s'agit de *R. augur zambesiensis*. Par contre, dans le même travail, THOMAS (1913) dit que le British Muséum possède un bon exemplaire de *R. deckeni*, provenant du Kenya (près de Mombasa); il en donne même une mesure crânienne; il le compare à sa nouvelle espèce, *R. foxi*, en précisant que ce dernier est "evidently a western représentative of *R. deckeni*". On a vu, plus haut, que je rattache *R. foxi* à *fumigatus*. Ceci montre bien l'étroite ressemblance de ces formes. Enfin, *R. deckeni* a été récemment signalé à Kisolo, en Ouganda[3]. En résumé, on ne connaît de

p. 233

la répartition géographique de *R. deckeni* que trois localités de l'Afrique orientale: côte du Tanganyika opposée à Zanzibar, près de Mombasa (Kenya) et Kisolo (Ouganda).

D'après les mesures publiées, *R. deckeni* est une espèce nettement plus grande que *R. silvestris* (cf. table des mensura-

p. 234

tions), mais en présentant tous les caractères essentiels, aussi bien externes que dentaires, pour autant que permettent d'en juger la description originale et les précisions de THOMAS (1913). Nous pouvons reprendre l'expression de ce dernire, à propos de *R. foxi*, en la modifiant ainsi: *R. silvestris* est très probablement le représentant forestier de *R. deckeni*, auquel il sera peut-être possible de le rattacher comme sous-espèce, lorsque l'on connaîtra mieux ce dernier.

Rhinolophus silvestris semble localisé au Gabon. Les régions forestières, assez bien prospectées du S du Cameroun et du bassin du Congo, n'ont fourni aucun Rhinolophe référable à la nouvelle espèce.

Dans le tableau de mesures ci-dessous, j'ai indiqué celles données par SANBORN (1953) pour son "*R. f. fumigatus*" du Gabon; on peut constater qu'elles sont presque identiques à celles du type de *silvestris*. A titre de comparaison, j'ai mis en parallèle les mesures de *R. deckeni*, selon PETERS (1867) et THOMAS (1913) et celles de *R. f. fumigatus* trouvées dans la littérature.

p. 235

Rhinolophus simulator K. Andersen, 1904

p. 384

Short diagnosis. - Small upper premolar separating the canine and posterior premolar. In outer aspect somewhat like a peculiarly small and long-tailed *Rh. capensis*. Forearm 43.5-45 mm.

Nose-leaves. - Horseshoe as in *Rh. capensis*; underlying leaf distinct, under the margin of the horseshoe. Sella longer (higher) and slightly broader than in *Rh. capensis*; constriction below the middle very shallow; lateral margins subparallel in their upper half; summit broadly rounded off; width at summit equal to half the vertical height of sella.

* I am very glad to see these facts in perfect accordance with the zoogeographicial subdivision of this part of S. Africa as proposed, five years ago, by Professor Matschie in his admirable book 'Die Megachiropteren des Berliner Museum für Naturkunde' (Berlin, 1899, p. 40).

p. 385

[table removed - eds.]

p. 386

Posterior connecting-process very short, rounded off above, scarcely projecting beyond the summit of sella (this kept in vertical position). Margins of lancet abruptly narrowed; tip of lancet behind constriction with slightly converging (nearly parallel) margins, about 2 mm. in length.

Ears. - Large; reaching far beyond the tip of the muzzle, when placed along the sides of the head. Tip of ears obtusely pointed, as in *Rh. capensis*. Outer margin strongly concave below tip. Notch on outer margin shallow, obtuse. Extreme width of ear somewhat greater than the distance from notch to tip.

Wings. - General form as in *Rh. capensis*, but all dimensions markedly smaller. 4th metacarpal slightly longer than 5th. In the folded wing the tip of the 1st joint of 4th finger reaches very nearly the posterior point of the elbow; tip of 1st joints of 3rd and 5th fingers slightly beyond. Plagiopatagium inserted at basal [corrected on paper in tarsal - eds.] joint.

Tail. - Considerably longer than in *Rh. capensis*, uropatagium therefore much broader. Hinder margin of uropatagium, between tips of calcars, square (concave in *Rh. capensis*) on account of the shorter tail). Tip of tail projecting about 1 mm.

Colour (1 skin). - Exactly as in Rh. augur. Length of hairs on middle of back about 8 mm. Young individuals (1 skin) considerably duller than adult ones; details exactly as in *Rh. augur*, juv.

Skull. - Very different from that of *Rh. capensis*: - Much smaller. Nasal swellings unusually prominent; nasal region deeply hollowed out behind swellings; for both these reasons the facial portion of the skull, from the swellings to crista sagittalis, more concave than in *Rh. capensis*. Palatal bridge much broader: median anterior point opposite front of m^1, in *Rh. capensis* opposite middle of the same molar.

Dentition. - Widely different from that of *Rh. capensis*: - Distance between tips of upper canines 3.8 mm., in *Rh. capensis* 5 mm. Upper canine and p^4 distinctly separated from each other, also internally; distance between tips of these teeth 2.1 mm.; in *Rh. capensis*, although the skull is much larger, 1.9 mm. Upper p^2 placed in the tooth-row, with a minute cusp distinctly projecting above the cingulum of canine. Highest cusp of p^4 somewhat more than half the height of canine. Inner lobes of molars less developed than in *Rh. capensis*: m^2 as long as broad, in *Rh. capensis* decidedly broader than long. Right p_3 extremely minute, in the outer angle formed by the cingula of p_2 and p_4;

p. 387

cingula of these latter in immediate contact internally; left p_3 wanting, without any trace of the alveolus.

Type. - M ad. (in alcohol). Mazoe, Mashonaland, collected by J. ff. Darling, Esq. B.M. no. 2.2.7.10.

Distribution. - Besides the type specimen I have seen only two skins, from the same locality and the same collector.

Remarks. - Owing to our still very defective knowledge of the Ethiopian *Rhinolophi*, the true affinities of this interesting species are somewhat obscure. I have compared it with *Rh. capensis*, only because it, by quite superficial inspection, could be taken for a curiously small and long-tailed form of that species. The totally different skull and dentition prove that it, in fact, has nothing to do with *Rh. capensis*, but, most probably, is to be regarded as an aberrant member of the *Rh. Landeri* group. It cannot be confounded with any other species; *Rh. Landeri, lobatus*, and *Denti* may, apart from many other differences, at once be distinguished by their very narrow sella.

Measurements.
M ad, type; M ad, typical locality
Nose-leaves: mm. mm.
Front of horseshoe to posterior point of lancet: 13.7; -
Extreme width of horseshoe: 8.3; -
Width of sella at base: 2.4; -
" " summit: 2.2; -
Ears:
Base of inner margin to tip: 20; -
Notch on outer margin to tip: 13.2; -
Extreme width: 14.5; -
Wings:
Forearm: 43.5; 45
3rd finger, metacarpal: 30; 30.8
" 1st joint: 13.6; 14.5
" 2nd joint: 22.9; 22.8
4th finger, metacarpal: 33.2; 34
" 1st joint: 8.1; 8
" 2nd joint: 14.8; 13
5th finger, metacarpal: 32.2; 33.3
" 1st joint: 10.7; 10.5
" 2nd joint: 12.5; 12
Tail, from anus: 25.7; -
Tibia: 19.2; -
Skull:
Basal length: -; 15.1
Extreme width of brain-case: -; 9.1
Zygomatic width: -; 9
Maxillar width across outer margins of m^3: -; 6.2

p. 388

Skull (con.):
Orbital constriction: -; 2.4
Palatal bridge: -; 2.7
Med. post, point of palate to front of premaxilla: -; 6
Med. post, point of palate to for. magnum: -; 9.1

Front of upper canine to back of m^3: -; 7
Front of lower canine to back of m^3: -; 7.5

Rhinolophus swinnyi Gough, 1908

p. 71

Two skins of an apparently new species of *Rhinolophus* were found in a small collection of skins prepared by Mr. H. H. Swinny, Ngqeleni, District W. Pondoland, which I propose to describe under the name.

Rhinolophus swinnyi, n. sp.

Size very small, not as large as the smallest yet known South African species of the genus.

Posterior upper praemolar separated from the canine, which is very large, anterior praemolar very small, in the tooth row, towards its outer side.

[Fig 1 & 2 - removed]

Horizontal portion of sella narrow, upper margin of the posterior connecting process rising above the sella, forming a marked projection, rounded terminally; sides of the vertical process of the sella parallel above, summit truncated with rounded off sides. Antitragal notch very shallow.

Horse shoe large, circular, its anterior margin notched in the centre; lancet moderate, its sides strongly concave, covered posteriorly with fur similar to that on the rest of the head, anteriorly somewhat less dense. Ears of medium size, the under edge convex in the distal half, then concave, convex again proximally, the concave portion very short. Tip sharply pointed, upper half of the outer margin concave,

p. 72

antitragal notch very shallow, lobe strongly convex. Hind limbs slender. Wings from the ankle. Interfemoral membrane finely finged posteriorly.

Fur close and fine, about 7 mm. long on the back. General colour mouse grey, lighter below, individual hairs ash grey with brown tips. Membranes dark brown or black, interfemoral membrane with a fringe of grayish hairs.

Dimensions of Type

Forearm, 40 mm.; "head and body, 42 mm.;" "tail, 18 mm.;" "ear, 18 mm.;" noseleaf, 10.5 by 6.5; lower leg and foot, 25 mm.; "foot, 8 mm."

The measurements in inverted commas were taken in the flesh by the collector.

Skull : Greatest length, 17 mm.; basal length to front of canines, 14.2 mm.; breadth of braincase, 6 mm.; front of upper canine to back of m^3, 6.4 mm.; front of lower canine to back of m^3, 6.8 mm.; from palatial notch to front of incisors, 5.8 mm.; width from the outside of m_3, 6.5. Length of free portion of canine, 2.5 mm.

Type, adult male (dried skin), in the Transvaal Museum.
The co-type, also a male, is slightly larger; forearm, 40.7; "head and body, 42 mm.;" "tail, 19 mm.;" "hindfoot, 8 mm.;" "ear, 18 mm."

Rhinolophus swinnyi rhodesiae Roberts, 1946

p. 304

Structurally similar to *R. swinnyi swinnyi* Gough, from Port St Johns, Pondoland, in respect of the flying integument starting from near the ankles and in its small size; but the tail a little longer, ear shorter and in colour bright ochraceous orange, the upper parts of body darker than the lower on account of the presence of dark-tipped hairs; the skull is slightly smaller than in the typical subspecies.

It has been previously recorded as *R. denti* (*Ann. Transv. Mus.* IV, 180; 1914).

Measurements of the type, and, in brackets for comparison, of eight specimens of *R. swinnyi swinnyi*: Head and body 52 (42 - 45); tail 22 (18 - 19); ear 15 (16 - 18). Forearm 40 (40 - 42); 3rd finger metacarpal 28.3 (27.9 - 29); 1st phalanx 12.5 (13 - 13.5); 2nd phalanx 22 (23 - 24); 4th finger metacarpal 31.5 (30.5 - 32.3). Tibia and foot (c.u.) 24 (25 - 25.5). Skull, greatest length from canines 17 (17.2 - 17.6); dorsal median length 14.7 (14.5 - 15); zygomatic width 8.3 (8.6 - 8.9); width of brain case at mastoid 8.5 (8.5 - 8.9); width across m^3 6.3 (6.2 - 6.4), across canines 4.2 (4.1 - 4.4)•

Type: T.M. No. 1325, adult F, Bezwe River, tributary of Wanetsi River, Southern Rhodesia.

Rhinolophus tridens E. Geoffroy Saint-Hilaire, 1813

p. 260

J'ai donné le nom de *trident* à ce rhinolophe, en l'empruntant de sa feuille qui est terminée par trois pointes bien distinctes; le fer à cheval; ou cette membrane située au-devant des narines, existe dans cette espèce, et dans les autres rhinolophes, tout comme dans les précédens: mais la feuille offre bien moins de complication: ce n'est qu'une lame formant bourrelet à sa base par l'effet d'un repli, et dont la partie moyenne, en-vertu de la même cause, fait corps avancé sur les bords latéraux placés plus en arrière.

Les oreilles sont plus larges que dans les précedens rhinolophes et en même temps moins fermées sur le devant: ce qui tient à une bride tégumentaire qui les attache en partie au chanfrein.

La queue est fort courte et, de plus, remarquable en ce qu'elle est dans un tiers de sa longueur, libre au-delà de la membrane interfémorale; celle-ci est coupée carrément et supplée à ce qui lui manque en longueur par plus de largeur

p. 261

Les principales dimensions du rhinolophe trident sont les suivantes.

Longueur du corps 0^m,055; - de la queue 0^m,024; - de l'envergure 0,240; - de la membrane interfémorale 0,006; - largeur de celle membrane 0,060.

J'ai trouvé ce rhinolophe en Egypte, et je l'ai figuré dans le grand Ouvrage sur l'Egypte; art. des Mammifères, pl. 2, n°. I.

Rhinopoma cystops Thomas, 1903

p. 496

Size comparatively small (forearm averaging about 52 millim., and rarely attaining 55). Nose-leaf more developed than in *R. microphyllum*. Ears proportionally large, the frontal band joining them particularly high. Tail very long and slender, longer than the forearm.

p. 497

Skull small, narrow and delicate (greatest length 16 - 17 millim., as compared with 19 - 20 in *R. microphyllum*); muzzle with two inflated projections, one on each side of and above the nasal opening, with a longitudinal groove between them. In *R. microphyllum* this region is almost flat, and its angles, although thickened, are not conspicuously inflated. Sagittal crest but little developed, not connected anteriorly with the nasal projections.

Dimensions of the type (an adult female, measured in spirit before skinning): -

Forearm 53 millim.

Head and body 53; tail 59; hind foot (s. u.) 11.5; ear 17.

Skull: greatest length 16.7; basal length 14; occipito-nasal length 14.5; zygomatic breadth 10; breadth of brain-case 7.2; front of canine to back of m^3 5.6.

Hab. (of type). Luxor, Lower Egypt. Other specimens from many Egyptian localities, southwards to Gebel Auli, Soudan (*H. F. Witherby*). Examples from Palestine (*Tristram*), Midian (*Burton*), and Aden (*Percival & Dodson*) are also assignable to *R. cystops*.

Type. Adult female. B.M. no. 2.1.17.2. Collected and presented by the Hon. N. Charles Rothschild.

Not only, however, are these two Egyptian species distinct from each other, but the members of the genus elsewhere appear to fall into two groups corresponding to them both in external proportions and in the characters of the skull.

To the first or *microphyllum* group, besides the type species, whose range extends from Egypt and Palestine (*Tristram*) to Persia (*Witherly*), there belongs the large form described below as *R. sumatræ*.

To the second, besides *cystops* itself, the species recognizable are *Hardwickei* from India and *muscatellum* from Muscat.

Apart from the differences in size and length of tail that separate the two groups, the species are very like each other externally; but the skull-characters are in all cases most obvious, and leave no room for doubt as to the distinctness of the various forms.

Rhinopoma hardwickei sennaariense Kock, 1969

p. 40

... Nach freundlicher Mitteilung von Dr. K. F. KOOPMAN existiert der Typus zu *sennaariense* FITZINGER (nec emendatio HEUGLIN 1877) im Mus. Wien und ist nach seiner Untersuchung eindeutig hardwickei zugehörig: dieser Name wird damit zum ältesten für eine Population verfügbaren. Da der geographische Begriff Sennar sehr verschieden Landschaft oder Provinz verstanden und gebraucht wurde, deren Grenzen Geschichte wechselten, beschränke ich den Fundort des Typus ausnahmsweise zweite Herkunftsangabe FITZINGER'S, Unter Fazogli wurde zwar ebenfalls Distrikt verstanden, der jedoch bedeutend geringere Ausdehnung als „Sennar" Ortschaft Fazogli (heute Fazughli) liegt am linken Ufer des oberen Blauen Nim am Fuß des gleichnamigen Berges.

Rhinopoma Lepsianum Peters, 1859

p. 222

Rhinopoma Lepsianum n. sp.; supra dilute cinnamomeum, subtus flavidum; cranium regione interorbitali cordiformi, concava, intumescentiis anteorbitalibus nullis.

Long, a rostri apice ad caudae basin 0,076; caudae 0,066; cap. 0,026; antibr. 0,070; crur. 0,026; exp. alar, 0,360.

Diese Art, welche von Hrn. Lepsius am blauen Nil entdeckt wurde, ist nicht allein durch viel beträchtlichere Grösse und andere Färbung, sondern auch durch eine andere Gestalt des Schädels von *Rh. Microphyllum* verschieden. Bei letzterer ist der Schädel jederseits vor und über den Augenhöhlen durch eine bereits von Geoffroy beschriebene blasige Auftreibung aus-

p. 223

gezeichnet, welche bei dieser neuen Art ganz fehlt. Auch ist das Foramem infraorbitale bei dieser letzteren viel grösser und von länglicher Gestalt.

Rhinopoma microphyllum tropicalis Kock, 1969

p. 58

Typus: Jebel Talao, 2 km NE von Kadugli (Kordofan), 550m, 12.11.1963; M jung ad. (Balg, Schädel und Skelett): SMF 33265.

Paratypoide: Fundort wie Typus, 13.X.1962, 12.11.1963, 6.1.1965; 4 M, 1 F, alle ad. (2 Bälge und Schädel mit Skeletten, 3 in alc., Schädel herauspräpariert): SMF 33198-33200, 33214-33215.

Körpermaße des Typus: KR 79, Schw 73.2, Ohr 22.9, Hf 15.8, Tb 30.0, Ua 71.5, 2.F 82.5, 5.F 67.3, Spw 409.

Schädelmaße des Typus: Crn 21.0, Cbl 19.4, Mast 10.5, Hk 9.6, Zyg 12.7, c-c^1 5.4; M-M^3 9.6, C-M^3 7.2, lor 2.6, Ukf 15.4, C-M_3 8.1.

Körpermaße der Typeserie: KR 79 - 86 (M 81.2), Schw 64.9 - 74.5 (M 72.3), Ohr 21.1 - 22.9 (M 22.1), Hf 15.5 - 16.4 (M 15.9), Tb 20 - 30 (M 28.9), Ua 70.2 - 74.0 (M 72.5), 3.F 76.° - 84.8 (M 80.9), 5.F 66.4 - 71.3 (M 68.7), Spw 404 - 422 (M 412).

Schädelmaße der Typenserie in Tabelle 9.

Diabnose: Die neue Unterart *tropicalis* unterscheidet sich von *R. m. microphyllum* aus Unter-Ägypten durch bedeutendere Größe un allen Körper-

p. 59

und Schädeldimensionen. Der Schwanz ist relativ länger, in den meisten Fällen länger als der Unterarm. Die Größe der Hinterfüße ist übereinstimmend. Die Mesopterygoid-Gruben sind breit u-förmig. - Trotz des Geschlechtsdimorphismus ist das einzige Weibchen größer als männliche Stücke anderer Populationen. Die Färbung (SETZER 1952, HARRISON 1964a) ist nicht grau, sondern bräunlich, Unterseiten nicht weißlich, sondern heller braun.

Die Unterart *sumatrae* kommt *tropicalis* in der Größe am nächsten, ist jedoch im Mittel kleiner mit relativ kürzerem Schwanz und dunkler brauner Färbung; die Mesopterygoid-Grube ist spitz v-förmig.

Die Unterart *kinneari* ist in der Färbung am ähnlichsten, doch durch alle übrigen genannten Merkmale unterschieden, also ebenfalls durchschnittlich kleiner mit einer mehr v-förmigen Mesopterygoid-Grube.

tropicalis ist von allen bisher gefundenen Unterarten von *Rhinopoma microphyllum* geographisch getrennt. Das von ROSEVEAR (1965) aus Nigeria beschriebene Exemplar rechne ich ebenfalls zu *tropicalis*.

THOMAS (1903b) scheint keine *Rhinopoma microyphyllum* aus dem Sudan untersucht zu haben, da sich bei ihm nur die "Egyptian Pyramids" als einziger afrikanischer Fundort finden, was umso überraschender ist, da gerade im Brit. Mus. ein *microphyllum*-Exemplar vom Jebel Aulia (leg. WITHERBY 1900) aufbewahrt wird (HARRISON in litt.). - Meine Nachforschungen ergaben weitere Stücke von *microphyllum* aus Kordofan (im BM, HARRISON in litt.), worauf sich wahrscheinlich schon DOBSON (1878) bezieht, vom Jebel Azraq bei Omdurman (Coll. HARRISON) und aus dem Gebiet 10 miles N von Khartoum (HAPPOLD in litt., 1967). Dieses bisher bekannte Material ist insgesamt zur Unterart *tropicalis* zu rechnen.

Aus Sennar meldet AELLEN (1957) ebenfalls *microphyllum* (leg. 1846) (Anm. Verf.: ? evtl. von KOTSCHY). Die Identität dieses Einzelstückes bedurfte einer Überprüfung. Dr. AELLEN ,(Genf) teilte mir freundlicherweise einige Maße mit (Ua gebrochen, jedoch über 63, 3.F 83.5, 4.F 70, 5.F 69, Schw 60) und machte mir die Angabe, daß er dieses Stück nach WROUGHTON (1912a) determiniert habe. Auf Grund der bereits geschilderten Variationsbreite und der teilweisen Unsicherheit von WROUGHTON's Auffassungen war es bisher nur vermutlich als *microphyllum* anzusehen. Die angegebenen Längen der Finger sind nahezu identisch mit den Mittelwerten des vorliegenden Sudan-Materials und bestätigen die Zuordnung.

Rhinopterus Miller, 1906

p. 85

Rhinopterus gen. nov. (Vespertilionidæ).

Type. Glauconycteris floweri de Winton.

Characters. Externally like a small *Vespertilio*, but upper surface of forearm, tail, and tibia thickly sprinkled with pointed, horny excrescences resembling those on edge of ear in some *Molossidæ*, but larger. Skull differing from that of *Vespertilio* in the much greater relative breadth of anterior portion of braincase, shorter, lower rostrum, and in the form of the upper toothrows, which are more concave on inner side and more convergent anteriorly.

Species. Rhinopterus floweri (de Winton).

Rhinopterus lowei Thomas, 1915

p. 559

Larger than *R. floweri*; white instead of buffy below. General characters as in *R. floweri*, but size, as gauged by

p. 560

skull, distinctly larger. Colour apparently, judged by spirit-specimens, very much as in *R. floweri* above, but the whole under surface is entirely white, while in the type of *R. floweri* it is buffy, "light buff" posteriorly, and "warm buff" on the throat ahd chest.

Skull much larger than in *R. floweri*, the muzzle less shortened in proportion to the brain-case.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 40 mm.

Head and body 45; tail 36; ear 12.5; third finger, metacarpal 36.5, first phalanx 11.5; lower leg and hind foot (c.u.) 12.

Skull: greatest length 13.5; condyle to front of canine 12.9; zygomatic breadt 9; interorbital breadth 4.6; intertemporal breadth 3.2; palato-sinual length 5.3; front of canine to back of m^3 5.

Hab. Sudan. Type from the Blue Nile, 20 miles above Sennar.

Type. Adult male. B.M. no. 15.3.6.70. Collected 13th December, 1913, by Willoughby P. Lowe.

Mr. Willoughby Lowe obtained five specimens of *Rhinopterus* at different localities on the Blue and White Nile. On examination of the skulls these prove all to belong to a larger form of the genus than *R. floweri*, living side by side with the latter in the same area - a phenomenon not unusual with the smaller bats. The *Rhinopterus* obtained by Dr. A. F. Wollaston at shendi, and referred to in Anderson and de Winton's 'Mammals of Egypt,' also belongs to this larger form. Whether the difference in the colour of the under surface is constant remains to be seen.

Rousettus aegyptiacus thomensis Feiler, Haft and Widmann, 1993

p. 22

Holotypus: MTD, B 16753, M, São Tome, bei Generosa, ca. 800 m ü. NN, 26.3.1991, Balg und Schädel.

p. 23

Paratypen: M, São Tome, bei Generosa, ca. 800 m ü. NN, MTD, B 16750, 27.3.1991, B 16751, 28.3.1991, Balg und Schädel; Staatl. Museum für Naturkunde Stuttgart, 8 1803, 1989, in Alkohol. F, Sao Tome, bei Generosa, ca. 800 m ü. NN, MTD, B 16752, 20.4.1991, B 16754, 19.4.1991, Balg und Schädel, B 1675.5, 26.3.1991, in Alkohol.

Diagnose: Die Tiere von São Tome besitzen eine extrem dunkle Oberkopffärbung, die sie von den Tieren des nahen westafrikanischen Festlandes unterscheiden. Morphometrisch gleichen sich beide Formen nahezu, wie ein Vergleich mit EISENTRAUT (1963) und seinem Material ergab. - Bemerkenswert ist das Vorkommen einer eigenen Fledermausfliegenart (*Eucampsipoda iterfacta* KOCK, 1993).

Das Gaumenfaltenmuster für die Exemplare von São Tome stimmt mit jenen des Festlandes überein (EISENTRAUT, 1976). Von uns untersuchte 4 MM und 4 FF hatten vom je 4 durchgehende Falten, gefolgt von je 4 unterbrochenen Falten mit Ausnahme eines M, das nur 3 unterbrochene Falten besaß. Die letzte, das Muster abschließende Falte war immer durchgehend. Die Formel lautet folglich: 4 - 4/3 - 1. Interessanterweise hatte EISENTRAUT (1963), wie wir auch, bei annähernd gleich vielen Exemplaren eine Farbmutante dabei: ein extrem helles und rotbraunes Tier. - Da Gewichtsangaben bei anderen Autoren meistens fehlen, teilen wir die folgenden für unser Material mit: 8 MM, 130 - 170 g, Mittelwert 153 g; 3 FF, 130 - 145 g, Mittelwert 135 g.

Nach einem Nachweis der Art (FEILER, 1984) schlossen sich weitere 1989 durch J. HAFT und J. FAHR und später 1991 durch alle Teilnehmer unserer São Tome-Reise an. Sie ist von der Küste bis in die Berge hinein verbreitet, nur auf der Spitze des Pico de São Tome haben wir sie nicht beobachtet. In der Bucht von Angra Toldo befindet sich ein *Rousettus*-Quartier. Die Höhle ist von See aus gut zu sehen und nur schwer zugänglich. Es ist eine Meeresgrotte, die am Wasserspiegel etwa 1.5 m breit ist und bis in eine Höhe von 7 bis 8 m reicht, wo sie spitz ausläuft.

R. aegyptiacus thomensis war des Nachts sowohl durch seine klickemden Ultraschall-Laute als auch durch kreischende Soziallaute auszumachen. Große Mengen von Höhlenflughunden fanden sich allabendlich in fruchtenden Brotfruchtbäumen nahe der Hauptstadt ein. In Gefangenschaft bevorzugten die Tiere Nektarersatz als Nahrung. Die bevorzugten Fruchte sind hier Mango und noch leicht grüne Bananen. In Mägen freilebender Tiere fanden wir Samen, die wahrscheinlich von *Musanga* spec. stammten. Die Flughunde nahmen auf São Tome auch im Lager herumliegende Papayas und Bananen auf.

Nach HAFT fingen sich die 1991 gefangenen Tiere (32 Ex.) an zwei verschiedenen Fangorten und bei annähernd gleichem Wetter zu unterschiedlicher Zeit: in São Nicolau ausschließlich vor 0 Uhr, meist zwischen 20 und 22 Uhr, in Cascata verstreut über die Nacht, viele jedoch erst gegen Morgen.

Die angesaugten Zitzen mehrerer gefangener Weibchen (26. u. 28.3.) lassen auf Jungtiere schließen. Ein flugfähiges Jungtier wurde im Juni 1983 auf São Tome in einem knapp über dem Boden hängenden Netz gefangen. FAHR hatte in Makokou (Gabun) am 2. und 3. Oktober relativ kleine Jungtiere vorgefunden (Unterarmlänge etwa 80 mm). EISENTRAUT (1963) stellte in Kamerun Ende November ein neugeborenes Jungtier fest, einige Weibchen waren zu dieser Zeit trächtig. Trächtige Weibchen fand er ebenfalls im Januar. Unsere Beobachtungen bestätigen einmal mehr, daß die Art keine eng begrenzte Fortpflanzungszeit hat.

Rousettus angolensis ruwenzorii Eisentraut, 1965

p. 3

Typus: M ad, Ruwenzori East, 5000 ft., März 1906, R. E. Dent leg. (British Museum Natural History, London, Nr. 6.12.4.1.). Kopf-Rumpf = 117, Schwanz = 13.5, Hinterfuß = 17.5, Ohr = 24.5, Unterarm = 76, Tibia = 31; größte Schädellänge = 43.1, Hirnkapselbreite = 16.1, Jochbogenbreite = 25.8, Interorbitalbreite = 6.9, Intertemporalbreite = 8.0, maxillare Zahnreihe = 16.7, Breite über oberen C = 9.0, Breite über oberen M = 13.3, Mandibellänge = 33.5, mandibulare Zahnreihe = 19.,0.

Die Ruwenzori-Rasse, von der ich im Britischen Museum außer dem zum Typus ausgewählten Stück 6 weitere Exemplare (2 MM ad,3 FF ad, 1 F sad), vergleichen konnte, stellt also die größten Vertreter des Rassenkreises. Außerdem zeichnet sie sich durch ihre besondere Langhaarigkeit gegenüber der Nominatrasse aus, wohingegen die mir zur Verfügung

p. 5

stehenden Stücke der Rasse *smithi* von Guinea besonders kurzhaarig sind. Im Durchschnitt beträgt die Länge der Rückenhaare bei *smithi* von Guinea 8 mm, bei *angolensis* von Kamerun 8.5 - 9 mm, bei *angolensis* von Fernando Poo 9 - 10 mm und bei *ruwenzorii* vom Ruwenzori East 11 - 12mm.

In Abb. l kommt die unterschiedliche Schädelgröße der 3 Rassen noch einmal deutlich zum Ausdruck. Ferner ist in Abb. 2 die an dem vorhandenen Material festgestellte Variationsbreite der Korrelation von größter Schädellänge: Jochbogenbreite graphisch wiedergegeben. Diese Darstellung veranschaulicht noch einmal die fortlaufende Größenentwicklung der einzelnen Populationen von West nach Ost.

Entsprechend der Zunahme der Schädelmaße finden wir auch eine Zunahme der Zahngröße. Die durchschnittswerte der Zahnmaße sind in Tabelle 2 zusammengestellt.

[table removed - eds.]

Bezüglich der Färbung des Rückenfells sind die Guinea- und Ruwenzori-Stücke jeweils relativ einheitlich. Erstere sind die hellsten von allen. Ihre Tönung ist mittelbraun und variiert ein wenig von brussels brown bis sudan brown. Die Stücke vom Ruwenzori haben einen tiefen kastanienbraunen Ton, der als brownish olive bis saccardo's umber zu bezeichnen ist. Innerhalb der beiden mir zur Verfügung stehenden sehr großen Serien vom Kamerunberg und von Fernando Poo ist die Variation der Färbung relativ groß und reicht etwa von sudan brown über saccardo's umber bis mummy brown. Ganz allgemein möchte ich jedoch der Färbung keine allzu große Bedeutung für die Rassencharakterisierung bei *R. angolensis* beimessen.

Leider liegen über das Vorkommen des Angola-Flughundes in einigen Teilgebieten innerhalb des Areals bisher offenbar keine oder nur sehr allgemeine Angaben vor, so z. B. für Nigeria, Ghana, Südkamerun und Gabun. Im Kongogebiet scheint die Art nur sehr sporadisch vorzukommen (vgl.

p. 6

u.a. Schouteden 1948; Frechkop 1954). Hier wäre noch zu untersuchen, ob die entsprechenden Stücke zu *angolensis* zu rechnen sind, oder bereits Annäherung an die Ruwenzori-Rasse erkennen lassen. Es ist durchaus möglich, daß ein spärliches Vorkommen oder vollständiges Fehlen in manchen Gegenden mit dem Mangel an geeigneten Biotopen zusammenhängt. Ich selbst kenne die Art aus dem Gebiet des Kamerungebirges und auf Fernando Poo als einen sehr häufigen Vertreter der Megachiropteren und als typischen Felshöhlenbewohner. Demgegenüber finde ich nur einmal, und zwar bei Hayman (1954), die Angabe, daß die von ihm untersuchten Togo-Stücke in hohlen Bäumen gefangen wurden. Da in den von mir besuchten Gebieten Felshöhlenquartiere relativ häufig sind, erklärt sich daraus wohl das beobachtete Massenauftreten. Vielleicht beruht das Fehlen der Art in anderen Gegenden auf dem Mangel an solchen geeigneten Tagesquartieren.

Rousettus kempi Thomas, 1909

p. 543

Allied to, but with heavier teeth than, *R. lanosus*.

External characters as in the Ruwenzori Mountain Fruit-bat, *R. lanosus*, except that the long hairs of the back, rump, and interfemoral region tend to be greyer. Palate-ridges 4 - 3 - 1.

Skull as in *lanosus*, the brain-case equally strongly deflected.

Teeth larger, broader, and heavier throughout, more as in ordinary Rousets, not so highly specialized as in *R. lanosus*. Incisors, canines, and anterior premolars as in *lanosus*. P^4 3 mm. in horizontal length as against 2.4 in *lanosus*; m^1 3.0 x 1.5 (*lanosus* 2.5 x 1.2); m^3 2.8 x 1.5 ; p_4 2.4; m_1 2.9 X 1.4; m_2 1.9 X 1.4.

Forearm of the type 86 mm.

Head and body (measured in flesh) 125 mm.; tail 15; ear 23.

Hab. Kirui, Mt. Elgon, British East Africa. Alt. 6000'.

Type. Subadult male. Rudd Collection. Original number 269. Collected 16th September, 1909.

This is evidently the Elgon representative of the Ruwenzori *A. lanosus*; the Shoa specimen mentioned by Dr. Andersen would appear, as is natural, to be the same as the Elgon rather than the Ruwenzori species.

Rousettus lanosus Thomas, 1906

p. 137

Rousettus lanosus, sp. n.

A member of the *R. collaris* group; the limbs thickly hairy.

Size and general characters about as in *R. collaris*. Fur loose and shaggy, very abundant, its limits not sharply defined as in *R. collaris*; that on the head about 8 mm. in length, mixed with a large number of much longer hairs, attaining over 20 mm. On the back the fur is thick and woolly, passes out on to the proximal half of the upperside of the forearms, and is continued thickly down the hind limbs and the wing-membrane external to them to the ankles, the feet being also thinly clothed above. Interfemoral thickly furry above, except just along its posterior margin. Below, the wings are thinly hairy to a point level with the middle of the forearm, the hind limbs and interfemoral membrane being also less thickly haired than on the upper surface. Ears narrow, rather longer than the muzzle. Palatal ridges as in *R. collaris*.

General colour above bistre-brown, becoming warmer posteriorly; head darker. Under surface near broccoli-brown, but with a yellowish suffusion; some of the longer hairs quite yellow.

Skull rather more delicately built than in *R. collaris*, the bones thinner and lighter, muzzle rather longer and narrower; postorbital processes very thin; anterior palatine opening unusually broad.

Teeth conspicuously smaller throughout, each molar and premolar slightly shorter and very much narrower than in the allied species.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 88 mm.

Head and body 134; tail 16, tail free from membrane 9; head 46; ear 23; third finger, metacarpus 60, first phalanx 41, second phalanx 57; lower leg and foot (c. u.) 62.

Skull: length to tip of nasals 42; basal length 37.5; zygomatic breadth 25; breadth of brain-case 17.4; palate length from anterior palatine foramina 19; breadth of palatine foramina 3.4; length of upper tooth-row from front of canine 14.5; the same below, 16.2; first upper molar 2.3 x 1.2.

Hab. Ruwenzori East, at 13,000'.

Type. Adult male (in spirit). B.M. no. 6.7.1.2. Collected by K. B. Woosnam. Three specimens obtained.

This species is allied to *R. collaris*, but is at once distinguishable from that and every other species by the thick

p. 138

woolly covering of its hind limbs and its remarkably narrow molars.

The occurrence of a fruit-but at such an altitude as 13,000' is very noteworthy.

Rousettus sjöstedti Lönnberg, 1908

p. 7

Usambara: 1 specimen from the Mkulumusi caves near Tanga, $^{4}/_{5}$, 1905.

Resembling *R. anqolensis* (*Bocage*). Fur woolly, greyish brown above, rather pale brownish grey beneath, a little lighter on the neck and this light colour extends up on the sides of the neck so as to form a collar which is narrowed and almost interrupted on the back. Head coloured like back, darker on snout and on both eyelids. Wing-membrane blackish speckled with light spots. Not quite half the forearm is hairy. Tibia naked. On the lower side the forearm is woolly in a similar degree as above but the wing-membrane is sparsely beset with woolly hairs between humerus and forearm and along the outer side of the latter. Tibia almost wholly naked below. Interfemoral membrane above and below with some very few scattered hairs. Wing-membrane rising from back of second toe but at the end curving to the interspace between first and second.

Palatal elevations six in number, three anterior complete, and three posterior mesially interrupted (in addition to these there is a rudiment of a fourth interrupted fold on one side between the last and next last). Behind these there is an angular serrated fold on the back of the palate.

Dimensions of *R. sjöstedti* (in spirit, F); *R. angolensis* (according to BOCAGE) M, F (in mm).
Length of head and body: 125; 120, 140
" " tail: 17; 13, 13
" " head: 43; 45, 48
Distance from eye to nostril: 16; 15, 15
Length of ear: 25; 23, 22
Forearm: 86; 80, 79
Thumb: 34.5; 32, 33
Metacarpus of third finger: 59; 56, 60
First phalanx of third finger: 38 (39); 40, 40
Second " " " " : 53; 50, 53
Metacarpus of fourth " : 57; 53, 56
First phalanx of " " : 32; 26, 26
Second " " " " : 35; 28, 29
Tibia: 35; 32, 33
Hindfoot: 25; 20, 21
Metacarpus of fifth finger: 56; -, -
First phalanx of fifth finger: 28,5; -, -
Second " " " " : 26; -, -

p. 8

Length of skull of *R. sjöstedti* about 40 mm. Frontal region of skull between postorbital processes somewhat convex. Molars not very narrow transversal diameter of first molar 2 mm. and last premolar still thicker.

This new bat is most nearly related to *Rousettus angolensis* (BOCAGE) and differs like that one from *R. leachi* (A. SMITH) = *R. collaris* auct., which lived in the same caves, most conspicuously with regard to the structure of the palate. Unlike *R. leachi*, the new species has only 3 complete palatal elevations and behind those 3 mesially interrupted folds. The presence of only 3 complete palatal elevations was pointed out by BOCAGE as a characteristic for the by him 1898 described species *angolensis*.

MATSCHIE used the same characteristic as well for the definition of his new genus *Myonycteris*, which comprised the species *torquata* and *anqolensis*. The latter has, however, proved to a true *Rousettus* by cranial characteristics. Te same is also the case with the present new species. As a specific characteristic the number of complete palatal elevations serves very well, and by among other characteristics the new species is easily separated from another East African bat *R. lanosus*. From *R. anqolensis* with the same number of complete palatal elevations, *R. sjöstedti* differs in the structure of the palate having only three (instead of four) mesially interrupted posterior palatal folds. This characteristic may, however, be variable as in the type specimen there are rudiments on one side of a fourth divided fold between the second and third. In addition to this there are many differences in dimensions and other exterior characteristics as is proved by the description above. *R. angolensis* is more hairy, for instance, on the tibia and interfemoral membrane. The former is said in *R. angolensis* to be covered "en dessous de poils longs et serrés" --- "jusqu'à l'articulation du pied", --- "en dessous jusqu'au premier tiers de la jambe" and the latter "presque entièrement couverte en dessous de poils aussi long at aussi fournis que ceux du dos", while in *R. sjöstedti* both these parts are practically naked.

The tibia of *R. sjöstedti* is longer than that of *R. angolensis* but shorter than that of *R. lanosus*. The latter is easily recognized by its small molars.

Rousettus smithii Thomas, 1908

p. 375

Most nearly allied to *R. angolensis*, with which it forms a distinct section of the genus, but differing in the following characters: - Size much smaller, the skull also narrower and with less widely expanded zygomata. Fur shorter and more resembling that of ordinary Rousets (that of *R. angolensis* being unusually long and silky), and not extending so far down the hind limbs, the proximal half only of the tibiæ being clothed. Ears narrower. Colour dull brown without rufous suffusion; neck more greyish.

p. 376

Skull more lightly built than in *R. angolensis*, but agreeing with it in all essential respects, such as the very slight deflection of the brain-case, the co-ossification of the premaxillæ, and the swollen supraorbital margins. Teeth of the same squarish form, but smaller throughout, and similar in relative proportions, with the exception that the last molar, both above and below, is very much smaller, about one-third instead of one-half the size of the tooth immediately preceding it.

Dimensions of the type (not fully adult): -

Forearm 70 mm.

Head and body (c.) 112; tail 11; pollex (c. u.) 28.5; third finger, metacarpal 49.5, first phalanx 32.5, second phalanx 41; lower leg and hind foot (c. u.) 46.

Skull: greatest length 38.5; zygomatic breadth 20.5; supraorbital foramina to tip of nasals 18; breadth of braincase 15; front of canine to back of m^3 14.8; p^4 2.3 X 1.8; m^2 1.4 x 1.2; p_4 2.7 x 1.7; m_3 1.3 x 1.1.

Hab. Sierra Leone.

Type. Nearly adult female. B.M. 8.9.11.1. Collected and presented by Canon F.C. Smith.

The many important characters by which *Rousettus angolensis* differs from all other members of the genus have recently been brought out in Dr. K. Andersen's admirable notes on the group, so that no comparison of *R. smithii* with other species is required. From *R. angolensis* it is at once distinguishable by its smaller size (allowing, of course, for the slight immaturity of the type), smaller teeth, and, especially, by its much smaller posterior molars.

I have much pleasure in naming this Rouset after its discoverer, to whom the National Museum is indebted for various acceptable specimens.

Scabrifer notius G.M. Allen, 1908

p. 46

Type. - Adult male, alcoholic, No. 4555, Museum of Comparative Zoölogy; collected at Cape Town, Africa, and received from E. L. Layard.

General Characters. - Size as in *S. floweri* (De Winton), but the fur very dark basally, with light tips. The curious wart-like papillae characteristic of this genus

p. 47

are sparsely scattered on both surfaces of the humerus, the forearm, finger bones, tail, and tibiae.

Description of the Type. - Color of the fur in alcohol dorsally and ventrally nearly mummy brown, lighter, approaching hair brown at the tips. As the type has been immersed in alcohol for many years, it is possible that the fur is still darker in the living animal. The ears and muzzle are pale.

Dorsally the fur covers the body thickly, but is practically absent from the membranes. The bases only of the ears are clothed, and the somewhat swollen muzzle is thinly clad with short minute hairs and sparser longer ones. Ventrally the membranes are likewise naked, save for the proximal half of the tail and interfemoral, which are thinly covered with short hairs.

The ear, laid forward, reaches nearly to the nostril; it is rounded at the inner basal angle, then nearly straight in outline to the broadly rounded tip. Externally there is a slight concavity below the tip, and the lower half is again nearly straight to the basal notch that separates off the low rounded terminal lobe. The tragus is narrow, bluntly pointed, and rather short.

The wing membrane arises from the base of the toes. The calcar is strongly keeled, but without a terminal lobe. The tip of the tail is free for about 2.5 mm. The curious wart-like papillae characteristic of this genus seem much fewer than in *S. floweri* from the Soudan and are practically absent from the membranes, whereas in the latter species the upper side of the forearms, legs, and tail, and all the proximal portion of the wings and interfemoral membrane are thickly studded with them. In the new species there are dorsally some half-dozen papillae on the humerus, a few at the proximal end of the forearm, but a thicker cluster of from 15 to 20 at the distal end of the forearm; a few are also scattered along the metacarpals and phalanges, and on the dorsal surface of the femora, tibiae, and metatarsals, as well as at the region of the joints on the upper side of the tail. Ventrally the distribution of these warts is about the same, but they are more numerous on the humerus and almost wholly lacking on the fingers, tibiae, and tail.

Skull and Teeth. - As stated by Miller, the skull resembles that of a small *Eptesicus*, and is somewhat flattened, with an almost straight dorsal profile. The inner upper incisors are long and slender with a faint indication of a cusp near the tip, laterally. The outer incisor is not quite half the height of the inner, and like that tooth has a strongly developed cingulum that forms a slight cingulum cusp. The outer cusps of the mandibular molars are long and rather slender.

Measurements: - The external measurements of the type are as follows: head and body, 49; tail, 37; ear, 13.5; tragus, 5; forearm, 35; thumb, 5.3; 2d digit, metacarpal, 30.5; 3d digit, metacarpal, 32.3; 1st phalanx, 12.7; 2d phalanx, 9; 3d phalanx and tip, 7; 4th digit, metacarpal, 32.5 ; 1st phalanx, 12; 2d phalanx and tip, 8; 5th digit, metacarpal, 32.5; 1st phalanx, 9.2; 2d phalanx and tip, 5.6; tibia, 12.8; foot, 6.

Skull; greatest length, 14.3; palatal length, 6.6; interorbital constriction, 3.6; mastoid breadth, 8; palatal breadth outside second molar, 5.6; mandible, 10.3; maxillary tooth row (exclusive of incisors), 5; mandibular tooth row (exclusive of incisors), 5.5.

p. 48

Remarks. - *Scabrifer foweri* from the White Nile and Soudan seems to be a pallid species, while the new species here described is dark-furred, with a much less development of the dermal papillae that give an encrusted appearance to those parts where they occur. The two appear not to differ in size.

Scoteinus schlieffeni australis Thomas and Wroughton, 1908

p. 539

M. 1967, 1975, 1993, 2000, 2005, 2007. F. 1995, 2001.

On laying out all the specimens of this species in connection with the identification of the present series, it became evident that there are several well-marked geographical races separable on colour characters.

Typical *S. schlieffeni* was based by Peters on a specimen from Cairo. He described it as "supra rufescens, subtus ex albo rufescens." A second species, *S. minimus*, based on a F from Tanganyika was described by Noack as "oben olivengelbbraun unten weissgelb. Seiten hell umbra ...." Unfortunately we have no undoubted specimen of either of these for comparison, but we consider that we are justified in describing three forms as certainly distinct from either typical *S. schlieffeni* or *S. minimus* (which latter is at most a local race of the former). These are: (1) a pale desert form from the Aden Hinterland; (2) a white-bellied desert form from Upper Egypt; and (3) the present series from S. Africa.

[possibly incomplete - eds.]

Scoteinus schlieffenii fitzsimonsi Roberts, 1932

pg. 17

Differing in coulour from its nearest geographical allies *S. s. australis* Thomas and Wroughton, of the eastern littoral and *S. s. minimus* Noack, of Central Africa in being clay colour above and cinnamon buff to pinkish buff below.

Type : T.M. No. 6550, adult M, Tsotsoroga Pan, Northern Bechuanaland, 19th June, 1930, No. 833. Vernay-Lang Kalahari Expedition. Length of head and body 48, tail 32, hind foot (c.u.) 6, ear 11, forearm 30. Skull : length, canines to occiput, 12.3, zygomatic width 8, width of brain case 6.2, width of palate across outside of m^2 5.5, length of upper tooth-row (c-m^3 4.3 mm.

Scotœcus Thomas, 1901

p. 263

Like *Scotophilus*, but with the following special characters: - The two lower premolars are subequal, instead of the first being far smaller than the second; the upper canines are flattened and grooved anteriorly; the last upper molars have much larger posterior lobes, so that they are triangular instead of equally narrow externally and internally; the talon of the last lower molar is bi- or tricuspidate and practically as large in cross-section as the main part of the tooth; the brain-

p. 264

case is decidedly more flattened and less dome-shaped; and both nasal and anterior palatal notches are much deeper, the latter reaching nearly to the line of the front of $m.^{1}$.

Type *"Scotophilus" albofuscus*, Thos.

In my first description of it *S. albofuscus* was only placed provisionally and with great doubt in *Scotophilus*. Mr. de Winton, in describing *S. hirundo*, expressed his opinion that neither were properly congeneric with the previously described species, and, now that a third member of the group has turned up, I think it advisable to form a special genus for all three. In the characters above noted the three precisely agree, and differ from any of the members of the true *Scotophilus*.

In some respects, perhaps, ***Scotœcus*** is even more nearly allied to the American *Nycticeius*, which shares with it the triangular $m.^{3}$ and more complicated $m._{3}$, but still has, like *Scotophilus*, the marked disproportion between the sizes of the two lower premolars, the canines rounded in front, and the comparatively shallow nasal and prepalatal notches

---

Scotœcus albigula Thomas, 1909

p. 544

Closely allied to *S. hindei*, Thos. (locality Kitui, Ukamba), but the whole under surface nearly uniform whitish, the bases of the hairs only faintly greyer (browner on the lower abdomen), the whitish underside of neck in particular contrasting markedly with the brown upperside. Fur a little softer and more woolly, as is natural at the higher elevation. A band of fine whitish hairs along the membrane just external to the forearm, this part being quite naked in *S. hindei*.

Skull slightly longer than that of *hindei* and its palate rather broader. A minute p^{1} present on each side in, or close behind, a deep notch in the cingulum of the canine. No such tooth is present in the type of *S. hindei*, but it occurs in the specimen from Nyasaland mentioned by Mr. Wroughton in 1907.

Dimensions of type (the starred measurements taken in the flesh): -

Forearm 38 mm.

Head and body * 58; tail * 35; ear * 13; third finger, metacarpal 36.5, 1st phalanx 12.5; lower leg and hind foot (c. u.) 20.

Skull: condylo-basal length 14.5; basi-siuual length 11; front of canine to back of m^{3} 6; breadth across palate outside molars 7.8.

Hab. Kirui, Mt. Elgon, Brit. E. Africa. Alt. 6000'.

Type Adult male. Rudd Collection. Original number 200. Collected 5th September, 1909, by R. Kemp.

Scotoecus artinii de Beaux, 1923

p. 98

(N. 1443). Tipo 1 F, a secco, cranio estratto, danneggiato *dopo* la misurazione. Paratipi 1 M, 1 F, in alc., crani non estraibili.

Archers Post, 26 12.1919. L. FRANCHETTI et L. TONKER.

Dedico la presente specie al chiarissimo Prof. E. Artini, Direttore del Museo civico di Storia Naturale di Milano.

p. 99

Il reivestimento peloso ha brillantezza sericea. La colorazione d'insieme delle parti dorsali varia secondo i soggetti dal brune cuoio nel Tipo (snuff brown, Ridgw. XXIX) al bruno oliva nel % (olive brown, XL), ed i singoli peli mostratno l'apice decisamente più chiaro. Le parti ventrali si avvicinano alla colorazione dello S. albigula, Thos. (Ann. M. Nat. Hist. IV, 1919, p. 544): la gola è bianca, il torace è superficialmente quasi peli brunastra (wood brown, XL); sull'addome il colore bruno aumenta quantitativamente. Il muso è bruno o bruno nerastro secondo i soggetti. Il mento è nerastro o porta almeno una larga macchia nerastra, diffusa, marginale mediana.

Il patagio è bruno nerastro, sottilmente marginato di chiaro e mostra sulla superficie ventral lungo l'avambraccio dei minutissimi peluzzi chiari scarsissimante disseminati su di una striscia larga 5 mm.

Il palato è molto largo. Un piccolo $\underline{P}_{1}$ è presente in tutti egli esempl.

Misure del Tipo (e paratipi: F - M): Avambraccio 32 (34 - 34). Testa e tronco ca. 53 (54 - 51). Coda 26 (29 - 26). Dito terzo, metacarpo 31 (31 - 31), prima falange 11.5 (12.5 - 11.5). Tibia e piede con unghia 10.5 (19.5 - 19). (Lunghezza del pene nel prepuzio 8.5). Il tipo fu misurato *prima* di essere messo in pelle.

Cranio del Tipo. Lungh. Occipite - C 14.2. Lungh. condilo-basale 13. Lungh. basi-sinuale 10. Larghezza orbitale 6.5. Largh. intertemporale 5. Larghezza della cassa cranica 8. Largh. mastoidea 8.1. Larg. estern massima sulle file dentali molari 7.5, Fila $\underline{C\text{-}M_3}$ 5.8; $\underline{P_4\text{-}M_2}$ 3.8; $C\text{-}M_3$ 6.1.

Sc. artinii si distingue facilmente dalle specie geograficamente più vicine. Dal *hindei*, Thos. (Ann. M.N. HisT., VII, 1901, p. 264), Kitui, Br. E. Afr., pel colore delle parti dorsali che in quest'ultimo è molto più scuro (chocolate, XXVIII) e delel parti inferiori che in quest'ultimo sono brune. Dall'*albigula*, Thos. (o.c. IV, 1909, p. 544), Mt. Elgon, che, come cortesemente mi confermano con lettera del 1.II.1923 i signori Kershaw e Hinton del Museo Britannico, ha le parti dorsali brune cioccolata, pel colore delle medesime e per le parti in-

p. 100

feriori decisamente meno chiare nell'artinii. Dal *woodi* Thos. (o.c. XIX, 1917, p. 280), Nyasalend, per il colore delle parti superiori, che in quest'ultimo sono molto più scure (mummy bronw XV), della membrana alare che in quest'ultimo è bianca e delle parti inferiori che nel medesimo sono brune. Dal *cinnamomeus*, Wettst. (Anz. Ak. Wissensch. Wien. 53, 1916, p. 191), Cordofan, per il colore delle parti superiori, che, come mi conferma l'autore, corrisponde in quest'ultimo al *cinnamon* di Ridgw. XXIX e per il colore del patagio, che nel medesimo non ha solo il margine ma anche intere porzioni marginali bianche.

Spiccate differenze di colorazione lo distinguono pure dalle specie geograficamente più lontane: *albofuscus*, Thos. (Ann. M. C. Genova, XXIX, 1890, p. 86), Gambia, che è più scuro ed ha le ali biancastre; *hirundo*, Winton (Ann. M. N. Hist. IV, 1899, p. 355), Costa d'Oro, che è molto più chiaro (grigio topo); *falabae*, Thos. (o.c. 19195, XVI, p. 447), Kabwir, Nigeria, sett. che ha i singoli peli più chiari nella porzione basale che nella apicale.

Debbo infini aggiungere, che a mezzo di un accurato controllo della colorazione di *Pipistrellus nanus*, Pet., *Scoteinus schlieffenii africanus*, Allen, e *Taphozous mauritianus*, Geoffr., *conservati in identiche condizioni* mi sono assicurato che *l'alterazione di colore subìta dai soggetti nell'alcool è assolutamente minima*.

Scotoecus cinnamomeus Wettstein, 1916

p. 191

Am ähnlichsten *S. albofuscus* (Thom.), aber Rücken "cinnamon", Unterseite weißlich, Tragus länger als bei allen gleichgroßen Formen. Flughautrand zwischen fünftem Finger und Tibia weiß gesäumt, mit weißer Verbreiterung in der Mitte dieser Strecke. Schwanzspitze über 1 mm frei aus der Flughaut herausstehend. Außenrand des Ohres gerade. Innenrand des Tragus gerade, 3 mm lang, Außenrand etwas unter der Mitte des Innenrandes stark konvex, dann gerade, am Ende schmal abgerundet.

Maße des Typus: Kopf und Körper 47, Schwanz 33, Unterarm 32, Ohrhöhe 12, Außenrand d. Tragus 4.8, Tragusbr. 2 mm.

Typus: 1 F Nubbaka, Kordofan, 17.III.1914
Cotypen: 1 F Nubbaka, 17.III
1 F Dilling, Kordofan, 20.III.1914.

Scotoecus falabæ Thomas, 1915

p. 447

Scotœcus falabæ, sp. n.

A medium-sized brown species, rather larger than *S. hirundo*.

General characters very much as in *S. hirundo*, to which the new form is most nearly allied. Size rather larger.

p. 448

Fur 3.5 mm. in length on the shoulders. General colour sepia-brown, but the light bases of the hairs showing through, especially across the shoulders, where the hairs are prominently buffy whitish for the greater part of their length, the tips only brown. Under surface dull buffy whitish, the throat clearer white, but nowhere so pure a white as in *S. hirundo*. Membranes blackish brown throughout. Tragus short, broad, rounded, slightly incurved, the inner margin concave. Wings to the end of the metatarsus. A distinct postcalcarial lobule present.

Skull, as compared with that of *S. hirundo*, larger, more rounded, higher, and less flattened than in *S. hirundo*, and still more so in comparison with the other species. The interorbital broadening less noticeable than in any known species.

Dentition as in *S. hirundo*, except that minute anterior premolars are present on each side, standing in the notch in the posterior base of the canines.

Dimensions of the type (the italicized measurements taken in the flesh): -

Forearm 36 mm.

Head and body 51; tail 36; ear 12; third finger, metacarpus 34, first phalanx 11.2; lower leg and hind foot (c.u.) 20.

Skull: occiput to base of canine 13.7; condylo-basal length 13.3; interorbital breadth 6.8; intertemporal breadth 4.8; breadth of brain-case 8.5; front of canine to back of m^3 5.6; front of p^4 to back of m^2 3.7.

Hab. Kabwir, Northern Nigeria. Alt. 2500'.

Type. Young adult female. B.M. no. 15.10.8.1. Original number 70. Collected July 28, 1915, and presented to the National Museum by Dr. J. C. Fox.

This species differs from *S. hirundo* by its larger size, higher skull, and more obviously bicolor fur. The type of *S. hirundo* is a very old female with worn teeth.

The inconvenient variability in the presence or absence of the small upper premolars is a character of *Scotœcus* unique in the Vespertilionidæ. How far these teeth will prove to be generally constant within each species remains to be seen, but in *S. hindei*, at least, they are absolutely inconstant.

The specific name is given in commemoration of Dr. Fox's escape from the peaceful liner 'Falaba,' barbarously sunk on its way out to Africa.

Scotœcus Hindei Thomas, 1901

p. 264

Size largest of the genus. Fur close and soft, hairs about 3 mm. in length on the back; not extending either above or below on limbs or membranes, except slightly on and around the base of the tail. General colour above chocolate-brown, the bases of the hairs darker; below the colour is paler, the hairs being brown basally and dull buffy terminally. Muzzle and chin blackish brown. Ears of medium length, their tips rounded, with a slight and even concavity below them. Tragus short, of equal breadth above and below, an indistinct lobe at its external base. Wings to the metatarsus. Postcalcaneal lobe well-defined. Penis very long, apparently provided with a bone.

Skull very similar to that of *S. hirundo*, but larger and heavier throughout; nasal notch very deep, its depth, measured from the base of $i.^1$, going only about three times in the distance from it to the occiput; prepalatal notch reaching to the level of the front of $m.^1$; sagittal crest fairly developed.

Upper incisors short, stout, strongly convergent. Lower incisors transverse, slightly overlapping. Anterior lower premolar three fourths the height of the posterior one.

Dimensions of the type: -

Forearm 35 millim.; height of ear 12, of tragus (on inner edge) 2.4.

p. 265

Skull: greatest length 15; basal length 12.9; orbital breadth 8; intertemporal breadth 4.9; breadth of brain-case 8.2; nasal notch 3.3 x 2.5; palate from bottom of prepalatal notch 5; front of upper canine to back of $m.^3$ 6; front of lower canine to back of $m._3$ 6.5.

Hab. Kitui, British East Africa; altitude 3500 feet.

Type. Male. B.M. no. 1.2.5.1. Original number 63. Collected 26th November, 1900, by S. L. Hinde.

Its larger size and different colour will readily distinguish this species from its nearest ally *S. hirundo*.

Scotoecus woodi Thomas, 1917

p. 280

Near *S. albofuscus* of the Gambia, but smaller.

Size about the smallest of the genus. General colour above dark brown (near mummy-brown), the tips of the hairs paler brown; under surface little paler, near Prout's brown. Wings coloured as in *S. albofuscus*, the forearms, digits, hind limbs, and tail blackish, the membranes internal to a line from elbow to knee, and the interfemoral dark brown, those external to forearms dull whitish, rather darker; terminally. Ears short, with large external basal lobe; tragus short and broad, its inner margin slightly concave.

Skull short and stumpy, of the characteristic broad shape usual in the genus, the lacrymal breadth even greater than in *S. albofuscus*. Nasal notch very deep. Median part of zygoma absent in type.

Incisors slender, their bases not touching the canines. Canines broadened transversely, their basal area broader than long, and flattened behind, close and parallel to the front edge of the large premolar; no small premolar or place for it present.

Dimensions o£ the type (the italicized measurements taken in the flesh): -

Forearm 28.5 mm.

Head and body 56 mm.; tail 21; ear-12.

Third finger, metacarpus 28, first phalanx 10, second phalanx 8; lower leg and hind foot (c. u.) 17.5.

Skull: greatest length 13.2; median upper length 11; basi-sinual length 9.8; greatest breadth 10.3; lacrymal breadth 6.7; mastoid breadth 9.1; palato-sinual length 4.5; front of canine to back of m^3 4.9.

Hab. Southern Nyasaland. Type from Chiromo; alt. 200'

p. 281

Type. Adult male. B.M. no. 17.2.1.1. Original number 173. Collected 2nd October, 1916, and presented by Rodney C. Wood, Esq.

This species may be distinguished from its only close, though geographically very distant, ally *S. albofuscus* by its smaller size, proportionally even broader skull, and the different shape of the base of its canines. The other members of the genus all have uniformly brown wing-membranes.

I may note that of twelve, skulls of *Scotœcus*, including examples of all the described species, only two have complete zygomata, although all have been prepared by that most skilful skull-cleaner Mr. W. Sherrin. Imperfection or, at least, excessive tenuity of the zygoma would therefore appear to be an additional character of the genus *Scotœcus*. Of forty skulls of *Scoteinus* similarly prepared by Mr. Sherrin, nearly all have perfect, although very slender, zygomata.

Scotonycteris bedfordi Thomas, 1904

p. 372
[Proc. zool. Soc. Lond., 1904, vol. i. - 2 August 1904]

Scotonycteris bedfordi, Thomas, Abstr. P.Z.S. 1904, No. 2, p. 14, March 8.

Footnote: The complete account of the new species described in these communications appears here; but as the names and preliminary diagnoses were published in the 'Abstract,' such species are distinguished here by geing underlined. - EDITOR

Near *S. zenkeri*, but ears much smaller.

Size rather less than in *S. zenkeri*. Fur close, fine and woolly, the hairs on the back about 6 mm. in length. Fleshy part of forearms, wing-membrane bordering flanks and hind limbs, upper side of legs to ankles, and interfemoral membrane (except terminal part near calcar) well clothed with fur; the centre of the interfemoral quite buried in thick fur. Below, the fur was less extended, the proximal part of the wing-membrane and the centre of the interfemoral.

General colour above mixed whitish and ochraceous buff, the hairs dark brown at base, then silvery white, their tips pale brownish buffy or "clay-colour," the peripheral hairs of membranes wholly of the latter colour. Head rather browner than back. Central white muzzle-patch present, as in the type species; eyes with dark rims, interrupted behind by small white postocular spots, only about 2 mm. in diameter. Owing to the general light colour, these patches are but little prominent. Ears very small and narrow, conspicuously smaller than in *S. zenkeri*. Throat and centre of chest creamy whitish, passing on shoulders, sides of body, and inguinal region into brown.

Dimensions of the type: -

Forearm 48 mm.

Head and body (original measure in the flesh) 71; ear (in flesh) 11; thumb (c. u.) 23; first finger - metacarpal 34, 1st phalanx 24, 2nd phalanx 30; fifth finger 63; tibia 20 ; calcar 6.

Hab. Fish Town, Fernando Po.

Type. Female. Original number 31. Collected 2 January, 1904, by E. Seimund.

This interesting Bat, which had been named in honour of its joint donor, the President of the Society, was the first representative of the the genus *Scotonycteris* received by the National Museum, and was therefore a most welcome accession. It differed from *S. zenkeri*, of the Cameroons, by its conspicuously smaller ears, which were only 11 mm. in length, while those of *S. zenkeri* were stated by Dr. Matschie to be 17 mm. long, a measurement that quite agreed with their appearance in his plate. *S. bedfordi* also seemed to have smaller postocular spots and a more hairy interfemoral membrane than its mainland ally.

Scotonycteris ophiodon Pohle, 1943

p. 78

Vor fast 50 Jahren, in der Sitzung vom 16.10.1894, legte MATSCHIE der Gesellschaft naturforschender Freunde einen Flughund vor, der eine neue Art einer neuen Gattung darstellte: *Scotonycteris zenkeri* Mtsch. Heute kann ich der Gesellschaft die zweite Art dieser damals geschaffenen Gattung vorlegen: *Scotonycteris ophiodon* sp. n.

Typus: Nr. 50051 des Berl. Mus.; F juv.-ad. von Bipindi, Bez. Kribi, Kamerun, Mai 1899, GEORG A. ZENKER S.V.. Die Zähne (auch die Eckzähne) sind voll in Stellung, die Basalnaht ist noch offen. Das Tier liegt in Alkohol; der leider auf der

p. 79

rechten Seite unter Verlust der Hirnkapselwand verletzte Schädel ist gereinigt.

Diagnose: Ein *Scotonycteris* von erheblicher Größe. Das vorliegende Weibchen ist ebenso groß wie ein gleich altes von *Epomops franqueti* Tomes. Das Tier ist also weit größer als *Sc. zenkeri* Mtsch. Unterarm über 75, größte Schädellänge über 36 mm. Ohren länger (über 20 mm) als bei *zenkeri* und zugespitzt. Gaumenfalten ähnlich denen von *Casinycteris argynnis*. Schädel weniger breit (Gr. Länge: Jochbogenbreite = 1.71 gegen 1.51 bei *zenkeri*). Gaumen sehr stark gewölbt. Backenzähne stärker als die von *zenkeri*, aber auch fast ebenso lang wie breit und geradezu ungeheuer hoch und stark gekrümmt, so daß die Reihe C-M^1 in Profilansicht an ein Schlangengebiß erinnert.

Aeußere Merkmale: Schnauze verhältnismäßig noch breiter als die von *zenkeri* und daher etwa wie eine Miniaturausgabe einer Bernhardiner-Schnauze wirkend. Ohren relativ länger (20.5 mm) bei relativ gleicher Breite (13 mm), zugespitzt und mit 8 deutlich erkennbaren queren Verstärkungsleisten. Schwanz als Höcker gut fühlbar. Flughäute denen von *zenkeri* entsprechend mit 20 - 22 Vertikalfacien auf dem Mesopatagium. Sie setzen sich an die erste Zehe (und zwar an deren erste Phalange) an. Schwanzflughäute wohlentwickelt, in ihrer ganzen Länge mindestens 7 mm breit. Ueber die Fingerlängen sagt umseitige Tabelle aus, daß sie zwar absolut erheblich größer, relativ aber etwa die gleichen sind wie bei *zenkeri*. Nur der Metacarpus des 2. Fingers ist auch relativ länger. Die übrigen Unterschiede liegen innerhalb von Fehlergrenze und Variationsbreite.

Verteilung der Behaarung wie bei *zenkeri*. Pelz lang, weich und dicht; Länge der Haare auf dem Rücken um 10 mm, der Leithaare um 14 mm; auf dem Bauch sind die Haare gröber und bis 7 mm lang. Die Rückenseiten der proximalen Hälfte des Unterarmes und der beiden proximalen Drittel des Unterschenkels sind (in distaler Richtung abnehmend, an den Gelenken aber dicht) behaart. Farbverteilung auch etwa wie bei *zenkeri*, doch sind die Töne erheblich heller und enthalten mehr Gelb. Da der Typus 44 Jahre in Alkohol gelegen hat, ist aber die exakte Beschreibung der einzelnen Farbtöne sinnlos. Auf dem Nasenrücken ein scharf begrenzter weißer Fleck vom Umriß eines Apfelkernes. Seine Spitze liegt etwa in der Mitte des behaarten Nasenrückens, sein abgerundetes Ende wenige Millimeter hinter den inneren Augen-

p. 80

[table removed - eds.]

winkeln. Hinter den Augen und an der Ohrbasis kein weißer Fleck. Dagegen sind Maul und Nasenballen weiß eingefaßt (etwa 3 - 4 mm breit).

Gaumenfalten: Bei *zenkeri*: 5 glattrandige Gaumenfalten zwischen den Zähnen. 1 gleich dahinter; dann 1 mm breite faltenfreie Fläche, und schließlich 6 eng gedrängte, gezähnte, postdentale Falten. Von der ersten, kräftigsten, direkt hinter den Eckzähnen liegenden Falte an nehmen sie an Stärke ab, an Krümmung zu. Die 12. besteht nur aus einzelnen Höckern. Zweite Falte zwischen den P^3, die dritte verbindet die P^4, die 4. die Zwischenräume zwischen den P^4 und M^1 und die 5. die M^1. Von der vierten an sind sie in der Mitte geteilt, die 6. besteht aus zwei Halbbogen; vor der 5. ein unpaarer mittlerer Höcker, vor der 6. jederseits einer. Von den sechs postdentalen ist die erste auch geteilt, die vier nächsten aber einheitlich.

Bei *ophiodon* haben wir auch die Andeutung der Teilung in eine vordere und eine hintere Faltengruppe, doch ist die Trennung unscharf, da ein faltenfreier Streifen fehlt. Auf 6 ungeteilte inter-

p. 81

dentale Falten mit glatten Rändern folgen etwa 12 teils in der Mitte geteilte, teils vollständige, teils unvollständige, postdentale, deren Teile oft durch Schaltstücke verbunden sind. Diese 12 hinteren Falten haben gezähnelte Ränder. Die erste aller Falten steht noch vor den C, dicht hinter den I, die zweite gleich hinter den C. Die dritte verbindet die P^3. Sie ist schon stark vorgewölbt, wird aber hierin von der 4. bis 6. erheblich übertroffen. Die vierte beginnt hinter der Mitte der P^4, ihre weiteste Vorwölbung trifft die Verbindungslinie der Hinterränder der P^3. Die 5. beginnt vor der Mitte der M^1 und wölbt sich bis über die Hinterränder der P^4, die 6. beginnt hinter der Mitte der M^1 und wölbt sich bis zur Mitte der P^4. Die ersten 5. sind dicke Falten mit hohem Kamm und breiter Basis. Die 6. dagegen hat den Charakter der postdentalen: sie ist flach und hat gezähnelte Ränder. Die Lage der postdentalen siehe Abbildung 1. Das Gaumensegel trägt keine Falten, sondern nur unregelmäßig angeordnete Höcker (in der Abb. fortgelassen). Insgesamt entspricht diese Anordnung der Gaumenfalten der von *Casinycteris argynnis* und nicht der von *Scotonycteris zenkeri*.

Schädel: In der Aufsicht und im Profil dem von *Nannonycteris* ähnlicher als dem von *Scotonycteris zenkeri*. Rostrum sehr kurz, relativ kürzer als bei *zenkeri*; seine Länge (Linie Nasaliaspitze bis Orbitarand) beträgt hier $26^1/_2$ % der größten Schädellänge, bei *zenkeri* 29 % (bei dem vorliegenden gleich alten F Schädel Nr. 10029 von *Epomops fr. franqueti* von Yaunde 31 %). Damit ist die Länge des Rostrums geringer als der Abstand der Außenseiten der P^4 von einander; bei *zenkeri* ist sie ebenso groß, bei *Epomops, Nannonycteris* und *Micropteropus* aber größer. Natürlich ist sie auch etwa gleich der Lacrymalbreite, aber dieser Vergleich trennt die kurzschnauzigen Gattungen der Epomophori nur schlecht von den F von Epomops, da auch bei diesen die Lacrymalbreite etwa gleich der Länge des Rostrums ist. Höhe des Rostrums über dem Diastema C-P^3 relativ etwas

p. 82

niedriger als bei *zenkeri*, fast genau gleich der Hälfte der Länge des Rostrums. Höhe hinter den M^1 größer als Länge des Rostrums. Der Winkel, den die obere Profillinie des Rostrums mit der Alveolarlinie bildet, ist ein größerer als bei *zenkeri*, somit wird der Abfall des Schädels nach vom plötzlicher. Postcanine Einschnürung des Rostrums sehr schwach, etwa $^1/_{10}$ mm betragend (bei *zenkeri* über $^2/_{10}$). Aufsteigende Aeste der Intermaxillaria bis oben hinauf etwa gleich breit, nicht zugespitzt; alveoläre Aeste verhältnismäßig hoch, nicht miteinander verwachsen, Vorderrand im Profil nicht senkrecht, sondern oberes Ende vorragend. Der Gaumen ist von rechts nach links sehr stark gewölbt, in der Hauptsache dadurch, daß der Alveolarfortsatz des Maxillare von vorn nach hinten immer mehr aus der Gaumenfläche heraustritt, Zahnreihen divergieren nach hinten so stark, daß der Abstand der buccalen Flächen der M^1 von einander (12.5 mm) fast doppelt so groß ist wie die kleinste Gaumenbreite (6.7 mm). Der hinter dem Jochbogenansatz liegende Teil des Gaumens ist etwa ebenso lang (6.4 mm) wie durchschnittlich breit (9.5 mm hinter M^1, 6.2 mm an der Choane). Er verjüngt sich also stark nach hinten wie auch bei *zenkeri*. Durch diese Verjüngung steigt der fast geradlinig verlaufende Rand dieses Gaumenteiles allmählich fast bis zur Höhe der Gaumenwölbung. Das hat zur Folge, daß in der Profilansicht dieser Rand nicht die geradlinige Fortsetzung der Alveolarlinie ist (wie bei *zenkeri*), sondern mit ihr einen nach oben offenen stumpfen Winkel bildet.

Auch die basicraniale Achse bildet mit der basifucialen einen stumpfen Winkel; der Hirnschädel ist also gegen den Gesichtsschadel abgeknickt (wie bei *Nannonycteris*). Die Verlängerung der Alveolarlinie läuft aber trotzdem unter den Condylen hindurch. Es liegt dies daran, daß durch die Gaumenwölbung der Gaumenrand (die Alveolarlinie) von vom nach hinten immer stärker hervortritt, also von vorn nach hinten fällt. Im Bereich des postdentalen Gaumens steigt dann die Profillinie wieder an und dann kommt die Abknickung der Schädelbasis, die nun etwa parallel der Alveolarlinie verläuft. Würde man die Mittellinie des Gaumens verlängern, so würde sie das obere Ende der Condylen treffen, bei *zenkeri* dagegen das untere. - Postorbitalfortsatz kurz und dick (Jugendmerkmal?). Temporalleisten weit getrennt, nur bis zur Kranznaht zu verfolgen (Jugendmerkmal?). In der Basalansicht treten die Hinterränder der Proc. zyg. max. nicht

p. 83

(wie bei *zenkeri* und *argynnis*) fast senkrecht zur Mittelebene des Schädels aus diesem heraus, sondern bilden damit einen spitzen Winkel (wie bei *Nannonycteris* und *Micropteropus*). Jochbogen dünn, wenig aufwärts gebogen und schwächer nach außen gewölbt als bei *zenkeri*. - Horizontaler Ast des Unterkiefers kräftig, am dicksten unter P_4 und M_1, dahinter dünner werdend; wie bei *zenkeri* und *argynnis* nach außen konvex, nicht fast gerade wie bei *Nannonycteris* und *Micropteropus*. Coronoidfortsatz relativ niedriger als bei *zenkeri* (Jugendmerkmal?), aber ebenso stark, Proc. ang. und Condylus wie bei *zenkeri*.

Gebiß: $^{I1}/_{I1}\,^{I2}/_{I2}\,^{C}/_{C}\,/_{P1}\,^{P3}/_{P3}\,^{P4}/_{P4}\,^{M1}/_{M1}\,/_{M2}$ x 2 = 28, also wie bei *zenkeri* und fast allen Epomophori. Schneidezähne wie bei *zenkeri*, im Oberkiefer jedoch höher, stärker gekrümmt und weniger rückwärts geneigt; I^1 deutlich höher als I^2. Im Unterkiefer bei *zenkeri* I_2 höher und kräftiger als I_1; auch hier ist der I_2 viel kräftiger, in der Höhe aber ist ein Unterschied wohl vorhanden aber nicht auffällig. Alle übrigen Zähne erheblich höher (auch relativ), kürzer und stärker rückwärts gekrümmt als bei *zenkeri*. Eckzähne oben und unten etwa ebenso breit wie lang (siehe Maßtabelle), am stärksten gekrümmt von allen Zähnen. Am Oberkiefer-Eckzahn laufen von der Spitze jederseits ein Cingulum in der Krümmung des Zahnes zur Basis; hier biegen beide nach hinten um und vereinigen sich unter Bildung des Basalwulstes, Zwischen jedem Cingulum und dem Zahn befindet sich eine vertikale Furche, die von der Zahnspitze bis zur Basis zieht. Durch die Cinguli wird die Zahnkrone (außer im basalen Teil) breiter als lang (in halber Höhe: Breite 2.0, Länge 1.5 mm). Das innere Cingulum bildet in etwa $^2/_3$ der Zahnhöhe durch plötzliche Verbreiterung einen Höckeransatz. Von hier nach unten läuft dann auch auf der Zahnvorderseite eine Furche bis zur Basis. Die übrigen oberen Backenzähne ähneln denen von *argynnis*, doch sind sie höher und stärker rückwärts gekrümmt. Die Innenhöcker sind am P^3 wohl niedriger als dort, aber scharf abgesetzt vom Hauptzacken, am P^4 und M^1 wie bei *argynnis*. - Auch die Unterkiefer-Caninen tragen die beiden vertikalen Furchen auf der caudalen Fläche und damit den von der Spitze außen abwärts laufenden, an der Basis nach hinten umbiegenden, als Basalwulst über die rückseitige Basis laufenden, nach oben umbiegenden und wieder zur Spitze laufenden Wulst, der

p. 84

wieder auf der Innenseite in etwa $^3/_4$ der Zahnhöhe infolge plötzlicher Verbreiterung eine Nebenzacke andeutet. Von hier aus läuft auch auf der Vorderseite des Zahnes eine kurze Vertikalfurche. Der P_1 ist deutlich stärker als ein I_2. Der P_3 ist fast ebenso hoch wie der Eckzahn. Sein innerer Höcker ist scharf abgesetzt, rostral durch eine Schmelzkerbe, caudal durch eine vertikale tiefe Grube. Auch bei ihm ist durch eine vertikale Furche auf der caudalen Fläche ein von der Spitze zur Basis laufendes Cingulum abgesetzt, das dann umbiegend einen Basalwulst bildet, der dann an der Nebenspitze wieder emporsteigt. P_4 und M_1 entsprechen ungefähr den gleichen Zähnen von *argynnis*, doch sind sie und die Innenspitze etwas höher.

Verbreitung: Bisher nur bekannt von Bipindihof, wahrscheinlich also ähnlich verbreitet wie *zenkeri* und viele andere Säuger (z. B. *Colobus satanas* Waterhouse), die von Fernando Po, dem südlichen Kamerun und dem nordwestlichen Gabun bekannt geworden sind.

Maße: Aeußere Maße: Kopfrumpflänge 105 mm, Schwanzlänge unter 1 mm, Hinterfußlänge 14 mm, Ohrlänge 20.5 mm.

Schädelmaße: Größte Länge 36 + mm ; Palation bis Foramina incisiva 17.6; Palation bis Basion 12.2; Länge des postdentalen Gaumens 6.4; Länge Orbiturand bis Nasaliaspitze 9.2; Breite der Hirnkapsel über dem Jochbogenansatz 16; Jochbogenbreite 21; Breite über den Kronen der M^1, außen 12.6; Lacrymalbreite 9.4; Breite über den Caninen, außen 6.7; Intertemporalbreite 8.9; Spitzenabstand 11.2; Interorbitalbreite 6.4; Choanenbreite 5.0; Mittlere Breite des postdentalen Gaumens 7.5; Innenabstand der M^1 von einander 7.9; desgl. der P^4 6.2; desgl. der Basen der C^1 2.5; Durchmesser der Orbita 9; Unterkieferlänge (vom Condylus aus) 16.5; Höhe des Coronoidfortsatzes 11.2 mm.

[table removed - eds.]

p. 85

Verwandtschaft: *ophiodon* zeigt eine eigenartige Mischung von Charakteren der Arten *Scotonycteris zenkeri* und *Casinycteris argynnis* mit Merkmalen, die ihm eigentümlich sind. Zur ersten Gruppe nenne ich das Fehlen des weißen Fleckes vor den Ohren, die Form des Intermaxillaria. Zur zweiten Gruppe gehören die längeren Ohren, die Anordnung der Gaumenfalten, die Höckeranordnung an den Backenzähnen. *ophiodon* eigentümlich sind die erheblichere Größe, die weiße Einfassung von Maul und Nasenballen, der Umriß des Schädels in der Aufsicht, die starke Gaumenwölbung, die Abnickung des Hirnschädels u. a. Den größten Teil der Merkmale aber hat er mit den beiden Arten gemeinsam. Seine systematische Stellung ist also nicht zweifelhaft, er gehört zwischen die beiden.

In welche Gattung muß er aber gestellt werden? Mancher Säugetierspezialist würde die Frage einfach beantworten: In eine neue. Nach dieser Methode erhalten wir aber einen Wust neuer Gattungsnamen, die nichts weiter sagen, als daß die Arten eben verschieden sind. Wir haben in der Säugetierkunde schon viel zu viele Gattungsnamen, denn ganze große Familien enthalten nur monotypische Gattungen. Wir müssen uns daran gewöhnen, Gattungen nur dort neu zu schaffen, wo wirklich prinzipielle Unterschiede vorliegen. Das ist aber in unserem Fall nicht zu behaupten. *ophiodon* gehört sicher in eine der beiden schon beschriebenen. Wir müssen also auf unsere Frage zurückkommen. Umm sie entscheiden zu können, wollen wir zunächst ANDERSON's Ausführungen über *Casinycteris* (pg. 671/2) zitieren, wobei wir seine Einschaltungen über Aehnlichkeiten mit *Pteropus*-Arten als unwesentlich für unsere Frage fortlassen: "If the single species of this genus were known only from its external appearance, it would unhesitatingly be considered a *Scotonycteris*, differing from *S. zenkeri* in nothing but its larger size, relatively larger ears, and small white ear-patches; so extraordinary is its resemblance in all external features to *S. zenkeri*, even in the general colour of the fur and the very peculiar white markings of the head. In the characters of the incisors and canines, the peculiarly short-and-broad, subcircular outline of the premolars and molars, and the heightening of their outer cusps the dentition of this genus is very similar to that of *Scotonycteris*, and the details in which it differs (chiefly the stronger development of the inner cusp of p^3 and p_3, the divergence of the outer and inner cusps of the large premolars and molars, and the less

p. 86

pronounced reduction of the posterior molars) would in themselves be far from justifying its generic separation from *Scotonycteris*. With this close extern al and dental resemblance to *Sotonycteris*, the present genus combines, however, a modification of the bony palate absolutely unique in Megachiroptera and more closely approaching to the type of palate predominant in Microchiroptera." Die Gattung *Casinycteris* ist also einzig und allein begründet auf die tiefe Spalte, die sich bei *argynnis* von der Choane bis zu den letzten Oberkieferzähnen zieht oder richtiger, die in diesem Bereich an die Stelle des harten Gaumens getreten ist. Dieses Merkmal scheint unzweifelhaft um so mehr Gewicht zu hahen, als es sonst in der ganzen Unterordnung der Megachiroptera nicht wieder vorkommt. Man müßte also ANDERSON und THOMAS ohne weiteres Recht geben in der Aufrechterhaltung dieser Gattung *Casinycteris*, wenn nicht von beiden eine Kleinigkeit übersehen worden wäre, die diesem Merkmal ein ganz anderes Gesicht gibt. Es ist dies die Tatsache, daß dieses Merkmal bei vielen Säugern als Mißbildung beobachtet worden ist und wahrscheinlich bei allen vorkommen kann als sogenannter Wolfsrachen oder Gaumenspalte. Wir können von *argynnis* nur einen einzigen Schädel, eben den des Typus der Art; wir können also nicht einmal behaupten, daß die Gaumenbildung bei allen Tieren der Art die vom Typus beschriebene ist. Es ist schon möglich, daß wir von dieser seltenen Art ausgerechnet nur ein teratologisches Stück in die Finger bekommen haben. Aber selbst wenn sich das Vorhandensein der Gaumenspalte bei allen Tieren der Art erweisen sollte, dann ist dieses Merkmal noch nicht ausreichend, um damit die Unterbringung der Art in einer anderen Gattung zu begründen. Merkmale, die innerhalb der ganzen Säugetierreihe als Anomalie erblich auftreten können, müssen durch eine verhältnismäßig einfache Genänderung bedingt sein und sind deshalb zu klein, um als Gattungsmerkmale zu gelten. Wenn nicht daneben noch andere Unterschiede vorhanden wären, so würden sie ja nicht einmal zur Begründung einer Art ausreichen. Die Gattung *Casinycteris* ist also zu streichen; *argynnis* ist als Art zur Gattung *Scotonycteris* zu stellen und in diese selbe Gattung kommt als dritte Art unser oben beschriebener *ophiodon*.

p. 87

Bemerkungen: Es ist nicht mehr als Pflicht darauf hinzuweisen, daß wir auch die Kenntnis dieser Art dem ausgezeichneten Sammler GEORG A. ZENKER verdanken, von dem ja das Berliner Museum so viele andere neu zu beschreibende Säugetierarten und Unterarten erhielt, von denen hier nur *Scotonycteris zenkeri* Mtsch., *Idiurus zenkeri* Mtsch., *Zenkerella insignis* Mtsch., *Cercocebus albigena zenkeri* Schwarz genannt seien. G. ZENKER ist am 12.2.1922 nach einem an Abenteuern reichen Leben in seiner Wahlheimat Kamerun (Bipindihof) im Alter von 67 Jahren verstorben. Er ist dem Berliner Museum treu geblieben wie wenige Sammler und hat sein Material hierher gegeben, obwohl wir ihm nur wenig dafür bezahlen konnten, und obwohl er wußte, daß er von London ein Mehrfaches der von uns bezahlten Preise hätte erhalten können.

Material: Nur der Typus.

Scotonycteris ophiodon cansdalei Hayman, 1946

p. 766

Type. - F skin and skull, B.M. No. 46.229, collectors' number 420. Collected at Oda, Oda District, Central Province, Gold Coast, December 24, 1945, by G. S. Cansdale. A very young specimen, No. 46.230, preserved in alcohol, was taken clinging to the type., "Suspended in tree in forest; solitary." (Note by collector.)

Diagnosis. - Closely similar to *Scotonycteris ophiodon* Pohle (1943) in size and most external, cranial and dental characters, but differing externally in having a conspicuous white patch at the posterior angle of each eye, an inconspicuous white spot at the anterior base of the ears (both spots lacking in *ophiodon*), and in the white border of the upper lips only reaching two-thirds of the way forward towards the nostrils (in *ophiodon* the white lip border is said to include the nostrils); and cranially in the long and thin postorbital processes (short and thick in the unique type of *ophiodon*), in the horizontal basicranial axis (deflected in *ophiodon*), and in having a distinct, though low, sagittal crest; the latter may well be an age character. (For measurements see Table I.)

Colour. - As the type of *Scotonycteris ophiodon* had been in spirit for forty-four years when Pohle described it, he was not in a position to give much account of its colour, beyond stating that it appeared to have the same general pattern as in *S. zenkeri* Matschie (1894), but somewhat lighter and yellower, a difference which might well be due, in my opinion, to the bleaching effect of long immersion in alcohol. The following general account of the colour

p. 767

of the Gold Coast form, *cansdalei*, based partly on Cansdale's notes from the fresh specimen, partly on the dry skin, shows that it has a striking similarity to *zenkeri* and also to *Casinycteris argynnis* Thomas (1910).

The dorsal hair above has three colour zones, dark brown basally, dirty white medially, fawn distally, the general effect varying according to the length of hair and length of the whitish zone. On the neck and shoulders the hairs are longer than on the hinder portion of the back and have a much wider whitish zone, which shows through the fawn tips. Further back the whitish zone is very narrow and the hair is shorter, so that the general effect is much darker, and on the rump the pale zone is absent and the hairs are almost uniformly brown. Below, the hair on throat and lower neck is very sparse, is almost white, and the pale flesh skin is exposed. From the lower neck a pale abdominal patch, a dirty whitish heavily washed with dull buif, continues for some way, and is set off by the contrasting dark brown of the sides of the belly, the flanks and the anal region. On the head the white patch on muzzle, the white border of the lips (not reaching the nostrils), and the white patch behind the eyes, are conspicuous, but the white spot at the anterior base of the ears mentioned by Cansdale *in litt*. is so small and indistinct that in the dry skin it could easily be overlooked, and it seems likely that the type of *ophiodon*, after forty-four years in alcohol, would probably be too bleached to show such an inconspicuous feature. According to the collector, the wing membranes are yellowish-brown, and the bare skin of mouth, eyelids and ears dark yellow (in the dry skin the three latter are dark brown). The wing membranes are prominently reticulated, and the joints of phalanges and metacarpals are pale yellow, much as in *Casinycteris*.

Remarks. - In 1943 Pohle described *S. ophiodon* from Bipindi, Cameroons, as the second species of the genus, previously known only by the genotype, *S. zenkeri*, whose range included the Cameroons and Fernando Po. *S. ophiodon* was characterised by its much greater size (forearm 75, in *zenkeri* 48 - 54), and by striking dental peculiarities, of which the most important are the secondary cusps on the inner edges of upper and lower canines, and the heightening of the canines and cheek

p. 768

[table removed - eds.]

p. 769

teeth, the latter being provided with prominent inner cusps. *S. ophiodon* also lacks the white spot behind the eye found in *zenkeri*, although agreeing with the latter in most other respects in facial pattern and body colour.

Pohle considered that some of the characters of *ophiodon*, particularly those of the cheek teeth, showed affinity to *Casinycteris argynnis*, whose close external similarity to *Scotonycteris* has been commented on by Andersen (1912); in fact Pohle expressed the view that the extraordinary shortening of the palate in *Casinycteris*, the chief diagnostic feature of the genus, is merely an abnormality, akin to the "cleft palate" sometimes found in mammals, and as such to be discounted. Moreover, he also took the view that even if it were not an abnormality in itself, such a feature, being found nowhere else in the Megachiroptera, should not on the evidence of one skull be regarded as a character of sufficient stability to justify the founding of a genus. On these grounds he proposed to relegate *Casinycteris* to the synonymy of *Scotonycteris*, while retaining the species *argynnis*. Unfortunately for this theory, however, it must be pointed out that Pohle's declaration that only the type skull is known of *argynnis* indicates that he overlooked the fact that at the time at least two other skulls of this rare bat had been reported on. One was recorded by J. A. Allen (1917) from the Eastern Congo (with comments on its peculiar skull and palate by Lang and Chapin (1917a); another was recorded from the Uele District of the Eastern Congo by Schwarz (1920), who gave measurements showing a similar extreme shortening of the palate as in the type. In view of these facts it seems clear that Pohle's dismissal of the chief generic character of *Casinycteris* as an abnormality must be disregarded, and that the genus must stand.

Although the heightening of the inner cusps of the cheek teeth in *ophiodon* and *cansdalei* is a feature more nearly approaching the dentition of *Casinycteris argynnis* rather than *Scotonycteris zenkeri*, the normal palate makes inclusion in the former genus out of the question; the prominent secondary cusps on all canines form the most marked feature in which both *ophiodon* and *cansdalei* differ from both *S. zenkeri* and *Casinycteris*, but I am not prepared to add a generic or subgeneric name to the

p. 770

literature on that account. I have used a subspecific name for this Gold Coast *Scotonycteris* chiefly for convenience in expressing its relationship to *ophiodon*, but am quite prepared to find eventually that *cansdalei* will be raised to specific rank; the cranial differences, particularly the absence of a basicranial deflection, combined with the external difference in the head markings, may later be regarded as of specific value.

The discovery in the Gold Coast of this most interesting fruit bat by Mr. Cansdale, whose name I am glad to link with it, shows that special search for Chiroptera in the forest zones of Africa is likely to produce yet more surprises, both in new forms and in furthering our knowledge of the distribution of species already known elsewhere.

Scotonycteris zenkeri occidentalis Hayman, 1947

p. 503

Type. - British Museum number 46.898, adult female skin and skull (originally an alcoholic specimen). Collected at Oda, Oda Province, Gold Coast, 1946, by G. S. Cansdale. "Found sleeping in plantain leaves. G. S. Cansdale."

Diagnosis. - In size, form, cranial and dental characters as well as face markings, similar to *Scotonycteris zenkeri* Matschie (1894), whose distribution is limited, so far as is known, to the Cameroons and Fernando Po, but general colour considerably darker, the overall hue above being sepia rather than russet or rust-brown.

As in *S. zenkeri*, the dorsal hairs have three distinct colour-zones, a very dark brown basal third, a pale grey median zone, and a terminal zone of sepia instead of the russet or rust-brown of *zenkeri*, giving the animal its distinctive dark appearance. On the head the white markings are well denned, the white patch on the rostrum extending back to the level of the anterior angle of the eye, and the white spot behind each eye, being similar in size and position to those found in zenkeri. Below, the rather sparse hairs on throat and sides of the neck are whitish, and a narrow line of white hairs runs forward from the angle of the mouth for a short way along the upper lip. The centre of the chest and abdomen is greyish white, rather sharply differentiated from the brown flanks. As compared directly with two specimens of *zenkeri* (including the type of *S. bedfordi* Thomas (1904) = *zenkeri*) it is noticeable that the general darkening extends to the wing-membranes, which are dark chocolate instead of light brown. The collector's notes on colour of the fresh specimen tally with the description given above, so that there is no question of the colour having changed as a result of a brief immersion in alcohol.

p. 504

Measurements. - Head and body 70 mm., hind foot 13, ear 13, forearm 52, pollex 19, fifth metacarpal 32. Skull: total length 24.6, palatal length 13, post-dental palate 4, rostrum (front of orbit to tip of nasals) 6.7, breadth of brain-case at zygomatic roots 11.7, zygomatic breadth 15.9, breadth across crowns m^1-m^1 7.6, breadth across crowns of upper canines 5.6, interorbital breadth 5, upper toothrow c-m^1 7.9.

Palate ridges. - Andersen's description (1912) of the palate ridges in *S. zenkeri*, as shown also in the figure given by Matschie (1899), applies also to those of *occidentalis*, in that there are six main ridges separated by a narrow space from five weaker and more crowded posterior ridges. There is also a weak ridge between the incisors and canines, not mentioned by Andersen, but indicated in Matschie's figure.

Remarks. - The discovery in the Gold Coast of a local race of *S. zenkeri*, itself a rarity in collections and restricted to the Cameroons and Fernando Po, comes soon after Mr. Cansdale's capture of a Gold Coast race of *S. ophiodon* Pohle (1943), which, like *zenkeri*, was previously known only from the Cameroons. The collection in 1946 of *S. ophiodon cansdalei* Hayman (1946) and of *S. zenkeri occidentalis* demonstrates that our knowledge of the distribution of African bats is still far from complete.

Scotophilus albofuscus Thomas, 1890

p. 84

Size small; body: stout and heavy compared to the size of the wings. Head very broad and flat; muzzle considerably swollen, the glandular prominences much developed. Ears rather thick and fleshy, especially along their outer edge; laid forward they reach to just about halfway between the eye and the tip of the nose; their internal basal lobe scarcely developed at all; inner margin nearly straight, tip narrowly rounded off; outer margin evenly convex in its upper third, slightly concave in its middle third and terminating in a long fleshy lobule running forwards towards the angle of the mouth. Tragus unusually short (see measurements below), its inner and outer edges straight and nearly parallel, tip broadly rounded off, external basal projection fairly well developed. Wings to the metatarsus. Post calcaneal lobe broad and prominent. Extreme tip of tail projecting.

Fur short and close, scarcely encroaching at all upon the membranes or limbs. Colour of body above and below dark umber brown; naked skin, of all those parts which are visible when the wings are folded dark brown or black, i.e. muzzle, ears, lines of arms, forearms and fingers, wing membranes internal to a line drawn from the elbow to the knee, and whole of hind-limb, interfemoral membrane and tail; on the other hand

p. 85

some of the more aberrant species of *Vesperugo*, and especially from those placed by M.r Dobson in his subgenus *Scotozous*, to which perhaps it may be thought the new species should have been referred. *Scotozous* was founded on the Indian *V. (S.) dormeri*, Dobs., a species with all the *facies* of a *Vesperugo*, with two upper premolars, and with a long and pointed anterior lower premolar, these characters being strictly those of *Vesperugo*, from which in fact it only differs by having but one upper incisor on each side, as in *Scotophilus*. On the other hand the second species referred to the subgenus by M.r Dobson, "*Nycticejus schlieffeni*" Peters, ought, it appears to me, to be rather called a *Scotophilus*. Before entering into this point however, some reference to its specific history is unfortunately necessary, as there has been considerable confusion in regard to it.

Its first description was given by D.r Peters in 1859 unless, *Vespertilio marginatus*, Cretzschm. be the same species, but the type of, the latter form was distinctly stated by Blasius to be referable to *Vesperugo kuhli*, Natt., and if he was right the species will stand under Peters's name. In 1878 M.r Dobson referred the bat, with one Museum specimen, to his subgenus *Scotozous*, of the genus *Vesperugo*, but at the same time, misled by an erroneous locality, he placed a second specimen of it under *Scotophilus pallidus*, a species described by him two years previously in India. That this specimen was wrongly named has since been proved by the receipt of genuine examples of *S. pallidus* from India, but in the mean time a comparison with it had caused the Marquis G. Doria and myself to refer to *S. pallidus* a bat from Massowa collected by Signor Gustavo Frasca; this extension of the range of the latter, commented upon by us at the time, must now be cancelled, the bat being, like the

p. 86

[there seems to be something wrong with the sequence here. Some text seems to be missing. - eds.]

the wing-membrane external to the same line is pure white "above and below, contrasting very markedly with the dark skin of the limbs and digits.

Number of teeth strictly as in *Scotophilus*. Upper incisors long, slender, unicuspid, close to the canines; without posterior ledges, but each with a very minute postero-external basal cusp. Lower incisors tricuspid, overlapping, placed at right angles to the direction of the jaws. Anterior lower premolar not as in *Scotophilus*, crushed in between the posterior one and the canine, but more as in *Vesperugo*, long, as long as the posterior one, and quite as large in section basally, its long simple cusp directed somewhat outwards, out of the general line of the teeth.

Measurements of the type, an adult male, preserved in spirit: Head and body 50 mm.; tail 31; head, length 17, breadth of muzzle across eyes 10.8; ear, length above crown 8.8, from base of outer margin 14.5; tragus, length of inner margin 2.0, of outer margin 3.7; forearm 31 (= 1.22 in.); lower leg 12; hindfoot without claws 7.1; calcaneum 13.

Hab. Bathurst, River Gambia. Collected by D.r Percy Rendall.

This species may be readily distinguished from all its allies by its white wings, which contrast very markedly with the dark coloured body and limbs, all the other known members of the genus having the body and wings more or less uniformly coloured. In this respect the bats of the Gambia present rather a remarkable instance of geographical isomorphism, a considerable proportion of the smaller forms, belonging to several different genera, being dark with white wings, a style of coloration comparatively rare elsewhere.

D.r Rendall is to be congratulated on his discovery of this striking species, which forms a worthy companion to the *Vesperugo (Vesperus) rendalli* described by me last year.

The characters of *Scotophilus albofuscus* add still further to the difficulty of properly distinguishing the genus Scotophilus from

p. 87

specimen with which it was compared, an example of *S. schlieffeni*. Finally in 1887 D.r H. Noack, when determining bat from Marungu, Central Africa, thinking (and as I believe rightly) that he had before him a true *Scotophilus*, described it as new under the name of *S. minimus*, but his detailed description leaves no doubt as to its identity, with *S. schlieffeni*, with which he naturally did not compare it, owing to the latter form being referred to *Vesperugo* in D.r Dobson's classical work.

Now this animal, round whose history so much confusion has gathered, has distinctly the general facies of *Scotophilus*; it has ordinarily no minute anterior upper premolar, and the corresponding tooth in the lower jaw is as small and almost as much crushed in between its neighbours as is the case in several of what are admittedly *Scotophili*. It is true that it has occasionally an anterior upper premolar, but this only occurs in one of the many specimens known to science, and may be simply an individual

variation, perhaps due to atavism. In fact M.r Dobson's own reference of a specimen of it to "*Scotophilus" pallidus*, and D.r Noack's description of it as "*Scotophilus*" minimus as already referred to, both strongly support this view.

But even if *S. schlieffeni* is a *Scotophilus*, it by no means follows that *S. albofuscus* is, for the latter is still further away from the typical members of the genus, owing to its long uncrowded anterior lower premolars, which agree more with those of the true *Vesperugo* or of *Scotozous dormeri*. In fact it tands in regard to the latter form just where *Vesperus* does to *Vesperugo, Glauconycteris* to *Chalinolobus*, and *Dasypterus* to *Atalapha*, differing, so far as dentition is concerned, only by the absence of the minute upper premolars. But whatever may be

p. 88

the ultimate arrangement of these various annectent species, it seems better for the present to call the new form a *Scotophilus* on account of its dental formula, irrespective of the shape of the teeth, rather than to consider it a member of the large genus *Vesperugo*, in which the number of its teeth would necessitate the foundation of a new subgenus for its reception.

There is another bat whose claim to generic distinction is considerably weakened, if not, as I believe, altogether removed, by the discovery of *Scotophilus albofuscus*, namely the American species called by D.r H. Allen and others "*Nycticejus crepuscularis*". This bat's sole, or at least chief, generic characteristic lies in the uncrushed state of its anterior lower premolars, a peculiarity which as already stated, *S. albofuscus* shares with it, while geographical considerations would prevent the two species from being regarded as specially closely related. It may also be noted that since Rafinesque's *Nycticejus humeralis* is, as D.r Allen has suggested, no doubt identical with Le Conte's "*N. crepuscularis*" and is earlier in date, the species ought to bear the former instead of the latter specific name. Its proper designation would therefore appear to be *Scotophilus humeralis*, Raf.

Scotophilus alvenslebeni Dalquest, 1965

p. 258

Type. - Adult male, skin and skull, no. 18767 Walter W. Dalquest, Midwestern University Collection, taken on the south bank of the Save River, 212 km SSW Beira, Mozambique.

Diagnosis. - A very large, dark *Scotophilus*, exceeded in size only by *Scotophilus gigas* among bats of this genus known from the African mainland. Sagital crest enormously developed, extending posteriorly over the occiput in an exaggerated crescent. Forearm, 77 mm; condylobasal length of skull, 26 mm.

Comparison. - This species needs comparison only with *Scotophilus gigas* Dobson, for no other *Scotophilus* from the African mainland approaches it in size. I have not seen specimens of *S. gigas*, but the forearm of that species is said to be more than 85 mm in length (Ellerman, Morrison-Scott and Hayman, p. 85), which is considerably greater than that of *alvenslebeni*. The fur of *alvenslebeni* is dark sooty or dusky brown. The ears and membranes are black. *S. gigas* is yellow in color. *S. alvenslebeni* has not been compared with *S. robustus* of Madagascar, but it is highly improbable that the insular form would occur on the African mainland.

Measurements. - External measurements of the type and only known specimen are: total length, 175; length of tail, 77; length of hind foot, 14; height of ear from notch, 20; height of tragus, 9. Cranial measurements are: length of skull from canines, 31.0; condylobasal length, 26.2; zygomatic breadth, 20.0; braincase breadth, 14.8; width across upper M3's, 12.4; width across upper canines, 9.6; upper canine-M3 length, 9.9; mandible length plus incisor, 21.4; lower canine-M3 length, 12.1; forearm, 77.

Remarks. - The type was shot as it flew over the camp clearing at Zinave in the late evening. The species is named for Baron Werner von Alvensleben, in partial recognition of his labors in behalf of our work in Mozambique.

It seems unlikely that this form will be found to intergrade with *S. gigas*. *S. gigas* is known from Nigeria, Nyasaland and Southern Rhodesia. The specimen from Southern Rhodesia is in the British Museum, and has a forearm in excess of 85mm. The forearm of the" type, from Nigeria, has a forearm 3.4 inches (85 mm). The Southern Rhodesian bat thus does not approach *S. alvenslebeni* in size.

Scotophilus angusticeps Shortridge and Carter, 1938

p. 282

Scotophilus angusticeps sp. n.

Two specimens ♀♀ from near Citrusdal.

General colour above drabby umber-brown (rather as in *Eptesicus capensis*), without gloss or sheen; below light drabby brown, centre of abdominal and anal regions strongly washed with rufous, throat tinged with sienna-brown; base of fur, above and below, dark seal-brown; ears and flying membranes dusky black.

Type (in the Kaffrarian Museum). - Adult female, original number 1937, collected 28th December 1937 at Hex River Estate, 10 miles north of Citrusdal, N.W. Cape Province.

Co-type. - Adult female, original number 3308, collected 3rd January 1938.

Dimensions of Type and Co-type. - H. and b., 77 (74); tl., 58 (57); hf., 12 (11.5); ear, 18 (17.5); forearm, 53 mm.

Skulls. - Total length, 20; basal length, 17(17.2); zygomatic width, 13.5; width of brain case, 10 (9.5); interorbital constriction, 4.5; length of palate, 9; upper dental series (from front of canine), 7 (7.5); lower dental series (from front of canine), 7.5 (8); mandible, 16 (15.5); height of brain case, 7.5 mm.

Skull flatter, less massive and with a markedly narrower zygomatic width than in *S. nigrita dingaani* or *S. n. herero*; cranially *S. n. herero* is in some respects intermediate between *S. n. dingaani* and *S. angusticeps*, although much more closely resembling the former.

Scotophilus damarensis Thomas, 1906

p. 175

Quite like *S. nigrita herero*, but markedly smaller. Colour above similarly "wood-brown." Below it is a pale whitish brown, without the buffy tone generally present in *herero*.

Dimensions of the type: -

Forearm 48 mm. (other specimens up to 51).

Skull: greatest length to occipital crest 17.3; zygomatic breadth 12.6; interorbital breadth 7.2; palate length in middle line 6.7; front of upper canine to back of m^3 6.5; greatest breadth of palate between outer corners of m^2 8.1; front of lower canine to back of m_3 7.

Hab. Elephant's Vley, Northern Damaraland.

Type. Male. Original number 276. Collected 10th August, 1859, by C. J. Andersson and received in the Tomes Collection. Four specimens.

Mixed up with the series of *S. nigrita herero* there occur four specimens of this smaller bat, otherwise indistinguishable from its larger ally, to which it would bear the same relationship that in Nigeria *S. nigritellus*, de Wint., does to the true *S. nigrita*. But as it is not quite so small as *nigritellus*, and specimens from the intermediate area are not yet known, I give it a binomial name, though I think it will very probably prove to be a subspecies of that form, from which it may be readily distinguished by its pale brown colour.

Scotophilus darwini Tomes, 1859

p. 70

The next species which I have to describe has been presented to me by Mr. Darwin, with the information that it had been received from the Canary Isles.

In a collection of Bats from Madeira, given to me also by Mr. Darwin, I could only enumerate two species, both European, viz. *S. leisleri* and *S. marginatus*; and I was somewhat surprised to find in the present species one which I had not before met with. None of the descriptions of African species in the works of Temminck, Wagner, Peters, Smith, and others, apply to this species; and I therefore regard it as new, and describe it as follows: -

It is one of the same group as the species just described, and as the *S. kuhlii* and *S. pipistrellus* of Europe. It is characterized by a somewhat more robust make than these species, and has rather broader ears and tragi.

The head is rather broad and flat, the crown being but little raised above the facial line; the glands of the lips are considerably developed, and bulge sufficiently to occasion the nostrils to open nearly straight forward, although the interruption in the outer margins of the latter sufficiently indicates that with a more pointed

p. 71

muzzle they would open sublaterally; were the specimen taken from the spirit in which it is preserved and dried, it is probable that this would be the case. In the middle of the face is a kind of hollow, occasioned by the labial glands on each side being developed in an upward direction, thus leaving a depression between them*. Between the nostrils is a space of moderate extent, and but very faintly emarginate. The ears are rather large, triangularly oval, as broad at the base as they are long, and have their tips brought to a rounded point; about the middle of their outer margin they have a distinct but shallow notch, below which is a lobular portion, as in many other species of this group, but differing from all others which I have seen in having a small but very well-defined notch about its middle. These organs altogether are more like those of *S. kuhlii* than of any other species, but are larger, besides having the double emargination just noticed**. The tragus is rather short and broad, curved inwards, and with the end very much rounded; on its outer margin, near the base, is a projecting angular point, without any accompanying notch.

The wing-membranes extend to the base of the toes, and the latter are half the length of the foot. The thumb is moderate, with the basal phalange much the shortest. The terminal vertebra of the tail is free.

The fur of the head extends forwards to between the eyes, and thence in a narrow strip towards the nose. Over each eye is a wart bearing a bundle of stiff hairs; and a similar tuft springs from the top of the labial glands; the upper lips are also slightly fringed with similar hairs, most conspicuous about the corners of the mouth. The remainder of the face, the ears, and the tragus are naked. The fur of the back spreads on the upper surface of the interfemoral membrane, sparingly, for nearly half its length, as in *S. kuhlii*, and similarly to a small extent on the membranes near the sides of the body. Beneath, the membrane immediately around the pubes is dusted with very short hairs, more abundant on the vertebræ of the tail than elsewhere. On the membrane contiguous to the sides of the body, fur of a much longer kind extends, to a much greater degree than in *S. kuhlii*.

On both surfaces of the body the fur is bicoloured: above, very dark brown at the base, tipped with lighter and more rufous brown, that on the membranes wholly of the latter colour; beneath, it is dark at the base, tipped with paler brown, with less of the rufous tinge than that of the upper parts. On the under surface of the membranes the fur is uniformly of the same colour as the tips of the hairs on the belly, but on the pubes it is paler. Membranes dark brown.

Such appear to be the colours of the fur, so far as can be gathered from the examination of a specimen in spirit; but it is necessary to

* In the *Romicia calcarata* of Dr. Gray the lip-glands are so much developed as to leave a deep pit between them. It belongs to the present group.

** I am here comparing a specimen in spirit with others in skin, - a plan not always attended with perfectly satisfactory results.

p. 72

consult others in skin before this point can be determined with accuracy.

Although in its external appearance *S. darwini* bears considerable resemblance to *S. kuhlii*, it differs, besides having a somewhat differently shaped ear and broader tragus, in the form and arrangement of the fore teeth. In *S. kuhlii* the upper incisors are rather long and slender; the inner ones are deeply forked at their apices, and longer than the outer ones, which are slender and pointed, somewhat like, small canines; and there is a visible interval between the points of the inner and outer ones. In *S. darwini*, on the contrary, they are short and obtuse, of nearly equal length, the inner ones faintly cleft at their points, and the outer ones so closely packed to them as to leave no space even between their points. Again in *S. kuhlii* there is a space between the canine and the "*carnassier*" or sectorial tooth; in which is placed a small and conical premolar, within the line of the teeth, but distinctly visible from the outside; whereas in *S. darwini* the canine and the "*carnassier*" are contiguous, and there is a very small anomalous premolar placed in the inner angle formed at their bases, visible only from inside.

These differences in the dentition are alone sufficient to distinguish the species from *S. kuhlii*. From *S. marginatus*, *S. ursula*, and *S. nathusii* it may be also recognized by the form of the upper incisors; and these are the only European species with which it could be confounded.

" ""

Hab. Palma, Canary Isles.

Obs. The Madeiran species being European ones, and one of them African also (i. e. *S. marginatus*), renders it not unlikely that the species inhabiting the Canaries may also occur in Africa, and perhaps in Europe. With a view to the chance of this, I have compared this species with what now remains of the types of *Vespertilio aristippe, V. leucippe, A. alcythoe, V. vispistrellus*, and *V. savii*, but find nothing which leads me to regard it as referable to any of them; and I have therefore given such a detailed description as will be amply sufficient to distinguish it from all recorded European species.

Scotophilus gigas Dobson, 1875

p. 122

Ear-conch and tragus like those of *S. borbonicus*, Geoffr.; but the internal basal lobe of the ear is more rounded and its inferior horizontal margin is straight, not in the least degree concave; the upper third of the outer margin of the conch is slightly but distinctly concave; and the tragus has the narrow ridge, proceeding from the base of its inner margin across its front margin, as well developed as in *S. Temminckii*.

Wings to the metatarsus near the base of the toes; last two caudal vertebræ and half the third last vertebra free.

Fur above deep chestnut, beneath yellowish white. The fur on the upper surface is short and does not extend anywhere upon the membranes, terminating by a well-defined line, and not extending posteriorly as far as the root of the tail; beneath, the wing-membrane is thinly covered as far as a line drawn from the elbow to the knee-joint, and a band of fur passes outwards, posterior to the forearm, to the carpus, as in *Vesperugo noctula*. The face in front of the eyes is nearly naked.

Upper incisors with a posterior horizontal expansion of the cingulum, as in *S. borbonicus*; lower incisors crowded. The other teeth as in *S. Temminckii*.

Length (of an adult female preserved in alcohol), head and body 4.6 inches, tail 3.6, tail free from membrane 0.35,

p. 123

head 1.45, ear 0.9, tragus 0.45 X 0.1, forearm 3.4, thumb 0.7, second finger 5.75, fourth finger 4.15, tibia 1.4, foot and claws 0.75.

This is by far the largest species of the family Vespertilionidæ yet described, its forearm exceeding that of *Vesperugo molossus* (hitherto known as the largest species) by half an inch, and exceeding by quite one inch the forearm of the largest species of *Scotophilus*.

Hab. Lagos, west coast of Africa. Type in the collection of the British Museum.

Scotophilus hirundo de Winton, 1899

p. 355

Colour of the body above mouse-grey, beneath silvery white; wings and interfemoral membrane wholly dark, with perhaps the exception of the postcalcaneal lobe, which in the dry skin appears pale grey. The tragus is short and rounded, spatulate in form as in *S. albofuscus*, with which species the dentition also closely agrees.

Type no. 99.6.15.8 in British Museum.

Sex not known. Gambaga, 1300 feet, 30th Nov., 1898.

Measurements (taken from the dry skin): -

Head and body c. 43 millim.; forearm 31.5; thumb 5.3.

Measurements of skull: -
Greatest length 14.5; across brain-case 9; between

p. 356

orbits 6 9; tip to tip of canines 4.1; tip to tip of incisors 1.9; front of canine to back of molar series 5.2; front of palate to foramen magnum 10; mandible, greatest length 10.2, height at coronoid 4.2.

The canines have a deep broad groove in front, the tips diverging; the incisors are strongly convergent. The lower incisors are not crowded, but grow in the direction of the jaws. The first premolar in the lower jaw is large and longer than the second premolar.

In all important characters this new species closely resembles *S. albofuscus*, the colour of the fur and win gmembranes alone distinguisheing the two species. There can be no doubt that these two species should be placed in a distinct genus from *S. nigrita* and company, the form of the canine teeth alone being a sufficient reason; but provisionally I follow Mr. Thomas (Ann. Mus. Genov., Feb. 1890, p. 3) in placing them in this genus until the whole of this group of bats shall have been worked out.

Scotophilus minimus Noack, 1887

p. 280

(Vergl. Taf. X, Fig. 36 - 37.)

LEACH in: Transact. Linn. Soc. XIII, S. 71; PETERS, Säugethiere S 65 - 67; PETERS in: M. B. Berl. Acad. 1866, S. 679; DOBSON in: Proc. L. Z. Soc. 1875, S. 369; DOBSON, Catalogue of the Chiropt. S 256 - 266.

Nachdem LEACH die Familie *Scotophilus* 1820 aufgestellt hatte, bestimmte PETERS den Namen *Scotophilus* für die östlichen, *Nycticejus* für die amerikanischen Arten, denen nahe verwandt ist die Gattung *Atalapha*.

Diagnose von *Scotophilus* nach DOBSON:

Körper klein, mit starken kurzen Beinen und starker Flughaut. Kurze konisch abgestumpfte nackte Schnauze, Nasenlöcher ziemlich genähert, vorn nach der Seite geöffnet, mit vorgestrecktem innerem Rande, Ohr länger als breit, kurzer als der Kopf,

oben gerundet, der untere Rand hinter dem Mundwinkel nach vorn und in einer convexen Grube in die Höhe gezogen, Tragus zugespitzt, Schwanz kürzer als Kopf und Leib, nur die Spitze zwischen der Flughaut frei, Sporn schwach. Flughaut zwischen den Schenkeln dick und lederartig. Schädel dick, Hinterhaupt concav; die Gaumenplatte endet hinter M 3 M in der Mitte der Jochlbogen, Raum zwischen den Bullae aud. breit. Färbung olivellbraun oder kastanienbraun, unten gelblich weiss.

Zähne I $^{1+1}/_{6}$ C $^{1}/_{1}$ P $^{1+1}/_{2}$ M $^{3}/_{3}$. Pullus mit einem kleinen 2. Schnedezalhn aussen. Schneidezähne mit Basalwulst, stark nach hinten und innen gerichtet mit einer Furche. Der Untere erste Praem. klein.

Scotophilus minimus, F mit Schädel, Qua Mpala, Marungu. August. Der ohne Schwanz nur 34 mm lange *Scotophilus* unterscheidet sichh schon durch seine Zwerggestalt von allen bisher bekannten afrikanischen Arten und hat nur in dem australischen *Scotophilus greyii* einen eben zo kleinen Genossen. Im Habitus und der Färbung hat er Aehnliehkeit mit dem fast doppelt so grossen *Scotphilus borbonicus*

p. 281

(vergl. v. d. DECKEN, Reise, S. 7; DOBSON in: Proc. L. Z. S. 1875, S. 376), ebenfalls mit dem noch grösseren *Scotophilus temminckii*. Nase und Lippen sehr wenig behaart, schwärzlich, Nasenkuppe nackt, gespalten, braun, die Nasenlöcher mit wulstigem Rande, 1 mm von einander enfternt, Lippenränder warzig, Mundspalte reicht hinter das Auge, letzteres nahe am Ohr, 1 mm entfernt, von der Nase 5 mm, Wangen dünn behaart, Ohr nackt, gelbbraun, elliptisch Zugespitzt, hinterer Ohrrand unten nach vorn umgelegt und mit einem Zacken fast bis zur Mundspalte reichend, Tragus über $^{1}/_{2}$ Ohrlänge, schmal elliptisch, in der Mitte mit einer Grube. Ohren vorn 8 mm von einander entfernt, Flughaut stark, braun, zwischen den Schenkeln gelbbraun, an den Seitell mit starken Papillen, zwischen den Schenkeln mit 8 hellen Querstreifen ähnlich wie bei *Plecotus auritus*, zwischen denen Längenpapillen stehen.

Daumen frei, an den Seiten reicht die Flughaut bis zu den Zehen, hinten bis zum Fersengelenk, 5 mm vor der Schwanzspitze mit starker Ausbuchtung, Beine kurz, kräftig, Füsse kurz, breit, Nägel kurz, gelbbraun. Schwanz stark, nach der Spitze verjüngt, 1 mm frei. Färbung oben hell olivengelbbraun, unten an der Kehle mehr gelb, Seiten hell umbra, Haar lang, fein und dicht. Flughaut unbehaart, nur die vordere Hälfte des Humerus behaart, Körper 34, Schwanz 23, Ohr 8 lang, 7 breit, Tragus 5 lang, 1.5 breit. Humerus 17, Radius 29, Daumen a 1.5, b mit Nagel 4.5; I 20; II a 30, b 12, c 12; III a 30, b 12, c 7; IV a 29, b 8, c 5. Femur -, Tibia 11, Fuss 5.5.

Schädel. Schnauze breit, Orbitalrander vorn wulstig, kleine Scheitelleiste, Schädelkapsel gewölbt, blasing nach hinten aufsteigend, Hinterhaupt schräg nach vorn abfallend, nach oben spitz zulaufend, keine Hinterhauptleiste über dem For. occipit., Bullae aud. bestehen aus 2 hinter einander liegenden Kapseln, deren vordere flache die grosse Ohröffnung enthält. Hinterhauptloch 3 mm breit, 2 hoch, Jochbogen zart, sehr dünn, in der Mitte hochgezogen, hinter M 3 beginnend und vor der Ohröffnung endend, Einschnürung zwischen den Augen mässig, Gaumen sehr gewöhlt, hinten 1 mm hinter M 3 gradlinig endend, hinten nach unten gezogen, wie bei *Epomophorus*, Zahnfläche concav, vorn nach oben gezogen, Zwischenkiefer knorpelig, Nasenöffnung klein, Scheitellänge 13.5, Scheitelbreite 6, zwischen den Augen 4, Breite zwischen den Jochbogen 9, Gaumenlänge 6, Breite zwischen M 3.5, zwischen C 3, Zahnreihe 7, Jochbogen: Länge von M 3 an 3.5.

p. 282

Unterkiefer. Horizontaler Ast gerade, unten wenig gebogen, aufsteigender Ast nach oben gezogen, Rahenfortsatz gross, dreieckig, hinter M 3 steil etwas nach vorn gerichtet aufteigend, die Spitze nach aussen gebogen, Condylus liegt dicht über dem kleinen mit der Spitze nach unten und aussen gebogenen Eckfortzatz. Länge bis zum Condylus 9.5, Höhe des horizontalen Astes 1.5, Zahnreihe 5.5; Breite bei M III 4, Rabenfortsatz 3 mm hoch.

Zähne wie oben angegeben, gelblich transparent, die beiden kleinen I oben mit Basalwulst, Spitzen nach innen, hinten ausgekehlt; C 1.5 lang, hinten aussen und breiter innen ausgekehlt mit scharfer Kante dazwischen, hinten und vorn kleiner Basalhöcker, P = $^{2}/_{3}$ C, aussen C-artig, ausgekehlt, innen hinten mit tiefer M-artiger Furche, deren vordere Leiste gebogen, kleiner scharfer innerer Seitenhöcker. M I und II identisch, dreizackiger, in der Kaufläche W förmiger, innen durch eine tiefe Furche getheilter Aussenhöcler, Aussenzacken 1 und 3 nach hinten und vorn gerichtet, scharfer Innenhöcker über $^{1}/_{2}$ M hoch. Basalwülste aussen unbedeutend, M III verkleinert, hinten nach oben gezogen, 1 scharfer hinten ausgekehlter Aussenzacken, 2 niedrigere ausgekehlte mittlere und ein niedriger mehr nach innen gerückter Innenzacken.

Unten die 6 kleinen I dreilappig auf hohen schmalen stielartigen Wurzeln, C 1 mm hoch, hinten ausgekehlt mit Basalwulst. Alle Basalwülste unten stärker als oben. P I sehr klein, P II grösser, C-artig, zweiwurzlig, Höhe $^{2}/_{3}$ C, hinten stark ausgekehlt, innen vorn und hinten mit kleinem Basalhöcker, M identisch, mit 3 hohen innen ausgekehlten Aussenzacken und 2 kleineren Innenzacken, der hintere AUssen- und Innenzacken bei M III niedriger. Die Details der Zähne nur bei starker Vergrösserungl zu erkennen, Höhe der sehr spitzen Aussenzacken 0.75 mm.

Von *Scotophilus* leben ausser *minimus* in Afrika: *borbonicus* quer durch Afrika, *gigas* in West-Afrika; *temminckii* in Südost-Asien, *heathii, pallidus, ornatus, coromandelicus* und *emarginatus* in Indien, *rueppellii* and *greyii* in Australien

---

Scotophilus nigrita colias Thomas, 1904

p. 207

A richly yellow (almost orange) bellied race of *S. nigrita*.

General characters as in this species, which is Dobson's "*S. borbonicus*." Fur long, rather shaggy; hairs of back 8 - 9 mm. in length. General colour above (of the tips of the hairs) olivaceous, but the bases of the hairs are a dull sulphur-yellow, which shows through on the upper surface. Below,

p. 208

the central line is a rich chrome-yellow, deepening laterally on the sides of the belly fo a golden yellow, which is especially bright on the broad band of fur extending on the wing-membrane between the elbows and knees.

Dimensions of the type: -

Forearm 55 mm. (57 in a second specimen).

Skull: greatest length 20.5; zygomatic breadth 14.5; cheek-tooth series 5.7.

Hab. Fort Hall, Kenya District, British East Africa.

Type. Male. B.M. no. 2.7.6.11. Original number 107. Collected 25th Jan., 1902, and presented by Mrs. Hinde.

The bats referable to *S. nigrita* seem divisible by colour into several geographical subspecies, of which *S. n. Dingani*, Smith, would be the Cape one, and *S. n. leucogaster*, Cretzschm., the Abyssinian. Specimens representing the true Senegalese *S. nigrita* and the Mozambique forms described by Peters are still wanting to the Museum Collection.

From any member of the group as yet described *S. n. colias* seems readily distinguishable by its brilliantly yellow under surface.

Scotophilus nigrita herero Thomas, 1906

p. 174

Hairs of back about 5.5 mm. in length.

General colour above "wood-brown," the hairs rather paler though not yellowish, towards their bases. Below dull "cream-buff."

Dimension of the type: -

Forearm 59 mm.

Greatest length of skull 20.1. Front of canine to back of m^3 7.1.

Hab. Northern Damaraland. Type from Elephant's Vley, about 18° S., 17° 30' E. Other specimens from Otjoro.

Type. Female. Original number 260. Collected 8th August, 1859, by Mr. C.J. Andersson, and received in the Tomes Collection. Twenty specimens examined.

This is the bat referred by Mr. Tomes to *Nycticejus planirostris*, Peters, but it is far paler, both above and below, than either that or any other described race of the widely distributed *S. nigrita*. The variation in colour among the large series collected by Mr. Andersson is much less than one would gather from Mr. Tomes's note. I can find no specimens which are anything like "as dark in colour as the

p. 175

figure given by Dr. Peters." Nor, in fact, in view of the faunal characteristics of the two regions concerned, would one expect to find any that were so.

Scotophilus nigrita nux Thomas, 1904

p. 208

A chestnut-brown subspecies of *S. nigrita*.

General characters of the smaller forms of the widely distributed *S. nigrita*. Fur short, close and fine; hairs of back about 5 mm. in length. Colour above uniform chestnut-brown, or "burnt umber" (Ridgway), the bases of the hairs slightly paler than the tips; very different therefore from the other pale brown or olivaceous representatives of the species. Under surface a rather lighter brown, approaching "russet" (Ridgway), the other forms being all yellowish or whitish below. Fur of body scarcely extending on the wing-membrancs below.

Dimensions of the type (measured in spirit before skinning): -

Forearm 55 mm.

Head and body 70; tail 47; ear 15.

Skull: greatest length 20.5; zygomatic breadth 14.7; upper cheek-tooth series 5.8.

Hab. Efulen, Cameroons.

Type. Adult male. B.M. no. 3.2.4.5. Collected by Mr. G. L. Bates.

Although conspicuously different in colour from any of the known forms of *S. nigrita*, this bat so clearly represents that species in the West-African forest country that for the prepent I prefer to give it only subspecific rank.

Scotophilus nigrita pondoensis Roberts, 1946

p. 304

Differs from *S. n. dinganii* (A. Smith, *S. Afr. Quart. J.* II, 59; 1834: 'Between Port Natal and Delagoa Bay') in its much darker shade of colour, like the

p. 305

smaller species *S. viridis* (Peters), above 'antique brown', below near 'cadmium yellow'.

Type: In the South African Museum, Cape Town, S.A.M. No. 6858, collected by Captain G. C. Shortridge at Port St Johns, Pondoland, 22 August 1902. Named with the kind permission of Dr K. Barnard, Acting Director of the South African Museum.

Measurements: Head and body 89; tail 50; hind foot 12.6; ear 16. Skull, greatest length from canines 22; zygomatic width 14.8; width of brain case 10.1; mastoid width 12.5; width across molars 9.8, across canines 7.7; c-m^3 series 7.2.

Scotophilus nigritellus de Winton, 1899

p. 355

Size smaller than *S. nigrita* (*S. borbonicus*), but apparently agreeing with that species in general form. The colour above is dark olive, the bases of the fur lemon-yellow. This colour is somewhat nearly matched in occasional specimens of both *S. nigrita* and the Indian species *S. Kuhli*; but size alone is sufficient to distinguish it from either of these forms.

The ears and tragus, also the teeth and skull, closely resemble those of *S. nigrita*, but are very much smaller in size.

Type no. 99.6.15.9 in British Museum.

M, Gambaga, 1300 feet, 9th Jan., 1899.

Measurements (taken in the flesh): -

Head and body 70 millim.; tail 37; hind foot 8; ear 15; forearm 44.5; thumb with claw 5.5.

Measurements of skull: -

Greatest length 18 millim.; greatest breadth 12.9; across brain-case 9; between orbits 6.5; tip to tip of canines 5.5; tip to tip of incisors 3.5; front of canine to back of molar series 6.1; front of palate to foramen magnum, middle line, 12; mandible, greatest length 12.5, height at coronoid 5.5.

Tragus long and pointed as that of *S. nigrita*.

Canines rounded in front. Incisors very slightly convergent at their tips. First premolar in lower jaw small, barely half the length of second.

Scotophilus robustus A. Milne-Edwards, 1881

p. 1034

Le Muséum d'Histoire naturelle vient de recevoir de Madagascar une collection fort importante et riche en objets rares ou inconnus; elle lui a été offerte par M. Humblot, qui a surtout exploré, sur la côte est, la région comprise entre Fou.apointe te le lac l'Aincatre.

p. 1035

Une très grosse Chauve-Souris, du genre *Scotophilus (Sc. robustus)*, se distingue de toutes les espèces déjà décrites; elle est de près d'un quart plus grande que le *Sc. borbonicus*; sa tête est relativement plus grosse, l'oreillon est long et eftilé, le poil est partout d'un brun fuligineux.

Scotophilus rusticus Tomes, 1861

p. 35

The present diminutive species resembles in the shape of its head, ears, and incisor teeth the *S. kuhlii* and the *S. minutus*. Top of the head nearly on a level with the face, nostrils somewhat crescent-shaped, and the snout grooved as in *S. minutus*; ears small and triangular, as in *S. minutus*; tragus of uniform breadth, rounded at the end and curving inwards, the notch in its outer margin, at the base, small, and the lobe below it small and pointed. As in *S. minutus* the outer margin of the ear does not advance nearer the angle of the mouth than the base of the tragus.

Thumb and feet rather large in relation to the size of the animal, being equal in size to those of *S. minutus*. They are proportioned just as in that species.

The fur is confined to the body, both above and beneath. It is everywhere thick, soft, of moderate length, and without gloss. On the upper surface it is dark brown at the roots, with the terminal half light cinnamon-brown; on the under parts of the body, dusky at the roots, with the terminal half brownish white, excepting on the pubes, where it is almost of a uniform dirty white. The nose, ears, and wing-membranes are dark brown, the latter very narrowly edged with white, which is most distinct on each side of the feet.

The cranium resembles that of *S. kuhlii*, both in general conformation and in the number and arrangement of its teeth, being possessed of one more premolar than *S. minutus*.

Dentition: M.$^{2-2}/_{6}$; Can. $^{1-1}/_{1-1}$; Premol. $^{2-2}/_{2-2}$; Mol. $^{3-3}/_{3-3}$ = $^{18}/_{18}$.

The upper incisors are unequal in size, just as in *S. minutus*; the canines are relatively stouter than in that species, which is due in some measure to a slight fullness, or rounded prominence, in the middle of the thin hinder edge of the tooth ; the first premolar is very small, being a mere tubercle, and is placed between the contiguous canine and premolar, and is visible only from within; the

p. 36

second resembles in shape the first and only one in *S. minutus*, which it represents. The true molars do not need mention; and the lower jaw with its teeth is so much like that of *S. minutus*, that it may in like manner be dismissed.

Scotophilus variegatus Tomes, 1861

p. 36

This handsome species, is about the size of the *S. leisleri* of Europe.

P. 37

The head is very short; the muzzle short and obtuse, but not very broad or depressed, being about as deep as it is wide. The forehead is elevated in only a trifling degree above the facial line; the nostrils are somewhat prominent, rather small, and open sublaterally, almost laterally; they are nearly round, with a narrow posterior elongation or slit not exceeding in length the diameter of the nostril; the lips are simple, thick, and rather overhanging. The ears are small, of an irregular roundish ovoid form, their inner margin having a kind of lobe, the lower outline of which projects downwards over the forehead, and is there distinct; but blends off in an upward and outward direction to the tip of the ear, which is rounded, and has a somewhat outward direction; the outer margin approaches in some degree to a straight line, and a very narrow piece of membrane passes forward along the side of the head to near the corner of the mouth, where it terminates in a small fleshy lobulus of a rounded form. The ear-conch is rather thin, but not papillated, and has a few distinct sulci near its outer margin, and a longitudinal seam near the inner one. The tragus is broad and short, and shaped somewhat like that of the *S. borealis* of Europe. Outwardly at its base is a descending point, and above this a broad notch, which varies in depth, but is usually rather shallow; and above this it is of nearly equal breadth, the outer margin being rounded, and forming with the inner margin, which is nearly straight, a blunt angular tip, which is directed inwards.

The penultimate phalange of the thumb is a little longer than the basal one, the claw short and not very hooked. Toes rather longer than the remaining part of the foot; the claws small and black. Wing-membranes extending barely to the roots of the toes. Calcaneum long, with a considerable cartilaginous lobe near the middle of its lower edge.

The fur of the forehead extends almost to the end of the nose, in some specimens quite as far forward as the nostrils; the sides of the face sprinkled rather thickly with fine, short, whitish hairs; over the eye and between it and the nostrils are some longish black ones, which are straight and stiff. Inside the ears are a few fine adpressed hairs; and their outer surface is thickly clothed with fine fur for halfway from their base. The fur of the back extends on to the membranes on all parts, but to a greater extent on the interfemoral membrane than anywhere else. Beneath, it spreads on to the membranes, chiefly on and under the humerus, occupying the space (but not thickly) between the elbow and the knee. On their upper surfaces the toes are clothed with fine adpressed hairs; but the other parts of the foot are perfectly naked.

On all parts of the body the fur is long, soft, and unicoloured, or very nearly so; that of the upper parts cream-coloured, palest on the head and neck, and becoming considerably darker on the hinder part of the back and on the interfemoral membrane; beneath, it is of a dirty-white colour. All that of the body, but not of the membranes, has a slight ashy tinge at its roots.

The membranes are so peculiarly marked as to deserve especial

p. 38

notice. They are rather ample, thin, and remarkably marked with veins, but are not papillated. The ground-colour is pale yellowish-brown, everywhere strongly marked with veins of a deep brown colour, which are faintest near the body and on the interbrachial membrane: on the interfemoral membrane they are very distinct, not very numerous, and have a transverse disposition; beneath the humerus they have a tessellated arrangement; but beneath the forearm they are more branched; whilst between the fingers and at the ends of the wings they are run together, and a dark-brown mottled appearance is produced. The ears and muzzle pale brown; legs, tail, and wing-bones darkish brown.

The skull is remarkable for its shortness and great depth in relation to its breadth, and for the almost total absence of ridges or crests. Although the facial line of the cranium makes a near approximation to a straight line, yet the occipital region is so high as to form a facial angle of 48 degrees*. This is due in some degree to the shape of the maxillary hones, the lower or alveolar margins of which curve upwards from the root of the zygoma to the intermaxillary bones. Some approach is made to this form of cranium by that of some of the species of *Lasiurus*, as the *L. noveboracensis*; but in that species the facial angle does not exceed 35 degrees*.

The upper incisors are four in number, very unequal in size, the outer ones being almost rudimentary. The inner ones are of moderate size, acute, and with a moderate cingulum, the outer ones very short and conical, with an evenly developed and broad cingulum. Canines rather slender and pointed. First and only premolar well developed and of the usual *carnassial* form; the three true molars of ordinary form, excepting the hinder one, which is very narrow from front to back, but has the usual number of cusps.

The lower jaw has a less prominent posterior angle than in other species of the genus, but does not otherwise differ materially. The incisors have the usual external trilobed appearance; but they are thicker from front to back than is usual, and the hinder part is produced into a kind of basal lobe, which has sufficient prominence to have the appearance of a fourth cusp. The canines are rather acute, and have the cingulum produced anteriorly into an acute point, a little above the level of the incisors. The first premolar is small, conical, and with a regular cingulum; the second somewhat similar, but considerably longer, and it is succeeded by the three true molars, of usual size and proportions, excepting the posterior one, which is rather smaller than usual.

Dentition: $M.^{2-2}/_{6}$; $Can.^{1-1}/_{1-1}$; $Premol.^{1-1}/_{2-2}$; $Mol.^{3-3}/_{3-3} = {}^{14}/_{18}$.

Hab. "Otjoro, December 1st, 1859."

Obs. I have chosen to give an ample description of this species because it differs in some respects from any other species of the genus which I have seen, the differences appearing to me to be such as may (if found in any other species) be sufficient to point out another minor group, parallel with those which have been partially indicated by Blasius, and more fully by Kolenati. Broadly, these differences may be stated thus: - *Cranial portion of the skull much raised, instead of being depressed; muzzle*

not depressed; cutaneous system thin and elaborately veined, instead of being thick and leathery; fur long, soft, and unicoloured, and covering nearly the whole of the face.

Scotophilus welwitschii Gray, 1866

p. 211

Among an interesting series of Bats from Angola, collected by Dr. Welwitsch, and most kindly presented to the British Museum, is a very interesting and ornamental species of *Scotophilus*, with the wings coloured like *Vespertilio pictus* of Pallas.

This coloration of the wings seems common to several Bats belonging to different genera; but I have not before observed it in a species of *Scotophilus*.

SCOTOPHILUS WELWITSCHII (Pl. XXIV.)

Brown. paler beneath; hair of the back black, with brown tips, which are longer and paler on the hairs of the under surface. The ears rather elongate, longer than head. tip rather acute; tragus elongate, lanceolate, acute, nearly half as long as the ear. The wings blackish brown. yellow-dotted, and yellow (or red brown perhaps when alive) near the body, and on and near the arms and fingers, and between the shoulders and arm-bone; interfemoral membrane yellow, black-dotted, and with a dark hinder edge, the upper surface near the base of the tail hairy; heel-bone elongate, as long as the shin. Feet pale yellow; toes black at the end; .wings to the base of the toes. Thumb - upper joint black, much longer than the lower, which is yellow. The face hairy to the end of the nose; just above the nostrils. Upper cutting-teeth 1,1 ?. large, blunt; premolars $^{2}/_{1}$ $^{2}/_{1}$, the front upper large, triangular; the hinder small. rudimentary. Forearm-bone 2 inches 1 line long.

Hab. Angola (*Dr. Welwitsch; B.M.*).

Selysius Bonaparte, 1841

Selysius

Dei *Vespertilionini* non dati per ora, ma forse da aggiungersi alla Fauna italiana, nomineremo il *V. mystacinus*, Leìsler, che facciam tipo di nuovissimo genere ben caratterizzato dalla forma del cranio, dalla dentatura, dal foltissimo pelo, dall'opacità e ìntaccatura delle orecchie, e soprattutto dall'inceppamento dei piedi: il nome di *Selysius* che gli apponiamo fa commendevole ricordo di stima al giovane naturalista di Liegi, autore della *Fauna belgica* e di altri applauditissimi scritti. Nè taceremo del vero *V. emarginatus*, Geoffr. suo congenere; avvertendo qui essere quello da noi figurato sotto tal nome il *V. nattereri*, Kuhl, anello di congiunzione tra i due generi *Selysius* e *Vespertilio*. E qui giova dire che per timore di confusione usiamo il nome *Vespertilio* a denotare quel gruppo cui per abbaglio lo restringemmo, ma che tal nome giustamente dovrebbe trasferirsi a quella suddivisione contenente il vero *Vespertilio murinus* di Linneo. Avendoci finalmente accertati il colore del vello, la frequenza in Svezia, ed altre ragioni inoppugnabili, che il *V. murinus*, L. corrisponde al *V. discolor*, Leisl. deve a questo ripristinarsi almeno il nome specifico, comunque siasene abusato, applicandosi nella Svezia stessa dal Nilsson, ora ricredutosi, al *V. daubentoni*, Leisl., dagl' Inglesi tenacemente al *V. pipistrellus*, Daub., e da noi stessi travolti nella piena corrente al *V. myotis*, Bechst.; cui preghiamo non chiamisi altramente d'ora innanzi, il nome *Myotis* potendo anzi divenir generico per chi non tollerasse eccezione di regola.

Spectrum vulgare Gray, 1870

p. 100

Ears small; fur soft, abundant, spreading, blackish chestnut; head pale yellow ; the upper arm, sides of the shoulders, back, and

p. 101

the rump bright golden yellow; underside of thighs and pubis yellowish.

La Roussette, *Brisson*. La Rossette, *Buffon*., H. N. x. t. 14. Vespertilio vampyrus, *Schreb*. Not *Linn*. Pteropus vulgaris, *Geoff. Ann. Mus*. XV. P. 92 ; *Temm. Mon*. i. p. 132 ; ii. P. 74, t. 38 (young).

Sphyrocephalus A. Murray, 1862

p. 8

Dental formulary :-

Incisors. 4/4 Canines. 1/1 Molars: Premolars? 1/2 True molars? 2/3

Head very large and oblong; the lips largely developed and expanded. Ears rather large, without tragus. Thumb and index-finger of hand unguiculate, the other fingers without claws. Tail wanting.

Sphyrocephalus labrosus A. Murray, 1862

p. 8

Brown, with a few whitish hairs at the base of the ears. The head very large, massive, half as long as the whole body, oblong, and as broad at the muzzle as at the top of the head, with some resemblance to a hammer, whence the name hammer-headed (*Sphyrocephalus*), rather more than twice as long as deep; ears rather large, destitute of tragus; eyes rather large; eyelids provided with eyelashes; nostrils large and tubular; lips extraordinarily developed; both upper and lower lips of a very smooth semi-muco-membranous texture, corrugated and tuberculated at the margins; the upper lip with a tuberculated prominence in the line of the two outer incisors, and a more elongated tuberculated ridge further up, in the line of the two inner incisors; the external lateral margin expanded into a sort of stiff semi-cupshaped flap with a tuberculated edge, rising to meet the nostril and then descending, following its lower edge, and terminating in a curved scroll-like coil in the nostril.

The same semi-muco-membranous lip is spread over the front of the lower jaw, forming a sort of chin. The skin in the neighbourhood of the lips, and extending upwards and backwards along the nasal bones, is covered with the same sort of fine velvety down which surrounds a horse's nostrils; the hair on the rest of the head is flocky; on the downy portion there are on the sides of the upper

p. 9

lip three rows of papillæ, each with a long whisker-hair springing from it. In the specimen before us these papillæ are arranged four in the two first rows and three in the last; similar papillæ and hairs run up the downy space covering the long nasal bones, in three rows, past the eyes and quite to the forehead, numbering each nine or ten papillæ, the middle row being shorter than the two others. The gape of the mouth is large, extending back fully a third of the head; the lip does not encroach on the outside of the face along the gape; it is only directly in front that it is so much developed; the upper lip is connected with the gum by a broad thick ridge uniting them together in the line of the symphysis of the intermaxillary bones.

The disposition of the teeth is as follows:-

They are all well separated from each other, none touching each other except, perhaps, the last molars; the incisors of the upper jaw are minute rounded points; in the lower jaw they are equally minute, but transversely oblong and bilobed. The canine teeth in both are well developed and of the usual form; beyond the canine there is a minute tooth (a mere point) in the lower jaw which is wanting in the upper jaw; the next tooth beyond it is almost exactly of the form of the canine, and is probably a pre-molar; the remaining teeth, two in the upper and three in the lower jaw (probably true molars), have their crown divided longitudinally; in the upper jaw each ridge slopes backwards, in the under jaw the external ridge is bilobed. The palate has strong, elevated, transverse ridges running across from interspace to interspace between each tooth. The tongue is rather large, and covered with a sort of tessellated pavement of large flat papillæ; it is free very far back. Under it and lying in the hollow of the mouth, occupying the whole breadth for a short space in front between the rami of the lower jaw, is a very curious membrane fringed with slips or plaits - a sort of second tongue, calling to recollection a somewhat similar organ or structure under the tongue of the Loris and Lemur. In these it assumes the form of an aponeurotic lamina, which is divided at its anterior thinner end into filaments or slips. "This arrangement (a development of the frenum of the tongue)," says Van der Hoeven, "has been described incorrectly, in my judgment, as though the tongue were double, or even as if a bird's tongue were under the mammalian tongue." It may be a development of the frenum, because two things connected together, although at opposite ends, may always be said to be parts of the same thing however distant they may be. B ut I would only observe that in the present instance the frenum of the tongue is situated very far back, and it seems to me that it may just as possibly be a development of the floor of the mouth as of the frenum of the tongue. I do not suppose that Dr. Van der Hoeven would think it necessary to look elsewhere than to the walls of the œsophagus to find the structure from which the elongated papillæ lining the œsophagus, in the hawk-billed turtle for instance, had been developed. There is a tendency to similar structure in other parts than the tongue in many animals - on the palate and back of the mouth, for example; and I should not be disposed to seek further than the place from

p. 10

which it springs for the source of this development. It does not extend much further back than the lower canine teeth; but there is a slight plait or perceptible line running on each side all the way to the back of the mouth, giving the appearance of a second thin flat tongue lying in the hollow of the mouth, tied down like the tongue of a crocodile; but the separation here is a mere trace, and it is only the fringed margin in front which is free.

The neck is distinct, and the skin has the appearance of having some cellular space between it and the muscles.

The body is oblong and compact; the ribs descend far, and the lower ribs are very large; the stomach is moderate in size, furnished internally with several large transverse folds; the small intestines are not very long; there is no cæcum.

The arms have the thumb and index unguiculate, the rest of the fingers are without claws; the thumb has two phalanges, the rest have three phalanges. The thumb is united to the wing by a membrane stretching on both sides over the whole of the proximal and half of the distal phalanx; the proximal phalanx of the thumb is shorter than the distal. The winged membrane is not extended across the back, but is very ample; the winged space between the third and fourth fingers, and between the fourth and the body, has in its middle numerous longitudinal bundles of muscular fibre interwoven without attachments, and one or two similar transverse bundles; these are probably for the purpose of assisting in the folding of the wing. Along these bundles of muscular fibre the membraneous wing is closely wrinkled; and there is little doubt that they will also strengthen the membrane where they occur.

The hind feet are uniform and all unguiculate; they are united to the body by an interfemoral membrane, which has a single large bundle of muscular fibres stretching obliquely across from the foot to the coccyx.

The testicles are situated under the skin on each side of the male organ, and are round.

There is no tail.

The length of the whole body, in the specimen from which the above description is taken, is nearly 7 inches; the length of the head 3 1/4 inches, its depth about 1 1/4 inch. The stretch of wings is 28 inches across.

The most remarkable features in this animal are its large hammer-shaped head, and the great external development of its lips. Its whole structure is essentially that of a Pteropine Bat, with some modifications showing a tendency towards the *Rhinolophi*. No species having any of the nasal appendages peculiar to that section of the Bats has yet been found among the Pteropine Bats. They are strictly frugivorous, and have the nose like that of a fox or dog. The present species, although it has not any nasal appendages, has labral expansions which may possibly be analogous to them, and the animal may possibly have peculiar habits to which the structure of these organs is especially adapted.

Unfortunately, in the only specimen yet received, the stomach and

p. 11

intestines were wholly empty; so that we cannot speak of its food with positive certainty. The teeth are Pteropine in character, but not so absolutely so as to preclude the possibility of this creature being at least partially insectivorous, the molars showing a tendency to mammillation on the external side of the longitudinal ridges into which they are separated. The large folds in the interior of the stomach seem to point to a vegetable diet.

The sublingual fringed membrane is also an interesting peculiarity, not only on account of its rarity, but because one of the few other instances where it has been noticed is in an animal having no one thing in common with the present, except that of living in the same country. We sometimes see this happen; an abnormal structure or peculiarity occurring in an animal restricted to one country will be found repeated in some other animal of that country no way connected with or allied to it.

This Bat was sent to me by my excellent friend, the Rev. Wm. C. Thomson, one of the missionaries of the United Presbyterian Church of Scotland, stationed at Old Calabar - a true Christian, an excellent naturalist, and one whose devotion to the cause he has undertaken, viz. the amelioration of the African negro, has been proved by the greatest sacrifices from his youth upwards.

footnote p. 8:

* Since this paper was in print, the last number of the 'Proceedings of the Academy of Natural Sciences of Philadelphia' has been received in this country (the first copies arrived on 19th February, 1862); and in it I find a description of a new Bat, which probably belongs to this species, by Dr. Harrison Allen (Proc. Acad. Nat. Sc. Phil. July 1861, p. 156). It is said to be taken from a specimen collected by M. Du Chaillu, and is named by Dr. Allen *Hypsignathus monstrosus*. If it is the same species, of course Dr. Allen's name must take precedence. His description does not quite correspond with mine, but, judging from the description of the nose, may, perhaps, have been taken from a dried skin, whereas mine is
from a fine example in spirits. M. Du Chaillu has exhibited no specimen of this Bat in England.

Tadarida (Chaerephon) cyclotis Brosset, 1966

p. 80

Type M ad. - Bélinga. - Janvier 1963.

Description

Molosse d'assez grande taille (avant-bras 51.5 mm), séparable à première vue des espèces africaines de dimensions voisines par des oreilles larges et arrondies, des formes moins massives et un pelage relativement long et épais. La morphologie crânienne, la dentition, le tragus présentent des particularités distinc.

p. 81

Longueur condylo basale: 18
Largeur zygomatique: 12.3
Largeur boître crânienne: 11.3
Rétrécissement interorbitaire: 4.4
Rangée dentaire supérieure (de l'incisive à la pointe postérieure de M 3): 9,1
Ecartement à la pointe des canines: 4.8
Longueur de la mandibule: 15
Longueur de la raneée dentaire inférieure: 9.7

Pelage et membranes:

Pons de couleur uniforme sur toute leur longueur. Le dos est brun rougeâtre. La partie ventrale présente une teinte plus claire, rougeâtre-orangée d'une tonalité chaude et brillante .. base de

p. 82

membrane réunissant les oreilles en avant existe l'amorce d'une "crête" basse, formée de poils mous et serrés, de couleur brun noirâtre. Le pelage se prolonge sur le patagium, de chaque côté du corps sur une bande d'environ 1 cm de largeur. L'uropatagium est couvert d'une pilosité décroissante, de la naissance de la queue jusqu'à la partie libre de celle-ci. Cette dernière est complètement nue. Sur la face dorsale, plantés au niveau du fémur, on note quelques longs poils raides. Les pattes, les doigts externes surtout, montrent des rangées de poils raides, clairsemés et courts, de couleur jaune doré. Des poils semblables, mais plus courts existent également sur un "bouton" sous mentonnier, aux commissures des lèvres, au point de jonction des deux oreilles, à l'extrémité supérieure de la membrane réunissant celle-ci.

La peau des avant-bras est brun-clair dessus, dépigmentée dessous, la face interne des avants-bras étant de couleur chair. La partie interne de l'uropatagium est également très claire. La lèvre supérieure est brune, l'inférieure est blanchâtre.

Tête et oreilles:

La lèvre supérieure est profondément plissée. La partie nasale est fortement proéminente, comme chez la plupart des Molossidés. Les oreilles sont grandes et larges. Le bord externe est arrondi. L'antitragus est grand, aplati, et bien détaché de l'ensemble de l'oreille. Le tragus est petit et caché par l'antitragus (fig. 9).

Une membrane sagittale, épaisse et haute de 6 mm réunit les deux oreilles en avant.

Corps:

Le corps ne présente pas les formes lourdes habituelles chez les *Tadarida*. Les membres inférieurs, du type molossidé, sont relativement grêles, tandis que la queue est également assez courte.

Le cinquième doigt est très court par rapport au troisième, ce qui réalise une aile longue et étroite, de faible surface portante. Ce rapport est caractéristique des formes à vol direct, élevé et rapide. Les ailes de *T. cyclotis* sont très semblables à celles de *T. condylura*.

p. 83

Le grand développement du pouce et des callosités du pouce désignent *T. cyclotis* comme un grimpeur apte à se glisser dans des fissures étroites.

Crâne:

Sa structure d'ensemble est légère par rapport à celle des autres *Tadarida*. La boîte crânienne relativement allongée est marquée sur le dessus d'une dépression accusée au niveau de la grande suture transversale. La région occipitale est fortement

convexe. La crête sagittale est nulle et les crêtes lambdoïdes peu développées. Les bulbes auditifs sont par contre grands, en liaison avec l'oreille externe qui est elle-même de forte taille (fig. 10).

La partie nasale est relativement étroite. Le rétrécissement interorbitaire est prononce. Le palais est allongé, fortement concave et trapézoïdal. L'échancrure du prémaxillaire, en arrière des incisives, qui est un'caractère du genre *Tadarida*, n'apparaît plus clairement. Mais le séjour du type de *T. cyclotis* dans le formol a durci les cartilages du crâne, qui ont pu oblitérer l'échancrure, si elle existe.

La dentition est peu spécialisée. Elle est plutôt faible, quoique la canine soit longue et mince. PM 1 est bien développée et située dans la rangée dentaire. Les incisives inférieures, au nombre de quatre, sont plantées en demi-cercle. Elles sont fortement bifides.

Mieux que toute description, le dessin ci-contre donne une excellente idée du crâne de *T. cyclotis*.

Comparaison entre *T. cyclotis* et les espèces africaines les plus voisines *Tadarida condylura* a l'avant-bras plus court; les formes sont plus lourdes, les oreilles beaucoup moins larges. L'antitragus est moins grand, le crâne est moins long, mais plus massif. Les crêtes lambdoïdes et sagittales sont beaucoup plus développées. La dentition enfin présente de notables différences. Le Muséum de Paris possède des séries de *T. condylura* qui nous ont facilité ces comparaisons.

Reste *T. trevori*, espèce plus rare, et que nous n'avons pu examiner. D'après les descriptions d'AELLEN et de VERSCHUREN, *T. trevori* aurait des dimensions et un aspect voisins de *T. cyclotis*. Mais le rapport du 3^{e} doigt et du 5^{e} est différent, réalisant chez *trevori* une aile moins étroite. L'oreille est beaucoup moins large, et le tragus n'est pas carré chez *cyclolis* comme il l'est chez *trevori*. Enfin le crâne de cette dernière espèce est plus grand dans toutes ses dimensions, et le rapport de sa longueur à sa largeur, ainsi que l'écartement des maxillaires, doivent lui donner un aspect massif et puissant, différent de celui de *cyclotis*.

p. 85

L'aspect de la tête et du crâne de *Tadarida cyclotis* rappelle un peu celui des Molossidés du genre *Otomops*. On notera qu'il s'agit là probablement de formes forestières, alors que les *Tadarida* sont en général liés aux zones découvertes: savanes et semi-déserts. L'évolution vers une structure plus légère et un grand développement de l'appareil auditif est peut-être caractéristique des Molossidés forestiers, circulant à la cime des arbres; ces espèces auraient développé une morphologie tendant à augmenter la maniabilité du vol, par un allégement des formes et une hypertrophie de l'appareil écholocateur.

Biologie

Ce beau Molosse se fit prendre au crépuscule dans un filet japonais, tendu sur une levée de terre qui traverse le marigot bordant le terrain d'aviation de Bélinga. L'animal venait de toute évidence boire à la surface de la nappe d'eau. Par la suite, nous avons passé une dizaine de soirées à cet endroit à faire le guet, pour essayer de voir et de tirer d'autres individus. Malheureusement, aucun Chiroptère de ce type ne fut observé. La biologie de *Tadarida cyclotis* reste donc inconnue. Tout au plus peut-on dire, compte tenu de la localisation de la capture, qu'il s'agit probablement, d'une forme forestière.

Tadarida (Chaerephon) faini Hayman, 1951

p. 82

Type (in the Congo Museum, Tervuren): M skin and skull, Congo Mus. n° 20509, original number 1, collected in June 1951 by Dr. A. FAIN at Wago Forest, between Blukwa and Lake Albert, Belgian Congo. (Blukwa lies at about 1° 45' N., 30° 37' E. at about 2.000 metres above sea-level). The paratype, a F skin and skull, original, number 2, Brit. Mus. n° 51.629, from the same locality and collector, has been presented to the British Museum (Natural History).

Diagnosis: The species is distinguished primarily by its light ochraceous-tawny body colour above and below, its semi-translucent wings and its medium size (forearm 38 mm. in the type).

Description: The head and body of the type, both dorsally and ventrally, are clothed with short hair of an almost uniform ochraceous-tawny colour. The underside is slightly lighter in tone than the back, and in the median line of the abdomen there is a slightly yellowish wash. The hairs everywhere are slightly paler basally, but the paler bases do not show through to affect the general colour. On the underside of the wing membrane a narrow band of yellow hair runs from the base of the humerus to the base of the femur, flanking the side of the body. The crown of the head is nearly naked, and the lappet of skin joining the bases of the ears is clothed with dense but short hairs of the same colour as those on the head and body.

p. 83

The ear membranes are dark, but the wing and interfemoral membranes are semi-translucent. The wing membranes are attached to the middle of the tibia.

The female skin, apart from being slightly paler above than the type, shows no differences.

The skull and teeth are characteristic of the subgenus.

Measurements: (in the absence of original measurements, those now given, taken from the dry skins, must be regarded as approximate only, except in the case of the forearm measurements). Type and paratype: (all measurements in millimetres), head and body 59, 60; tail 33, 29; hind foot 10, 10; ear 15, 16; forearm 38, 39. Skulls of type and paratype: greatest length 15.7, 15.8; condylobasal length 14.8, 14.5; zygomatic breadth 10, 10.1; mastoid breadth 9.8, 9.4; maxillary breadth 6.8, 6.9; interorbital

width 4, 4.1; breadth at base of canines 4.1, 4.1; upper tooth row, including canine, 5.7, 5.7; length of mandible 11.1, 10.9; lower tooth row, including canine, 5.7, 5.9.

Remarks. No other African member of the group combines the distinct colouration and size of the present species.

Nyctinomus ochraceus J. A. ALLEN (1917) from Medje, Ituri Forest, is one of the more brightly coloured forms of about the same overall size, but according to the description is dark chestnutbrown above, with only the bases of the hairs ochraceous buff- and is orange below. It has also a considerably longer skull.

SIMPSON (1945) has regarded *Chaerephon*, as well as *Mops*, as no more than subgenerically distinct from *Tadarida*, which antedates *Nyctinomus*. TATE(1941) has pointed out that certain skull characters used in the past to distinguish *Chaerephon* are not constant, and it therefore seems best to treat *Chaerephon* as a subgenus of *Tadarida*.

Tadarida (Chaerephon) gallagheri Harrison, 1975

p. 313

Holotype.

Harrison Zoological Museum (Reg. No. 1.7797), now deposited in the British Museum (Natural History). Adult male, obtained on 14th Nov. 1974 at Scierie Forest, 30 km SW of Kindu, Zaire (3° 10' S, 25° 49' E), by Major M. D. Gallagher.

Diagnosis.

A small bat, forearm 37.5 mm; greatest length of skull 16.0 mm. General features are those of subgenus *Chaerephon*, the conjoined ears with a frontal crest, the premaxillae co-ossified and m^3 complete. This species is, however, unique amongst Molossid bats in the possession of large paired nasal inflations highly reminiscent of *Rhinopoma*. It is also at once distinguishable from all other African Molossids by the presence of a deep, well-defined inter-aural pocket, containing the frontal crest. The anterior extension of this pocket projects into the inter-aural membrane as a bulbous anterior protrusion, which in profile overhangs and projects in front of the muzzle.

Description.

The holotype is the only known specimen. The ears are large and extend well in front of the muzzle when laid forwards; their anterior

p. 314

borders are squarish; there is a well-developed subrectangular anti-tragal lobe, at the base of their convex, external margin; the tragus is very small, its upper surface with two small indentations distinct minute basal lobule posteriorly. The ears are united across the forehead by an inter-aural membrane, with a flat-topped convex superior margin, resembling a truncated triangle; a prominent globular swelling projects from the middle of its anterior surface, projecting above and well in front of the muzzle in profile. This swelling, which has a faintly marked median rib dorsally, is in fact the anterior extremity of a remarkable inter-aural pocket, situated on the crown of the head, behind the inter-aural membrane. The pouch is deep, lined by two vertical hairless folds of skin 3.2 mm high, which extend from the posterior aspect of the inter-aural membrane on each side of the globular swelling and unite with each other on the crown of the head. The floor of the pocket is smooth, but it contains a frontal crest of hairs, which are uniformly dark brown; in colour and some 9 mm in length. The muzzle is blunt, with a transverse ridge above the nostrils, and the upper lip is marked by vertical furrows. The wings are long and narrow; the wing membranes, tail membrane and ears uniformly greyish black in colour. The long tail projects for three-quarters of its length beyond the short tail membrane. The pelage is uniform in colour, umber brown, so far as can be ascertained

p. 315

in the single alcoholic holotype, and scarcely lighter on the ventral surface, where there is no pattern. It extends as a narrow band on to the ventral wing membrane from axilla to groin, but not significantly elsewhere on to the membranes. The toes are fringed with short whitish hairs.

The skull is extremely distinctive, its general form elongated and narrow. The rostrum is very long and terminated anteriorly by pronounced paired nasal inflations, surrounding the broadly flask-shaped nasal aperture and imparting an extremely unusual truncated aspect to the front of the rostrum. The inflations extend laterally so as to be visible from the ventral aspect of the skull. Pronounced lachrymal projections are present at the anterior orbital margins and the infraorbital foramina open on the sides of the rostrum between these and the back of the nasal inflations, at the level of the anterior border of the second upper premolar. The interorbital region is long, with slightly swollen sides; supraprbital ridges are almost absent. The zygomatic arches are slender and not-widely flared, rather straight-sided when viewed from above. The braincase is moderately inflated, lacking any sagittal crest and the lambdoid crests are weak. The dorsal profile is rather low, with the braincase only slightly elevated above the rostrum. The premaxillae are completely co-ossified and there is no palatal emargination; the palate is long, with a median concavity and slightly excavated on each side postero-laterally behind the level of m^3. The mesopterygoid space is broadly rounded anteriorly; the basial pits are deep and rounded, well defined posteriorly; the tympanic bullae are moderately large. The mandible is long and slender, with a blunt angular process and low coronoid.

The dentition is not heavy; the upper incisors are relatively large; well, separated from one another, flattened pyriform in shape, with their points directed inwards slightly and each with a small outer basal cingular cusp. The upper canines arc slender, with small posterior basal cingular cusps. The small upper premolar is situated in the toothrow just behind and lateral to the cingular

cusp of the canine; the second upper premolar is well developed, attaining fully three-quarters of the height of the canine; m^1 and m^2 are subequal, each with well developed hypocones; the metacone dominant in each and the styles well formed: m^3 has a well developed third commissure. Four well spaced lower incisors are present, the inner pair larger and faintly bifid. The lower canines are slender with anterior and posterior basal cingular cusps. The second lower premolar clearly exceeds the first in crown area and height, while m_1 is clearly larger than m_2, especially in width of the talonid; m_3 is distinctly smaller; in all the lower molars the protoconid is dominant.

p. 317

Measurements of the Holotype.

Total length 77 mm; forearm 37.5 mm; hind foot (s. u.) 7.8 mm; tail 28 mm; ear 19 mm. Cranial measurements: greatest length 16.0 mm; condylobasal length 14.9 mm; zygomatic width 8.9 mm; breadth of the braincase 7.8 mm; postorbital constriction 4.2 mm; width of the rostrum across nasal inflations 5.3 mm; median palatal length 7.0 mm; mandible 10.6 mm.

Remarks.

This remarkable little bat is at once distinguishable from all other known Molossids by its unique nasal inflations, highly reminiscent of *Rhinopoma*, a feature so distinctive as to demand consideration of generic status for it. It is clear, however, that in most features it represents a highly specialised *Chaerephon*, a swift-flying species which has perhaps developed some special modification of the nasal region for echolocation. Amongst the African Molossids, which have been

p. 318

recently listed and keyed by Hayman and Hill (1971), it finds resemblances with *Tadarida (Chaerephon) major* (Trouessart, 1897), which however lacks a clearly defined inter-aural pocket, as well as having several cranial differences in addition to the lack of nasal inflations. These are an upturned occipital region, wide flattened braincase and shallow, diffuse basial pits. It is also larger, with a forearm length of 42 - 44 mm and greatest cranial length 18.5 - 19 mm (Rosevear, 1965). In respect of the remarkable inter-aural pocket *T. gallagheri* most closely approaches an Oriental species, *Tadarida (Chaerephon) johorensis* (Dobson, 1873), which has a rather well defined pocket, differing however, in some details of structure from this species. The structure of the pocket in *johorensis* has been well described by Hill (1974). It differs particularly by being partially divided by a median septum, and the anterior face of the membrane does not project forwards in such a striking manner. *T. johorensis* also differs in some cranial features, as well as lacking nasal inflations, thus the narial emargination is rounded posteriorly, instead of being flash-shaped, with a pointed posterior extension as in *T. gallagheri*. It is also a larger species (forearm 46 - 50 mm). The discovery of a female *T. gallagheri* will be awaited with interest as its aural structure particularly may differ from the male.

Tadarida (Chaerephon) tomensis Juste and Ibáñez, 1993

p. 901

Holotype. - Adult female; skin, skull, and partial skeleton; Estacion Biologica de Donana (EBD) 18256, field number B7085; from Praia das Conchas, 3 km NW Guadalupe, Sao Tome Island, Republic of Sao Tome and Principe (0°24'N, 6°37'E); obtained on 22 April 1988 by Javier Juste and Antonio Ayong.

Paratypes. - Two adult females; in alcohol, skulls removed; EBD 17371 and 17734. EBD 17371 is from Agua Izé, São Tomé Island, and was collected by Javier Juste and Carlos Ibañez on 11 April 1988. EBD

p. 902

17734 is from Praia das Conchas, São Tomé Island, and was collected by Javier Juste and Antonio Ayong on 22 April 1988.

Distribution. - Known only from São Tomé Island where it has been collected at two localities.

Diagnosis. - Interaural membrane bearing a characteristic globular swelling on the anterior margin, similar to that found only in *T. (Chaerephon) gallagheri* among all African species. In lateral view, the interaural swelling extends slightly forward of the muzzle (Fig. 1). The anterior rostrum is inflated on each side of the anterior nares from (and including) the premaxillae to the lacrimals. The nasal opening is elongated when viewed from above (the nasals appear emarginate) with the posterior margin extending posterior to the lacrimal processes and the maxillary root of the zygomatic arches (Fig. 2). Also in this dorsal view the nasal orifice is shaped as an elongated bell; not flaskshaped as in *T. gallagheri*.

Description. - A small free-tailed bat (length of forearm of holotype, 38.5 mm; other measurements in Table 1) with round-tipped ears wider than long that extend forward slightly ahead of the muzzle. The well-developed antitragal lobe is subrectangular. The tragus is minute, and bears three lobes on its upper margin and a lower basal lobule.

A striking feature is the appearance of the interaural membrane (Fig. 1). The anterior margin of this membrane has the form of a truncated triangle when displayed that is slightly elevated centrally and has a small depression. The anterior margin of the in-

p. 904

teraural membrane also bears a central globular mass that extends a little beyond the muzzle. This mass is divided longitudinally by a medial groove and surrounds a 3-mm-deep pouch connected to the interaural membrane by a small median ridge. The base of the pouch is lined with a dense layer of brown hair that contrasts with the essentially naked interaural membrane.

The wing membrane is narrow, whitish, and nearly transparent in the middle and at the tips of the wings, and brownish black proximally along the sides of the body and the uropatagium. The body is dark brown dorsally, brown on the ventral sides and flanks, but whitish to pale-brown on the venter medially. The body pelage is dense, relatively long, and extends as a narrow strip along the flanks and uropatagium, where it is most conspicuous on the venter. The dorsal pelage is longest (ca. 7.0 mm) and has a whitish to pale-brown base; that of the venter is shorter (4.0 mm) and the individual hairs are tricolored-whitish basally, brown medially, and with pale-brown tips.

The rostrum is inflated laterally from the lacrimals to and including the premaxillae (Fig. 2a) on each side of the comparatively long and broad narial opening. The lacrimal processes are well developed, but not as long as in *T. gallagheri*. The braincase is rounded and only slightly elevated above the rostrum. In the specimens examined (females), supraorbital ridges and a sagittal crest are lacking; lambdoidal crests are weakly developed. The anterior insertion of zygomatic arches shows a conspicuous flattened space anterior to the orbital fossa. The zygomatic arches are slender and relatively straight when viewed dorsally. The premaxillae are fused; the degree of anterior palatal emargination resembles level 2 of Freeman (1981). The palate is broad, concave medially, and achieves its anterior maximum width at the level of the last premolar. The mesopterygoid fossa becomes wider posteriorly. The basisphenoidal pits are well defined (diameter, 1.2-1.6 mm) and deep (level 4 of Freeman, 1981), separated by a 0.2-mm septum (Fig. 2c). A line connecting the glenoid fossae passes through the anterior one-half of the pits. The auditory bullae are of moderate size. The mandible is slender, has a low coronoid process and a somewhat more developed angular process.

The dental formula is i 1/2, c 1/1, p 2/2, m 3/3, total 30. The upper incisors are large and separated by a space equal to the width of the cingulum of either incisor. The canines have a small posterior cusp on the posterolingual cingulum. The first upper premolar is small, aligned with the toothrow, and in contact with the canine and second upper premolar. The last upper premolar is well developed with a high crown and > 50 % the length of the canine. The first two upper molars are similar in size; labially the metacone is higher than the paracone, and lingually the protocone is much better developed than the hypocone. The third commissure of M3 is well developed and about the same length as the second (stage 2 of Freeman, 1981, scale).

Each of the lower incisors is small and separated from each other, the inner pair is larger and weakly bilobed. The lower premolars are caniniform, the second almost twice the size of the first. The first two lower molars are subequal in size; the third is smaller. The protoconid is the dominant cusp, followed by the hypoconid.

Comparisons. - Among African members of the subgenus *Chaerephon* with interaural membranes, only *T. major* shows some similarity to *T. tomensis* and *T. gallagheri* in the interaural structure, but *T. major* lacks a well-defined interaural pocket and shows striking differences in the skull, such as its flattened braincase and its shallow basisphenoidal pits (Freeman, 1981; Harrison, 1975).

Based on morphology of the interaural membrane and longer rostral inflations in the skull, the closest relative to *T. tomensis* among all African molossids is *T. gallagheri*, known only from the holotype, a male, from Kindu (Kivu region, East Zaire) and

p. 905

[table removed - eds.]

described by Harrison (1975). Body measurements are similar, but the two female specimens from São Tomé Island are slightly larger; the remaining female from São Tomé Island is noticeably smaller (Table 1). The interaural membrane in *T. tomensis* differs from that of *T. gallagheri* because the globular swelling is less projected over the muzzle. The fold that borders the pouch in *T. gallagheri* (Harrison, 1975) is absent in *T. tomensis*.

The most conspicuous differences between the two species occur in the skull (Figs. 2a and 2b). Specimens from São Tomé Island have a narrow postorbital constriction; yet a broader zygomatic width, especially as shown by the females from São Tomé Island, when compared with the holotype of *T. gallagheri* (Table 1). The shapes of the anterior insertions of the zygomatic arches are wider and flared in *T. tomensis* (Fig. 2a). While the nasal inflations are much less conspicuous in *T. tomensis* than in *T. gallagheri*, the nasal aperture is longer in *T. tomensis*, and the posterior border lies behind a line across lacrimals. The form of the nasal opening clearly is different for the continental and insular species (Fig. 2a). The palate differs by being narrower posteriorly in *T. tomensis*. Basisphenoidal pits are larger

p. 906

and deeper, and the septum is narrower in *T. gallagheri* (Fig. 2c). Finally, the occipital is blunter in *T. tomensis* than in *T. gallagheri* when seen laterally, being more similar to that of *T. pumila*. Although the teeth are similar, they all average significantly larger in *T. tomensis*, especially the canines (Fig. 2b) and upper first premolars (minuscule in *T. gallagheri*). Because the usual pattern of sexual dimorphism in *Tadarida* is one in which males typically exhibit greater body size, larger skulls, and more powerful teeth (Peterson, 1969, 1970, 1972), we argue that *T. gallagheri* and *T. tomensis* are not conspecific. *T. tomensis* clearly differs from the other similarly sized molossid on the island, *T. pumila*, because it has a different pattern of color in body pelage and because it has conspicuous differences in the interaural membrane and skull morphology.

Remarks. - The specimens from São Tomé Island show the unique interaural membrane that Dobson (1878) used to define the subgenus *Chaerephon*. They also share other features typical of the group such as an unreduced upper last molar, well-developed antitragal lobule, a relationship between the second phalanx and the total length of the fourth digit around 14 - 17 % (17.3 % in the holotype, 16.4 and 15.4 % in the paratypes of *T. tomensis*); a range assigned to *Chaerephon* by Freeman (1981), and finally, all dental attributes established by Legendre (1984). Indeed, on a supraspecific level, the specimens of São Tomé Island belong to *Tadarida (Chaerephon)*. Nevertheless, at this level, and supported by the appearance of *T. tomensis*, we could restrict the definition of the subgenus *Chaerephon* to the original character state defined by Dobson (1878). This would reduce the taxon to include only the species *johorensis, gallagheri*, and *tomensis*. However, the presence of a variably complex interaural membrane in other related species, as in *T. major*, makes it difficult to establish clear boundaries and therefore the restriction of *Tadarida (Chaerephon)* requires more detailed studies. The similarities of the structure of the interaural membrane clearly indicate a close phylogenetic relationship among *johorensis, gallagheri*, and *tomensis*. Such a relationship, however,

poses an interesting biogeographic dilemma: how does one reconcile the geographic gap of > 2,000 km between the two African species within the same forest block, and between these and *T. johorensis* from Sumatra and the Malayan Peninsula (Hill, 1961, 1974)? This great second gap could be explained by an early/middle Miocene forest corridor connecting these two areas (K. F. Koopman, pers. comm.). Among African species, the simpler structure of the interaural membrane and the less marked inflations in the cranial rostrum suggest the presence of less derived features in the insular *T. tomensis*, in contrast to *T. gallagheri* (D. L. Harrison, pers. comm.).

We expect that males of *T. tomensis* will be larger in size, and will show the same interaural structure described here for females. The ear formation is similar in both sexes of *T. johorensis* (Hill, 1974).

The discovery of this molossid increases to five the number of families of bats known for São Tomé Island; the emballonurid *Taphozous mauritianus* also was captured for the first time on the island. The known bat fauna of São Tomé Island now includes *Eidolon helvum, Rousettus aegyptiacus, Myonycteris brachycephala, Taphozous mauritianus, Hipposideros commersoni, Hipposideros ruber, Miniopterus minor, Tadarida pumila*, and *Tadarida tomensis*.

Tadarida [(Xiphonycteris)] petersoni El Rayah, 1981

p. 3

Holotype

Adult male in alcohol with skull extracted (ROM 55813) from 15 km S Kumba, Cameroun (04°39'N 09°26'E), collected 27 January 1970, by R. L. Peterson (Field No. 0364).

Specimens Examined (Holotype and 36 Paratypes)

CAMEROUN: Holotype and 18 topotypes (ROM MM 55748, 55752, 55753, 55812, 55813, 55814; FF 55780, 55746, 55747, 55749, 55754, 55755, 55756, 55815, 55816, 55817, 55818, 55819); Mawutu Village, 30 km N Buea Station (03°10'N 12°20'E) 6 (ROM FF 69096, 69097, 69098, 69100, 69102, 69104); 6 km SE Eseka (03°35'N 10°44'E) 3 (AMNH M 236332, F 236333), (CM F 42293); 30 km E Nanga Emboko (04°38'N 12°21'E)2 (AMNH M 241076, F 241078); near Okola (04°00'N 11°33'E) 1 (AMNH M 241075). GHANA: 12 km NE Kade (06°05'N 00°50'W) 6 (ROM MM 36563, 36564, 36600, 39427, FF 36601, 39380).

Distribution

Known only from the above localities in Cameroun and Ghana.

Diagnosis

A small member of the subgenus *Xiphonycteris* as defined by Koopman (1975) with open anterior palate and reduced third commissure, similar in skull size to *Tadarida nanula* and *T. spurrelli* but with a short distinct third commissure and deeper arched cranium. Wing bones longer than either *T. nanula* or *T. spurrelli* but shorter than *T. brachyptera* with which it is allied in overall shape characteristics.

Measurements of the Holotype

Total length, 93 mm; tail length, 27 mm; hind foot, 9 mm; ear, 19 mm; tibia, 13.3 mm (for other measurements see Tables 1 and 2).

Description

Muzzle short with vertically wrinkled thick upper lips (Fig. 1). Ears medium in size and joined on the muzzle by a deeply cleft band; tragus small, rectangular (about 1 mm wide and 1.8 mm high); antitragus somewhat rectangular (about 4.3 mm long and 3.3 mm high).

Feet small (about 9.0 mm), sparsely covered with hair to tip of toes. Calcar short (about 6.5 mm). Wing membrane insertion about 3.5 mm above the ankle at the base of the metatarsus. Dorsal pelage uniform Prout's Brown and extending to the sides of the neck immediately ventral to the antitragus. Base of dorsal hairs pale brown, darker distally. Ventrally, fur colour varies from Pale Ochraceous-Buff on chin and throat to light Pinkish Cinnamon on chest and abdomen. Pelage Cinnamon-Drab ventrolaterally along the insertion of the endopatagium to the base of the humerus and femur. Ventral pelage with white basal band, darker distally. Dorsally hair short (about 2 mm), ventrally slightly longer only on throat (about 4 mm). Hair extends to the endopatagium above and below. Posterolateral edge of uropatagium sparsely fringed with long bristles (about 6.5 mm).

Skull (Figs. 2 and 3) with first upper premolar small, in line with toothrow and filling the space between canine and second premolar; upper incisors vertical, parallel, separated from canines by pre-canine diastema (about 0.6 mm). Anterior palatal emargination extends posterior to upper incisors (covered by the soft palate in the holotype). Soft palate transversed by five palatal ridges. Third commissure on the last upper molar (M^3) reduced, much shorter than second (Fig. 3). Lower incisors small, bifid, and filling the space between canines. First lower premolar as high as second but wider at the base. Basisphenoid pits similar in shape to those of *T. brachyptera*, well defined, and oval in shape with a dividing septum, that is wide posteriorly and gradually narrowing anteriorly.

p. 6

Comparisons

Differs from *Tadarida nanula* in having longer and wider wings and skull; septum separating basisphenoid pits small and more triangular but pits larger; smaller canines; narrower postorbital constriction and larger braincase (Table 1). Differs from *T. spurrelli* (forearm 26.6-30.0) in having longer and wider wings and skull; upper and lower canines without enlarged cingula; higher braincase and longer mandible. Differs from T. brachyptera (=leonis) in having smaller wings and skull; shorter upper and lower canines; shorter mandible and the absence of well-developed sagittal or lambdoidal crests (Fig. 3).

Taphozous Dobsoni Jentink, 1879

p. 123

First phalanx of middle finger folded (in repose) on the upper surface of the metacarpal bone. Radio-metacarpal pouch well developed. Gular sac large in the male; as we have received no female, we cannot state if she too possesses a simular organ.

Ears shorter than the head; inner margin not papillate. Lower lip with a distinct groove.

Wings from the ankles. Interfemoral membrane greatly developed.

Under surface of the base of the thumbs with small fleshy pads. There is also a little rounded cushion near the base of the under surface of the footsoles.

The face in front of the eyes is covered with short blackish brown hairs.

General color as in *Taphozous mauritianus*: fur above buff brown near the base, then brown with grey extremeties. Chest and abdomen pure white. Hairs round gular sac colored as the sides of throat which is embellished with a chestnut collar.

On the upper surface the wing-membrane as far outwards as a line drawn from the ankle and the thumb to the elbow and also the hairy antehumeral and interfemoral membranes are brown, the hairs being colored as on the back: the wing membranes for the rest white, except a brown patch inside the first phalanx of the longest finger: beneath all the hairs and membranes are white, except the brown-colored interfemoral membrane.

Lower incisors distinctly trifid.

Length of the only specimen, an adult male, preserved in alcohol.

Hab : Madagascar, Mahambo (J. Audebert).

This species is the largest among the other hitherto known African species of the genus *Taphozous*, which are provided with a distinct radio-metacarpal pouch.

Taphozous hamiltoni Thomas, 1920

p. 142

A fairly large species of the group with a naked gular patch in the female - a pouch therefore probably present in the male.

p. 143

Size rather smaller than in *hildegardeæ*, decidedly larger than in *sudani*. General external appearance as to colour and distribution of fur much about as in *perforatus* and its allies. Fur covering, but restricted to, the body, short; hairs of back barely 3 mm. in length. Colour above dark sepia-brown, the extreme tips of the hairs lighter, their bases white; below similar, but paler, the light tips being longer. Throat with a sharply defined naked patch, no doubt indicating that the male has a gular pouch.

Skull broad an stout, much more heavily built than that of *T. sudani*, and approaching that of the large *T. nudiventris*, though its muzzle is conspicuously shorter than in that animal and is without the great projection forward of the incisors. Forehead broad and flat, little hollowed out, the rise of the brain-case behind it not nearly so great as in processes well developed, short. Brain-case broad, more parallel-sided, less oval, than in *sudani*. Mesopterygoid fossa penetrating the palate to the level of the hinder edge of m^2. Basial pits broadly triangular, not very deep.

Teeth as usual, rather stout and heavy throughout, breadth across canines greater than in other species of the same size.

Dimensions of the type: -

Forearm (c.) 66 mm.

Head and body 80; tail 35; third metacarpal 60.

Skull: condyl to front of canines 22; zygomatic breadth 15; interorbital breadth 7.3; intertemporal breadth 5; breadth of brain-case 11.2; mastoid breadth 13; palato-sinual length 6.2; postpalatal length 11.2; basial pits, length 3, combined breadth 5. Teeth: front of canine to back of m^3 9.7; front of p^4 to back of m^2 6.5.

Hab. Mongalla, Sudan.

Type. Adult female. B.M. no. 19.12.18.1. No. 118 of Stevenson Hamilton collection. Collected 13th June, 1918. Presented to the National Museum by Wellcome Research Laboratories.

It is difficult to say to which of the older-known species this *Taphozous* is most nearly allied. Its skull is much stouter than that of *perforatus, sudani*, and their allies, while, of course, the widely differnt fur-distribution of *nudiventris* and the peculiar colour of *mauritianus* at once separate those forms from it. *T. hildegardeæ* has a much narrower and

p. 144

more slender skull, and no naked gular patch in the female. It is to be hoped that male specimens will shortly be obtained, so that the pouch-structure in that sex can be observed.

Major Stevenson Hamilton states that the specimen was captured in the verandah of his house.

Taphozous hildegardeæ Thomas, 1909

p. 98

Taphozous hildegardeæ, sp. n.

An African representative of the Asiatic black-bearded *T. melanopogon*.

p. 99

Radio-metacarpal pouch distinct. Lower lip scarcely grooved. No gular sac in male or female; a well-marked blackish beard in the male, covering the whole under surface of the throat. Upper surface pale brown, the bases of the hairs while, their tips chocolate-brown. Lips and chin anterior to the beard pale brown. Belly white, a few hairs tipped with brown. Limbs pale brown. Upperside of antebrachial, interfemoral, and wing-membranes near the body also brown, the more distal part of wing-membrane whiter; underside of all membranes white, as is the fur on the membrane on each side of the body. Ears, feet, and tail about as in *T. melanopogon*.

Skull as in *T. melanopogon*, but rather larger, and the brain-case broader.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 70 mm. (another M 67.5, a F 65.5).

Head and body 83; tail 22; ear 20; third finger, metacarpal 61, first phalanx 21.5, second phalanx 24; lower leg and foot (c. u.) 37.5.

Skull: greatest length 21.7; front of canine to back of m^3 9.2.

Hab. Mombasa district. Type from Rabai, 700'; others from Shimoni, sea-level.

Type. Adult male. B. M. no. 9.6.12.7. Original number 613. Collected and presented by Dr. and Mrs. Hinde. Four specimens.

This is a most interesting species, as it represents in Africa the Asiatic black-bearded *T. melanopogon*, not known west of India proper. From this it is distinguished by its larger size, the greater extension over the throat of the black beard (more as in *T. theobaldi*) , and its broader skull. No known African species are at all like it.

I have named the species in honour of Mrs. Hinde, who has so ably assisted in her husband's East-African collecting-work, and who has taken a special interest in bats.

Taphozous leucopterus Temminck, 1835

p. 284

TAPHOZOUS LEUCOPTERUS.
TAPHIEN LEUCOPTERE.

Planche 60. fig. 7.

Taille intermédiaire entre le *Taphien à ventre nu* et le *Taphien perforé*. Museau glabre; base des oreilles poilues; partie de l'antibrachium, membrane inter-brachiale et moitié de la partie supérieure de l'interfémorale très poilues; le reste couvert de poils ras et rares; osselets du calcaneum très longs; queue perforant la membrane vers le milieu de sa longueur; une grande partie de la membrane des ailes d'un blanc pur. Oreilles à peu-près rondes, tragus en forme de large fer-de-hache. Dents incisives supérieures nulles, 4 très petites et trilobées à la mâchoire inférieure: canines à talon pointu dirigé en avant; molaires 5 en haut, dont une, large et très courte anomale; l'arrière molaire de moitié moins large que sa voisine: en bas 5 molaires dont 4 parfaites et une petite anomale. La denture du jeune-âge n'a pas été examinée.

Pelage court, bien fourni, tricolore aux parties supérieures et sur les côtés du cou, unicolore en dessous. Tout le dessus du corps et les côtés du cou ont une teinte cendrée fourure de petit-gris; les poils sont d'un brun c1air à leur base, noirâtres au milieu et terminés de gris-clair; tout le dessous du corps, du cou et les rubans de poils le long des flancs et de l'antibrachium sont d'un blanc pur. La membrane alaire de l'antibrachium est en grande partie blanche, et celle entre les doigts de l'aile d'un gris-clair; l'interfémorale et la membrane qui s'étend le long des flancs sont noirâtres.

Longueur totale depuis la pointe du museau au bout de l'interfémorale 3 pouces 6 ou 7 lignes; osselet du calcanum 8 lignes; envergure 12 pouces 4 ou 6 lignes; antibrachium 2 pouces ou 1 ligne de plus.

Cette espèce est nouvelle; elle a fait partie d'un envoi d'objets recueillis dans l'intérieur de l'Afrique méridionale; les mœurs n'ont pas été observées; elle fait partie du Musée des Pays-Bas.

Lange von dem Scheitel bis zu der Schwanzspitze:	-	4	3
Flügelweite:	1	4	6
Länge des Kopfes:	-	1	-
Länge der Ohren:	-	-	9

Beschreibung.

Gesicht spitz zulaufend und von der Nase bis zu der Augengegend nackt. Lippen wulstig mit einzelnen Härchen besetzt. Unter dem Kinn ein kleiner Blindsack der durch eine Hautfalte entsteht. Der innere Rand des Ohres etwas ausgezackt, der Ohrdeckel kurz, zugerundet. Die Nasenlöcher klein, nach vornen gerichtet; die Augen mittelmäßig groß, schwarz von Farbe. Die Farbe auf dem oberen Theil des Körpers aus dem Lichtbraunen in das Weisgraue spielend, auf dem Unterkörper noch heller, ins Weißliche übergehend. Die Flug- und Intercrural-Membranen hellbraun; die letztere nach vornen aufgeschürzt, von dem Schwanzende durchbohrt. Der Steiß, die Schwanzgegend, der Unterbauch und die Schamgegend sind nackt und fleischfarbig. An dem Nagelglied jeder Zehe ein Büschel von steifen, gekrümmten Härchen.

Der hier bescbriebene Taph. nudiventris unterscheidet sich von dem von Geoffroy in Egypten aufgefundenen Taph. perforatus nicht nur durch die Dimensionen seines Körpers *), indem er um ein Drittheil größer ist als der letztere, sonderit durch die Nacktheit aller Körpertheile, welche der hinteren und vorderen Seite der Beckengegend angehören und bei allen, sowohl alten als jungen Thieren bemerkt wird. Bei Taph. perf. Geoffr. sind dagegen alle diese Theile vollkommen behaart. Eben so ist die Färbung der Haare bei dieser Art durch eine oben dunklere unten hellere graue Farbe verschieden. Auch die Schädel beider Thiere sind sehr verschieden und wir können um so mehr eine zuverläßige Bestimmung darüber erlassen, da uns Rüppell aus verschiedenen Gegenden Egyptens viele alte und junge Individuen beider

*) Die Abbildung ist um 1/3 kleiner als die naturliche Größe.

p. 71

Arten eingesendet hat. Auf der Tafel 27 haben wir zur besseren Verdeutlichung unter No. 1.2.3. die obere und untere Fläche des Schädels und den Unterkiefer von *Taph. nudiventris*, so wie unter 4.5.6. dieselben Theile von *Taph. perforatus* (Geoffr.) abbilden lassen. An dem Oberkiefer des letzteren sind die Backenzähne so sehr abgenutzt, daß ihre Schmelzleisten ganz geebnet und nicht mehr zu erkennen sind, woraus wir auf das hohe Alter dieses Individuums zu schließen uns berechtigt glauben. Somit sind denn beide Arten durch Größe des Körpers, Farbe und Vertheilung der Behaarung, so wie durch den Schädelbau vollkommen verschieden und können unbezweifelt als Species gelten.

p. 83

à nu toutes les parties postérieures, de même que tout le système cutané.

Le pelage du corps, du cou et de la tête est en dessus d'un marron vif et lustré, en dessous d'une teinte un peu plus claire et terne. Sous le menton qui est à nu, s'ouvre une poche, dans les replis de laquelle s'opère la sécrétion de la matière onctueuse. La face n'est couverte que de quelques poils rares et noirs. Les oreilles sont grandes; à leur base se forme un prolongement du derme, dirigé sur les joues; le tragus est grand, en fer-de-hache. La queue assez longue; perce la membrane interfémorale vers le milieu de son étendue: toutes les autres parties du derme sont nues et noires. Les dents sont en tout semblables et en même nombre que dans les autres Taphiens; les quatre incisives inférieures sont trilobées.

Longueur de la pointe du museau au bout de l'interfémorale 6 pouces; de la queue 1 pouce 4 lignes, dont 6 lignes de libre; envergure 19 à 20 pouces; antibrachium 3 pouces 1 ou 2 lignes.

Patrie. Cette espèce nouvelle a été tuée sur la riviere de Boutry, côte de Guiné.

Taphozous Sudani Thomas, 1915

p. 561

T. perforatus group. No gular sac. Feet comparatively large.

Size slightly greater than in *T. perforatus*. Distribution of fur about as in that species, except that the longer hairs are less extended on the thighs and interfemoral membrane. General colour above and below sepia-brown, the hairs white for their basal two-thirds. Wing-membranes whitish or white beyond a line connecting the elbow with the knee; rest of the membranes brown, more whitish below. No gular sac in male or female, nor any trace of it on the skin. Feet decidedly larger than in *T. perforatus*, about 13 mm. in length or upwards, as compared with about 11 mm. in the allied species. Wing-membrane inserted on the end of the tibia, instead of the ankle.

Skull in general like that of *T. perforatus*, but slightly

p. 562

larger and the brain-case more swollen. Male skull decidedly larger than that of the female.

Dimensions of the type (measured on the spirit-specimen): -

Forearm 64 mm.

Head and body 71; tail 23; ear 17; third finger, metacarpal 58; first phalanx 21.5; lower leg and hind foot (c.u.) 39; hind foot only 13.5

Skull: greatest length to base of canine 20.2; condyle to front of canine 19.7; interorbital breadth 6.1; breadth of brain-case 10; palato-sinual length 6.5; maxillary toothrow 8.8.

Hab. Upper Nile. Type from Mongalla, just north of Lado; other specimens from Khartoum (*Major H. N. Dunn*) and Lake No (*Willoughby Lowe*).

Type. Adult male. B.M. no. 2.7.4.2. Collected and presented by W. L. S. Loat, Esq.

This species is distinguishable from *T. perforatus* by its larger feet, more swollen brain-case, and whitened wing-membranes; from *T. hildegardeæ* by its smaller size, the absence of any gular beard, and generally darker colour.

Taphozous sudani australis Harrison, 1962

p. 763

As type specimen of this new form an adult male, no. 9932, is nominated. It was obtained on the 5 May 1960 at the junction of the Limpopo and Shashi Rivers, Southern Rhodesia. The specimen is now in the National Museum of Southern Rhodesia, Bulawayo.

DESCRIPTION OF THE TYPE

The specimen agrees in all essential characters with the typical form of the species. The gular sac is absent, nor is there any gular beard. The radio-metacarpal pouch is present. Hind feet large, 13 mm. in the dried skin, without claws. Wing membranes strongly whitish beyond a line connecting the elbow with the upper tibia. Skull decidedly lighter and

p. 764

more delicate than in the typical form, not exceeding that of *Taphozous perforatus* in size, although with the same relatively swollen braincase in comparison with the rostrum as in *T. s. sudani*. Hence in comparison with typical *T. s. sudani* the rostrum and interorbital region are very distinctly lighter and narrower and in relation to this the dentition also is more delicate, this being particularly noticeable in respect of the upper and lower canines. The external and cranial measurements are given in the tables below and it will be seen that the cranial measurements are distinctly smaller, the external measurements differing but little from the typical form.

[table removed - eds.]

The brown tips of the hairs on the dorsal surface are slightly darker than the specimens of the typical form examined (nearly matching Hudson Seal A9, Pl. 8 of Maerz & Paul, 1950) while the pale creamy buff hair bases where they are exposed over the shoulders contrast more sharply with the dark brown hair tips than in the typical form. On the ventral surface the pelage extends uniformly over the whole abdomen to the base of the tail, the distal part of the belly therefore not naked. On the throat and neck the fur is brown and little lighter than the dorsal surface, while over the chest and abdomen it becomes lighter and tinted with ashy grey (closely matching Slate - Gy + Kasha - Beige Oriental Pearl -, A2, Pl. 14 of Maerz & Paul). Some whitish hairs are found in the inguinal region. A band of ashy grey hairs extends along the proximal

p. 765

part of membrane from the axilla to the upper femur, while a narrow band of whitish hairs extends along the lateral border of the radius as far as the base of the fifth metacarpal. The ears, proximal wing membranes and whole interfemoral membrane are dusky, blackish, the latter rather lighter ventrally. The distal wing membranes are whitish beyond a line joining the elbows to the upper tibia, but the tips of the wings are again slightly dusky although translucent. The form of the ears and tragus does not differ significantly from the typical form. The upper canines are tall and slender, much more delicate than typical *T. s. sudani* with the antero-medial and postero-medial cusps both less prominent. The lower canines are similarly lighter but no other significant dental characters are observed in comparison either with *T. s. sudani* or with *T. p. perforatus*.

[table removed - eds.]

The paratypical series is in general closely similar to the type, although in one example (9928) the tips of the hairs on the dorsal surface are decidedly more rufous brown than the others, especially on the head, while the whole distal wing membrane in this specimen is strongly whitish. It has been previously noted (Harrison, 1958) that in the West African *T. p. swirae* Harrison the distal wing membrane is slightly paler in some specimens than is usual in *T. perforatus*, but in all the specimens of this series the wing membranes are far more strongly white than in any example of *T. perforatus* yet seen. The cranial measurement of the series average smaller than those of *T. s. sudani* but the lachrymal

p. 766

breadth and tooth-rows are constantly smaller, thus confirming the cranial characters noted in the type (see Table 6). The discovery of this bat so far to the south of its previously known range is of great interest and the constantly large hind feet and whitish wing membranes confirm the existence of two species of the *T. perforatus* group in Africa, both of which are now known to be widely but differently distributed. T he small-footed and dusky winged *T. perforatus* extending from Egypt southwards to Kenya and Sudan, eastwards to southern Arabia, Cutch and Kathiawar in India and westwards at least to northern Nigeria, while the large-footed *T. sudani* with whitish wings is known from Sudan, Belgian Congo, Togoland (Hayman, 1954) (British Museum specimen) (*vide* Booth, 1956) and now by the newly described form from Southern Rhodesia.

Triænops aurita G. Grandidier, 1912

p. 8

Cette Chauve-Souris , qui appartient au genre *Triænops*, a été capturée par M. le Dr Mazières aux environs de Diego-Suarez, dans l'extrême Nord de Madagascar; des trois espèces de ce genre connues jusqu'à ce jour dans la grande île, deux vivent dans la forêt tropicale de la côte orientale, d'où M. Humblot a rapporté les premiers exemplaires, tandis que j'ai recueilli les individus types de la troisième dans la grotte de Sarondrano, à quelques kilomètres de Tulear, c'est-à-dire dans le Sud-Ouest de notre colonie. On voit donc que non seulement ce nouveau *Triænops*, comme nous allons le montrer, se distingue de ses congénères par des caractères anatomiques importants, mais aussi par son habitat.

Le *Triænops aurita* n'est représenté dans nos collections que par un unique exemplaire mâle adulte qui malheureusement a été plongé dans le formol, puis desséché accidentellement au cours du voyage, de sorte que, quoique son état de conservation extérieure soit très bon, il a été impossible de dégager le crâne de la peau. Néanmoins les caractères externes sont si nets qu'il n'y a aucun doute qu'il faille rapporter ce nouvel animal au genre *Triænops*. Ses appendices nasaux cutanés se composent d'un fer à cheval formé d'une seule feuille repliée en volute dans sa partie antérieure; au fond du fer à cheval, en arrière, se trouvent trois petites éminences que dominent trois lobes en fer de lance de longueur à peu près égale; sur

p. 9

l'éminence centrale se dresse une petite languette. Les fossettes sont situées, l'une grande et bien ouverte en avant et au pied des trois éminences, et les autres, latérales, à la base du trident.

Les oreilles sont proportionnellement très grandes pour une Chauve-Souris de ce genre; pointues à leur extrémité supérieure, très rapprochées sur le sommet du crâne, elles dominent toute la tête; elles sont plus longues que larges et à peine échancrées. A première vue, seules elles suffiraient à différencier le *Triænops aurita* des autres espèces du genre.

La queue est courte, ne dépasse pas la membrane qui forme un angle assez ouvert et non pas aigu comme chez le *Tr. Rufus* ou comme chez *Tr. Humbloti*. Son extrémité n'atteint pas les pieds, tandis que chez les autres *Triænops*, elle les dépasse beaucoup.

Le pelage est gris noir sur le dos (la base des poils est presque blanche, tandis que la pointe est fréquemment noire, surtout sur le dos et les reins); le ventre est gris sale. Les poils ne dépassent pas le corps proprement dit et n'empiètent ni sur la membrane claire ni sur l'interfémorale.

Le *Triænops aurita* semble être jusqu'à présent la plus petite espèce du genre. Ses dimensions sont, en millimètres: tête et corps, 35; queue, 15; tête, 16; avant-bras, 45; pouce (ongle compris), 5; deuxième doigt, 38; troisième doigt, 60; oreilles: longueur, 16; largeur, 11; tibia, 20; pieds (ongles compris), 7.

La silhouette que nous donnons ci-dessus et qui représente la tête du *Triænops aurita* au double de la grandeur naturelle n'a pour but que de montrer les proportions relatives de la face et des oreilles, et la disposition de ces dernières.

Triaenops persicus majusculus Aellen and Brosset, 1968

p. 450

TYPE. - M adulte, en alcool. Grotte de Doumboula, Loudima, République du Congo, 19.6.1964; coll. J.-P. Adam. Muséum de Paris 1968-412.

PARATYPES. - 5 MM ad., 5 FF ad. Mêmes lieu, date et coll. Que le type. Muséum de Paris.

4 MM ad., 2 FF ad. Mêmes lieu et date que le type, coll. Taufflieb (3403-1, 3403-4). Muséum de Genève 1074.41 à 46.

2 FF ad. Grotte de Meya-Nzouari, 29.11.1966, coll. Adam (503 A, 504 A). Muséum de Paris.

DIAGNOSE. - Semblable à *Triaenops persicus afer* Peters, mais plus grand: avant-bras 53.4 à 60.1 mm (moyenne 55.0 mm), crâne, longueur totale 18.9 à 21.2 mm (moyenne 20.4 mm).

DESCRIPTION. - Les spécimens de notre série ont été comparés à des *T. persicus afer* du Muséum de Paris, provenant de Zanzibar. Ils sont semblables, sauf pour les dimensions, qui sont plus grandes dans la nouvelle sous-espèce (cf. tableau ci-dessous).

Le caractère invoqué par DORST (1948: 18) pour séparer *afer* de *persicus*, soit le prolongement lancéolé de la selle bifide chez le premier, unicuspide chez le second, ne nous paraît pas très valable, bien que nous n'ayons pas eu à notre disposition des *persicus* typiques. Dans notre série du Congo et sur les exemplaires de Zanzibar, cette lancette présente un bord supérieur très oblique, droit ou légèrement concave, ce qui détermine parfois un semblant de deux pointes. La variabilité de ce caractère n'avait d'ailleurs pas échappé à DOBSON (1879: 717), qui ne trouve aucune différence importante entre ces deux formes.

Il nous paraît superflu de reprendre ici une description détaillée de notre nouvelle forme, car nous ne ferions que répéter ce qu'ont dit plusieurs auteurs sur *persicus* sensu lato. Le lecteur pourra se référer aux descriptions originales et à celles de TATE (1941), de DORST (1948), de HARRISON (1955, 1963, 1964).

Actuellement, le statut taxonomique et la répartition géographique des formes du genre *Triaenops* sont les suivants:

Triaenops Dobson, 1871
furcula Trouessart, 1906: Madagascar
rufus Milne-Edwards, 1881: Madagascar

humbloti Milne-Edwards, 1881: Madagascar
persicus Dobson, 1871

p. 451

persicus Dobson, 1871: Perse
macdonaldi Harrison, 1955: Oman
afer Peters, 1877: Aden, ex-Somaliland, Kenya, Tanzanie, Zanzibar, Mozambique
majusculus, subsp. Nov. : Congo (Brazzaville)

Dans sa révision, DORST (1948) considère encore *afer* comme spécifiquement distinct de *persicus*. Mais, HARRISON (1964), qui est certainement l'auteur qui a examiné le plus de matériel de *persicus s. l.*, admet que *afer* n'est qu'une sous-espèce de *persicus*, suivant en cela la notion ancienne de DOBSON (1879).

D'après les descriptions et mensurations publiées, les quatre sous-espèces aujourd'hui reconnues de *Triaenops persicus* se distinguent avant tout par leur taille:

[table removed - eds.]

Précisons encore que dans notre nouvelle sous-espèce la première prémolaire supérieure (P^2) est située dans la rangée dentaire, sur le bord externe, et sépare nettement la canine © de la deuxième prémolaire (P^4). Cela correspond à la figure de *T. afer* donnée par DORST (1948: fig. 2 C).

Il nous paraît intéressant, d'autre part, d'étudier l'os pénien de notre nouvelle sous-espèce, puisque celui de la forme la plus voisine, soit *T. persicus afer*, est déjà connu et peut servir de comparaison (MATTHEWS, 1941).

La forme générale est assez semblable, mais l'extrémité proximale est sagittée et non lancéolée. Cependant, la différence la plus remarquable est la taille: chez *p. afer*, le baculum mesure 2.8 mm, selon la figure 15 D de MATTHEWS; il n'atteint pas 2 mm chez *p. majusculus* (1.88 et 1.57 mm sur deux spécimens examinés).

REMARQUES. - La présence d'un *Triaenops* au sud de la République du Congo est une donnée inattendue. En effet, le genre passait pour typiquement oriental. Cette notion classique est à revoir. En fait, ces chiroptères ont dû pousser vers l'ouest, à partir du Zanzibar et de la Tanzanie, et à travers le couloir écologique constitué par les lisières méridionales du Massif congolais, des populations don't

p. 452

[table removed - eds.]

p. 453

l'extrême pointe de répartition se situe près de l'Atlantique. On peut penser qu'une exploration plus complète des régions intermédiaires conduirait à la découverte de nouveaux jalons illustrant cette progression des *Triaenops* vers l'occident. C'est du reste la forme qui peuple l'Afrique orientale qui est la plus proche de notre nouvelle sous-espèce.

Triænops rufus A. Milne-Edwards, 1881

p. 1034

Le Muséum d'Histoire naturelle vient de recevoir de Madagascar une collection fort importante et riche en objets rares ou inconnus; elle lui a été offerte par M. Humblot, qui a surtout exploré, sur la côte est, la région comprise entre Fou.apointe te le lac l'Aincatre.

P. 1035

Plusieures Chauve-souris n'étaient pas connues; j'indiquerai d'abord deux espèces remarquable par la complication des appendices cutanés de la face et appartenant au genre *Triænops*; elles se distinguent du seul Triænops propre à l'Afrique (*Triænops afer* Peters) mar la forme lancéolée et simple de la feuille centrale du nez et du Triænops de Perse (*Triænops persicus* Dob.) par la disposition des conques auditives, don't le bord interne est plus profondément échancré. L'un de ces Triænops, que j'ai désigné sous le nom de *T. rufus*, se reconnait facilement à la couleur rousse de son pelage; l'autre (*Triænops Humbloti*) est un peu plus grand, et son poil est d'un gris qui rappele à la teinte de nos Rhinolophes.

V[espertilio] acetabulosus Hermann, 1804

V[espertilio]. acetabulosus. Caudatus , fusco-niger , pilis ad extremos plantarum digitos longissimis, membrana acetabulosa nuda ad sternum. Commers. mscr. n.° 51.

Vansonia Roberts, 1946

p. 304

Vansonia n.g., genotype *Pipistrellus vernayi* Roberts

Ann. Transv. Mus. XV, 16; 1932: Tamalakane River, Ngamiland.

This genus differs from *Pipistrellus* and related genera, in which the cranium is slightly raised above the level of the muzzle and with the same number of teeth, in having the inner of the two upper incisors deeply bifurcate, while the outer upper incisor is much reduced in size; the anterior upper premolar, though small, lies within the tooth row and separates the canine and large premolar. Presumably this name displaces *Alobus* Peters, genotype *Vespertilio temminckii* (1867) (which I have not examined), which is preoccupied by *Alobus* Leconte (1856).

Vespertilio borbonicus E. Geoffroy Saint-Hilaire, 1803

p. 55

7. Esp. Le vespert. de l'île de Bourbon. *Vespertilio borbonicus*. (Geoff.)

Caract. Oreilles courtes, ovales; oreillon en demi-coeur; pelage marron en dessus, blanchâtre en dessous.

Espèce inédite.

Descript. T. 0,^{m}08 (2 p. 11 l.). Cette espèce se rapproche beaucoup de la Noctule, dont elle diffère cependant par l'orreillon plus long et en forme de demi-coeur, et par les couleurs du ventre: les poils sont d'une teinte uniforme dans toute leur longueur.

Patrie. L'île de Bourbon.

N°. CXXII. Individu n'ayant que deux incisives à la mâchoire supérieure.

N°. CXXIII. Cet autre individu n'a que trois incisives, ce qui prouve que les deux autres manquent de même dans l'individu précédent: ces deux individus nous ont été envoyé par Macé, naturaliste.

Vespertilio Capaccinii Bonaparte, 1837

Vespertilio capaccinii

VESPERTILIONE DEL CAPACCINI

VESPERTILIO auriculis laleralibus, capite tertio brevioribus, ovato-lanceolatis, margine integris; trago brevi, gracillimo: pedibus robustis a patagio anali angusto villosissimo valde excedentibus: vellere griseo-rufescenti, subtus cinereo-flavido.

Si astennero dalle orgie di Bacco le tre Miniadi sorelle, e sdegnarone perfino di credere che concepito da Semele compiesse quel favoloso Nume i suoi nove mesi dentro un femore del padre Giove. Nemiche di tai crapule e di tai ciance, quel tempo che le altre femmine spendevano in feste ed in sì poco ragionevoli riti, consumavano esse nelle faccende dimestiche e nelle arti di Minerva:

Solae Minaeides intus
Intempestiva turbantes festa Minerva,
Aut ducunt lanas, aut stamina pollice versant,
Aut haerent telae, famulasque laborìbus urgent.

Ma siccome tulto in que'giorni era Bacco, e della sua onnipotenza non si dovea dubitare, dicesi che ammonite invano da' prodigi raccontatici da Eliano nella sua storia varia, fossero finalmente colpite dallo sdegno divino, e in brutti Vespertilioni tramutate, traendo con una morale soverchiamente naturale, che Ie odiatrici di tanta luce giustamente si condannavano ad assumere le mostruose forme descritteci dal Sulmonese:

Lucemque perosae
Nocte volant, seroque trahunt a vespere nomen.

I diversi tempi però, i diversi costumi, le utilità conosciute delle arti, che ancor diciam di Minerva, massime a rimpetto della dannosa licenza de'Baccanali, assai diversa ci additano l'applicazion della favola; ed invece di scorgere in questo animale gli effetti della miscredenza e della empietà, siamo piuttosto condotti da miglior senno a deplorare la poetica finzione che a lai volatili apparentemente brutti, messaggieri e compagni della tristezza notturna, assegnasse una origine da evitarsi, ch' è quanto dire si spendessero ad accreditare il pazzo culto di Bacco. Ad oggetto pertanto di rivendicar la memoria delle buone e studiose Miniadi, più che all'uomo di stato vogliam raccommandarla al filosofo che in mezzo a gravissimi affari coltiva le già familiari scienze naturali, cui tutto modestamente amerebbe in pace di dedicarsi. Ond' è che intitoliamo a Monsignor Francesco Capaccini, il quale degna del suo favore Ia nostra Iconografia, questa nuova specie di Vespertilione a' suoi meriti non del tutto disacconcia, sì per lo amore sviscerato che alberga nel cuore per le arti di Minerva già da lui grandemente protette, sì per la ritiratezza, assiduità, vigilanza, cui fin da giovinetto consecratosi ad onore del sacerdozio, sempre vieppiù si dedica coll'adempiere scrupolosamente gli officii dell' altissimo ministero senza curarne lo abbagliante splendore.

Pervenutoci dalla poco esplorata Sicilia ha questo Vespertilione il trago assai più gracile e più sottile dello stesso *V. emarginatus*. La grandezza del pollice alare, la esimia robustezza de' piedi pochissimo inceppati dalla membrana interfemorale piena, tenace, assai pelosa, e scarsamente estesa, son poi caratteri tutti suoi proprj, mercè de' quali ad altri gruppi si approssima, che non sono di questa parte di mondo.

Il suo muso è molto erto e grosso, sporgente al di là delle orecchie quanta proprio è la distanza che corre tra l'una e l'altra: il naso ottusissimo offre larga ma superficiale depressione tra le narici: gli occhi grandicelli e molto infossati son quasi tre volte più vicini all' orecchio che alla punta ,del muso, e tanto distanti tra loro quanto dalla sudetta punta: la bocca è pochissimo fessa, non

giungendo all'angolo anteriore dell' occhio; i denti sono piccoli e sottili: le orecchiette collocale molto in basso sui lati del capo sotto la linea degli occhi, son lunghe una volta e mezza appena di quanto son larghe, e due terzi al più della lunghezza del capo; la forma loro è lanceolato-ovale, e non mostrano intaccatura, ma un semplice dolcissimo seno sotto la metà del lembo esterno; il trago che non arriva a mezz' orecchia è retto, ed oltre modo sottile: le estremità del muso e le labbra sono scarsamente coperte di peli, che però folleggiano moltissimo sulla fronte, e nello spazio interoculare: mostrasi di sotto il mento una grossa glandula. Le bucce, alte. circa la metà di lor lunghezza, se chiudonsi addosso al corpo oltrepassano di poco l'estremità del muso. La membrana interfemorale assai tarpata obliquamente di qua e di là, riesce a forma di triangolo acuto che lascia molto liberi i piedi, orlando strettamente la coda, della quale lascia sporgere una puntarella sottilissima; spargesi di molti peli dalla base fino alla metà, non meno sopra che sotto, alcuni dei quali le fanno ciglio io prossimità dei piedi: pelosissima è parimente la membrana delle ali lungo i fianchi, particolarmente al di sotto. La coda uguale all' antibraccio è poco più breve del corpo. Le cinque dita dei piedi ugualissime fra loro portano lunghi peluzzi bianchi, e son terminate da unghiette bianche, robuste, molto uncinate, acutissime. Il pelame è molle e folto, dì color cannellino chiaro che verge alquanto in rossastro, inferiormente cinereo-giallastro, essendo i peli dì sopra cinerei dalla base fino alla metà, e di un bel castagno cupo fino ai due terzii nelle parti inferiori. Le bucce, la membrana interfemorale e le stesse orecchie rosseggiano alquanto invece di tendere più o meno al filiggine come in altre specie. Il cranio è similissimo per le forme e le proporzioni a quello del *V. emarginatus*, essendo lungo quasi due volte quanto la propria altezza, con l'encefalo assai rigonfio e senza cresta occipitale.

Vespertilio Capensis A. Smith, 1829

p. 435

Vespertilio Capensis, mihi.

V. suprà flavo-fuscus, subtùs flavO-albus; membranis nigro-fuscis, interfemorali longè ultra pedes extensâ et posticè acuminatâ, ubi caudæ est terminatio; auriculis indentatis externè, et apicibus subacutis, trago lineari, subfalciformi.

Above yellowish brown, beneath yellowish white; membranes blackish brown, the interfemoral one extending considerably beyond the feet and pointed behind, where the tail terminates; auricles indented on their outer edges and with their tips sub-acute; tragus linear and falciform; head short, its sides and the muzzle bare and black, lips margined towards the angles of the mouth with strong brownish hair. Length of body, an inch and three-quarters; length of tail, three-quarters of an inch; expanse of wings, nine inches.

This species has a strong affinity to the *Vespertilio Temmmckii* of Dr. Horsfield, and perhaps when the two are accurately compared together will be found to be the same, and the trifling apparent differences to be dependent upon changes which take place during the preparation of specimens. In the Cape example the posterior part of the interfemoral membrane is inclined to a semicircular form, whilst in that of Java it will be found to be more acuminated. Other slight differences are also observable, independent of those of colour and size.

Vespertilio d'asythrix Temminck, 1840

p. 268

VESPERTILIO D'ASYTHRIX.
VESPERTILION À POIL TOUFFU.

Ressemble plus ou moins au *vespertilion blépote* de l'archipel des Indes; mais il est moins grand, et ses oreilles quoiqu'aussi amples et près que totalement arrondies ont une conque plus développée et leur forme est en angle tres ouvert.

Museau très obtus et large, garni d'un pelage abondant jusqu'à la pointe de muffle, où deux bouquets de poils raides sont disposés en moustache. Oreilles plus larges que hautes, orbiculaires, mais terminées en un angle très ouvert; à moitié poilues en dehors, un repli s'avance vers la commissure des lèvres; tragus court, en feuille arrondie. L'articulation du pied avec les métatarses totalement libre. Queue très longue, à membrane développée. Museau court; boîte cérébrale bombée. Dents incisives supérieures 4 par paire et d'égale grandeur; inférieures 6 petites et trilobées; molaires 5 en haut dont une fausse, et 6 en bas dont deux fausses.

Pelage de moyenne longueur, touffu, cottoneux et mat; face très poilue; base de l'interfémorale poilue seulement en dessus; membranes des flancs poilues à claire-voie en dessous seulement; pieds totalement libres; les membranes très amples, ne

prennent attache qu'au dessus de l'articulation des métatarses. Couleurs des parties supérieures, de la tête, et des touffes mystacales d'un noir mat; celles des parties inférieures d'un noir enfumé, également mat; ruban de poils à claire voie, disposé le long des flancs, d'un noir grisâtre terne. Membranes d'un noir clair.

Longueur totale 3 pouces 9 lignes, dont la queue prend 1 pouce

p. 269

6 lignes; tendon fémoral du calcaneun 8 lignes; envergure 10 pouces; antibrachium 1 pouce 8 lignes.

Cette nouvelle espèce, remarquable par ses membranes développées, son large museau obtus, ses larges oreilles et son pelage laineux, a été rapportée de l'intérieur de la Caffrérie par Mr. Verreaux de Paris. Le sujet sur lequel cette description est prise, fait partie du musée des Pays-Bas.

On peut classer cette nouvelle espèce d'Afrique après le *vespertilion leucomèle* de cette monographie pag. 204.

Vespertilio Dinganii A. Smith, 1833

p. 59

Vespertilio Dinganii, Smith. (Dingan's Bat.) Fur long and silky; above, the surface colour is dull olive-green, beneath a pale greenish yelllow; head short and broad; nostrils prominent; ears blackish brown, and slightly pointed; tragus long, falciform, and tapering towards the tip, which is rounded; auricular appendage semicircular, very distinct, and in a measure separated from the anterior and outer margin of the auricle, inside of the latter with a thin sprinkling of short olive-green hair; wing membranes black; interfemoral membrane pointed, with part of the last joint of the tail protruding beyond it; claws pale greenish yellow; lower incisors placed obliquely across the jaw. Length from nose to base of tail three inches and a half; length of tail two inches; expanse of wings about twelve inches. - Above the hairs are yellowish green, towards their bases below they are of one colour throughout.

Inhabits South Africa, - between Natal and Delagoa Bay.

Vespertilio goudoti A. Smith, 1834

p. 244

Vespertilio Goudotii, Smith. (Goudot's Bat.) Hair of moderate length, longer on the face, head, and upper parts of

p. 245

body, than on the lower parts. Head rather small; point of nose bare and black; nostrils round, and opening laterally; upper lip on each side behind nostrils thickly covered with long hair; ears as long as the head, slightly rounded at points, and each with a large deep notch on its outer edge; on the outer surface towards base covered with chesnut hair, on the inner surface toward inner edges with a thin sprinkling of short tawny hair ; tragus long and tapering to a point. The surface colour of the upper parts of head and body light maronne or dull chesnut; of the under parts dull tawny or pale brown; the bases of the hairs above dusky, of those beneath dull black; membranes brown with a purplish tint; tail of the same length as the interfemoral membrane. Length from nose to base of interfemoral membrane two inches and a half; length of interfemoral membrane one inch and three quarters; expanse of wings nine inches.

Inhabits Madagascar.

Vespertilio hesperida Temminck, 1840

p. 211

VESPERTILIO HESPERIDA.
VESPERTILION HESPÉRIDE

Taille d'un tiers moins forte que la *pipistrelle* d'Europe; système cutané peu développé en raison du volume du corps; museau court, obtus; oreilles courtes, aussi larges que hautes, à tragus en feuille courbée et à pointe arrondie; membrane interfémorale veinée en losange, un peu poilue à sa base; les quatre membres nus. Dents incisives 4 par paire en haut et 6 en bas, petites et bien rangées: les molaires n'ont pas été observées.

Pelage court, lisse et bien fourni, de deux couleurs partout, en dessus noirâtre à la base et brun roussâtre à la pointe; en dessous noir à la base et cendré roussâtre à la pointe; la pointe du museau très poilue et noire; les membranes brunes veinées de brun plus clair.

Longueur totale du mâle adulte 2 pouces 8 lignes dont la queue prend seulement 1 pouce; antibrachium 1 pouce. La femelle a des dimensions moins fortes.

Synonymie. Pas indiquée dans l'atlas du voyage de Mr. Rüppell en Egypte.

Habite. Les bords de la Mer rouge vers les côtés d'Abyssinie; des sujets font partie du Musée de Francfort et des Pays-Bas.

Bearded bat. PENN. *fyn. p. 367. n. 282*.

Die Schnauze ist lang, unter der Stirne stark eingedrückt. Die Nase ist von einer besondern Struktur. Die Nasenlöcher, sagt Herr Daubenton, sind nicht, wie an andern Thieren, durch eine bis vor gehende Scheidewand von einander abgesondert; sondern jedes Nasenloch befindet sich an der Spitze einer kleinen Rinne, welche von einem Ende zum andern oben offen ist. Der innere Rand der Rinne ist sehr klein, der äussere stärker, und dehnt an seinem hintern Ende in eine Wust aus. Die äussern Ränder der beiden Rinnen vereinigen sich über der Oberlippe, und formiren durch diese Vereinigung den Anfang einer starken Furche, welche sich von da bis and die Stirne erstreckt, wo sich eine breite und kahle Vertiefung bedinget, deren Rand mit langem Haar besetzt ist. Die Ohren sind land und schmal. Das Haar auf dem Rücken von dem Scheitel an ist rothbraun; das übrige weißlich mit einem gelbbräunlichen,

p. 170

an andern auch mit einem aschgrauen Schatren schwach überlansen. Die Ohren und die Flughaut rötlich und schwartzlich braun. Der Schwanz liegt ganz in der Flughaut, und ist fast so lang as der Leib, desser Länge anderhalb Zoll beträgt.

Das Vaterland dieser Fledermaus is Senegal. Herr Adanson hat sie entdeckt.

Vespertilio Hottentota A. Smith, 1833

p. 59

Vespertilio Hottentota, Smith. (Hottentot Bat.) Above a dull indistinct dark brown, sometimes nearly black; beneath the surface colour is a sort of pale tawny brown or tawny white, lighter towards the pubis; he middle and basilar portions of the hair brownish black. Ears about half the length of the head, black and acutely rounded at their tips, the inner surface bare, the outer hairy towards the base; tragus linear tapering, and with a rounded point; muzzle covered with dense fur till near its point; wing membranes brownish black; interfemoral membrane with a sprinkling of fine short brownish fur for half its length above; claws pale flesh-coloured. Length from nose to base of tail two inches and a half, of tail two inches; expanse of wings twelve inches.

Inhabits South Africa, - Uitenhage and Albany.

Vespertilio isabellinus Temminck, 1835-1841

p. 205

VESPERTILIO ISABELLINUS.
VESPERTILION ISABELLE.

Planche 52 fig. 1 et 2.

Taille du *vespertilion discolore* d'Europe, mais les formes semblables a celles du *V. murin*. Museau obtus; oreilles larges ovoïdes, munies vers leur bord antérieur d'un repli longitudinal et saillant, qui forme comme la duplicature du derme; un lobe distinct termine le bord postérieur et s'étend vers la commissure des lèvres. Tragus court en feuille; bout de la queue libre. Toutes les membranes nues, fortement veinées; le tendon du calcaneum portant un lobe externe. Dents incisives 4 par paire en haut, l'interne longue et forte, bilobée dans le jeune, pointue chez l'adulte; l'interne vers la canine très petite; 6 incisives en bas, trilobées dans le jeune âge, tranchantes chez l'adulte; molaires 4 en haut sans fausse; 5 en bas dont une petite fausse molaire pointue.

Pelage de moyenne longueur, fin, soyeux, peu fourni. Les parties supérieures dans l'adulte, d'une belle teinte isabelle; la pointe du museau et les lèvres noires; toutes les parties inférieures d'une teinte isabelle très claire; la base externe des oreilles couverte de poils. Les membranes d'un brun noirâtre et abondamment veinées de lignes jaunâtres. Une grande portion du bout de la queue libre.

Les jeunes ont le pelage court, peu fourni, d'un isabelle cendré, en dessous d'un blanchâtre légèrement teint de couleur isabelle.

L'adulte porte en longueur totale 4 pouces 2 ou 3 lignes, dont la queue prend 1 pouce 7 lignes; envergure 11 pouces 7 ou 8 li-

p. 206

gnes; antibrachium 1 pouce 8 lignes. - Le jeune de l'année porte 3 pouces 6 ou 7 lignes en longueur totale, 9 pouces 6 lignes d'envergure, antibrachium 1 pouce 6 lignes. - Le jeune moins avancé, n'a que 3 pouces en longueur sur 7 pouces d'envergure.

Cette espèce que je crois nouvelle, a été envoyée au musée des Pays-Bas, en un grand nombre d'exemplaires, par les soins de Mr. le consul Clifford van Breugel.

Habite l'Afrique septentrionale, vit en grand nombre dans les environs de Tripoli.

Vespertilio leucomelas Cretzschmar, 1826

p. 73

Zweifarbige Fledermaus.

Diagnes. Vespertilio corporis colore supra nigro; infra ex nigro et albo variegato. Rhinarium prominens incisura ad frontem porrecta utrinque labro sejunctum. Auriculae medio frontis contiguae.

Ausmessungen.
Fuß. Zoll. Lin.
Länge von dem Scheitel bis zu dem Schwanz: - 1 9
Länge de Schwanzes: - 1 3
Höhe der Ohren: - - 7
Länge des Kopfes: - - 6

Beschreibung.

Oberkörper, Kopf, Gesicht, Nase, Ohren, Hals und der obere Theil der Brust schwarz. Auf der Brust haben die Haare weiße Spitzen und werden am Unterleib ganz weiß, so daß an diesen Theilen eine aus Schwarz und Weiß vermischte Färbung entsteht. Die Nase erhebt sich wulstig über die Oberlippe, ist auf dem Rücken breit, und schmal an dem Lefzenrand; so daß sie wie ein mit der Spitze nach unten gekehrtes Dreieck aussieht. Dieses entsteht durch zwei Einschnitte, welche den Nasenkörper gleichsam von der Oberlippe auf beiden Seiten trennen und nach der Stirne hin verlaufen. Die Nasenlöcher oben, auf dem breiten Theile der Nase. Hinter der Nase eine Vertiefung. Die Ohren sind am Rande dieser Vertiefung zusammengewachsen und zur Seite dieser Vertiefung liegen die Talgdrüsen. Der Ohrdeckel breit an der Wurzel, an der Spitze schmal auslaufend. Die Flug- und Intercrural-Membranen braun. Die Flughaut an ihrer Verbindung mit dem Körper mit feinen weißen Härchen besetzt.

Der ganzen Gestalt nach würde dieser Cheiropter mit unserem *Vespert. auritus* namentlich in der Ohren- und Nasenbildung übereinstimmen, und mit diesem eine Abtheilung der Gattung Vespertilio bilden. Die Zahnbildung ist aber verschieden, und verdient hier angeführt zu werden. Von den vier oberen Schneidezähnen sind die zwei mittleren oder inneren am längsten und an der Spitze zweizackig. Backenzähne haben wir oben nur vier bemerken können, selbst der erste steht ganz nahe an dem Eckzahn, weswegen wir Anstand nehmen den fünften als ausgefallen zu betrachten. Ist diese Zahnbildung constant, so würde sich dieser Cheiropter besser an die Gattung *Noctilio* anreihen.

Vaterland. Das petraeische Arabien

Aufenthalt. Alte verödete Wohnungen

Vespertilio marginatus Cretzschmar, 1830

p. 74

Saumrandige Fledermaus.

Diagnos. Vespertilio corporis colore supra rubiginoso, infra ex rubido cinereo. Patagium diilale ET intercrurale limbo flavescenti marginatum.

Ausmessungen.
Fuß. Zoll. Lin.

Länge des Kopfes: - - 6
Länge des Daumens: - - 2

Buschreibung.

Die saumrandige Fledermaus ist die kleinste von den Fledermäusen, welche Rüppell in dem nordöstlichen Afrika aufgefunden hat. - Die Stirne, der Scheitel, Nacken, Seiten des Halses und ganzer Oberkörper sind rothbraun von Farbe und alle diese Theile mit einem wolligen dichten Haar besetzt. Der ganze Unterkörper ist mit einem mehr länglichen glatten Haare bedeckt,

welches von der Wurzel an schwärzlich grau ist und mit graubrauner Spitze endiget, wodurch dieser Theil eine etwas gemischte graubraune Farbe erhält. Die Nase ist in der Mitte gefurcht und die Nasenlöcher seitlich, beinahe trichterförmig hervorgetrieben. Die Augen klein, und über denselben so wie auf den Lippen einzelne schwarze Borstenhaare. Die Flug- und Intercrural-Membranen schwarzbraun und an dem unteren Rande mit einem gelblichen wulstigen Saum eingefaßt. Der Sporn-Knorpel stark, mit seiner Spitze nach außen gerichtet, welches der Intercrural-Membran eine winkelige Gestalt gibt; an seinem äußeren Rande mit einer blätterigen, fast knorpeligen Membran versehen, welche in der Nähe des Fußes breiter ist und schmal endiget. Der Daumen mit einem sehr kurzen stark gekrümmten Nagel versehen.

Vaterland. Nubien und das petraeische Arabien.

Aufenthalt. Wurde überall einzeln und selten gefunden, aber immer in der Nähe von Wäldern oder Gebüsch, welche sie zu bewohnen scheint.

Vespertilio megalurus Temminck, 1835-1841

p. 206

VESPERTILIO MEGALURUS
VESPERTILION MÉGALURE

Le corps grêle, avec une tête déprimée, le museau pointu et les narines rapprochées, mais les membranes du vol et celles de la queue très développées. Oreilles médiocres, distantes et pointues vers le bout; tragus très long, en forme de feuille de saule. Queue très ample par l'extension de sa membrane soutenue par des cartilages métatarsiens ou calcanés très longs, et par une queue très longue à grand bout libre. Chanfrein et botte déprimés. Dents incisives 4 par paire; celles internes longues et convergentes, les externes près de la canine à peine visibles; molaires 4 en haut sans dent anomale, en bas 5 molaires dont une três petite anomale.

Pelage long, lisse, soyeux, bicolore partout: en dessus noirâtre à la base et d'un brun olivâtre jusqu'à la pointe: en dessous brun à la base; les poils du devant du cou et du ventre d'un brun cendré jusqu'à la pointe, ceux des flancs d'une teinte isabelle, et la région pubinale toute blanche depuis la base des poils jusqu'à leur pointe. Flancs en dessous poilus; seulement un ruban poilu le long des flancs etautonr du coccyx aux parties supérieures.

Longueur totale 4 pouces 3 lignes dont la queue prend à peu-près 2 pouces; envergure de 11 pouces à 11 pouces 6 lignes; antibrachium 1 pouce 10 lignes; dimensions de l'adulte; celles des jeunes ne sont pas connues.

p. 207

C'est probablement à cette espèce caractérisée par la large membrane intefémorale qu'il faudra rapporter•le *Vespertilio capensis* très succintement indiqué par Smith. Zool. Jour. part. 16; pag.435. Le sujet dont il est question a été comparé au *Vespertilio Temminckii* de Horsfield; ce dernier est un *Nycticée*. Je présume que le sujet de Mr. Smith est la même espèce que notre *mégalure*, mais dans un développement moins parfait et plus jeune que les nôtres.

Quelques sujets ont fait partie d'un envoi d'objets rassemblés, très récemment, dans l'intérieur de l'Afrique méridionale. On ne sait rien du genre de vie, ni sur les lieux qu'elle habite de préférence: elle fait partie du Musée des Pays-Bas.

Vespertilio minuta Temminck, 1840

p. 209

VESPERTILIO MINUTA.
VESPERTILION MINUTA.

Je n'ai eu connaissance de cette très petite espèce africaine, que longtems après la publication de la dissertation zoologique sur les mammifères du Cap de Bonne Espérance, publiée par Mr. Smuts, ce qui est la cause que je n'ai pu faire placer l'indication dans l'opuscule mentionnée.

Elle est plus petite que notre *pipistrelle* d'Europe, dont elle a les formes totales. Les oreilles sont ovoïdes, aussi larges que hautes; le tragus en feuille, à pointe arrondie et moitié longueur de l'oreille. Le museau est nu, garni de quelques poils clair-semés. Le pelage est court, bicolore partout; en dessus noir à la base et la pointe des poils d'un brun foncé couleur de terre d'ombre; en dessous à base noire avec la pointe d'un brun-clair. Les membranes sont noires.

Dents 4 par paire en haut; l'incisive accolée aux canines, extrêmement petite, l'autre longue bifurquée; 6 en bas, entassées; molaires

p. 210

4 en haut et 5 en bas; les premières sans fausse molaire et les inférieures avec une fausse, très petite et pointue.

Longueur totale 2 pouces 6 ou 7 lignes; envergure 7 pouces; antibrachium 1 pouce 1 ligne.

Elle vit comme notre pipistrelle et habite les lieux boisés près des eaux dans plusieurs parties de la pointe méridionale de l'Afrique.

Le Musée des Pays-Bas a reçu quelques individus par les soins de Mr. Horstok, médecin au Cap de Bonne Espérance.

Vespertilio minutus somalicus Thomas, 1901

p. 32

Closely allied to the typical *V. minutus*, Temm., but distinguished by smaller size, at least of head, and much paler coloration.

General characters as in *V. minutus*, the description of that animal in Dobson's Catalogue agreeing in all details except those referring to colour, though it may be also noticed that the inner margin of the ear, instead of being "slightly convex to the tip," is flat or even faintly concave for its middle third.

General colour of fur above dull buffy, the hairs blackish slate for two thirds of their length, with their tips buffy; beneath the bases are equally dark, the tips being dull whitish. Hairs of back rather more than 8 millim. long. Wing-membranes smoky brown, interfemoral membrane paler brown, both prominently edged with whitish, recalling the white edging of *Pipistrellus Kuhlii* on the same parts.

Skull very small and delicate, smaller than South-African

p. 33

specimens; although the forearm measurement does not appear to be less. The head is therefore apparently rather smaller in proportion.

Dimensions of the type (measured in flesh): -

Forearm 31 millim.

Head and body 44; tail 85; ear 10.

Skull: greatest length 12.5; basipalatal length 9.6; zygomatic breadth 8; interorbital breadth 3.1; breadth of braincase 6.7.

Dimensions of a spirit-specimen (F): -

Forearm 30.

Head and body 42; tail 35; ear 11; tragus on inner edge 3.3; lower leg 13.

Hab. Somaliland. Type from Hargaisa, 3500 feet; other specimens from Berbera.

Type. B.M. no. 98.6.9.1. Collected 14th November, 1897, and presented by R. McD. Hawker, Esq. Other specimens presented by E. Lort Phillips, Esq.

This subspecies may be readily distinguished from the typical form by its far paler colour and prominently white-edged wing-membranes.

Vespertilio nanus Peters, 1852

p. 63

Tafel XVI. Fig. 2.

V. magnitudine pipistrelli; colore supra umbrinofusco, subtus pallidiore; pilis in basi piceis; alis nigris; auriculis retro excisis; lobulo semicirculari, trago securiformi; rostro tumido, prominente; dentibus primoribus inferioribus secundum mendibulae directionem positis.

Longitudo tota 0,080; caudae 0,040; antibrachii 0,030; volatus 0,220.

Habitatio: Africa orientalis, Inhambane, 24° Lat. Aust.

Von der Gröfse des *Vespertilio pipistrellus*, Daubenton. Der hintere Rand des Ohres ist ausgeschnitten und endet in der Höhe der Mundspalte, $2^1/_2$ Mm. hinter dem Mundwinkel; das Ohr ist weniger breit als die Höhe des vorderen Randes; die Entfernung der vorderen Ohrränder von einander ist gröfser als die Entfernung derselben von der Schnauzenspitze; in der hintern Hälfte des Ohrs befinden sich fünf fächerförmig auseinander strahlende Querfalten; der Tragus ist am Ende breit, beilförmig, mit seiner Spitze nach innen gerichtet; der Antitragus halbkreisförmig, vorn eben so hoch wie hinten. Die Schnauze ist breit, stumpf und in der Mitte niedergedrückt; die Lippen sind wulstig, die Oberlippe an jeder Seite inwendig mit einem warzigen Vorsprunge versehen. Die Gaumenfalten haben dieselbe Zahl und Lage wie bei *V. pipistrellus*; es sind sieben, von denen die beiden ersten ungetheilt sind. Der fünfte Finger ragt über die erste Phalanx des dritten Fingers hervor, und die erste Phalanx des fünften

Fingers reicht bis zum letzten Drittheil der ersten Phalanx des vierten Fingers. Die Flughäute sind bis zur Zehenwurzel angewachsen und längs dem Unterarm unbehaart. Die Schenkelflughaut ist dagegen auf den Querfalten der Bauchseite mit Haaren bewimpert.

Die Farbe des Kopfes und der Rückenseite ist umbrabraun, an der Bauchseite blasser. Sämmtliche Haare sind an den unteren zwei Drittheilen pechschwarz. Flughäute und Ohren sind schwarz, die Nägel schmutzig weifs.

Gebifs $^{3\,2}/_{3\,2}{}^{1}/_{1}{}^{2\,2}/_{6}{}^{1}/_{1}{}^{2\,3}/_{2\,3}$. Die beiden oberen Vorderzähne stehen entfernt vom Eckzahn, sind gleich lang, und an der Basis von gleicher Dicke; der innere ist am Ende in zwei parallele, nicht divergirende, Spitzen getheilt; der äufsere zeigt hinten und oben einen spitzen Absatz. Die unteren Vorderzähne sind dreilappig und nach der Richtung des Kieferrandes befestigt. Der erste kleine obere Lückenzahn ist ganz nach innen gedrängt. Die Wirbelsäule besteht aus 7 Halswirbeln, 12 Rückenwirbeln, 5 Lendenwirbeln, 4 Kreuzheinwirbeln und 9 Schwanzwirbeln. In dem Bau der Eingeweide zeigt sich die gröfste Uehereinsummung mit *V. pipistrellus*.

Ich erhielt diese Art in grofser Anzahl aus unbenutzten Schornsteinen in Inhambane, im 24° S. Br.

Vespertilio minutus, Temminck, unterscheidet sich von dieser Art durch die Ohren, welche ebenso breit wie hoch sind, durch den schmalen, um hintern Rande convexen Tragus, durch die Kleinheit der nahe an die Eckzähne angedrängten obern äufsern Vorderzähne und durch die Kürze des fünften Fingers, welcher nur bis zur Mitte der ersten Phalanx des vierten Fingers reicht. *Vespertilio Temminckii*, Rüppell, ist schon wegen der Farbe der Bauchseite, deren Haare bis zur Basis weifs sind, nicht mit ihr zu verwechseln. *Vespertilio marginatus*, Rüppell, läfst ebenso wenig eine Verwechselung mit derselben zu, da sowohl die Form der Ohren als die Färbung eine ganz andere ist. Bei *Vespertilio platycephalus*, Temminck, beträgt die Länge des Schwanzes nur ein Drittheil der Totallänge, und der hintere Ohrrand bildet an seinem Ende hinter dem Mundwinkel einen breiten häutigen Anhang. *Vesperugo subtilis*, Sundevall, mit oblongen, ganzrandigen Ohren, kurzem, halbovalem Tragus und schmaler Schnauze ist ehenfalls eine durch ihre Gröfse verwandte Art.

Vespertilio Natalensis A. Smith, 1833

p. 59

Vespertilio Natalensis, Smith. (Natal Bat.) Fur soft and of moderate length, the surface colour above deep clear brown; beneath light brown, inclining to tawny brown; the baselar

p. 60

half of all the hairs clear black. Ears naked, broad towards base, and slightly emarginate on the outer side, the tips rounded; tragus narrow, straight, and rounded at the point; muzzle and upper lip black, with a thin sprinkling of short black hair, nostrils opening directly in front; no appearance of a cleft in the fore part of the upper lip; wing and interfemoral membranes black. Length from nose to base of tail two inches, of tail an inch and a quarter; expanse of wings eight inches and a half.

Inhabits South Africa, - towards Natal.

Chauve-souris étrangère. BUFF. hist. nat. 10. p.82. tab. 18.
Senegal bat. PENN. syn. p. 3669. n. 281.

The snout is of average length, in front thick, the ears are thick and pointed, the tragus is narrow, almost half as long as the ears, and pointed. The tail is about a quarter shorter as the body, enclosed in the tailmembrane, to the two last vertebras, which project beyond the edge. The hairs on the head, throat and back are yellowish brown mixed with ashgrey; on the breast and belly entirely pale yellowish brown to grey colour. The tail membrane is blackish. The length is four inches.

This is in Senegal discovered by Mr. Adanson.

Vespertilio Pipistrellus varietas africana Rüppell, 1842

p. 156

footnote: Ganz gleiche Grösse und Verhältnisse wie bei den europäischen *V. Pipistrellus*, nur der Bauch etwas mehr gelbbraun gefärbt.

Vespertilio platyops Thomas, 1901

p. 31

A large pale-coloured species, with the bicuspid incisors of *V. serotinus*, but with a broad blunt tragus.

Size rather less than in the Serotine. Head very flat. Ears of medium length, their inner margin strongly convex in its basal third, evenly slightly convex above to the rounded tip; outer margin slightly concave above, then convex to the notch, and ending in a low rounded lobe. Tragus broad, expanded above its broadest point at about the middle of its inner margin; inner margin straight, joining above at a rounded angle the strongly convex outer margin; a small triangular external basal lobule present.

Wings from the base of the toes. A small postcalcareal lobule. Tail projecting from the membrane by the last vertebra.

Colour above (in spirit) uniform dull fawn or sandy; below dull whitish. Membranes brown, the plagiopatagium and interfemoral inconspicuously edged with whitish behind.

Skull very broad and flat; crests meeting posteriorly, but

p. 32

not drawn out into a marked projecting angle, as in the Serotine.

Teeth very much as in the Serotine. Inner upper incisors bicuspid, outer minute. Lower incisors tricuspid, overlapping, their line more directly transverse and less angular than in the Serotine. Anterior lower molar slightly smaller in proportion to the second than in the allied species.

Dimensions of the type (in spirit): -

Forearm 46 millim.

Head and body 62; tail 39; hind foot (s. u.) 8.5; ear 16; tragus, length on inner edge 4, breadth 3; third finger, metacarpal 43, first phalanx 16, second phalanx 14; lower leg 20.5.

Skull: greatest length 19; basipalatal length 15; zygomatic breadth 14; breadth between orbits 8; constriction 4.3; palate, length 7.5; breadth across outer corners of *m.*[2] 8.5.

Hab. Lagos.

Type. Female in spirit. B.M. no. 88.5.17.3. Presented by the late Dr. G. E. Dobson.

The characters of this species are strongly confirmatory of the view that "*Eptesicus*" should not be separated from *Vespertilio*, for with the large size, heavy build, and more or less the crested skull of the former it has the broad tragus of the typical *Vespertilio*.

V. megalurus, the only other African species as large as *V. platyops*, has unicuspidate middle upper incisors.

Vespertilio smithii Wagner, 1855

p. 747 footnote

A. Smith's *V. minutus* (zool. of South Afric. I. Tab 51) = dessen *V. capensis* kann nicht zul Temminck'schen *V. minutus* gehöhren, da die von Smith angegebenen Maasse eher auf *V. megalurus* passen. Körper 2 ½", Schwanz 2", Vorderarm 1" 8"'. Ohren so breit als hoch, Klappe halb so lang als das Ohrn Schwanzende nicht vorragend. Backenzähne jeder seits $^{4}/_{6}$. Oberseite tief röthlichbraun, die Haare am Grunde leberbraun; Unterseite ebenso, an den Haarspitzen blass gelblichbraun. Flughäute zwischen bräunlichroth und leberbraun. Man könnte diese Art, die von *V. minutus* Temm. Entschlieben abweicht und doch auch nicht recht zu *V. megalurus* passen ???, als *V. Smithii* bezeichnen.

Beschreibung

Der Kopf und Rücken dieser kleinen Fledermaus is dunkel mäusegrau mit bräunlichem Ueberzug, der ganze untere Körper glänzend schneeweiss. Der Kopf is stark behaart und ein Büschel von Haaren ragt über die eine Line lange und eine Linie breite Nasenkuppe (Rhinarium) hervor, welche ganz nackt und bräunlich ist. Die Nasenflügel sind stark, wulstig, und die

Nasenlöcher beinahe ganz zur Seite geöffnet. Die runden Ohren sind hinten ganze nakt, vorn mit feinen graunen Härchen bekleidet. Das Orhläppchen ist blattförmig, an der Spitze breiter und zugerundet. Die braunen Flügelhäute sind an der vordern und hinteren Fläche ganz nackt, die hintere Fläche der Schwanz - Flughaut etwas behaart.

Die männliche Thiere sind von den weiblichen eben so wenig im Äusseren verschieden als die jungen von den alten.

Vaterland. Nubien. Rüppel hat 7 Exemplare in der Umgegend von Dongola gesammelt.

Aufenthalt. Fliegt in der Abenddämmerung und wurde an Waldungen und buschigten Gegenden gefunden.

Die mit der Redaction dieses Werkes Beauftragten haben, durch die Benennung der hier berschriebenen Fledermaus, die Huchachtung zu erkennen geben wollen, welche sie für die grossen Verdienste hegen, die

p. 18

sich Herr Director Dr. Temminck um die Erweiterung und Berichtigung der Naturwissenschaften durch seine gehaltvollen Arbeiten erworben hat. Sie ergreifen zugleich diese Gelegenheit, um ihrem verehrten Freunde im Namen der Senkenbergischen naturforschenden Gesellschaft öffentlichen Dank abzustatten, für die derselben so oft erwiesene Theilnahme und Mitwirkung an ihrem Gedeihen.

Der von Horsfield beschriebene und mit Temminck's Namen bezeignete Cheiropter*) gehört zu der von Rafinesque aufgestellten Gattun *Nycticejus*. Dieses Geschlecht wird von Herrn Temminck in seinem Monographieen der Säugethiere nächstens bearbeitet un die *vespertili Temminckii* (Horsfield) als *Nycticejus* aufgeführt erscheinen, worauf wir einstweilen hinweisen wollten.

*) Die von Horsfield in seinen *Zoological researches of Java* angegebene Beschreibung desselben ist afgefasst wie folgt: *Vespertilio Temminckii*, capite cuneato supra lateribusque planis; auriculis capite brevoribus, oblongis, rotundatis, margine exteriore parum excisis, trago elongato falcato; vellere sericato, pilis brevissimis supra fuscis, subtus sordide flavis, lateribus capitis corporique nitore dilute rufescente.

Dentes primores $^{1-1}/_{6}$, laniarii $^{1-1}/_{1-1}$ molares $^{4-4}/_{5-5}$, Körperlänge 4" 6"', Kopflänge 1", Länge der augebreiteten Flügel 12'.

Vesperugo (Vesperus) grandidieri Dobson, 1876

p. 500

Head, ears, and tragus very similar to those of *Vesperugo abramus*, Temm. Ears short, rounded off above; outer margin of the ear-conch straight or faintly concave in upper two thirds, emarginate opposite the base of the tragus, terminating in a small rounded lobe midway between the base of the tragus and the angle of the mouth: crown of the head scarcely elevated above the face-line; nasal apertures separated widely, opening forwards, their margins not projecting.

Wing-membrane from the base of the toes; postcalcaneal lobe very shallow; half the last caudal vertebra free.

p. 501

Fur short on both surfaces, scarcely extending upon the membranes; reddish brown above, paler beneath.

Upper inner incisors bicuspidate, the shorter outer cusp nearly equalled in vertical extent by the unicuspidate outer incisor; lower incisors trifid, not crowded; the single upper premolar close to the canine.

The other species of this subgenus known from Southern Africa are *V. minutus*, Temm., and *V. capensis*, Smith. From both *V. grandidieri* is easily distinguished by the large size of the outer upper incisor.

Length: - head and body 1.75 inch; tail 1.4; ear 0.5; tragus 0.22 x 0.08; forearm 1.25; thumb 0.28; second finger - metacarp. 1.2, first phalanx 0.45, second phalanx 0.55; fourth finger - metacarp. 1.1, first phalanx 0.28, second phalanx 0.2 ; tibia 0.5; foot and claws 0.3.

The above measurements are taken from the only specimen of this species yet obtained, an adult female with *fœtus in utero*, preserved in alcohol in the Paris Museum, which, by the kindness of H. Alph. Milne-Edwards, I have been enabled to examine and describe. It was brought from Zanzibar by M. Grandidier (who has added so much to our knowledge of the fauna of South-eastern Africa and Madagascar), with whose name I have much pleasure in associating the species.

Vesperugo (Vesperus) Innesi Lataste, 1887

p. 625

Vesperugo (Vesperus) Innesi, n. sp.

Formule dentaire (un seul coté de chaque machoire étant considéré):

2 / 3 + 1 / 1 + 1 + 3 / 2 + 3

L'incisive inférieure externe a disparu par caducité sur le sujet dont j'ai préparé le crâne.

La pointe des incisives supérieures est trop usée, sur mes deux sujets, pour que je puisse dire si ces dents étaient fourchues ou non; pour tout le reste, le système dentaire de l'espèce nouvelle est très-semblable à celui de l'espèce *V. serotinus* Schreber. L'incisive supérieure externe, notamment, est, de même, très distante de la canine et accolée à l'incisive interne ([1]), les centres de figure des quatre incisives supérieures se trouvant

([1]) Les incisives supérieures de *Miniopterus Schreibersi* Natterer sont bien différentes de celles de *Vesperugo serotinus* Schreber, mais elles ne me paraîssent pas plus écartées que ces dernières soit de la canine, soit entr'elles sur la ligne mediane. C'est donc à tort que G. E. Dobson voit, dans cet écartement, un caractère propre au groupe des *Miniopteri*, dans la famille de *Vespertilionidae* (*loc. cit.*, p. 170, B).

p. 626

situés sur une même ligne droite; l'incisive externe, est en outre très-petite et presque entièrement cachée dans la gencive.

Les crânes des deux espèces ont aussi la même forme générale; mais celui de l'espèce nouvelle est beaucoup plus petit. Le crâne du sujet que j'ai preparé (M, donne au Musée Civique de Gènes) mesure 16^{mm},3 de longueur maximum, tandis que celui d'un *V. serotinus* subsp. *isabellinus* Temminck (F, n° 2408) mesure 19^{mm},3. Les bulles osseuses de l'espèce nouvelle sont aussi très-semblables à celles de *V. serotinus* et *isabellinus*; elles présentent le même développement considerable de l'os tympanique, mais elles sont relativement beaucoup plus grosses.

Dimensions (en millimetres) des deux sujets (conservés dans l'alcool):

	F, M
Corps (tête et tronc), jusqu'à l'origine de la queue:	58, ?
Queue:	40, 35
Tête:	20.3, ?
Oreille (depuis l'origine de son bord externe):	15, 15
Oreillon (depuis l'origine de son bord externe):	6.5, 6.5
Largeur maximum de l'oreillon:	2, 2
Avant bras:	42, 40
Pouce (ongles compris):	6, 6.5
Troisième doigt:	70, 65
Cinquième doigt:	50, 47
Jambe:	20, 19.5
Calcaneum:	18, 18
Pied (ongles compris):	9, 9

Description:

La tête de l'espèce nouvelle est très-semblable à celle de *V. serotinus*; son front est plus convexe; son museau est plus

p. 627

plat, par suite du développement plus considérable des bourrelets glanduleux latéraux; il est aussi un peu moins velu. Les oreilles sont plus courtes que la tête et construites sur le même

type que celles de *V. serotinus*; le lobe antéro-inférieur de leur bord interne est proportionellement plus développé en avant et plus arrondi; le lobe antéro-inférieur de leur bord externe est relativement plus saillant et il est isole de ce bord par une encoche moins élargie et plus profonde. L'oreillon est assez effilé, en pointe obtuse, et il présente, à la base de son bord externe, un tout petit lobule triangulaire; au-dessus de ce lobule, le bord externe est d'abord assez fortement convexe, puis légèrement concave, presque rectiligne; le bord interne est droit. Quand on rabat l'oreille sur les côtés du museau, elle couvre l'oeil et son sommet arrive à peu près au niveau du bout de la machoire inférieure.

Callosités du pouce et du tarse, comme chez *V. serotinus*. Insertion de l'aile, au même point que chez ce dernier. Lobe postcalcanéen, très étroit. Queue, à huit vertèbres, dont la dernière, sans compter le cartilage terminal, est libre, la longueur de cette partie libre sur mes deux sujets variant presque du simple au double. Les orteils, même sans les ongles, sont plus longs que la moitié du pied; le premier est sensiblement plus court que les autres, ce qui n'a pas lieu chez *V. serotinus*.

En dessus, le poil s'étend moins loin sur les ailes et, surtout, sur la membrane interfémorale que chez *V. serotinus*; sur. Cette

p. 628

dernière membrane, il dépasse à peine le corps, et, sur les premières, il ne s'avance qu'à sept ou huit millimètres de lui. Le lobe antéro-inférieur du bord externe de l'oreille est nu, tandis qu'il est velu chez *V. serotinus*.

Couleur, isabelle très-pâle en dessus, plus pâle, presque blanche, en dessous. Les membranes sont plus foncées. L'aile est bordée par un fin liseré blanc, comme celle de *V. Kuhli* Natterer ([1]).

Habitat:

L'espèce nouvelle habite les maisons de la ville du Caire, en Égypte. Je suis heureux de la dédier à M. Walter Innes, conservateur du Musée de l'Ecole de Médecine de cette ville; car c'est à lui que je dois les deux sujets, M et F, conserveé dans l'alcool, qui ont servi à cette description, ainsi que beaucoup d'autres Mammifères et Reptiles égyptiens que j'ai utilisés ou que j'utiliserai de mon mieux au profit de la science.

Le sujet dont le crâne a été prepare, le male, a été offert par moi au Musée civique de Génes; la femelle est conservée dans ma collection.

Affinités et caractères distinctifs.

Par son oreillon, relativement long, attenué au sommet, incliné en dehors, atteignant sa plus grande largeur au-dessous du milieu de son bord interne, à bord externe convexe, l'espèce nouvelle se rapproche du groupe de *Vesperus* sud-américains qui comprend les espèces *V. velatus* Is. Geoffroy, *V. macrotus* Poeppig, *V. montanus* Philippi et *V. magellanicus* Philippi; il se distingue, d'ailleurs, des trois premières, par ses oreilles absolument libres et nullement réunies par un pli cutané, et, des quatre, par ses oreilles plus courtes que la tête; les oreilles sont un peu, chez *V. magellanicus*, et beaucoup, chez les trois autres, plus longues que la tête.

([1]) Plis du palais:
Entre les incisives, une éminence, prolongée, à droite et à gauche, derrière chaque incisive, par une crête courte; entre les canines, un pli transversal, ses extremités repliées en arrière; un autre pli semblable entre les prémolaires. Cinq paires de plis, arqués et à concavité postérieure, entre les molaires, les derniers moins saillants et moins arqués.

p. 629

Parmi les autres espèces du sous-genre *Vesperus*, nous pouvons de suite éliminer les *V. tenuipinnis* Peters, *V. pumilus* Gray, *V. Grandidieri* Dobson, *V. propinquus* Peters, *V. borealis* Nilsson, *V. discolor* Natterer, *V. atratus* Blyth, *V. pachyotis* Dobson et *V. albigularis* Peters, dont l'oreillon a une forme bien différente, atteignant sa plus grande largeur plus ou moins haut et jamais au-dessous du milieu de la hauteur de son bord interne.

Restent les espèces *V. serotinus* Schreber avec sa sous-espèce *V. isabellinus* Temminck, *V. Andersoni* Dobson, *V. Hilairei* Is. Geoffroy, *V. platyrrhinus* Dobson, *V. minutus* Temminck, *V. capensis* Smith, *V. megalurus* Temminck et *V. nasutus* Dobson, qu'il est nécessaire de comparer une à une à l'espèce nouvelle.

Je ne possedè, pour cette comparaison, que les *V. serotinus* et *isabellinus*; je m'en rapporterai, pour les six autres espèces, aux descriptions qui en ont été données, notamment par Dobson (Catalogue Chiroptera, 1878).

L'espèce nouvelle est certainement voisine de *V. serotinus* et, surtout, de sa sous-espèce *isabellinus*; mais elle s'en distingue par sa plus petite taille, par son oreille moins largement arrondie au sommet et plus profondément échancrée vers le tiers supérieur de son bord externe, *par son oreillon plus long et plus atténué au sommet*, par l'angle postérieur plus aigü de sa membrane interfémorale, par sa couleur beaucoup plus pâle, par le fin liseré blanc qui borde sa membrane alaire, etc.

Les autres espèces du même groupe ci-dessus mentionnées me paraissent différer à leur tour de celle que je viens de décrire:

V. Andersoni, par sa taille beaucoup plus grande, par le petit développement du lobe situé à la base du bord interne de son oreille, et par la forme différente de son oreillon; le bord externe de celui-ci présente un petit lobe arrondi et non triangulaire, et, à partir de l'échancrure qui isole ce lobe, il demeure convexe jusqu'au sommet;

V. Hilairei, par ses oreilles plus longues, atteignant presque le bout du museau, et échancrées, dans le tiers supérieur de

p. 630

leur bord externe, plus profondément même que les oreilles de *V. serotinus*; en outre, par son habitat sud-americain;

V. platyrrhinus ([1]), par la forme de son oreille, nullement échancrée vers le haut de son bord externe et coupée anguleusement à la base de son bord interne, par la forme de son oreillon, plus élargi au dessus de sa base et plus courtement aigü au sommet, par le développement plus considérable et la forme différente des bourrelets glanduleux du museau;

V. minutus, par sa taille considérablement plus petite;

V. capensis, par l'insertion de la membrane alaire à la base de l'ongle du cinquième orteil et non à la base du cinquième orteil;

V. megalurus, par sa taille plus grande, égale à celle de *V. serotinus*, par son oreillon plus court même que celui de *V. serotinus*, par son incisive supérieure externe, dont la base est large et située exactement entre l'incisive interne et la canine, au lieu d'être étroite et située sur le même niveau transversal que l'incisive interne;

V. nasutus, enfin, par la forme de son museau, conique et projeté en avant comme dans le genre *Nyctinomus*, par l'absence de lobe arrondi à la base du bord interne de l'oreille, etc.

Paris, 8 mai 1887.

([1]) Voir Dobson, *loc. Cit.*, pl. XII, fig. 1.

Vesperugo (Vesperus) Moloneyi Thomas, 1891

p. 528

Vesperugo (Vesperus) Moloneyi sp. n.

Vesperus with the tragus extraordinarily short, with the outer upper incisors nearly as long as the inner, and with the anterior lower premolar minute.

Size of body medium, but the extremities so short that the forearm-length makes the species appear to be among the smallest of the genus. Head very broad and flat, much as in *Nycticejus** or in *V. pachypus*: facial glands swollen, but not raised vertically above the level of the centre of the muzzle. Ears very short, their edges evenly continuous, not emarginate externally either above or opposite the base of the tragus; the small keel usually present just behind the base of their inner margin nearly or quite obsolete. Tragus (see figure) extraordinarily small, quite unlike that of any other member of the group, *its height, measured along its inner edge, less than half its breadth*, its upper and its outer margins rounded; its outer base without any projection. Anterior extremities much reduced throughout, especially distally; the forearm but little more than half of the combined lengths of the head and body, the thumb very short, the two phalanges of the middle finger together only about half the length of the short forearm, and those of the fifth finger less than a fifth of it; finally the usual distal cartilaginous extension of the third finger is nearly obsolete. Hind legs unusually thick and muscular. Calcar feeble, post-calcareal lobule absent. Extreme tip of tail only free from membrane.

Fur short, uniformly very dark brown or black above and beneath.

Upper inner incisors long, their tips bicuspid ; outer ones

* When showing (Ann. Mus. Genov. (2) ix. p. 88, 1890) that the American *Nycticejus humeralis* could not be separated generically from the Old-World *Scotophilus*, I did not notice that the name *Nycticejus* (1819) was anterior in date to *Scotophilus* (1822). Mr. Blanford has since pointed this out to me; and it is evident that the former name must be used for all the species hitherto called *Scotophilus*.

p. 529

cylindrical, unicuspid, not reaching quite to the level of the outer cusps of the inner incisors. Upper premolars very close to and but little shorter than the canines. Lower incisors tricuspid, overlapping. Anterior lower premolar very small, scarcely exceeding in height the cingulum of the large posterior one.

Dimensions of the type, a male preserved in spirit: -

Head and body 50 millim.; head, length 16, breadth across muzzle 11; ear, length from base of inner edge 9, length from base of outer 11.5; tragus, length of inner margin 1.0, length of outer margin 3.8, breadth above 1.9, height of base 3.2. Forearm 29 (= 1.15 inch); thumb, including claw, 5.5; third finger, metacarpal 29, first phalanx 8.5, second phalanx 7.8; lower leg 11; hind foot, including claws, 8.2; tail 30.

Hab. Lagos, West Africa. One specimen, collected and presented by Sir Alfred Moloney.

This most remarkable species is distinguished by its proportionally large body and head and the reduction in length of all its extremities, including in this term the ears, tragus, wings, legs, and tail. This reduction, combined with the markedly more muscular condition of the legs, no doubt indicates a less exclusively aerial manner of life; and we may be prepared to find when its habits are known that it seeks for its prey creeping about either the trunks and branches of trees or the rocks of cliffs and caves, rather than flying about in the open.

Vesperugo (Vesperus) Rendalli Thomas, 1889

p. 362

Crown of the head flat, scarcely raised above the level of the muzzle; muzzle broad, the glandular prominences much swollen. Ears short; laid forward they reach barely more

p. 363

than one half the distance between the eye and the tip of the nose; their inner margin straight, tip narrowly rounded off, upper third of outer margin straight, middle third slightly convex, basal third with a marked lobe separated by a notch opposite the base of the tragus.

Tragus of about the same breadth from base to tip, its inner margin evenly but slightly concave, its tip rounded, its outer margin evenly convex, its base with a triangular lobule; when laid forward its tip reaches to between the posterior canthus and the middle of the eye.

Pads at the bases of the thumbs scarcely more marked than usual, but the soles of the feet broad, swollen, and wrinkled, projecting posteriorly behind the level of the origin of the calcaneum. Wings from the metacarpus close to the base of the toes. Calcaneum reaching about halfway from the heel to the end of the tail, its tip forming a small projecting point like that found in *V. Daubentoni*; postca1caneal lobule distinct, but rather narrow. Tail involved in the interfemoral membrane to its extreme tip. Penis with a distinct bone.

Fur scarcely extending on the membranes except on the interfemoral in the centre below.

Colour of body, above and below, of the skin or the forearm, digits; and legs greyish brown, of the membranes everywhere white, the reticulations well marked.

Teeth. - Upper incisors (figs. b-d), or at least the outer

p. 364

pair, quite different from those of any other member of the genus. The inner one with a large secondary cusp about halfway up its posterior edge, and the hinder edge of the main cusp, above the secondary one, markedly sinuous, as though the tooth were occasionally trifid (fig. b). Outer incisor well developed, triangular in section at the base (see fig. c), its angles each with a cusp, the antero-internal bearing the long main cusp, three fourths the height of the inner incisor; cusp on the postero-internal angle about half the height of the secondary cusp of the inner incisor; cusp on the external angle minute, but quite distinct (fig. d); postero-external side of the tooth close to the base of the canine (fig. c). No trace of a minute anterior premolar; large premolar pressed closely against the back of the canine and leaving no room for another tooth between.

Lower incisors trifid, overlapping, placed at right angles to the direction of the jaws. Second lower premolar two thirds the height of the canine, and first premolar two thirds its height.

Dimensions of the type (an adult male in spirit): - Head and body 50 millim.; tail 39; forearm 36 (= 1.4 inch); head 16.5; muzzle to eye 7.0; ear, above crown 9.0, from base of external margin 13.0; thumb, including claw, 6.2; lower leg 13.6.

The type specimen of this most interesting bat was obtained by my friend Dr. Percy Rendall at Bathurst, on the River Gambia, and I have much pleasure in connecting his name with it.

Vesperuqo Rendalli presents a combination of characters which prevents it falling into anyone of the subgenera of *Vesperugo* as recognized and defined by Dr. Dobson (Cat. Chir. B.M. p. 184). But I am far from regarding it as representing a new subgenus, and only consider it as showing that *Hesperoptenus*, Peters, in which a penis-bone is present and the outer incisors are minute, should be amalgamated with *Vesperus*, in which there is no penis-bone and the outer incisors are well developed. The swollen and probably adhesive hinder pads of this species give it a second point of resemblance to *V. ("Hesperoptenus") Blanfordi*, Dobs.; but, as Dr. Dobson has shown, this character is not one on which generic or subgeneric division can be based.

Vesperugo [(Vesperugo)] maderensis Dobson, 1878

p. 231

Ears and tragus generally like those of *V. kuhlii*, but the outer margin of the ear-conch is much more deeply emarginate above, and the middle third consequently more abruptly convex (Plate XII, fig. 5, ear, double natural size).

Postcalcaneal lobe distinct, placed on the calcaneum about the length of the foot from the ankle; extremity of the tail free; wings from the base of the toes; feet small.

Fur, above, dark brown with light brown extremities to the hairs; beneath, the hears are dull black with yellowish-brown tips. No trace of a white margin to the membranes.

On the upper surface the fur extends upon the wings almost as far as a line drawn from the proximal third of the humerus to the knee, and upon the base of the interfemoral membran; beneath, the wing-membrane is clothed as sar as a line drawn from the

p. 232

elbow to the knee; fur longer on the ventral than on the dorsal surface.

Inner upper incisor on each side very slender, long, and unicuspidate, the outer incisor very small and close to its base; lower incisors at right angles to the direction of the jaw; second upper premolar separated by a narrow space from the canine, through which the summit of the minute first premolar can in some specimens be seen.

Length (of an adult M), head and body 1".6, tail 1".5, head 0".55, ear 0".5, tragus 0".22, forearm 1".3, thumb 0".22, second finger 2".25, fourth finger 1".6, tibia 0".45, foot 0".25.

(Three specimens (from Palma and Madeira) have been examined and measured by me and found to agree in all respects.)

Hab. Madeira and Canary Isles.

This species is closely allied to *V. kuhlii*, but may be at once distinguished by the much shorter body and longer tail, by the very deep emargination on the outer side of the ear, and by the complete absence of the white margin to the membranes.

Vesperugo Anchieta Seabra, 1900

p. 26

Treze femeas de Cahata representam esta nova especie angolense que caracterisamos assim: cabeça notavelmente deprimida; o focinho curto; narinas proeminentes e bem distanciadas; as orelhas grandes, largas na sua base; o chanfro da orla externa

muito escavado, a ponta arredondada; o tragus bem desenvolvido e ligeiramente serrilhado na orla posterior; o anti-tragus bem visivel e triangular. A pelagem abundantissima tanto na cabeça como sobre o dorso e ventre; de um pardo-escuro um pouco avermelhado sobre o dorso, mais claro no ventre; membrana branchial nua; a inter-femural coberta de pellos tanto pela parte superior como pela parte inferior, até meio do comprimento da cauda. Estes pellos, como em geral succede, são muito claros e curtos na parte inferior d'esta membrana. Na região comprehendida entre o humero e o femuro, pela parte inferior (região ventral), o pello estende-se com bastante abundancia e é longo. Pela parte dorsal estende-se apenas ligeiramente sobre o femuro. O paladar apresenta os caracteres genericos; os lóbos anteriores são deprimidos e as pregas encontram-se, como procuramos representar no schema 22, quasi egualmente distanciadas entre si.

Dentição: incisivos superiores simples; o interno bem desenvolvido, o externo attingindo apenas metade do comprimento d'este; o canino separado apenas por um pequeno espaço do segundo premolar e deixando entre si e este ultimo dente o primeiro premolar pequenissimo e difficil do reconhecer. Os molares perfeitamente conformados. Os incisivos inferiores trilobados.

Dimensões: cabeça e corpo 40 mili.; cabeça 15; orelha (da base do tragus á penta) 11; cauda 32; ante-braço 35; polex 4; 3° dedo: 3.° dedo: metacarpô 31; 1.ª phalange 12; 2.ª phalange 16; 4.° dedo: metacarpo 30, 1.ª phalange 10, 2.ª phalange 8; 5.° dedo: metacarpo 20, 1.ª phalange 9, 2.ª phalange 5; tibia 43; pé 6. Nos outros individúos as dimensões correspondem exactamente a estes.

p. 26

Thirteen females from Cahata represent this new Angolan species that are characterised as follows: notably depressed head; short snout; prominent nostrils and well-spaced; big ears, large at the base; the bevel of the external edge is concave, with a rounded tip; the tragus is well developed and slightly serrated on the back edge; the anti-tragus is very visible and triangular. The coat of hair is equally abundant on the head, back and belly; from a dark brown it becomes a little red on the back, and clearer on the belly; the branchial membrane has no hair; the inter-femur is covered by hairs on the top and the bottom, halfway of the length of the tail. These hairs, as generally, are very light and short on the bottom part of the membrane. In the region between the humerous and femur, on the bottom part (belly region), the hair extends abundantly and is long. On the dorsal part it extends over the femur. The palate presents general characteristics; the anterior lobes are depressed and the folds are, as we sought to represent scheme 22, they are almost equally spaced.

Dentition: simple superior incisors; the interior is under developed, the external reaches about half the length of this one; the canine separated by a small space between the second premolar and in between these two is a small first premolar which is difficult to identify. The molars are perfectly conformed. The inferior incisors are tri-lobed.

Measurements: head and body 40 mill.; head 15; ear (from the base of the tragus to the tip) 11; tail 32; forearm 35; thumb 4; third finger: metacarpal 31; 1.ª phalange 12; 2.ª phalange 16; fourth finger: metacarpal 30, 1.ª phalange 10, 2.ª phalange 8: fifth finger: metacarpal 20, 1.ª phalange 9, 2.ª phalange 5; tibia 43; foot 6. The measurements of other individuals correspond exactly with these.

Vesperugo hypoleucus Heuglin and Fitzinger, 1866

p. 546

In Sennaar, zwischen Kereri, Halfäye und Surerat am Nil in der Nähe von Chartum gesammelt. Ausgezeichnet durch die rein weiße Färbung des Bauches.

Vesperugo pagenstecheri Noack, 1889

p. 220.

Taf. II, Fig. 3, Taf. V, Fig. 64 - 65.

Zwei Spiritus-Exemplare F. Netonna. Im Wipfel einer Kokuspaluie gefangen. Coll. Hesse.

Diagnose. Kleiner *Vesperuqo*, der *Vesperugo nanus* PETERS nahe steht, aber erheblich kleiner und viel heller gefärbt ist. Ohr lang und schmal zugespitzt, hinten etwas ausgeschnitten, der äussere Ohrrand mässig gegen den Mundwinkel vorgezogen, der kleine und schmale Tragus innen gerade, aussen convex. Färbung oben hell gelblich olivenfarben, unten noch heller weisslichgelb mit olivenfarbenem Anfluge.

Beschreibung. *Vesperugo pagenstecheri* in zwei identischen Exemplaren unterscheidet sieh von *V. nanus* durch die geringere Grösse, die längeren und schmaleren Ohren, den anders geformten Tragus, den längeren zweiten Finger und die viel hellere Färbung.

p. 221

Der Kopf ist klein, die Nase, deren Seiten mit borstigen, nach vorn gerichteten Wimpern besetzt sind, stumpf, die seitwärts geöffneten Nasenlöcher mit wulstigem Baude durch eine seichte Furche getrennt, die Unterlippe ohne Warzen, fein behaart. Die langen, niedergedrückt die Nasenspitze überragenden Ohren sind sehr schlank zugespitzt, aussen nur wenig eingebuchtet, der untere Dach vorn vorgezogene, etwas verdickte Rand endet in einen hochstehenden Lappen von 0.75 mm Länge. Der schmale Tragus ohne Furche steht ziemlich vertical und ist nicht beilförmig wie bei *V. nanus*, sondern oben einfach abgerundet, die innere Kante gerade, die äussere etwas gebogen. Der Daumen ist frei. Die unbehaarte Flughaut am Ende des zweiten

Fingers scharf zugespitzt, der letzte Wirbel des Schwanzes ist frei. Die im Basaltheile dichter, unten spärlicher mit gelblichen, oben mit bräunlichen Härchen besetzte Schwanstlughaut ist schlank zugespitzt und entbehrt der Ausbuchtung, die Schenkelflughaut reicht bis über die erste Phalange des Fusses. Bein und Fuss sehr zart, Nägel weisslichgelbbraun. Flughaut schwarzbraun, Schenkelflughaut heller, gelbbraun, Humerus, Unterarm, zweiter Finger, Unterschenkel weissliehgelb. Wimpern und Nagenseite schwärzlichbraun. Haarbasis hell graubraun, bei *nanus* schwarzbraun, Haar lang, fein, flockig, hell gelblichumbra mit Stich ins Olivenfarbene, unten heller mit vielfach durchschimmernder graubrauner Haarbasis. Bei *V. nanus* ist die Färbung viel dunkler braun. Vergl. PETERS, Säugethiere Mosamb., p. 63, Taf. 16, 3; DOBSON, Cat. Chiropt., p. 237.

Maasse. *V. pagenst.*, *V. nanus*.
Körper: 40, Körper und
Schwanz: 28, Schwanz: 80
Ohr lang: 9.5, 11.5 - 12
" breit: 6, 7

Humerus: 16, 19 - 20
Unterarm: 30, 31.5
Daumen: 5, 5.5
II: 35, 29 - 30
III: 52, 54 - 57
IV: 44, 45 - 49
V: 37, -
Femur: 12; 12.5 - 13
Unterschenkel: 11, 12
Fuss mit Krallen: 6, 7
Sporn: 5, -

p. 222

Der Schädel (Tf. V, Fig, 64) ist ziemlieh schmal, Scheitel und Hinterhaupt abgerundet, Scheitel- und Lambdanaht fehlen, das sehr grosse Hinterhauptloch wird erheblich von der Squama occipit. überragt, die Stirn ist gewölbt, die Nasenbasis eingesenkt, die rundlichen Nasenbeine durch eine mediane Furche getrennt. Der Orbitalrand ist vorn wulstig, die sehr feinen Jochbogen wenig gebogen, der kurze Oberkiefer nach oben gebogen, der Gaumen ist hinten breit, vorn zugespitzt. Von den 7 Gaumenfalten gehen die beiden ersten quer durch, die folgenden sind gebrochen und die inneren Bogen stark nach hinten gezogen. Am Unterkiefer ist der aufsteigende Ast niedrig und sehr breit, der Proc. coron. mit scharfer Spitze, etwas nach vorn gerichtet, die Massetergrube tief mit scharfen Leistenrändern.

Maasse. Scheitellänge 11 (bei *Vesperuqo nanus* 12), grösste Scheitelbreite 6.25, Einschnörung 3.5, Schädelkapsel 7, Nasenbreite 3.5, Hinterhauptloch 2.5 hoch und breit, Höhe der Squama occipit. über dem For. occipit, fast 2, hintere Gaumenbreite 3.5. Unterkiefer bis zum Condylus 7, aufsteigender Ast 2, Höhe des horizontalen Astes 1.

Gebiss (Taf. V, Fig. 65) von *Vesperugo*: $I^{2+2}/_{6}$ $C^{1+1}/_{1+1}$ $P^{2+2}/_{2+2}$ $M^{3+3}/_{3+3}$.

I innen mit der Spitze nach innen und vorn gerichtet, zweispitzig, der hintere Zacken stark, nicht ganz so lang wie der vordere. I aussen vorn mit kräftigem Basalwulst. kürzer und schmaler als I innen. C mit breitem Basaltheil, aber schlank zugespitzt und nach vorn gerichtet, vorn, aussen und hinten mit scharfer Kante, innen stark cannelirt. Der Basalwulst springt nach hinten höckrig vor und ist röthlich gefärbt, wie auch P und M einen hellröthlichen Anflug haben. P I ein sehr kleiner, rudimentärer, nach innen gerichteter Zacken. P II = $^{3}/_{4}$ C, länger als M. Basalwulst vorn höckrig, hinten ausgezogen, der Innenzacken vertieft. M I und II identisch, die beiden Aussenzacken gleich hoch, der Innenhöcker vertieft mit nach vorn gerichtetem Innenzacken. M III kleiner, der hintere Theil des W unbedeutend, der Innenzacken nach vorn gerichtet. C ist 1 mm hoch, die übrigen Zacken entsprechend niedriger.

Unten I nach vorn gerichtet, klein, gestielt, stark dreilappig, C schmal und gerade, der Basalwulst innen mit kleinem Nebenzacken. P und M mit Basalwulst, P I und II einspitzig, I etwas niedriger. Bei M der vordere Aussenzacken etwas höher als der hintere, innen 3 Zacken, der vordere nach vorn, der hintere nach hinten gerichtet. M III etwas kleiner

---

Vesperugo pulcher Dobson, 1875

p. 471

Crown of the head slightly elevated above the face-line; muzzle shaped more like that of some species of *Vespertilio* (*V. emarginatus*, e. g.), and the glandular prominences between the nostrils and eyes less developed than in most species of *Vesperugo*. Ears about four fifths the length of the head, the ascending inner margin straight or faintly convex, the upper half of the outer margin slightly concave, terminating in a line directly below the eye, but on a lower level than the angle of the mouth ; tragus nearly half the length of the ear, shaped like that of *V. serotinus*.

Posterior margin of the interfemoral membrane festooned with distinct papillæ arranged like the teeth of a comb.

Fur above sienna-brown, with shining tips, beneath wholly pure white; the dark-coloured fur of the back does not pass beyond a line connecting the angle of the mouth (when the head is extended) and the under surface of the humerus. Interfemoral, antebrachial, and wing-membranes between the humerus and femur white; the remaining parts of the wing-membrane pale brown.

p. 472

Inner upper incisor long, with a second cusp on its outer side near the extremity. Outer incisor short, lying close to the base of the inner incisor. Second premolar in the upper jaw separated from the canine by a short interval, through which the small first premolar is distinctly visible from without. Lower incisors not crowded.

Length (of an adult male preserved in alcohol), head and body 2".0; tail 1".6; head 0".7 ; ear 0".6; tragus 0".25; forearm 1".35; thumb 0".28; second finger 2".6; fourth finger 1".9; tibia 0".52; foot and claws 0".3.

Hab. Zanzibar.

Type in the collection of the British Museum.

This species resembles *V. (Alobus) temminckii*, Rüpp., but may be at once distinguished by the form of the tragus, which is narrowed towards the tip and subacutely pointed, by the deeply fimbriated margin of the interfemoral membrane, by its much greater size, &c.

In Sennaar, in der Umgegend von Chartum.

Vesperugo stampflii Jentink, 1888

p. 54

An adult male, Farmington River (Stampfli).

p. 55

The smallest *Vesperugo*-spedes hitherto recorded. Ears ronnded off, inner margin convex, outer margin straight for its greatest part, then convex, terminating in a small rounded lobe at a short distance behind the angle of the mouth. Inner margin of tragus slightly concave, outer margin convex, tip rounded off.

Wings from base of toes, calcaneum long with projecting tip; extreme tip of tail free. Interfemoral and wing-membranes margined with white.

Fur above black with brownish red tips, beneath black with light brown tips. Ears and membranes black.

Inner upper incisors bifid, outer incisors unicuspidate; lower incisors trifid. First upper premolar very small, hardly visible from without; first lower premolar three fourth of the size of the second premolar.

Measurements of the adult male, in alcohol (in mm):

Length of head and body: 38
" " tail: 24
" " ear: 9
" " tragus: 4
" " forearm: 33
" " thumb: 5

I call it after its discoverer, Mr. Stampfli.

Vesperus bicolor Bocage, 1889

p. 5

Museau obtus, large et renflé. Oreilles courtes, mésurant à peine $^2/_3$ de la longueur de la tête, avec le bord interne fortement convexe à partir de la base et l'externe émarginé dans sa moitié supérieure; l'extrémité arrondie. Tragus allongé, cultriforme, à bords parallèles et avec un petit lobe triangulaire à la base du bord externe. Ailes par-

p. 6

tant de la base du 1er orteil; un lobe calcanéen distinct et convéxe. Queue presque entiérement comprise dans la membrane interfémorale.

Poils des parties supérieures brun-marron avec les extrémités d'un roux ferrugineux; ceux des parties inférieures d'un marron plus foncé, presque noir, avec les extrémités blanches; les poils du museau roux-ferrugineux. Les membranes alaires transparentes, d'un brun-roussâtre pâle; les membres de cette même couleur.

Incisives supérieures internes indistinctement bilobées, larges et courtes, les externes rudimentaires; pas de trace de la première prémolaire à la mâchoire supérieure; les incisives inférieures trilobées, disposées transversalement par rapport au bord de la mâchoire; la premiére prémolaire inférieure petite, ayant à peine la moitié de la hauteur de la deuxième.

Deux individus femelles de *Caconda* par M. d'Anchieta.

De la taille à peu-près du *V. minutus*, Temm., et du *V. tenuipinnis*, Peters, et se rapprochant du second par ses couleurs. Malheureusement ces deux espèces manquent aux collections du Muséum, de Lisbonne, de sorte que nous avons à nous prononcer d'après les descriptions de ces deux espèces: il doit ressembler au *V. minutus* par la forme du tragus, mais s'en écarte par la forme et les dimensions relatives de ses incisives supérieures et aussi par ses couleurs; ces derniers caractéres semblent s'accorder mieux avec ceux du *V. tenuipinnis*, mais le tragus de cette espèce doit avoir une forme toute différente, ayant été comparé par Peters au tragus du *V. noctula*.

Voici maintenant les dimensions des parties les plus intéressantes à comparer chez les trois espèces:

V. bicolor, nova sp.; *V. minutus* (Dobs.), *V. tenuipinnis*, (Peters)
Tête et corps: 43 mm.; 45 mm; 46 mm.
Queue: 26; 27; 30
Oreille: 12; 11; 11
Tragus: 6; 5.7; 4.5
Avant-bras: 30; 31; 29
Pollex: 6; 5.5; 5
3^e doigt: 53; 50; 53
Jambe: 11; 10; 11

Vesperus damarensis Noack, 1889

p. 213

Taf. V, Fig. 59.

Ueber *Vesperus* s. DOBSON, Cat. Chiropt., p. 184 ff.

Drei Exemplare F, zwei in Spiritus. Damaraland, Omburo und Golabu, Coll. SCHINZ.

Diagnose. Mittelgrosser *Vesperus* mit langen, oval zugespitzten Ohren, deren äusserer Rand aber etwas eingebuchtet ist, und geradem, aussen halbmondföriuig abgerundetem Tragus, mit dunkelbrauner, zwischen Schenkeln und Schwanz hell gelbbrauner, von weissen parallelen Adern durchzogener Flughaut, oben von hell sepiagelber mit Graubraun gemischter, unten von weisegrauer mit Schwarzbraun gemischter Farbe der ziemlich langen und flockigen Haare.

Beschreibung. Die spärlich behaarte Nase ist kurz und breit, schwarz gefärbt, die nach aussen geöffneten Nasenlöcher mit wulstigem Rande sind weit vorgestreckt und durch eine breite Furche getrennt, die Oberlippe verdickt, die Stirn stark behaart. Die 12 mm lange Zunge schmal, hinten nur wenig verdickt. Das oval zugespitzte Ohr reicht niedergedrückt bis zur Nasenspitze, nur der Basaltheil des vorderen Randes und die hintere Basis sind behaart. Der äussere Rand ist wenig ausgebuchtet und unten verdickt, der untere Lappen mässig, bei weitem nicht bis gegen den Mundwinkel vorgezogen. Der Tragus ist etwas nach vorn geneigt, der innere Rand desselben gerade, der äussere halbmondförmig convex und unten umgebogen. Daumen und Zehen dünn behaart, der kleine Daumen mit basaler Schwiele und weissem oder weisslichbraunem Nagel frei, der dritte Finger stark

p. 214

verlängert, daher die Flughaut zwischen zweitem und drittem Finger stark zugespitzt; die distale Hälfte des Oberarmes nackt, die Flughaut zwischen Arm und Schenkeln mit starken Papillen, von weissen parallelen Adern durchzogen, oben am proximalen Rande und unten etwas weiter hin dünn behaart. Die Schwanzflughaut schliesst den Schwanz ganz ein, ist hinter dem Caleaneus stark ausgebuchtet und oben und unten am proximalen Theile dünn weiselich behaart; auch hier verlaufen weisse parallele Adern schräg nach dem Schwanze.

Das lange weiche Haar ist von ungleicher Länge, erscheint daher flockig, die Basis dunkel schwarzbraun, die Spitze weisslich-gelb mit Sepiabeimischung und Silberglanz. Am Oberarm und der Unterseite sind die Haarspitzen weisslich. Stirn, Scheitel und Ohr sepiagelbbraun, Kinn und Gesichtsseiten etwas heller. Die Färbung ist der von *Vespertilio lanosus* SMITH ähnlich; letztere, der SMITH ungeheuerlicher Weise einen halbmondförmigen an seinem Exemplar offenbar zufällig entstandenen Ausschnitt des äusseren Ohrrandes zuschreibt, ist falsch bestimmt und muss nach DOBSON *Kerivoula lanosa* heissen, da sie gar nicht das Gebiss von *Vespertilio* hat.

Maasse: Körper 43 - 50 mm, Schwanz 26 - 30, Ohr 9 - 10 lang, 7 - 8 breit, Tragus 4, Humerus 19, Unterarm 32 - 33, Daumen 4.5 - 5, II 57.5 - 60, III 52 - 54, IV 45 - 47, Oberschenkel 12, Untenschenkel 11 - 12, Sporn 10 - 10.5.

Schädel. Die obere Profillinie ist ziemlich gerade, die Nase sehr wenig eingebogen, die Stirn sehr wenig convex, die Scheitelnaht schwach, die Stirnbeine nach hinten rundlich pfeilförmig (im maurischen Kielbogen) verlaufend, der Schädel zwischen den Stirnbeinen eingeschnürt. Die Nasenbeine und Zwischenkiefer sind durch die Wurzeln von I und C verdickt. Der Jochbogen sehr fein, in der Mitte etwas nach oben gezogen. Hinterhaupt rundlichdreieckig, etwas gewölbt und unten nach vorn abfallend, das Foramen occipit. sehr gross. Das Tympanum an der Aussenseite flach mit etwas verdicktem Rande, der knöcherne Gaumen hinten mit einem Zacken. Das rundliche Foramen Infraorbit. sitzt hoch, dicht am Orbitalrande.

Der horizontale Ast des Unterkiefers ist mässig gebogen, nach hinten verjüngt, der Proc. coron. wie gewöhnlich dreieckig, etwas nach vorn gerichtet, die Massetergrube tief, vorn mit dreieckigem scharfem Rande.

Maasse: Scheitellänge 19.5 - 20, Basilarlänge 18 - 18.5, Höhe des Hinterhauptes und Scheitelhöhe 5, Breite des Hinterhauptes zwischen

p. 215

dem Tympanum 8.5, hinter den Jochhogen 8, Weite zwischen den Jochbogen 10, Scheitelbeine fast 7, Nasen- und Stirnbeine 5, knöcherner Gaumen 6.5, Breite vor den Jochbogen 5, Länge des Jochbogens 5, For. occipit. 2.5 hoch, 3 breit. Unterkiefer bis zum Proc. cor. 8, bis zum Condylus 10.25; Höhe des horizontalen Astes fast 1, unter dem Proc. coron. 2.75.

Gebiss von *Vesperus*: $I\ ^{2+2}/_{6}\ C\ ^{1+1}/_{1+1}\ P\ ^{1+1}/_{2+2}\ M\ ^{3+3}/_{3+3}$

Oben I (Taf. V, Fig. 59) mit Basalwulst, I innen klein, mässig gebogen mit sehr kleinem hinterem Zacken, der bei *Vesperus* im Alter verschwindet und nur bei einem Exemplar noch deutlich sichtbar ist. I aussen sehr klein, eng an I innen gedrängt, etwas nach vorn gerichtet. C mässig gebogen, senkrecht zur Kieferachse gestellt, hinten und innen ausgekehlt mit scharfer äusserer Kante, $P = {}^{1}/_{2}$ C, mit starkem hinterem Basalzacken, vorderem Basalwulst und starkem innerem Zacken mit vertiefter Kaufläche, Spitze nach innen gerichtet. M I und II W-förmig, die Aussenzacken doppelt, die innere Reihe höher, vor dem ersten Aussenzacken noch ein kleiner Basalzacken. Der innere tief liegende Kauhöcker innen gefurcht mit scharfem mittlerem Zacken. M III nach hinten gerichtet = ${}^{1}/_{2}$ M III, aussen ein, daneben, nach innen zwei Zacken, hinten zwei Zacken, der innere höher.

Unten I mit gestielter Wurzel, die Krone scharf dreilappig, die I stehen nicht senkrecht, sondern schräg nach vorn zur Achse des Kiefers C senkrecht zur Kieferachse, schlank, mässig gebogen, mit Basalwulst, der nach hinten und vorn in einen Zacken endet,

wie auch bei P II und M. Die hintere Fläche von C ist mässig ausgekehlt. P I klein, eng zwischen C und P II eingekeilt, kleiner als $^1/_2$ C, etwas höher als $^1/_2$ P II; P II = $^3/_4$ C. M I aussen und innen mit je 2 Zacken, I aussen höher mit kleinem vorderen Nebenzacken, M II aussen 2, innen 3 Zacken, ebenso M III, der erste viel höher als der zweite, innen der letzte mit kleinem Hinterzacken.

Von den Afrika, resp, die südafrikanische Subregion bewohnenden *Vesperus*-Arten bind zu vergleichen *V. serotinus* und *capensis*, da, wie aus der Beschreibung erhellt, *V. minutus, andersoni*, welcher viel grösser ist, *tenuipennis* und *grandidieri* nicht in Frage kommen, vollends nicht *V. nasutus* und *platyrrhinus*. Es ist an und für sich nicht wahrscheinlich, dass *V. serotinus* sich bis in die südafrikanische Subregion erstreckt, und da bei diesem das nach vorn gebogeue Ohr nur über die Mitte zwischen Auge und Muffel, bei *damarensis* bis zur Nasenspitze reicht, ist eine Identificirung mit *V. serotinus* nicht mög-

p. 216

lich. Das Ohr von *V. damerensis* hat die Proportion wie bei dem kürzlich von F. LATASTE (in: Ann. Mus. Civ. Stor. Nat, Genova (Ser. 2), Vo1. 4, 1887) aus Kairo beschriebenen *Vesperus innesi*, nur ist der Tragus ganz anders. Auch das Ohr von *V. capensis* unterscheidet sich erheblich, hier liegt der verstärkte Aussenrand des Ohrs viel höher als bei *V. damarensis*, der Tragus ist bei *damarensis* unten an der Aussenseite umgebogen, die äussere Schwanzspitze ist frei, die Ausbuchtung der Schenkelflughaut ist viel kleiner, die Färbung ist oben röthlichbraun mit hellerer Haarspitze, die inneren I oben stehen bei *damarensis* weiter von den äusseren ab als bei *capensis*, die unteren I stehen bei *V. capensis* senkrecht zur Kieferachse, der hintere Ansatz von P oben ist breiter

---

Vesperus guineensis Bocage, 1889

p. 6

Museau obtus, portant de chaque côté entre la narine et l'œil un renflement glandulaire arrondi. Oreilles plus courtes que la tête, triangulaires, arrondies au bout, avec le bord externe distinctement émarginé dans sa moitié supérieure. Tragus plus court que la moitié de la hauteur de l'oreille, cultriforme, à bords droits et à pointe arrondie, atteignant sa plus grande largeur vers le milieu du bord externe, qui porte à la base un petit lobe triangulaire. Ailes partant de la base du premier orteil; le lobe postcalcanéen convexe à son bord libre. Queue

p. 7

comprise jusqu'à près de l'extrémité dans la membrane interfémorale.

Les poils en dessus et en dessous d'un beau marron uniforme, à l'exception de ceux qui couvrent la région pubienne, la membrane alaire des deux côtés de l'abdomen et la membrane interfémorale, lesquels sont blancs teints légèrement de fauve. Les membres et la membrane alaire marron foncé, comme le corps.

Incisives supérieures internes bilobées, les externes pointues et arrivant presque à l'extrémité de la pointe extérieure de la 1^e incisive. La prémolaire supérieure accolée à la canine et à la première molaire, triangulaire et assez forte. A la mâchoire inférieure la premiére prémolaire de la même forme que la seconde et ayant deux tiers de la hauteur de celle-ci. Les incisives inférieures trilobées et implantées en travers des bords de la mâchoire.

Plus petit que le *V. tenuipinnis*, Peters; inférieur même en dimensions aux *Vesperugo pipistrellus* et *V. Kuhli*, desquels il se raproche par son systéme de coloration. L'absence de la premiére prémolaire supérieure ne permet pas de le confondre avec ces espèces. La couleur des régions inférieures et la forme du tragus, cultriforme et non pas securiforme, doivent servir à le distinguer du *V. tenuipinnis*, qui vient également de la Guinée.

Dimensions: Tête et corps 35 mm.; queue 25; oreille 9; tragus 5; avant-bras 26; pollex 4; 3^e doigt 43; jambe 10; pied 5.

Deux femelles envoyées de *Bissau* en 1879 par M. Rodrigo da Costa.

Vesperus Humbloti A. Milne-Edwards, 1881

p. 1034

Le Muséum d'Histoire naturelle vient de recevoir de Madagascar une collection fort importante et riche en objets rares ou inconnus; elle lui a été offerte par M. Humblot, qui a surtout exploré, sur la côte est, la région comprise entre Fou.apointe te le lac l'Aincatre.

p. 1035

Un petit *Vesperus* (*V. Humbloti*, nov. sp.) se rapproche beaucoup du *V. minutus*, mais ses dimensions sont plus fortes et ses dernières vertèbres caudales sont complètement incluses dans la membrane interfémorale.

Vesperus pusillus Noack, 1889

p. 216

Taf. II, Fig. 2, Taf. V, Fig. 60 u. 61.

Spiritus-Exemplar M. Boma, März, Coll. HESSE.

Diagnose: Winzig kleiner *Vesperus* mit langem, schmalem, wenig eingebuchtetem Ohr, nach oben breit dreieckig verbreitertem, mit der Spitze nach innen gebogenem Tragus, kurzer stumpfer Nase, dreizackigen äusseren Incisiven, geringer Ausbuchtung der Schenkelflughaut, freiem letzten Schwanzwirbel, von tief russschwarzer, unten wenig hellerer Farbe.

Beschreibung: Nase kurz und stumpf mit runder Muffel, die Nasenlöcher durch eine sehr seichte Furche getrennt. Die wulstige Oberlippe ist durch eine tiefe horizontale Furche abgesetzt. Die Oberlippe an der Seite dick wulstig, unter dem Kinn (nicht an der Oberlippe) eine starke runde Warze. Von den Gaumenfalten sind die beiden ersteren ungebrochen, die folgenden durch einen breiteren Zwischenraum getrennt und gebrochen, die Halbbogen auf der Innenseite nach hinten gezogen, die letzte, stark wulstige Doppelfalte innen sehr weit nach hinten reichend. Das lange schmale Ohr mit oval abgerundeter Spitze oben am äusseren Rande etwas eingebuchtet, unten der Lappen fast bis zum Mundwinkel hin vorgezogen. Tragus an der Basis schmal, nach oben verbreitert, innere Kante concav, äussere fast gerade, die Spitze bildet ein rundliches Dreieck, dessen Spitze nach innen gerichtet ist. Die vordere Fläche des Tragus ist ausgehöhlt. Der Daumen ist frei, der Humerus oben in der proximalen Hälfte behaart, unten nur zunächst dem Körper, die Flughaut auf 2 - 3 mm vom Körper dünn behaart, die Schwanzflughaut, aus welcher

p. 217

der letzte Wirbel herausragt, ist stark zugespitzt, oben nackt, die Ausbuchtung unbedeutend. Der Hinterleib ist auffallend schmächtig, der Penis lang herabhängend. Scrotum ziemlich gross. Färbung des Körpers und der Flughaut tief schwarzbraun, das Ohr tief schwarz, auf der Unterseite sind die Haarspitzen gelblichbraun, doch ist die Gesammtfärbung nur wenig heller als oben.

Maasse: Körper 31 mm, Schwanz 22, Ohr 7, mittlere Breite 4, Tragus 4, Humerus 17, Unterarm 26, Daumen 3; II 20.5; III 35; IV 31; V 28. Femur 10, Unterschenkel 10.5, Fuss 4.5.

An dem sehr zarten Schädel (Taf V, Fig.60) mit etwas blasig aufgetriebenen Stirnbeinen ist die Schädelkapsel doppelt so lang wie die Nase, die Kapsel ziemlich flach und breit, vor den Augen mässig eingeschnürt, die obere Contour mässig gebogen, die Stirn etwas gewölbt und die Nasenbasis mässig deprimirt. Der Oberkiefer ist vorn nur wenig in die Höhe gezogen, das Hinterhaupt mässig gerundet und unten nach vorn gezogen, besonders am unteren Rande des grossen For. occipit., die ziemlich grossen runden Bullae aud. nicht vom Tympanum getrennt, mit langem seitlichen Halbringe. Die Basis cranii liegt auffallend hoch, so dass die Scheitelhöhe eine geringe ist.

Der Unterkiefer ist nach vorn schmal zugespitzt, die Symphyse kräftig, unten mit rundlichem Zacken, der horizontale Ast ziemlich stark gebogen, so dass der Winkelfortsatz bis in die Höhe der Zahnbasis emporgezogen ist. Der Proc. cor. ist etwas nach vorn, der Winkelfortsatz nach aussen, die hintere Kante des aufsteigenden Astes schwach S-förmig gebogen.

Maasse: Scheitellänge 10.5, Basilarlänge 9, grösste Scheitelbreite in der Mitte 7, am Hinterhaupt 6.5, Einschnürung 3.25; Breite des Oberkiefers 4, Gaumenlänge 4, das runde Hinterhauptloch 3.

Unterkiefer bis zum Condylus 7, Höhe des horizontalen Astes in der Mitte 0.75, aufsteigender Ast unter dem Proc. coron. 2, Breite desselben 2.

Gebiss. Oben I (Taf. V, Fig. 61) innen einspitzig, hinten mit kleinein Basalzacken, hakig gekrümmt, die Spitzen stark convergirend. I aussen sehr klein, dreispitzig, indem der vordere kleinere Zacken eine Doppelspitze hat. Der Zahn steht fast senkrecht, ein wenig nach aussce. C mit unbedeutendem Basalwulst, der hinten etwas ausgezogen ist, schlank, wenig gebogen, nach hinten gerichtet, innen mässig cannelirt. P = $^3/_4$ C, fast gerade, senkrecht, conisch zugespitzt,

p. 218

durch eine Lücke von C getrennt, dicht an M I gerückt. M I und II identiseh, mit niedrigen Zacken, von den beiden Aussenzacken der erste nach vorn gerichtet, W-förmige Kaufläche, die beiden inneren Nebenzacken höher als die äusseren, der vordere etwas höher, der vertiefte innere Nebenhöcker klein, der innere Rand vorn mit Zacken. M III schmal, der hintere Theil des W von der Mitte des ersten Haarstrichs an fehlt, hinter dem inneren Nebenzacken noch ein ganz kleiner.

Unten I klein, dreilappig. nach vorn gerichtet. C, P und M mit Basalwulst. C schlank, ziemlich gerade, wenig nach vorn, aber nicht nach aussen gerichtet. Zwischen C und P I eine kleine Lücke, die übrigen Zähne in geschlossener Reihe. P I = $^2/_3$ C, mässig gebogen, etwas nach hinten gerichtet, innen cannelirt, der Basaltheil nach hinten ausgezogen. P II etwas höher, aber viel schlanker, fast senkrecht stehend. M I und II identisch, der vordere Aussenzacken höher, fast so hoch wie C, etwas nach vorn gerichtet, die beiden inneren Zacken niedriger, etwas nach hinten gerichtet. Bei M III der hintere Aussenzacken und die beiden Innenzacken niedriger.

Von *Vesperus brunneus* THOMAS (in: Ann. Mag. Nat, Hist. 1880, p. 165, DOBSON, Geogr. distrib. Chiropt., p, 17) unterschieden durch geringere Grösse, längere, schmalere Ohren, die freie Schwanzspitze, die dunklere Färbung. *Vespertilio pusillus* LE CONTE vom Gabun (in: Proc. Ac. Nat. Hist. Philadelphia 1857, p. 10 u. 11) sieht ähnlich aus hat aber ein viel kürzeres Ohr und lanzettförmigen Tragus, ist übrigens, da LE CONTE nichts über die P sagt, so oberflächlich beschrieben, dass die Gattung, geschweige die Species, fraglich ist.

Die genannten drei tief dunklen Chiroptera sind meines Wissens ausser *Vesperugo stampflii* Jent. (in: Notes 1888, p.55), der schwarz mit rothbrauuen Flecken ist, die einzigen bisher in Afrika gefundenen, während sich diese tief schwarzbraune Färbung bei südamerikanischen Arten öfter findet.

Vesperus tenuipinnis Peters, 1872

p. 263

Eine durch ihre Färbung sehr auffallende Art: oben dunkel rostbraun mit einfarbigen Haaren, Ohren, Gliedmafsen und die ganze Bauchseite schneeweifs, nur die Basis der Haare braun; Flughäute farblos durchsichtig.

Der erste obere Schneidezahn ist breit, an seiner Vorderseite gefurcht, fast zweispitzig. Der zweite ist sehr kurz und liegt vor dem äufsern Theile des ersten und durch einen Zwischenraum von dem Eckzahn getrennt. Die unteren dreilappigen Schneidezähne stehen dem Kieferrande fast parallel. Der erste untere Prämolarzahn ist etwa $^{1}/_{3}$ niedriger, aber im Querschnitt wenig kleiner als der zweite; er ist ungefähr halb so hoch wie der untere Eckzahn.

Die Ohren sind dreieckig abgerundet, an der Basis des Aussenrandes mit einem abgerundeten, deutlich abgesetzten Läppchen

p. 264

versehen und im Allgemeinen ebenso wie die breite beilförmige Ohrklappe denen von *V. noctula* ähnlich.

Die Körperbehaarung dehnt sich seitlich aus über das erste Drittel des Oberarms, die Hälfte des Oberschenkels und die Basis des Schwanzes.

Die Flughäute sind sehr dünn und durchsichtig, so dafs man jede Schrift durch sie unbehindert lesen kann und gehen bis an die Zehenbasis. Der Schwanz ist bis auf die äufserste Spitze von der Schenkelflughaut eingeschlossen.

Ein weibliches scheinbar ausgewachsenes Exemplar aus Guinea.

Xiphonycteris Dollman, 1911

p. 210

Size similar to that of the smaller species of *Nyctinomus*. Wings small, membranous area much reduced. Ears, feet, and tail much as in *Nyctinomus*.

Skull with median anterior palatal emargination like that of *Nyctinomus*, but emargination quite small and inconspicuous,though extending behind roots of incisors. Teeth according to the following formula: -

i. $^{1-1}/_{1-1}$, c. $^{1-1}/_{1-1}$, p. $^{2-2}/_{2-2}$, m. $^{3-3}/_{3-3}$ = 28.

Upper incisors quite small and closely in contact with canines; widely separated from each other, wider apart at base than at tip. Upper canine rather similar to that of *Nyctinomus*, but with cingulum very prominent and shaft of tooth longer, much flatter anteriorly, and pointing slightly outwards. Base of canines much enlarged, the anterior edges of the cingula on a level with the anterior limit of the upper incisors; when looked at from above the cingula appear as two prominent crescentic ridges with the minute incisors between them, the incisors being so placed as to resemble two anterointernal cusps on the cingula of the canines. Behind the shaft the cingulum is expanded to form a large flat area, its posterior edge closely in contact with the small anterior premolars. Upper premolars and molars as in *Nyctinomus*, the molars with well-developed hypocones. Lower incisors reduced to a single pair of very minute functionless teeth, bridged over by the junction of the lower canines; cutting-edges deeply bifid. Lower canines with well-developed cingula, forming anteriorly prominent secondary cusps, which meet together in the mid-line as a bridge over the minute incisors; posterior portion of cingulum large and well developed, much more so than in the allied genera. Lower molars and premolars as in *Nyctinomus*.

Type, *Xiphonycteris spurrelli*.

This genus would appear to be most nearly related to the

p. 211

genus *Nyctinomus*, which it resembles in general external characters and in the presence of the small upper premolar; but the absence of i_2, the peculiar position of the single pair of minute lower incisors, and the unusual shape and arrangement of the upper and lower canines are more than sufficient reasons for considering the genera as quite distinct. As regards the genus *Chærephon* the same differences hold good, with the additional character of the median anterior palatal emargination present in *Xiphonycteris*.

In the possession of only a single pair of lower incisors, and in having the lower canines in contact with one another, this genus in some ways resembles the South-American genus *Molossops*; but the two genera, on account of numerous important differences, cannot be looked upon as close allies.

Xiphonycteris spurrelli Dollman, 1911

p. 211

General appearance and size much as in the smaller species of *Nyctinomus*. Ears roughly triangular in shape, with rounded corners; tragus and antitragus apparently normal. Feet comparatively small; toes hairy, the hairs extending along the margin of the interfemoral membrane for about 10 mm. Wings small, forearm only 27 mm. long; wing-menbrane very narrow. Hair on back short, a few longer hairs near base of tail. General colour of back rusty red, hairs rather lighter at base than at tips. Under surface of body buffy white, the hairs becoming brownish on the flanks and sides of neck. Tail, as described above, with terminal half free. Interfemoral membrane naked on upper surface, below thinly clad with very minute white hairs.

Skull with rather narrow brain-case, markedly so in the occipital region. Supraoccipital crest well developed, extending back some distance beyond the exoccipital region. Sagittal crest but little developed. Zygoma fairly strong, expanded posteriorly. Anteprbital foramen large. Lachrymal ridge faintly indicated. Anterior palatal emargination about as large as base of upper incisor, extending well behind the roots of incisors. Palate slightly arched laterally, nearly flat antero-posteriorly; pterygpids almost parallel, slightly divergent behind; basisphenoid pits moderately developed. Auditory bullæ small and rather flat.

Teeth as described above.

Dimensions of the type (measured in flesh): -

Head and body 56 mm.; tail 24; hind foot 8; ear 13; forearm 27.

Skull: greatest length 17; basilar length 12.2; condylo-basilar length 14; greatest zygomatic breadth 10; inter-

p. 212

orbital breadth 3.5; breadth of brain-case (across squamosal region) 8.6; breadth of rostrum (across lachrymal region) 6; palatilar length 5.8; width of palate inside m^2 3.3; width across palate outside m^2 7; postpalatal length 6.5; length of upper tooth-row from front of canine to back of m^3 6.4; length of upper tooth-row from front of first premolar to back of m^3 4.9 ; height of canine 3.2.

Hab. Bibianaha, 60 miles W. of Kumasi, Gold Coast. Altitude 700 feet.

Type. Adult male. B.M. no. 11.1.11.1. Original number 34. Collected on December 8th, 1910, by the donor, Dr. H. G. F. Spurrell.

It gives me great pleasure to associate this new and interesting bat with the name of Dr. Spurrell, to whom the National Collection is already indebted for many rare and unique West-African mammals.

Appendix 4: Collector Information

In this appendix all the information related to the collectors is brought together. This might be useful to find discrepancies between the collector, collection date and locality.
All subtables contain the following data: collector, collection date, country and locality, museum code and number of specimens. Totals per category are also given.

Appendix 4a: Follow the Collector

In this appendix, the trail of the collector is followed, since it contains the records sorted by collector and date.

The underlined numbers indicate the number of specimens for the locality present in one or more collections. The **bold numbers** represent the number of specimens for the country and the **bold and underlined numbers** the totals for the specific date.

Boncard, A.

Collection Date Unknown: South Africa: "Cape of Good Hope" [=syn. "Kaap Goede Hoop"]: MSNG: 1 [1 - **1** - **1**].

Total Specimens for Boncard, A.: 1

Bonhote, John James Lewis
(1875: London - 1922)

1 March 1914: Egypt: Aburoash: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Bonhote, John James Lewis: 1

Bonhote, John James Lewis; Flower, Stanley Smyth

Collection Date Unknown: Egypt: Gizeh: BMNH: 1 [1 - **1** - **1**].
3 March 1909: Egypt: Abu Rawash: BMNH: 1 [1 - **1** - **1**].
13 March 1909: Egypt: Lake Moeris: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Bonhote, John James Lewis; Flower, Stanley Smyth: 3

Bonnevie

Collection Date Unknown: Congo (Democratic Republic of the): Beni: RMCA: 6 [6] - Lesse: RMCA: 1 [1 - **7** - **7**].

4 November 1913: Congo (Democratic Republic of the): Lesse: RMCA: 3 [3 - **3** - **3**].
2 June 1914: Congo (Democratic Republic of the): Beni: RMCA: 1 [1 - **1** - **1**].

Total Specimens for Bonnevie: 11

Booth, Angus H.

Collection Date Unknown: Ghana: Unknown locality: BMNH: 2 [2] - Akeniem: BMNH: 3 [3 - **5** - **5**].
15 April 1954: Ghana: Akeniem: BMNH: 1 [1 - **1** - **1**].
19 July 1954: Ghana: Akeniem: RMCA: 1 [1 - **1** - **1**].

Total Specimens for Booth, Angus H.: 7

Boshoff, P.

11 February 1989: South Africa: Farm Klipfontein 407, Echo caves: TM: 8 [8 - **8** - **8**].

Total Specimens for Boshoff, P.: 8

Botha, K.

20 February 1983: South Africa: Mahlangeni: KNP: 1 [1 - **1** - **1**].

Total Specimens for Botha, K.: 1

Botswana Mammal Survey

9 July 1965: Botswana: Chobe NP, Kasane: USNM: 3 [3 - **3** - **3**].
30 November 1965: Botswana: Chobe NP, Kasane: USNM: 2 [2 - **2** - **2**].
3 December 1965: Botswana: Chobe NP, Kasane: USNM: 1 [1 - **1** - **1**].
9 December 1965: Botswana: Chobe NP, Kasane: USNM: 2 [2 - **2** - **2**].
11 December 1965: Botswana: Chobe NP, Kasane: USNM: 3 [3 - **3** - **3**].
10 November 1966: Botswana: Chobe NP, Kasane: USNM: 1 [1 - **1** - **1**].

Total Specimens for Botswana Mammal Survey: 12

Botta, Paolo Emilio
(1802 - 1870)

1 January 1837: Sudan: Sennar: RMNH: 1 [1 - **1**].
Yemen: no specific locality: MNHN: 1 [1 - **1** - **2**].

Total Specimens for Botta, Paolo Emilio: 2

Böttcher

Collection Date Unknown: Cameroon: Victoria: ZMB: 1 [1 - **1** - **1**].

Total Specimens for Böttcher: 1

Bottego, Vittorio
(29 July 1860: Parma - 17 March 1897: Daga Roba)

Collection Date Unknown: Somalia: Pozzi Meddo Erelle: MSNG: 1 [1 - **1** - **1**].

Total Specimens for Bottego, Vittorio: 1

Boucard, Adolphe
(1839: France - 15 March 1905: Hampstead)

Collection Date Unknown: Réunion: Bourbon, île [=Réunion]: ZMB: 2 [2 - **2** - **2**].

Total Specimens for Boucard, Adolphe: 2

Bouet

21 May 1910: Benin: Agouagon: MNHN: 1 [1 - **1** - **1**].
12 August 1910: Benin: Agouagou: MNHN: 1 [1 - **1** - **1**].

Total Specimens for Bouet: 2

Bouillon, A.

Collection Date Unknown: Congo: Unknown locality: RMNH: 5 [5 - **5** - **5**].

11 July 1953: Congo (Democratic Republic of the): Kalenda [Kasai]: RBINS: 1 [1 - **1** - **1**].

Total Specimens for Bouillon, A.: 6

Boulton, Rudyerd

21 June 1934: Cameroon: Buéa: FMNH: 2 [2] - Mount Cameroon: FMNH: 3 [3 - **5** - **5**].
2 July 1934: Cameroon: Buéa: FMNH: 3 [3] - Mount Cameroon: FMNH: 10 [10 - **13** - **13**].
15 July 1934: Cameroon: Buea: USNM: 1 [1] - Buéa: FMNH: 8 [8 - **9** - **9**].
5 August 1934: Nigeria: Ifon: FMNH: 2 [2 - **2** - **2**].
6 August 1934: Nigeria: Ifon: FMNH: 3 [3 - **3** - **3**].
7 August 1934: Nigeria: Ifon: FMNH: 3 [3 - **3** - **3**].
8 August 1934: Nigeria: Ifon: FMNH: 6 [6 - **6** - **6**].

Total Specimens for Boulton, Rudyerd: 41

Boulton, Rudyerd; Boulton, Laura

2 June 1929: Tanzania: Rungwe District: AMNH: 2 [2 - **2** - **2**].

1 January 1929: Somalia: Oddur: MSNG: 1 [1 - **1** - **1**].

Total Specimens for Brozzi, N. Mosconi: 1

Brummer, V.

22 May 2000: South Africa: Doonside: DNSM: 1 [1 - **1** - **1**].

Total Specimens for Brummer, V.: 1

Buchanan, Angus

Collection Date Unknown: Nigeria: Kano: BMNH: 1 [1 - **1**].
Tanzania: Kisaki: BMNH: 1 [1] - Kissaki: BMNH: 1 [1 - **2** - **3**].
19 December 1919: Nigeria: Parniso: BMNH: 1 [1 - **1** - **1**].
23 December 1919: Nigeria: Farniso: BMNH: 1 [1 - **1** - **1**].
30 January 1920: Niger: Zinder: BMNH: 1 [1 - **1** - **1**].
27 July 1922: Niger: Tebeig Asben: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Buchanan, Angus: 7

Buchanan, Angus; Rothschild, Nathanial Charles

30 January 1920: Niger: Zinder: BMNH: 2 [2 - **2** - **2**].

Total Specimens for Buchanan, Angus; Rothschild, Nathanial Charles: 2

Buchanan, Stuart A.

17 June 1978: Central African Republic: Gounda camp: CM: 1 [1 - **1** - **1**].
2 October 1978: Central African Republic: Koumbala Camp: CM: 1 [1 - **1** - **1**].
9 October 1978: Central African Republic: Gounda camp: CM: 3 [3 - **3** - **3**].
13 October 1978: Central African Republic: Gounda camp: CM: 9 [9 - **9** - **9**].
14 October 1978: Central African Republic: Gounda camp: CM: 7 [7 - **7** - **7**].
21 October 1978: Central African Republic: Ndele and Vakaga, between: CM: 1 [1 - **1** - **1**].
24 October 1978: Central African Republic: Koumbala Camp: CM: 3 [3 - **3** - **3**].
25 October 1978: Central African Republic: Koumbala Camp: CM: 1 [1 - **1** - **1**].
26 October 1978: Central African Republic: Koumbala Camp, 11.5 km NW: CM: 1 [1 - **1** - **1**].
24 June 1979: Central African Republic: Koumbala Camp: CM: 1 [1 - **1** - **1**].
29 June 1979: Central African Republic: Koumbala Camp: CM: 2 [2 - **2** - **2**].

Total Specimens for Buchanan, Stuart A.: 30

Buchanan, W.J.

13 February 1933: Angola: Chitau: AMNH: 1 [1 - **1** - **1**].

Total Specimens for Buchanan, W.J.: 1

Buchet

1 January 1904: Morocco: Hercules caves: FMNH: 2 [2 - **2** - **2**].

Total Specimens for Buchet: 2

Buchholz

Collection Date Unknown: Cameroon: Unknown locality: ZMB: 4 [4] - Mungo Anchoncho [Moungo river?]: ZMB: 5 [5 - **9**].
Equatorial Guinea: Bioko Island: ZMB: 1 [1 - **1**].
Gabon: Cape Lopez: ZMB: 1 [1] - Dongila [=Donguila]: ZMB: 2 [2] - Lambarene: ZMB: 1 [1 - **4** - **14**].

Total Specimens for Buchholz: 14

Buchner

Collection Date Unknown: Angola: Malange [= Malanje]: ZMB: 1 [1 - **1** - **1**].

Total Specimens for Buchner: 1

Buckle, J.

26 February 1987: South Africa: St. Lucia Crocodile centre: TM: 1 [1 - **1** - **1**].

Total Specimens for Buckle, J.: 1

Bunting

Collection Date Unknown: Ghana: Gold Coast [=Goldküste]: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Bunting: 1

Buonajun, A.

16 June 1964: Kenya: Lake Naivasha: WNMU: 1 [1 - **1** - **1**].

Total Specimens for Buonajun, A.: 1

Burda, H.

Collection Date Unknown: Malawi: Unknown locality: SMF: 1 [1 - **1** - **1**].

Total Specimens for Burda, H.: 1

Burgeon

14 September 1932: Congo (Democratic Republic of the): Katanda Road, km 411: RMCA: 1 [1 - **1** - **1**].
29 October 1932: Congo (Democratic Republic of the): Katana: RMCA: 1 [1 - **1** - **1**].

28 December 1932: Burundi: Nyanza-Lac: RMCA: 1 [1 - **1** - **1**].

Total Specimens for Burgeon: 4

Burgess,H.H.

2 May 1944: Liberia: Division 24 Camp [see: Division Twenty-Four [Labor] Camp]: AMNH: 1 [1 - **1** - **1**].

Total Specimens for Burgess,H.H.: 1

Burmester

6 March 1909: Namibia: Keetmannshoop: ZMH: 1 [1 - **1** - **1**].

Total Specimens for Burmester: 1

Burne, Clayton

8 November 1998: South Africa: Vernon Crookes Nature Reserve: DNSM: 1 [1 - **1** - **1**].

Total Specimens for Burne, Clayton: 1

Burrard, C.; Jordan, Karl

Collection Date Unknown: Angola: Moks, mount: BMNH: 1 [1 - **1** - **1**].
11 October 1933: Namibia: Klein Windhoek: BMNH: 2 [2 - **2** - **2**].

Total Specimens for Burrard, C.; Jordan, Karl: 3

Burrows, John; Cohen, Lientjie; Fernsby, Nigel

Collection Date Unknown: South Africa: Buffelskloof Private Nature Reserve: TM: 1 [1 - **1** - **1**].
14 November 2003: South Africa: Buffelskloof Private Nature Reserve: TM: 1 [1 - **1** - **1**].

Total Specimens for Burrows, John; Cohen, Lientjie; Fernsby, Nigel: 2

Burting (or Bunting), R.K. (or R.H.)

Collection Date Unknown: Liberia: Barclay, mount [see Rosevear: BMNH: 1 [1 - **1** - **1**].
20 July 1914: Sierra Leone: Njala: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Burting (or Bunting), R.K. (or R.H.): 2

Burton, 2

3 June 1972: Kenya: Elgon, Mount: ROM: 1 [1 - **1** - **1**].

Total Specimens for Burton, 2: 1

Burton, M.

Collection Date Unknown: Sierra Leone: Unknown locality: MCZ: 1 [1 - **1** - **1**].
17 February 1990: South Africa: Lynwood: TM: 1 [1 - **1** - **1**].

Total Specimens for Burton, M.: 2

Busink, R.J.

12 October 1971: Liberia: Robertsfield Airport: ZMA: 1 [1 - **1** - **1**].

Total Specimens for Busink, R.J.: 1

Busto, B.

27 September 1978: Morocco: Peñon de Alhucemas island: EBD: 2 [2 - **2** - **2**].
3 October 1978: Morocco: Peñon de Alhucemas island: EBD: 2 [2 - **2** - **2**].
5 October 1978: Morocco: Peñon de Alhucemas island: EBD: 1 [1 - **1** - **1**].

Total Specimens for Busto, B.: 5

Butler, A.L.

29 March 1907: Sudan: Dad Majok: BMNH: 2 [2 - **2** - **2**].

Total Specimens for Butler, A.L.: 2

Butler, J.

Collection Date Unknown: Sudan: Jebel Moba: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Butler, J.: 1

Büttikofer, Johan
(1850 - 1927)

Collection Date Unknown: Liberia: Unknown locality: RMNH: 4 [4 - **4** - **4**].

Total Specimens for Büttikofer, Johan: 4

Büttikofer, Johan; Sala, C.F.

Collection Date Unknown: Liberia: Unknown locality: RMNH: 1 [1 - **1** - **1**].
19 October 1880: Liberia: Muhlenberg Mission: RMNH: 1 [1] - Mühlenburg-Mission: RMNH: 1 [1 - **2** - **2**].
11 January 1887: Liberia: Schieffelinsville: RMNH: 1 [1 - **1** - **1**].
1 November 1887: Liberia: Schieffelinsville: RMNH: 1 [1 - **1** - **1**].

Total Specimens for Büttikofer, Johan; Sala, C.F.: 5

Büttner

Collection Date Unknown: "Africa": Kimpoko: ZMB: 1 [1 - **1**].
Gabon: Unknown locality: ZMB: 1 [1 - **1**].

Togo: Bismarckburg [=Adéle]: ZMB: 6 [6 - **6** - **8**].

Total Specimens for Büttner: 8

Button, E.J.

12 April 1943: Zambia: Kasempa: TM: 1 [1 - **1** - **1**].

Total Specimens for Button, E.J.: 1

Buxton, A.P.

Collection Date Unknown: Uganda: Kampala: AMNH: 1 [1 - **1** - **1**].
8 August 1950: Uganda: Entebbe: AMNH: 9 [9 - **9** - **9**].
9 November 1950: Uganda: Entebbe: AMNH: 1 [1 - **1** - **1**].
19 May 1951: Uganda: Kampala: AMNH: 1 [1 - **1** - **1**].
21 May 1951: Uganda: Kampala: AMNH: 1 [1 - **1** - **1**].
12 June 1951: Uganda: V.R.I.: AMNH: 1 [1 - **1** - **1**].
19 June 1951: Uganda: V.R.I.: AMNH: 1 [1 - **1** - **1**].
25 June 1951: Uganda: V.R.I.: AMNH: 1 [1 - **1** - **1**].

Total Specimens for Buxton, A.P.: 16

Buxton, A.P.; Oxford University Expedition, The

Collection Date Unknown: The Gambia: Gambia river, lower: BMNH: 1 [1] - Kontaur: BMNH: 1 [1] - Kuntaur, 5 mi N: BMNH: 2 [2] - Makka: BMNH: 1 [1 - **5** - **5**].
31 July 1948: The Gambia: Makka: BMNH: 1 [1 - **1** - **1**].
24 August 1948: The Gambia: Kuntaur, 10 mi [=16 km]SE: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Buxton, A.P.; Oxford University Expedition, The: 7

Buys

19 October 1966: Namibia: Swartbooidrift: TM: 1 [1 - **1** - **1**].

Total Specimens for Buys: 1

Buys, P.J.

15 July 1964: Namibia: Karakuwisa: SMW: 4 [4 - **4** - **4**].
6 August 1964: Namibia: Omuramba, Omatako: SMW: 3 [3 - **3** - **3**].

16 January 1975: Congo (Democratic Republic of the): Kinshasa: HZM: 2 [2 - **2** - **2**].

Total Specimens for Gallagher, Michael D.: 214

Galpin, R.

30 May 1967: South Africa: Mosdene Nature Reserve: ROM: 1 [1 - **1** - **1**].

Total Specimens for Galpin, R.: 1

Galton, Francis
(16 February 1822: near Sparbrook - 1911)

Collection Date Unknown: "Africa": Unknown locality: BMNH: 1 [1 - **1**].
Sudan: 5th cataract of the Nile: BMNH: 1 [1 - **1** - **2**].

Total Specimens for Galton, Francis: 2

Gans, Carl
(1923 -)

24 July 1961: Somalia: Mogadisio: AMNH: 1 [1 - **1** - **1**].
28 July 1961: Somalia: Balad: AMNH: 1 [1 - **1** - **1**].
3 August 1961: Somalia: Balad: AMNH: 1 [1 - **1** - **1**].
9 August 1961: Somalia: Balad, 5 mi S: AMNH: 1 [1 - **1** - **1**].
10 August 1961: Somalia: Afgoi: AMNH: 1 [1 - **1** - **1**].
11 August 1961: Somalia: Balad, 1 mi S: AMNH: 12 [12 - **12** - **12**].
21 August 1961: Somalia: Candala: AMNH: 2 [2 - **2** - **2**].
27 August 1961: Somalia: Mogadisio, 3 mi N: AMNH: 27 [27 - **27** - **27**].
6 September 1961: Tanzania: Seronera: AMNH: 1 [1 - **1** - **1**].

Total Specimens for Gans, Carl: 47

Gardiner, J. Stanley

Collection Date Unknown: Seychelles: Silhouette: BMNH: 1 [1] - Silhouette Island: BMNH: 1 [1 - **2** - **2**].

Total Specimens for Gardiner, J. Stanley: 2

Gathura, Peter Baaro

9 September 1966: Kenya: Voi: ROM: 1 [1 - **1** - **1**].

Total Specimens for Gathura, Peter Baaro: 1

Gatter, Wulf

1 January 1982: Liberia: Mount Nimba: SMF: 2 [2 - **2** - **2**].

Total Specimens for Gatter, Wulf: 2

Gaucher, Ph.; Brosset, André

1 January 1984: Tunisia: Gabès, 100 km S: MHNG: 1 [1 - **1** - **1**].

Total Specimens for Gaucher, Ph.; Brosset, André: 1

Gaudchau, M.

19 March 1964: Sudan: Abu Tiga Forest Reserve: SMF: 6 [6 - **6** - **6**].

Total Specimens for Gaudchau, M.: 6

Gauteng Bat Intrest Group, The

20 September 2003: South Africa: Farm Makapansgat 39KS: TM: 1 [1 - **1** - **1**].

Total Specimens for Gauteng Bat Intrest Group, The: 1

Gauteng Nature Conservation, The

18 July 2004: South Africa: Farm Tweefontein 523 JQ: TM: 1 [1 - **1** - **1**].

Total Specimens for Gauteng Nature Conservation, The: 1

Geene, R.

5 March 1990: Egypt: Port Said, 10 mi S: ZMA: 2 [2 - **2** - **2**].

15 April 1990: Egypt: Shak Shouk: ZMA: 1 [1 - **1** - **1**].
10 May 1990: Egypt: Manzala East: ZMA: 3 [3 - **3** - **3**].

Total Specimens for Geene, R.: 6

Geertsema, C.C.

25 August 1963: Botswana: Moremi Game Reserve: ZMA: 1 [1 - **1** - **1**].
28 August 1963: Botswana: Kwaai River: ZMA: 1 [1 - **1** - **1**].

Total Specimens for Geertsema, C.C.: 2

Grauer, Rudolf
(1870 -)

Collection Date Unknown: "Africa": Karagwa: ZMB: 6 [6 - **6**].
Burundi: Russissi, bank [=Rusizi delta]: ZMB: 2 [2 - **2**].
Congo (Democratic Republic of the): Baraka: ZMB: 1 [1] - Beni: NMW: 1 [1] - Kindu: ZMB: 1 [1] - lake Tanganyika, NW bank: ZMB: 1 [1] - Moera: NMW: 1 [1] - Rutshuru: NMW: 1 [1] - Ukaika: NMW: 5 [5] - Uvira: NMW: 2, ZMB: 4 [6 - **17**].
Tanzania: Tanganyika, lake: ZMB: 2 [2] - Usambara [mountains]: ZMB: 3 [3 - **5** - **30**].

Total Specimens for Grauer, Rudolf: 30

Grauer, Rudolf; Rolle, Hermann

Collection Date Unknown: Congo (Democratic Republic of the): Ruwenzori: ZMB: 1 [1 - **1**].
Uganda: Entebbe: ZMB: 2 [2 - **2** - **3**].

Total Specimens for Grauer, Rudolf; Rolle, Hermann: 3

Graupner, O.F.

19 January 1969: South Africa: Stolzenfels, Orange R: USNM: 2 [2 - **2** - **2**].
15 April 1969: South Africa: Buffelshoek Farm 446 KQ: USNM: 31 [31 - **31** - **31**].
16 April 1969: South Africa: Buffelshoek Farm 446 KQ: USNM: 5 [5 - **5** - **5**].
17 April 1969: South Africa: Buffelshoek Farm 446 KQ: USNM: 1 [1 - **1** - **1**].
22 April 1969: South Africa: Buffelshoek Farm 446 KQ: USNM: 11 [11] - Thabazimbi, 16 mi SE [=Waterval Farm]: USNM: 38 [38] - Thabazimbi, 20 km SE: USNM: 2 [2 - **51** - **51**].

Total Specimens for Graupner, O.F.: 90

Grauvet, R.

1 January 1941: Congo (Democratic Republic of the): Kipangaribwe river: RBINS: 1 [1 - **1** - **1**].

Total Specimens for Grauvet, R.: 1

Gray, M.

1 January 1961: Tanzania: Unknown locality: MSB: 2 [2 - **2** - **2**].

Total Specimens for Gray, M.: 2

Great Abbai Expedition, The

Collection Date Unknown: Ethiopia: Unknown locality: BMNH: 47 [47 - **47** - **47**].

Total Specimens for Great Abbai Expedition, The: 47

Greaves; Richardson

20 December 1998: South Africa: Burman Bush Nature Reserve: DNSM: 1 [1 - **1** - **1**].

Total Specimens for Greaves; Richardson: 1

Green, Arthur A.

Collection Date Unknown: Benin: Pendjari Park: ROM: 4 [4 - **4** - **4**].
9 July 1978: Benin: Pendjari Park: ROM: 1 [1 - **1** - **1**].
10 July 1978: Benin: Pendjari Park: ROM: 1 [1 - **1** - **1**].
11 July 1978: Benin: Pendjari Park: ROM: 1 [1 - **1** - **1**].
14 July 1978: Benin: Pendjari Park: ROM: 1 [1 - **1** - **1**].
20 July 1978: Benin: Pendjari Park: ROM: 2 [2 - **2** - **2**].
22 July 1978: Benin: Pendjari Park: ROM: 3 [3 - **3** - **3**].
23 July 1978: Benin: Pendjari Park: ROM: 1 [1 - **1** - **1**].

Total Specimens for Green, Arthur A.: 14

Green, R.

4 May 1994: South Africa: Tshokwane, 10 km S: KNP: 1 [1 - **1** - **1**].

Total Specimens for Green, R.: 1

Greenberg, Stuart N.

10 January 1958: Uganda: Katwe: CAS: 1 [1 - **1** - **1**].
14 July 1958: Uganda: Katwe: CAS: 1 [1 - **1** - **1**].
22 July 1958: Kenya: Molo river: CAS: 1 [1 - **1** - **1**].
18 August 1958: Kenya: Nairobi: CAS: 1 [1 - **1** - **1**].

Total Specimens for Greenberg, Stuart N.: 4

Grey, G.L.

31 October 1961: Zimbabwe: Southerton: ROM: 1 [1 - **1** - **1**].

Total Specimens for Grey, G.L.: 1

Greyling, A.

Collection Date Unknown: South Africa: Elandsklip, P.K. Santa: TM: 1 [1 - **1** - **1**].

Total Specimens for Greyling, A.: 1

Griesel, W.J.H.J.

1 June 1987: South Africa: Farm Katrina: TM: 1 [1 - **1** - **1**].

Total Specimens for Griesel, W.J.H.J.: 1

Griffin, M.R.

18 April 1975: Namibia: Autabib 100: LACM: 3 [3 - **3** - **3**].
17 September 1983: Namibia: Gam Waterhole: USNM: 5 [5 - **5** - **5**].

Total Specimens for Griffin, M.R.: 8

Griffin, M.R.; Wallis, V.

13 November 1983: Namibia: Dosa: USNM: 1 [1 - **1** - **1**].

Total Specimens for Griffin, M.R.; Wallis, V.: 1

Grimbeek, Anton

28 May 1984: South Africa: Old Picnic Site: TM: 1 [1 - **1** - **1**].

Total Specimens for Grimbeek, Anton: 1

Grimwood

Collection Date Unknown: Zambia: Lukanga Swamp: BMNH: 2 [2 - **2** - **2**].

Total Specimens for Grimwood: 2

Grindley, J.

5 August 1956: South Africa: Table Mountain, Wynberg cave: TM: 1 [1 - **1** - **1**].

Total Specimens for Grindley, J.: 1

Grindly, J.R.

5 August 1956: South Africa: Table Mountain, Wynberg cave: TM: 2 [2 - **2** - **2**].

Total Specimens for Grindly, J.R.: 2

Groenewald

23 October 1978: South Africa: Pretoria: TM: 1 [1 - **1** - **1**].

Total Specimens for Groenewald: 1

Groschaft, J.; Ryšavý, B.

19 July 1971: Egypt: Abu Rawash: NMP: 3 [3 - **3** - **3**].

Total Specimens for Groschaft, J.; Ryšavý, B.: 3

Grossmann, H.

29 August 1985: Tanzania: Mazumbai Forest Reserve: SMF: 1 [1 - **1** - **1**].

Total Specimens for Grossmann, H.: 1

Grote, Hermann
(1882 - 1951)

Collection Date Unknown: Tanzania: Mikindani: ZMB: 10 [10 - **10** - **10**].

Total Specimens for Grote, Hermann: 10

Grubb, Peter

7 November 1971: Ghana: Kwabenya: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Grubb, Peter: 1

Grützner

Collection Date Unknown: South Africa: Gerlachshoop: ZMB: 1 [1 - **1** - **1**].

Total Specimens for Grützner: 1

Gruvel, Abel
(1870 - 1941)

9 May 1910: Congo (Democratic Republic of the): Banana: MNHN: 4 [4 - **4** - **4**].

Total Specimens for Gruvel, Abel: 4

Gruwell, J.A.

17 September 1971: Ghana: Accra, 9 mi [=14.5 km] NE: CM: 1 [1 - **1** - **1**].
23 October 1971: Côte d'Ivoire: Lakota, 15 km N: CM: 1 [1 - **1** - **1**].
31 October 1971: Côte d'Ivoire: Bouaké, 25 km N: CM: 1 [1 - **1** - **1**].
12 November 1971: Côte d'Ivoire: Abidjan, 15 km NW: CM: 1 [1 - **1** - **1**].
5 December 1971: Cameroon: Mamfe, 12 km SE: TTU: 4 [4 - **4** - **4**].

21 April 1949: Congo (Democratic Republic of the): Kilo [mines]: RMCA: 1 [1] - Kilo mines: RMCA: 1 [1 - **2** - **2**].

Total Specimens for Hiernaux, Jean: 33

Higgins

Collection Date Unknown: Namibia: Damaraland: ZMB: 3 [3 - **3** - **3**].

Total Specimens for Higgins: 3

Hildebrandt, Johann Maria
(1847 - 1881)

Collection Date Unknown: Comoros: Anjouan Island: ZMB: 3 [3] - Comoro Islands: ZMB: 1 [1 - **4**].
Kenya: Kitui: ZMB: 4 [4] - Mombas [=Mombassa]: ZMB: 9 [9] - Ndi: ZMB: 8 [8] - Taita: BMNH: 2 [2] - Ukamba [=Kitui]: ZMB: 2 [2 - **25**].
Madagascar: Anteseranana: ZMB: 3 [3] - Betsileo: ZMB: 3 [3] - NW Madagascar: ZMB: 1 [1 - **7**].
Somalia: Barawa: ZMB: 1 [1 - **1**].
Tanzania: Kotur: ZMB: 2 [2] - Ukambesi: ZMB: 1 [1] - Zanzibar: ZMB: 1 [1 - **4** - **41**].
1 January 1877: Angola: Biballe and Rio Coroca, Caconda: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Hildebrandt, Johann Maria: 42

Hillenius, Dick
(29 May 1927: Amsterdam - 4 May 1987: Amsterdam)

9 March 1974: Kenya: Lake Nakuru: ZMA: 1 [1 - **1** - **1**].

Total Specimens for Hillenius, Dick: 1

Himmelheber, Hans
(1908 -)

21 September 1960: Liberia: Kpeaple: SMF: 4 [4] - Tappita: SMF: 1 [1 - **5** - **5**].

Total Specimens for Himmelheber, Hans: 5

Hinde, Hildegarde

3 January 1901: Kenya: Kitui: BMNH: 1 [1 - **1** - **1**].
25 January 1902: Kenya: Fort Hall: BMNH: 1 [1 - **1** - **1**].
17 October 1902: Kenya: Fort Hall: BMNH: 1 [1 - **1** - **1**].
1 January 1903: Kenya: Fort Hall: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Hinde, Hildegarde: 4

Hinde, Sidney Langford
(1863 - 1930)

Collection Date Unknown: Kenya: Fort Hall: BMNH: 1 [1] - Gedi National Park: FMNH: 1 [1] - Machakos district: BMNH: 1 [1] - Muranga: BMNH: 3 [3 - **6** - **6**].
26 November 1900: Kenya: Kitui: BMNH: 1 [1 - **1** - **1**].
7 January 1901: Kenya: Kitui: BMNH: 1 [1 - **1** - **1**].
14 February 1901: Kenya: Kitui: BMNH: 1 [1 - **1** - **1**].
11 July 1901: Kenya: Machakos district: BMNH: 1 [1 - **1** - **1**].
26 January 1902: Kenya: Fort Hall: BMNH: 1 [1 - **1** - **1**].
6 February 1902: Kenya: Fort Hall [=Muranga]: BMNH: 1 [1 - **1** - **1**].
20 November 1902: Kenya: Muranga: BMNH: 1 [1 - **1** - **1**].
18 April 1903: Kenya: Muranga: BMNH: 1 [1 - **1** - **1**].
12 June 1903: Kenya: Muranga: BMNH: 1 [1 - **1** - **1**].
20 June 1903: Kenya: Muranga: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Hinde, Sidney Langford: 16

Hintz

Collection Date Unknown: Guinea-Bissau: Bissau [island]: ZMB: 1 [1 - **1** - **1**].

Total Specimens for Hintz: 1

Hirsch, U.

Collection Date Unknown: Kenya: Mombas [=Mombassa]: ZMB: 1 [1 - **1** - **1**].

Total Specimens for Hirsch, U.: 1

Hirst, A.S.

Collection Date Unknown: Egypt: Luxor: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Hirst, A.S.: 1

Hist, H.

25 October 1926: Ethiopia: Sanfords Ranch: TM: 1 [1 - **1** - **1**].

Total Specimens for Hist, H.: 1

HJH

11 April 1967: South Africa: Newington, 7 mi N: TM: 1 [1 - **1** - **1**].

Total Specimens for HJH: 1

Hobbard, C.H.

20 September 1961: Tanzania: Amani: TM: 1 [1 - **1** - **1**].

Total Specimens for Hobbard, C.H.: 1

Hobson, L.; Shortridge, Guy Chester (Captain)

Collection Date Unknown: South Africa: Louisvale: BMNH: 1 [1 - **1** - **1**].

Total Specimens for Hobson, L.; Shortridge, Guy Chester (Captain): 1

Hodgson, Duncan M.; Coultas, William F.

16 August 1938: Congo (Democratic Republic of the): Bomili: MCZ: 1 [1 - **1** - **1**].
17 August 1938: Congo (Democratic Republic of the): Bomili: MCZ: 1 [1 - **1** - **1**].
14 October 1938: Burundi: Usumbura: MCZ: 1 [1 - **1** - **1**].
